AB Objective To determine genome-wide methylation profiles of bone from patients with hip osteoarthritis (OA) and those with osteoporotic (OP) hip fractures. Methods Trabecular bone pieces were obtained from the central part of the femoral head of 27 patients with hip fractures and 26 patients with hip OA. DNA was isolated, and methylation was explored with Illumina methylation arrays. RNA was extracted, pooled, and deep-sequenced to obtain the whole transcriptome. Differentially methylated regions were identified, and connections between genes with differentially methylated regions were explored by pathway and text-mining analyses. Results After quality control, methylation of 23,367 CpG sites (13,463 genes) was analyzed. There was a genome-wide inverse relationship between methylation and gene expression in both patient groups. Comparison of OP and OA bones revealed 241 CpG sites, located in 228 genes, with significant differences in methylation (false discovery rate <0.05). Of them, 217 were less methylated in OP than in OA. The absolute methylation differences were >5% in 128 CpG sites and >10% in 45 CpG sites. The differentially methylated genes were enriched for association with bone traits in the genome-wide association study catalog. Pathway analysis and text-mining analysis with Gene Relationships Across Implicated Loci software revealed enrichment in genes participating in glycoprotein metabolism or cell differentiation, and particularly in the homeobox superfamily of transcription factors. Conclusion Genome-wide methylation profiling of bone samples revealed differentially methylated regions in OP and OA. These regions were enriched in genes associated with cell differentiation and skeletal embryogenesis, such as those in the homeobox superfamily, suggesting the existence of a developmental component in the predisposition to these disorders.

ID induced osteoporosis; knee osteoarthritis; fracture repair; rank; mass; osteoclastogenesis; stimulation; osteoblasts; metabolism; disorders
AB Growing evidence has demonstrated that pulsed electromagnetic field (PEMF), as an alternative noninvasive method, could promote remarkable in vivo and in vitro osteogenesis. However, the exact mechanism of PEMF on osteopenia/osteoporosis is still poorly understood, which further limits the extensive clinical application of PEMF. In the present study, the efficiency of PEMF on osteoporotic bone microarchitecture and bone quality together with its associated signaling pathway mechanisms was systematically investigated in ovariectomized (OVX) rats. Thirty rats were equally assigned to the Control, OVX and OVX+PEMF groups. The OVX+PEMF group was subjected to daily 8-hour PEMF exposure with 15 Hz, 2.4 mT (peak value). After 10 weeks, the OVX+PEMF group exhibited significantly improved bone mass and bone architecture, evidenced by increased BMD, Tb.N, Tb.Th and BV/TV, and suppressed Tb.Sp and SMI levels in the MicroCT analysis. Three-point bending test suggests that PEMF attenuated the biomechanical strength deterioration of the OVX rat femora, evidenced by increased maximum load and elastic modulus. RT-PCR analysis demonstrated that PEMF exposure significantly promoted the overall gene expressions of Wnt1, LRP5 and b-catenin in the canonical Wnt signaling, but did not exhibit obvious impact on either RANKL or RANK gene expressions. Together, our present findings highlight that PEMF attenuated OVX-induced deterioration of bone microarchitecture and strength in rats by promoting the activation of Wnt/LRP5/b-catenin signaling rather than by inhibiting RANKL-RANK signaling. This study enriches our basic knowledge to the osteogenetic activity of PEMF, and may lead to more efficient and scientific clinical application of PEMF in inhibiting osteopenia/osteoporosis.

TI The effects of physical activity on apoptosis and lubricin expression in articular cartilage in rats with glucocorticoid-induced osteoporosis
SO JOURNAL OF BONE AND MINERAL METABOLISM

DT Article
DE Articular cartilage; Glucocorticoids; Lubricin; Caspase 3; Physical activity
ID temporomandibular-joint disc; superficial zone; synovial-fluid; chondrocytes; bone; osteoarthritis; protein; cells; immunolocalization; proteoglycan
AB Glucocorticoids are considered the most powerful anti-inflammatory and immunomodulating drugs. However, a number of side-effects are well documented in different diseases, including articular cartilage, where increases or decreases in the synthesis of hormone-dependent extracellular matrix components are seen. The objective of this study has been to test the effects of procedures or drugs affecting bone metabolism on articular cartilage in rats with prednisolone-induced osteoporosis and to evaluate the outcomes of physical activity with treadmill and vibration platform training on articular cartilage. The animals were divided into 5 groups, and bone and cartilage evaluations were performed using whole-body scans and histomorphometric analysis. Lubricin and caspase-3 expression were evaluated by immunohistochemistry, Western blot analysis and biochemical analysis. These results confirm the beneficial effect of physical activity on the articular cartilage. The effects of drug therapy with glucocorticoids decrease the expression of lubricin and increase the expression of caspase-3 in the rats, while

after physical activity the values return to normal compared to the control group. Our findings suggest that it might be possible that mechanical stimulation in the articular cartilage could induce the expression of lubricin, which is capable of inhibiting caspase-3 activity, preventing chondrocyte death. We can assume that the physiologic balance between lubricin and caspase-3 could maintain the integrity of cartilage. Therefore, in certain diseases such as osteoporosis, mechanical stimulation could be a possible therapeutic treatment. With our results we can propose the hypothesis that physical activity could also be used as a therapeutic treatment for cartilage disease such as osteoarthritis.

TI Bone cysts after osteochondral allograft repair of cartilage defects in goats suggest abnormal interaction between subchondral bone and overlying synovial joint tissues
SO BONE
LA English
DT Article
DE Osteochondral allografts; Bone cysts; Micro-computed tomography; Animal model
ID term-follow-up; knee osteoarthritis; stored allografts; femoral condyles; hip; microstructure; association; storage; lesions; people
AB The efficacy of osteochondral allografts (OCAs) may be affected by osseous support of the articular cartilage, and thus affected by bone healing and remodeling in the OCA and surrounding host. Bone cysts, and their communication pathways, may be present in various locations after OCA insertion and reflect distinct pathogenic mechanisms. Previously, we analyzed the effect of OCA storage (FRESH, 4 degrees C/14d, 4 degrees C/28d, FROZEN) on cartilage quality in fifteen adult goats after 12 months in vivo. The objectives of this study were to further analyze OCAs and contralateral non-operated (Non-Op) CONTROLS from the medial femoral condyle to (1) determine the effect of OCA storage on local subchondral bone (ScB) and trabecular bone (TB) structure, (2) characterize the location and structure of bone cysts and channels, and (3) assess the relationship between cartilage and bone properties, (1) Overall bone structure after OCAs was altered compared to Non-Op, with OCA samples displaying bone cysts, ScB channels, and ScB roughening. ScB BV/TV in FROZEN OCAs was lower than Non-Op and other OCAs. TB Bwry in FRESH, 4 degrees C/14d, and 4 degrees C/28d OCAs did not vary compared to Non-Op, but BsTry was lower. (2) OCAs contained "basal" cysts, localized to deeper regions, some "subchondral" cysts, localized near the bone-cartilage interface, and some ScB channels. TB surrounding basal cysts exhibited higher Bwry than Non-Op. (3) Basal cysts occurred (a) in isolation, (b) with subchondral cysts and ScB channels, (c) with ScB channels, or (d) with

subchondral cysts, ScB channels, and ScB erosion. Deterioration of cartilage gross morphology was strongly associated with abnormal mu CT bone structure. Evidence of cartilage-bone communication following OCA repair may favorfluid intrusion as a mechanism for subchondral cyst formation, while bone resorption at the graft-host interface without affecting overall bone and cartilage structure may favor bony contusion mechanism for basal cyst formation. These findings suggest that cysts occurring after OCAs may result from aberrant mechanobiology due to (1) altered compartmentalization that normally separates overlying cartilage and subchondral bone, either from distinct ScB channels or more general ScB plate deterioration, and (2) bone resorption at the basal graft-host interface. TI Effects of calcitonin on knee osteoarthritis and quality of life
SO RHEUMATOLOGY INTERNATIONAL
LA English
DT Article
DE Osteoporosis; Osteoarthritis; Calcitonin treatment; Rescue analgesic
ID salmon-calcitonin; articular chondrocytes; cartilage degradation; postmenopausal women; biochemical markers; turkish version; ii degradation; bone turnover; index; osteoporosis
AB There has been a recent interest in calcitonin as a potential treatment for osteoarthritis, based on its metabolic activities in both bone turnover and cartilage. The aim of this study was to evaluate the effects of nasal form calcitonin on knee osteoarthritis and quality of life in women who receive calcitonin treatment for postmenopausal osteoporosis. Two hundred and twenty postmenopausal women, aged between 55 and 65 years with knee pain and knee osteoarthritis, graded II-III by using Kellgren-Lawrence radiographic scoring system, were included. Western Ontario and McMaster Universities (WOMAC) osteoarthritis index, the quality of life questionnaire of the European Foundation for Osteoporosis (QALEFFO-41) and visual analog scale were used for the algofunctional assessments. Need of rescue analgesic was recorded. Pain ($P < 0.001$), stiffness ($P < 0.05$), functional capability ($P < 0.05$) and total score of WOMAC ($P < 0.05$) revealed statistically significant improvements after 3 months of the treatment and remained consistent throughout 1 year of the treatment period. Participants experienced significant reductions in WOMAC perceptions of pain (-53 %), joint stiffness (-44 %) and limitations in physical function (-49 %) at the end of 1 year of calcitonin treatment. Need of rescue analgesic intake was reported to have decreased approximately by 60 % at the end of the 1-year treatment period. QUALEFFO_41 scores improved: 37.6 (baseline), 30.9 (3 months), 28.0 (6 months) and 24.4 (1 year). In conclusion, nasal calcitonin treatment provided dual action on osteoporosis and osteoarthritis with significant improvements in quality of life and algofunctional results in knee osteoarthritis.

TI Examination of osteoarthritis and subchondral bone alterations within the stifle joint of an ovariectomised ovine model
SO JOURNAL OF ANATOMY
LA English
DT Article
DE bone mineral density; bone turnover; osteoarthritis; osteoporosis; ovariectomy; remodelling
ID articular-cartilage; mineral density; animal-models; biomechanical property; knee arthroplasty; cancellous bone; united-states; femoral-head; osteoporosis; estrogen
AB The exact relationship between osteoporosis and osteoarthritis is still a matter for debate for many. The ovariectomised ewe is frequently used as a model for osteoporosis, resulting in significant alterations in bone morphometry and turnover in both trabecular and subchondral bone after 1year. This study examines whether ovariectomy has any impact on development of osteoarthritis within the ovine stifle joint at the same time point. In addition, we investigate whether there are any significant correlations present between articular cartilage degeneration and alterations in microstructural parameters or turnover rates in the underlying bone. Twenty-two sheep were examined in this study; 10 of the sheep underwent ovariectomy and 12 were kept as controls. Five distinctive fluorochrome dyes were administered intravenously at 12-week intervals to both groups, to label sites of bone turnover. All animals were then sacrificed 12months postoperatively. Although most specimens showed some evidence of osteoarthritis, no measurable difference between the two study groups was detected. Osteoarthritis was associated with a thinning of the subchondral plate, specifically the subchondral cortical bone; however, whereas previous studies have suggested a link between trabecular thinning and osteoarthritis, this was not confirmed. No correlation was found between osteoarthritis and bone turnover rates of either the subchondral trabecular bone or bone plate. In conclusion, despite the fact that ovariectomy results in marked morphological and structural changes in the ovine stifle joint at 1-year postoperatively, no evidence was found to suggest that it plays a direct role in the aetiology of osteoarthritis.

TI Treatment of osteoporosis in men
SO BONE
LA English
DT Review
DE Bone mineral density; Fracture risk; Gonadal hormone status; Treatment; T-score
ID bone-mineral density; parathyroid-hormone 1-34; yearly zoledronic acid; postmenopausal women; fracture risk; hip fracture; elderly-men; randomized-trial; strontium ranelate; older men
AB Aspects of osteoporosis in men, such as screening and identification strategies, definitions of diagnosis and intervention thresholds, and treatment options (both approved and in the pipeline) are discussed. Introduction: Awareness of osteoporosis in men is improving, although it remains under-diagnosed and under-treated. A European Society for Clinical and Economic Aspects of Osteoporosis and Osteoarthritis (ESCEO) workshop was convened to discuss osteoporosis in men and to provide a report by a panel of experts (the authors). Methods: A debate with an expert panel on preselected topics was conducted. Results and conclusions: Although additional fracture data are needed to endorse the clinical care of osteoporosis in men, consensus views were reached on diagnostic criteria and intervention thresholds. Empirical data in men display similarities with data acquired in women, despite pathophysiological differences, which may not be clinically relevant. Men should receive treatment at a similar 10-year fracture probability as in women. The design of mixed studies may reduce the lag between comparable treatments for osteoporosis in women becoming available in men. (C) 2012 Elsevier Inc. All rights reserved.

DT Article
DE microtomography; osteoarthritis, osteoporosis; bone morphometry; image processing
ID trabecular bone; cancellous bone; resolution; osteoporosis
AB Introduction. Micro-CT analysis is a powerful technique for a non-invasive evaluation of the morphometric parameters of trabecular bone samples. This elaboration requires a previous binarization of the images. A problem which arises from the binarization process is the partial volume artifact. Voxels at the external surface of the sample can contain both bone and air so thresholding operates an incorrect estimation of volume occupied by the two materials. Aim. The aim of this study is the extraction of bone volumetric information directly from the image histograms, by fitting them with a suitable set of functions. Methods. Nineteen trabecular bone samples were extracted from femoral heads of eight patients subject to a hip arthroplasty surgery. Trabecular bone samples were acquired using micro-CT Scanner. Hystograms of the acquired images were computed and fitted by Gaussian-like functions accounting for: a) gray levels produced by the bone x-ray absorption, b) the portions of the image occupied by air and c) voxels that contain a mixture of bone and air. This latter contribution can be considered such as an estimation of the partial volume effect. Results. The comparison of the proposed technique to the bone volumes measured by a reference instrument such as by a helium pycnometer show the method as a good way for an accurate bone volume calculation of trabecular bone samples.

TI Bone and cartilage demonstrate changes localized to bone marrow edema-like lesions within osteoarthritic knees
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE Osteoarthritis; Knee; Marrow lesion; Edema; Subchondral bone; Histopathology; CT; MRI; FTIR; Tissue quality
ID cancellous bone; trabecular bone; femoral-head; mineralization; osteoporosis; association; tomography; thickness; turnover; pain
AB Objective: Our objective is to understand the biological and mechanical pathways linking cartilage, bone, and marrow changes in the progression of osteoarthritis (OA). The aim of the present study was to evaluate bone structure and composition within bone marrow edema-like lesion (BMEL) regions associated with knee OA. Methods: Tibial plateau specimens (n = 18) were collected from 10 subjects with knee OA during total knee arthroplasty (TKA). Magnetic resonance (MR) imaging was used to identify BMEL and quantify metrics of cartilage composition. Micro-computed tomography (mu CT) and high-resolution peripheral quantitative computed tomography (HR-pQCT) were used to quantify density and microstructure of the subchondral trabecular bone. Fourier transform infrared (FTIR) spectroscopy was used to quantify tissue composition. Results: Trabecular bone within BMEL was higher in volume fraction, with more and thicker trabeculae that were more plate-like in structure compared to unaffected regions. BMEL trabecular tissue composition had decreased phosphate and carbonate content. Marrow infiltration by a fibrous collagen network and evidence of increased bone remodeling were present. Structural and compositional changes were specifically localized to regions underlying cartilage degradation. Conclusion: These results support the paradigm of focal interactions among bone, marrow, and cartilage in the progression of knee OA. Quantitative evaluation of tissue changes and interactions may aid in the understanding of disease pathophysiology and provide imaging markers for disease progression. TI High prevalence of vitamin D deficiency in elderly patients with advanced osteoarthritis scheduled for total knee replacement associated with poorer preoperative functional state
SO ANNALS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND
LA English
DT Article
DE Vitamin D; Deficiency; 25-hydroxyvitamin; Osteoarthritis; Knee; Replacement; Arthroplasty
ID bone-mineral density; serum-levels; osteoporosis; female; women
AB Vitamin D deficiency has been reported previously in patients with osteoarthritis undergoing total hip arthroplasty. We found a high prevalence of vitamin D deficiency in elderly patients with advanced knee osteoarthritis scheduled for total knee replacement and also a significant association with a lower preoperative functional state. A review of the literature is given on vitamin D deficiency in patients with knee osteoarthritis and the association with lower outcome scores after arthroplasty is discussed.

TI Vertebral Fracture Assessment by Dual X-Ray Absorptiometry: A Valid Tool to Detect Vertebral Fractures in Community-Dwelling Older Adults in a Population-Based Survey
SO ARTHRITIS CARE & RESEARCH
LA English
DT Article
ID morphometric radiography; postmenopausal women; osteoporosis; deformity; risk; men; densitometry; mortality; spine; osteoarthritis
AB Objective Vertebral fractures are associated with higher morbidity and mortality. Since 70% of vertebral fractures are clinically silent, a radiologic image of the spine has to be acquired for the diagnosis. The aim of this study was to compare the performance of Vertebral Fracture Assessment (VFA) by dual x-ray absorptiometry (DXA) with radiographs to identify vertebral fractures in community-dwelling older adults. Methods A total of 429 older adults (ages 65 years) were enrolled in this cohort. VFA by DXA measurements were evaluated by 2 expert rheumatologists by consensus, and spine radiographs were analyzed according to the semiquantitative method by an expert radiologist. The correlation between VFA and spine radiographs to identify vertebral fractures was analyzed by kappa scores. Results The prevalence of vertebral fractures in VFA and radiographs was 29.1% and 29.4%, respectively ($P = 0.99$). The frequency of unavailable vertebrae was significantly lower in spinal radiographs than in VFA (0.9% and 5.6%, respectively; $P < 0.001$), particularly in T4T6. According to VFA, 5,013 vertebrae (96%) were identified as normal and 144 (2.7%) had grade 1, 58 (1.1%) had grade 2, and 12 (0.2%) had

grade 3 fractures. The sensitivity of VFA was 72.9% and the specificity was 99.1% to identify vertebral fractures. The sensitivity increased to 92% and the specificity increased to 99.9% when excluding grade 1 deformities. A good correlation between VFA and radiographs (= 0.74) was observed, and the exclusion of grade 1 resulted in even better agreement (= 0.84). Conclusion In community-dwelling older adults, VFA and radiographs had comparable performances in identifying vertebral fractures, particularly if mild deformities are excluded. Therefore, this methodology is a feasible and promising alternative to improve the management of patients with a high risk of osteoporotic fractures.

TI No effect of risedronate on articular cartilage damage in the Dunkin Hartley guinea pig model of osteoarthritis
SO SCANDINAVIAN JOURNAL OF RHEUMATOLOGY
LA English
DT Article
ID bone-mineral density; subchondral bone; knee osteoarthritis; biochemical markers; alendronate; turnover; progression; osteoporosis; degradation; inhibition
AB Objectives: To investigate whether treatment with a bisphosphonate would influence the subchondral bone plate stiffness and the development of cartilage damage in Dunkin Hartley guinea pigs, which develop osteoarthritis (OA) spontaneously. Method: Fifty-six 3-month-old male Dunkin Hartley guinea pigs were randomized into a baseline group and six groups receiving either the bisphosphonate risedronate (30 mu g/kg) or vehicle five times a week for 6, 12, or 24 weeks. The medial condyle of the right stifle joint was investigated by histology, using the Osteoarthritis Research Society International (OARSI) score, along with static and dynamic histomorphometry. The subchondral bone plate of the left tibia was tested mechanically with indentation testing. Degradation products of C-terminal telopeptides of type II collagen (CTX-II) were measured in serum. Results: The OARSI score did not differ between risedronate-treated and control animals at any time point. The fraction of bone surfaces covered with osteoclasts (Oc.S/BS) was significantly suppressed in risedronate-treated animals at all time points, as were the fractions of mineralizing surfaces (MS/BS) and osteoid-covered surfaces (OS/BS), and also serum CTX-II. This was accompanied by a significant increase in the epiphyseal content of calcified tissue and in the thickness of the subchondral bone plate. However, this did not result in a stiffer subchondral bone at any time point. Discussion: The risedronate treatment inhibited osteoclastic resorption of calcified cartilage in the primary spongiosa under the epiphyseal growth plate, explaining the risedronate-mediated decrease in CTX-II. Moreover,

the serum CTX-II level was not related to the OA-induced articular cartilage degradation seen in this model. Conclusions: Risedronate did not influence the OARSI score and subchondral plate stiffness, but decreased serum CTX-II in Dunkin Hartley guinea pigs.

TI Expression of vascular endothelial growth factor in normal, osteoarthritic and osteoporotic osteoblasts
SO CLINICAL AND EXPERIMENTAL MEDICINE
LA English
DT Article

DE VEGF; Osteoblasts; Osteoarthritis; Osteoporosis
ID subchondral bone; 1,25-dihydroxyvitamin d-3; cells; vegf; angiogenesis
AB To evaluate vascular endothelial growth factor (VEGF) mRNA expression and protein synthesis in primary human osteoblast cultures from healthy, osteoporotic and osteoarthritic subjects. Normal primary human osteoblast cultures were obtained from healthy subjects undergoing surgery for the reduction in traumatic fractures. Pathological osteoblasts were obtained from patients undergoing to total hip replacement for osteoporotic hip fracture or advanced osteoarthritis. VEGF mRNA expression and protein synthesis were evaluated in cultured cells, by semiquantitative real-time PCR and ELISA, respectively, both under basal conditions than after vitamin D-3 stimulation. Osteoarthritic osteoblasts showed a significantly higher VEGF expression compared to the normal and OP osteoblasts, both under basal conditions than in the presence of vitamin D-3, whereas no difference was found between osteoporotic and normal osteoblast. Vitamin D-3 significantly enhanced VEGF expression in normal and pathological osteoblasts. This preliminary study supports the hypothesis that VEGF is involved in the pathogenic mechanisms underlying the bone alterations typical of osteoarthritis and confirms the crucial role of vitamin D-3 supplementation in metabolic bone diseases.

TI Distribution of vitamin K2 in subchondral bone in osteoarthritic knee joints
SO KNEE SURGERY SPORTS TRAUMATOLOGY ARTHROSCOPY
LA English
DT Article
DE Vitamin K2; High-performance liquid chromatography; Subchondral bone; Osteoarthritis knee joint; Total knee arthroplasty
ID fermented soybean natto; ovariectomized rats; postmenopausal women; mineral density; k status; cartilage; menaquinone-7; phylloquinone; osteoporosis; tissue
AB Vitamin K may have multiple effects on articular cartilage and subchondral bone that could modulate the pathogenesis of osteoarthritis (OA). The purpose of this study was to evaluate the distribution of vitamin K2 in harvested bones obtained during total knee arthroplasty in knee OA patients. High-performance liquid chromatography was used to measure vitamin K2 in harvested bones obtained during 58 TKA procedures. Vitamin K2 levels were analysed in the medial (FM) and lateral (FL) femoral condyles and in the medial (TM) and lateral (TL) tibial condyles. There was significantly more vitamin K2 in the lateral femoral and tibial condyles than in the corresponding medial condyles (FL vs. FM, $p < 0.0001$; TL vs. TM, $p < 0.0001$). There was significantly more vitamin K2 in the FL than in the TL ($p = 0.003$), and in the FM, vitamin K2 levels were higher than those of the TM, although this was not significant (n.s.). There were no significant differences in vitamin K2 levels in men versus women nor was there a significant correlation with age. This study suggested that vitamin K2 might affect bone turnover since medial condyles showing advanced OA had lower vitamin K2 levels, while lateral condyles showing less advanced OA contained more vitamin K2. Gender and age were not correlated with vitamin K2 localization. All cases had Grade IV OA, and this study suggested that OA grade might be important in controlling the vitamin K2 levels in human bones.

TI Towards elucidating the role of SirT1 in osteoarthritis
SO FRONTIERS IN BIOSCIENCE-LANDMARK
LA English
DT Article
DE Ageing; osteoarthritis; OA; Histone Modifying Enzymes; Silent Information Regulator 2 Type 1; Sirt1; Inflammation; Review
ID interleukin-1-beta-induced nitric-oxide; articular chondrocytes; histone deacetylase; candidate genes; cartilage; expression; aggrecan; matrix; proteoglycan; apoptosis
AB Osteoarthritis (OA) is a degenerative joint disease particularly affecting the elderly population. Although several genetic features have been characterized as risk factors for OA susceptibility, a growing body of evidence indicates that epigenetic effectors may also modulate gene expression and thus contribute to OA

pathology. One such epigenetic regulator of particular relevance to OA is Silent Information Regulator 2 type 1 (SirT1) which has been linked to aging and caloric intake, Consistently, SirT1 has been also connected with various age-associated diseases such as diabetes type II, Alzheimers and osteoporosis. Recent reports show that OA is linked to changes in SirT1 activity or levels within cartilage. In human chondrocytes, SirT1 plays a role in cartilage extracellular matrix (ECM) synthesis and promotes cell survival, even under proinflammatory stress. It appears that SirT1 fine tunes many cellular biochemical processes through its capacity to interact and modify various histone and non-histone proteins. Taken together these investigations demonstrate that SirT1 is involved in cartilage biology and could potentially serve as novel drug target in treating OA even at its premature stages, thereby possibly reversing mechanical-stress induced cartilage degeneration.

DT Review
ID stress-fractures; mineral density; d supplementation; postmenopausal women; parathyroid function; calcium-absorption; osteoporosis; association; osteoarthritis; rickets
AB Vitamin D is important for normal development and maintenance of the skeleton. Hypovitaminosis D adversely affects calcium metabolism, osteoblastic activity, matrix ossification, bone remodeling and bone density. It is well known that Vit. D deficiency in the developing skeleton is related to rickets, while in adults is related to osteomalacia.. e causes of rickets include conditions that lead to hypocalcemia and/or hypophosphatemia, either isolated or secondary to vitamin D deficiency. In osteomalacia, Vit. D deficiency leads to impairment of the mineralisation phase of bone remodeling and thus an increasing amount of the skeleton being replaced by unmineralized osteoid. The relationship between Vit. D and bone mineral density and osteoporosis are still controversial while new evidence suggests that Vit. D may play a role in other bone conditions such as osteoarthritis and stress fractures. In order to maintain a "good bone health" guidelines concerning the recommended dietary intakes should be followed and screening for Vit. D deficiency in individuals at risk for deficiency is required, followed by the appropriate action.

ID body-mass index; strontium ranelate; subchondral bone; knee osteoarthritis; salmon-calcitonin; cartilage degradation; postmenopausal women; ctx-ii; articular chondrocytes; estrogen
AB Osteoarthritis (OA) and osteoporosis (OP) are highly prevalent health problems, associated with considerable morbidity. In the past, attention was focused on a supposed inverse relationship between OA and OP, since both disorders usually affect the elderly, but were regarded to rarely coexist in a single person. However, recent studies have revealed several factors which contribute to the pathogenesis of both disorders. These insights might contribute to the development of shared

new treatment options in the near future. Increased subchondral bone loss is a characteristic feature of OP and the early stage of OA, and this finding is the rationale for studies on the effect of anti-osteoporotic drugs in OA. In addition, inflammation and unfavourable body composition have been recognized as contributing factors for both disorders. Underweight is a risk factor for OP, while obesity stimulates the development of OA, by mechanical overloading of weight-bearing joints but also by supposed unfavourable effects of adipokines.

TI Association of lumbar disc degeneration with osteoporotic fractures; the Rotterdam study and meta-analysis from systematic review
SO BONE
LA English
DT Article
DE Lumbar disc degeneration; Osteoporotic fractures; Bone Mineral Density; Disc space narrowing; Vertebral fractures
ID bone-mineral density; quality-of-life; postmenopausal women; vertebral fractures; risk-factors; back-pain; incident; osteoarthritis; spine; men
AB Objective: To investigate the relation between lumbar disc degeneration (LDD) and all type of osteoporotic (OP) fractures including vertebral. Methods: This study is part of the Rotterdam study, a large prospective population-based cohort study among men and women aged 55 years and over. In 2819 participants spine radiographs were scored for LDD (osteophytes and disc space narrowing (DSN)) from L1 till Si, using the Lane atlas. Osteoporotic (OP) fracture data were collected and verified by specialists during 12.8 years. We considered two types of vertebral fractures (VFx): Clinical VFx (symptomatic fractures recorded by medical practitioners) and Radiographic VFx (using the McCloskey-Kanis method). Meta-analysis of published studies reporting an association of LDD features and VFx was performed. Differences in Bone Mineral Density (BMD) between participants with and without LDD features were analyzed using ANOVA. Risk of OP-fractures was analyzed using Cox regression. Results: In a total of 2385

participants, during 12.8 years follow-up, 558 suffered an OP-fracture. Subjects with LDD had an increased OP fracture risk compared to subjects without LDD (HR: 129, CI: 1.04-1.60). LDD-cases have between 03 and 0.72 standard deviations more BMD than non-cases in all analyzed regions including total body BMD and skull BMD (P < 0.001). Only males with LDD had increased risk for OP-fractures compared to males without LDD (adjusted-HR: 1.80, 95%CI 1.20-2.70, P = 0.005). The risk was also higher for VFx in males (HR: 1.64, CI: 1.03-2.60, P: 0.04). The association LDD-OP-fractures in females was lower and not significant (adjusted-HR: 1.08, 95%CI: 0.82-1.41). Meta-analyses showed that the risk of VFx in subjects with LDD has been studied only in women and there is not enough evidence to confidently analyze the relationship between LDD-features (DSN or/and OPH) and VFx due to low power and heterogeneity in phenotype definition in the collected studies. Conclusions: Male subjects with LDD have a higher osteoporotic fracture risk, in spite of systemically higher BMD. (C) 2013 Elsevier Inc. All rights reserved.

TI Vitamin D supplementation in elderly or postmenopausal women: a 2013 update of the 2008 recommendations from the European Society for Clinical and Economic Aspects of Osteoporosis and Osteoarthritis (ESCEO)
SO CURRENT MEDICAL RESEARCH AND OPINION
LA English

DT Review
DE Bone health; Guidance; Osteoporosis; Supplementation; Vitamin D
ID circulating 25-hydroxyvitamin d; d deficiency; pooled analysis; fracture risk; d inadequacy; calcium; mortality; prevention; population; frailty
AB Background: Vitamin D insufficiency has deleterious consequences on health outcomes. In elderly or postmenopausal women, it may exacerbate osteoporosis. Scope: There is currently no clear consensus on definitions of vitamin D insufficiency or minimal targets for vitamin D concentrations and proposed targets vary with the population. In view of the potential confusion for practitioners on when to treat and what to achieve, the European Society for Clinical and Economic Aspects of Osteoporosis and Osteoarthritis (ESCEO) convened a meeting to provide recommendations for clinical practice, to ensure the optimal management of elderly and postmenopausal women with regard to vitamin D supplementation. Findings: Vitamin D has both skeletal and extra-skeletal benefits. Patients with serum 25-hydroxyvitamin D (25-(OH)D) levels <50 nmol/L have increased bone turnover, bone loss, and possibly mineralization defects compared with patients with levels >50 nmol/L. Similar relationships have been reported for frailty, nonvertebral and hip fracture, and all-cause mortality, with poorer outcomes at <50 nmol/L. Conclusion: The ESCEO recommends that 50 nmol/L (i.e. 20 ng/mL) should be the minimal serum 25-(OH)D concentration at the population level and in patients with osteoporosis to ensure optimal bone health. Below this threshold, supplementation is recommended at 800 to 1000 IU/day. Vitamin D supplementation is safe up to 10,000 IU/day (upper limit of safety) resulting in an upper limit of adequacy of 125 nmol/L 25-(OH)D. Daily consumption of calcium-and vitamin-D-fortified food products (e.g. yoghurt or milk) can help improve vitamin D intake. Above the threshold of 50 nmol/L, there is no clear evidence for additional benefits of supplementation. On the other hand, in fragile elderly subjects who are at elevated risk for falls and fracture, the ESCEO recommends a minimal serum 25-(OH)D level of 75 nmol/L (i.e. 30 ng/mL), for the greatest impact on fracture.

TI Associations between measures of adiposity over 10 years and patella cartilage in population-based asymptomatic women
SO INTERNATIONAL JOURNAL OF OBESITY
LA English
DT Article
DE body mass index; adiposity; patella; magnetic resonance imaging
ID knee cartilage; geelong-osteoporosis; radiographic osteoarthritis; body-composition; defects; adults; volume; healthy; cohort; prevalence
AB OBJECTIVE: Osteoarthritis (OA) most commonly affects the patellofemoral compartment of the knee, and is a major cause of pain and disability. Structural changes that evolve prior to the onset of symptoms can be visualised using magnetic resonance imaging (MRI). There is little known information about the role of adiposity on the early structural changes in the patella cartilage in younger, asymptomatic adult females. METHODS: One hundred and sixty asymptomatic women (20-49 years) participating in the Geelong Osteoporosis Study underwent knee MRI (2006-8). Weight and body mass index (BMI) were measured 10 years prior (1994-7, baseline) and at the time of MRI (current), with change over the period calculated (current-baseline). Relationships between measures of adiposity and patella cartilage volume and defects were examined. RESULTS: After adjustment for age and patella bone volume, there was a reduction of 13 ml (95% confidence interval (95% CI), -25.7, -0.55) in patella cartilage volume for every 1

unit increase in current BMI, and a reduction of 27 ml (95% CI - 52.6, - 1.5) per BMI unit increase over 10 years (P = 0.04 for both). No significant association was observed between baseline BMI and patella cartilage volume (P = 0.16). Increased baseline and current weight and BMI were associated with increased prevalence of patella cartilage defects (all P<0.001). CONCLUSIONS: Adiposity and weight gain during midlife are associated with detrimental structural change at the patella in young to middle-aged healthy non-osteoarthritic women. Maintaining a healthy weight and avoiding weight gain in younger asymptomatic women may be important in the prevention of patellofemoral OA.

TI Hip structural analysis: a comparison of DXA with CT in postmenopausal Japanese women
SO SPRINGERPLUS
LA English
DT Article
DE Hip structural analysis; CT-based finite-element method; Bone strength; QCT
ID proximal femur; fracture risk; diagnostic-criteria; femoral-neck; bone; strength; prediction; osteoporosis; geometry; osteoarthritis
AB Geometry of the proximal femur is one determinant of fracture risk, and can be analyzed by a simple method using dual-energy X-ray absorptiometry (DXA). The aim of the present study was to investigate the accuracy of hip structural analysis (HSA) using clinical data in postmenopausal Japanese women. A total of 184 postmenopausal women aged 51-88 years (mean, 70.5 +/- 8.7 years) who underwent artificial joint replacement surgery for osteoarthrosis of the hip or knee joint were included. Computed tomography (CT) data from preoperative assessment were utilized for analysis of proximal femoral geometry (CT-HSA) using QCTPro Software (Mindways Software Inc., Austin, TX) and compared with HSA results based on DXA (DXA-HSA). The results of femoral geometry were further compared with a CT-based finite-element method (CT/FEM). There was moderate to high correlation between DXA-HSA and CT-HSA ($r = 0.60$-0.90, $p<0.001$), except for the buckling ratio in the intertrochanteric region. Moreover, the correlation of HSA with CT/FEM was similar between DXA-HSA and CT-HSA. The present results suggest that the geometry of proximal femoral cross sections can be reasonably

well characterized using DXA.

TI The relationship between peak knee extension at heel-strike of walking and the location of thickest femoral cartilage in ACL reconstructed and healthy contralateral knees
SO JOURNAL OF BIOMECHANICS
LA English
DT Article
DE ACL reconstruction; Knee kinematics; Osteoarthritis; Walking; Cartilage
ID cruciate ligament reconstruction; articular-cartilage; high prevalence; soccer players; gait mechanics; level walking; osteoarthritis; joint; kinematics; motion
AB Reports that knee cartilage health is sensitive to kinematic changes, combined with reports of extension loss following ACL reconstruction, underscores the importance of restoring ambulatory knee extension in the context of preventing premature osteoarthritis. The purpose of this study was to test the relationship between individual variations in peak knee extension at heel-strike of walking and the anterior-posterior location of thickest cartilage in the medial and lateral femoral condyles of healthy contralateral and ACL reconstructed knees. In vivo gait analysis and knee MR images were collected from 29 subjects approximately 2 years after unilateral ACL reconstruction. Knee extension was measured at heel-strike of walking and 3-D femoral cartilage thickness models were reconstructed from MR images. The ACL reconstructed knees had significantly reduced knee extension (-1.5 +/- 4.2 degrees) relative to the contralateral knees (-4.6 +/- 3.4 degrees) at heel-strike of walking but did not have side-to-side differences in the anterior-posterior location or magnitude of thickest medial and lateral femoral cartilage. The anterior-posterior location of the thickest medial femoral cartilage was correlated with knee extension at heel-strike in both the healthy contralateral ($R^2=0.356$, $p<0.001$) and reconstructed ($R^2=0.234$, $p=0.008$) knees. These results suggest that ACL reconstruction can impair terminal extension at periods of ambulatory loading known to be related to cartilage morphology in healthy joints. The fact that the femoral cartilage thickness distribution had not changed at 2 years post-op, even in the subset of subjects with extension loss, suggests that loads may be shifted to thinner cartilage regions, which could have important implications on long-term joint health. TI Diet-induced obesity alters the differentiation potential of stem cells isolated from bone marrow, adipose tissue and infrapatellar fat pad: the effects of free fatty acids
SO INTERNATIONAL JOURNAL OF OBESITY

AB INTRODUCTION: Obesity is a major risk factor for several musculoskeletal conditions that are characterized by an imbalance of tissue remodeling. Adult stem cells are closely associated with the remodeling and potential repair of several mesodermally derived tissues such as fat, bone and cartilage. We hypothesized that obesity would alter the frequency, proliferation, multipotency and immunophenotype of adult stem cells from a variety of tissues. MATERIALS AND METHODS: Bone marrow-derived mesenchymal stem cells (MSCs), subcutaneous adipose-derived stem cells (sqASCs) and infrapatellar fat pad-derived stem cells (IFP cells) were isolated from lean and high-fat diet-induced obese mice, and their cellular properties were examined. To test the hypothesis that changes in stem cell properties were due to the increased systemic levels of free fatty acids (FFAs), we further investigated the effects of FFAs on lean stem cells in vitro. RESULTS: Obese mice showed a trend toward increased prevalence of MSCs and sqASCs in the

stromal tissues. While no significant differences in cell proliferation were observed in vitro, the differentiation potential of all types of stem cells was altered by obesity. MSCs from obese mice demonstrated decreased adipogenic, osteogenic and chondrogenic potential. Obese sqASCs and IFP cells showed increased adipogenic and osteogenic differentiation, but decreased chondrogenic ability. Obese MSCs also showed decreased CD105 and increased platelet-derived growth factor receptor alpha expression, consistent with decreased chondrogenic potential. FFA treatment of lean stem cells significantly altered their multipotency but did not completely recapitulate the properties of obese stem cells. CONCLUSIONS: These findings support the hypothesis that obesity alters the properties of adult stem cells in a manner that depends on the cell source. These effects may be regulated in part by increased levels of FFAs, but may involve other obesityassociated cytokines. These findings contribute to our understanding of mesenchymal tissue remodeling with obesity, as well as the development of autologous stem cell therapies for obese patients.

TI The "bone morphogenic proteins" pathways in bone and joint diseases: Translational perspectives from physiopathology to therapeutic targets
SO CYTOKINE & GROWTH FACTOR REVIEWS
LA English
DT Review
DE Bone morphogenic proteins; Signaling pathways; Osteoporosis; Fracture healing; Osteoarthritis
ID growth-factor-beta; stimulates osteoblast differentiation; fibrodysplasia ossificans progressiva; single nucleotide polymorphisms; human articular chondrocytes; mesenchymal stem-cells; ia receptor bmpria; formation in-vitro; osteogenic protein-1; signal-transduction
AB A large body of evidence supports an important role of bone morphogenic proteins (BMPs) pathways in skeletal development in the embryo. BMPs are also involved in skeletal homeostasis and diseases in the adult. They were first identified as major bone anabolic agents and recent advances indicate that they also regulate osteoclastogenesis and joint components via multiple cross-talks with other signaling pathways. This review attempts to integrate these data in the pathogenesis of bone and joints diseases, such as osteoporosis, fracture healing, osteoarthritis, inflammatory arthritis, or bone metastasis. The use of recombinant BMPs in bone tissue engineering and in the treatment of skeletal diseases, or future therapeutic strategies targeting BMPs signal and its regulators, will be discussed based on these considerations. TI Nicotine-induced retardation of chondrogenesis through down-regulation of IGF-1 signaling pathway to inhibit matrix synthesis of growth plate chondrocytes in fetal rats
SO TOXICOLOGY AND APPLIED PHARMACOLOGY
LA English
DT Article
DE Nicotine; Skeletal growth retardation; Glucocorticoid; Insulin-like growth factor 1; Growth plate

ID pituitary-adrenal axis; cigarette-smoking; factor-i; prenatal overexposure; binding proteins; maternal smoking; skeletal growth; over-exposure; bone; dexamethasone
AB Previous studies have confirmed that maternal tobacco smoking causes intrauterine growth retardation (IUGR) and skeletal growth retardation. Among a multitude of chemicals associated with cigarette smoking, nicotine is one of the leading candidates for causing low birth weights. However, the possible mechanism of delayed chondrogenesis by prenatal nicotine exposure remains unclear. We investigated the effects of nicotine on fetal growth plate chondrocytes in vivo and in vitro. Rats were given 2.0 mg/kg . d of nicotine subcutaneously from gestational days 11 to 20. Prenatal nicotine exposure increased the levels of fetal blood corticosterone and resulted in fetal skeletal growth retardation. Moreover, nicotine exposure induced the inhibition of matrix synthesis and down-regulation of insulin-like growth factor 1 (IGF-1) signaling in fetal growth plates. The effects of nicotine on growth plates were studied in vitro by exposing fetal growth plate chondrocytes to 0, 1, 10, or 100 mu M of nicotine for 10 days. Nicotine inhibited matrix synthesis and down-regulated IGF-1 signaling in chondrocytes in a concentration-dependent manner. These results suggest that prenatal nicotine exposure induces delayed chondrogenesis and that the mechanism may involve the down-regulation of IGF-1 signaling and the inhibition of matrix synthesis by growth plate chondrocytes. The present study aids in the characterization of delayed chondrogenesis caused by prenatal nicotine exposure, which might suggest a candidate mechanism for intrauterine origins of osteoporosis and osteoarthritis. TI Microstructural differences between osteoporotic and osteoarthritic femoral cancellous bone: an in vitro magnetic resonance micro-imaging investigation
SO AGING CLINICAL AND EXPERIMENTAL RESEARCH
LA English
DT Article
DE NMR; T-2; Osteoporosis; Osteoarthritis; Femur; Micro-imaging
ID diffusion; architecture
AB Recently has been highlighted that topological properties of trabecular microstructure and microarchitectural deterioration of bone tissue are important factors in determining bone strength and its resistance to fracture. Magnetic resonance (MR) techniques allow investigation of both trabecular networks and bone marrow providing precious information on the physiological and functional changes associated with osteoporosis. The aim of the present work was to show the ability of MR micro-imaging investigation to describe cancellous bone status as related to its trabecular bone density and quality. For this purpose we measured in vitro, at high magnetic field (9.4T), the MR parameter T-2(APP) of cancellous bone samples extracted from femoral head of osteoporotic and osteoarthritic women as classified by dual energy X ray absorptiometry bone mineral density. We assessed T-2(APP) associations with T-scores, Harris Hip score and age. Results show that T-2(APP) is able to discriminate between osteoarthritic and osteoporotic bone samples. Moreover, the micro-imaging T-2(APP) investigation has highlighted a different trabecular bone density in cancellous bone specimens of osteoarthritic patients only, which is higher in subchondral compared to metaphysis section of

each sample.

TI Chlamydia pneumoniae and osteoporosis-associated bone loss: a new risk factor?
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE C. pneumoniae; Osteoporosis; sRANKL/OPG; IL-6; IL-1; TNF-alpha
ID atherosclerosis; infection; pathogens; cytokines; cells
AB We found an association between the presence of Chlamydia pneumoniae DNA both in osteoporotic bone tissue and peripheral blood mononuclear cells (PBMCs) and the increase in circulating resorptive cytokines. Our study was designed to determine whether C. pneumoniae infection may be involved in osteoporosis-associated bone loss. The study included 59 women undergoing hip joint replacement surgery for femoral neck fracture: 32 with osteoporosis and 27 with osteoarthritis. A total of 118 tissue specimens (59 bone tissues, 59 PBMCs) were examined for C. pneumoniae DNA by real-time polymerase chain reaction

(PCR). Serum levels of soluble receptor activator of nuclear factor kappa B ligand (sRANKL), osteoprotegerin (OPG), interleukin (IL)-1 beta, tumor necrosis factor-alpha, and IL-6 were also measured. C. pneumoniae DNA was detected in osteoporotic bone tissue whereas it was not found in non-osteoporotic bone tissue ($p < 0.05$). A significantly higher rate of C. pneumoniae DNA ($p < 0.05$) was found in PBMCs of osteoporotic patients than in those of osteoarthritis patients. Among osteoporotic patients, serum sRANKL, IL-1, and IL-6 concentrations as well as sRANKL/OPG ratio significantly differ between patients with bone tissue and PBMCs positive to C. pneumoniae and C. pneumoniae-negative patients. The association between the presence of C. pneumoniae DNA, both in bone tissue and PBMCs, and the increase in sRANKL/OPG ratio as well as in IL-1 beta and IL-6 levels observed in osteoporotic patients suggests C. pneumoniae infection as a new risk factor for osteoporosis.

TI Alendronate treatment for hip osteoarthritis: prospective randomized 2-year trial
SO CLINICAL RHEUMATOLOGY
LA English
DT Article
DE Alendronate; Hip osteoarthritis; Randomized controlled trial; Structure-modifying effects; Symptom-modifying effects
ID knee osteoarthritis; biochemical markers; cartilage degradation; bone; risedronate; progression; arthritis; symptoms; pain; associations
AB We examined the clinical efficacy of alendronate treatment for hip osteoarthritis using multiple outcome measures. Fifty patients with symptomatic hip osteoarthritis were enrolled in this prospective trial. The patients were randomly assigned to an alendronate group (35 mg/week alendronate and 600 mg/day calcium lactate) or a control group (600 mg/day calcium lactate) for 2 years. The groups were compared with regard to the following five parameters. The primary outcome measures are the following: (1) the Western Ontario and McMaster Universities (WOMAC) osteoarthritis pain score and the visual analog score (VAS). The secondary outcome measures are the following: (2) joint space width (JSW) measured on radiographs using a semiautomatic computer software, (3) the biochemical markers urinary N-telopeptide of type I collagen (NTX-I) and C-terminal cross-linking telopeptide of type II collagen (CTX-II), (4) dual-energy X-ray absorptiometry of the hip and lumbar spine, and (5) bone marrow edema on magnetic resonance images. The alendronate group showed pain improvement trends in VAS and WOMAC scores, whereas the control group showed worsening of pain. The alendronate group showed significant improvement in WOMAC pain scores after 12 months ($p = 0.031$) but no significant prevention of structural osteoarthritis progression, defined as a decrease in JSW > 0.30 mm or conversion to total hip arthroplasty. There was significantly larger decrease in the biochemical markers and significantly increased bone density in the alendronate group. Alendronate treatment by standard dose for osteoporosis showed clinical efficacy for decreasing pain but failed to show preventive effects for structural progression of hip osteoarthritis.

DT Review
DE osteoimmunology; cytokines; osteoclasts; RANKL; osteoporosis
ID tumor-necrosis-factor; nf-kappa-b; collagen-induced arthritis; nitric-oxide synthase; bone-mineral-density; growth-factor-beta; t-cell production; loss in-vivo; receptor activator; interferon-gamma
AB Bone and immune system are functionally interconnected. Immune and bone cells derive from same progenitors in the bone marrow, they share a common microenvironment and are being influenced by similar mediators. The evidence on increased bone resorption associated with inappropriate activation of T cells such as during inflammation, is well established. However, the molecular mechanisms beyond this clinical observation have begun to be intensively studied with the advancement of osteoimmunology. Now days, we have firm evidence on the influence of numerous proinflammatory cytokines on bone cells, with the majority of data focused on osteoclasts, the bone resorbing cells. It has been shown that some proinflammatory cytokines could possess osteoclastogenic and/or anti-osteoclastogenic properties and can target osteoclasts directly or via receptor activator of nuclear factor kappa B (RANK)/RANK ligand(RANKL)/osteoprotegerin (OPG) system. Several studies have reported opposing data regarding (anti) osteoclastogenic properties of these cytokines. Therefore, the first part of this review is summarizing current evidence on the influence of pro-inflammatory cytokines on osteoclasts and thus on bone resorption. In the second part, the evidence on the role of pro-inflammatory cytokines in osteoporosis and osteoarthritis is reviewed to show that unravelling the mechanisms beyond such complex bone diseases, is almost impossible without considering skeletal and immune systems as an indivisible integrated system.

DE DXA; dual-energy x-ray absorptiometry; precision; monitoring; least significant change; LSC; regions of interest; ROIs; standard scores
ID bone-density; osteoporosis; women; hip; osteoarthritis; risk; men
AB Physicians and other health care providers requesting dual-energy x-ray bone density studies must be able to critically review and interpret such studies. This requires an understanding of the computerized result components of the studies and how such data can be applied in clinical practice. The timing and interpretation of serial bone density studies is governed by the concepts of precision and least significant change. These statistical concepts are well within the purview of the practicing physician. Serial bone density studies cannot be interpreted without prior knowledge of the precision and least significant change of the test.

TI Osteoporosis and shoulder osteoarthritis: incidence, risk factors, and surgical implications
SO JOURNAL OF SHOULDER AND ELBOW SURGERY
LA English
DT Article
DE Osteoporosis; Shoulder osteoarthritis; Risk factors; Shoulder CT scan; Hounsfield units; Implant size
ID bone-mineral density; primary implant stability; hip; women; knowledge; fracture; men; turnover; older
AB Background: Patients with osteoarthritis undergoing shoulder arthroplasty may suffer from osteoporosis. The purpose of this study was to determine whether computed tomography (CT)-derived Hounsfield unit (HU) measurements correlate with bone mineral density (BMD) and whether these data could predict implant size and fixation choice. Materials and methods: The study analyzed preoperative dual energy x-ray absorptiometry and shoulder CT scans for 230 patients who underwent total shoulder arthroplasty. Hip BMD and T scores and HU attenuation in the humerus were correlated. HU cutoff values were developed to aid in differentiating patients whose BMD values were within normal reference ranges from patients with osteopenia or osteoporosis. Risk factors associated with low BMD were correlated, and the effect of BMD on humeral stem size, and fixation method was investigated. Results: Significant correlations between HU and hip BMD and T score were identified ($P < .001$). HU value ranges were identified that may alert the surgeon of metabolic bone disease. Significant correlation ($P < 0.05$) was found between low BMD and certain osteoporosis risk factors. Age at time of surgery was a predictor of cemented stem fixation ($P = .024$). Patients with a lower BMD were statistically more likely to receive a larger-diameter humeral stem ($P = .016$). Conclusions: Orthopedic surgeons may be able to use data obtained from shoulder CT scans to predict the need for larger stem size or cement fixation during shoulder arthroplasty. In combination with the risk factor profile, these data may be useful in predicting the need for an osteoporosis workup and treatment. Level of evidence: Level III, Study of Nonconsecutive Patients, Diagnostic Study. (C) 2013 Journal of Shoulder and Elbow Surgery Board of Trustees.

TI Leptin in Joint and Bone Diseases: New Insights
SO CURRENT MEDICINAL CHEMISTRY
LA English
DT Article
DE Cartilage; chondrocyte; bone; inflammation; leptin; rheumatic diseases; synovium
ID infrapatellar fat pad; sympathetic-nervous-system; diet-induced obesity; body-mass index; rheumatoid-arthritis; adipose-tissue; weight-loss; knee osteoarthritis; synovial-fluid; chondrocyte differentiation
AB Leptin is an adipokine with pleiotropic actions that regulates food intake, energy metabolism, inflammation and immunity, and also participates in the complex mechanism that regulates skeleton biology, both at bone and cartilage level. Leptin is increased in obesity and contributes to the "low-grade inflammatory state" of obese subjects causing a cluster of metabolic aberrations that affects joints and bone. In this review, we report the most recent research advances about the role of leptin in bone and cartilage function and its implication in inflammatory and degenerative joint diseases, such as osteoarthritis, rheumatoid arthritis and osteoporosis.

AB The microbiota of Westerners is significantly reduced in comparison to rural individuals living a similar lifestyle to our Paleolithic forefathers but also to that of other free-living primates such as the chimpanzee. The great majority of ingredients in the industrially produced foods consumed in the West are absorbed in the upper part of small intestine and thus of limited benefit to the microbiota. Lack of proper nutrition for microbiota is a major factor under-pinning dysfunctional microbiota, dysbiosis, chronically elevated inflammation, and the production and leakage of endotoxins through the various tissue barriers. Furthermore, the over-comsumption of insulinogenic foods and proteotoxins, such as advanced glycation and lipoxidation molecules, gluten and zein, and a reduced intake of fruit and vegetables, are key factors behind the commonly observed elevated inflammation and the endemic of obesity and chronic diseases, factors which are also likely to be detrimental to microbiota. As a consequence of this lifestyle and the associated eating habits, most barriers, including the gut, the airways, the skin, the oral cavity, the vagina, the placenta, the blood-brain barrier, etc., are increasingly permeable. Attempts to recondition these barriers through the use of so called 'probiotics', normally applied to the gut, are rarely successful, and sometimes fail, as they are usually applied as adjunctive treatments, e.g. in parallel with heavy pharmaceutical treatment, not rarely consisting in antibiotics and chemotherapy. It is increasingly observed that the majority of pharmaceutical drugs, even those believed to have minimal adverse effects, such as proton pump inhibitors and anti-hypertensives, in fact adversely affect immune development and functions and are most likely also deleterious to microbiota. Equally, it appears that probiotic treatment is not compatible with pharmacological treatments. Eco-biological treatments, with plant-derived substances, or phytochemicals, e.g. curcumin and resveratrol, and pre-, pro- and synbiotics offers similar effects as use of biologicals, although milder but also free from adverse effects. Such treatments should be tried as alternative therapies; mainly, to begin with, for disease prevention but also in early cases of chronic diseases. Pharmaceutical treatment has, thus far, failed to inhibit the tsunami of endemic diseases spreading around the world, and no new tools are in sight. Dramatic alterations, in direction of a paleolithic-like lifestyle and food habits, seem to be the only alternatives with the potential to control the present escalating crisis. The present review focuses on human studies, especially those of clinical relevance. (C) 2012 Elsevier Ltd. All rights reserved.

DT Review
DE calcitonin; cancer; drug safety; fracture; osteoporosis; pharmacovigilance; salmon calcitonin
ID postmenopausal bone loss; established osteoporosis; controlled-trials; clinical-trials; oral calcitonin; dose-response; women; prevention; osteoarthritis; fractures
AB Objective: To evaluate the strength of evidence supporting a possible association between salmon calcitonin (SCT) use and cancer incidence. Data Sources: Searches of MEDLINE/PubMed, MEDLINE/OVID, and EMBASE (January 1973 to September 20 I 3) were performed using the key search terms salmon calcitonin, humans, nasal calcitonin, and (for EM BASE only) randomized controlled trial. We also performed a manual review of data reviewed by the US Food and Drug Administration (FDA) committee in 2013. Study Selection and Data Extraction: All articles identified from the data sources were evaluated and all information deemed relevant was included for this review. Data Synthesis: Intranasal and injectable SCT are FDA-approved for the treatment of postmenopausal osteoporosis. After a safety signal suggested a possible link between SCT use and prostate cancer, the European Medicines Agency and FDA regulatory agencies conducted analyses of SCT randomized controlled trial data to assess cancer-related adverse events and to readdress the approval status of SCT. Eighteen studies were found that compared nasal or oral SCT and placebo. In 15 of the 18 studies, the percentage of malignancy was greater in the SCT arm. The studies varied in quality, outcomes, and length. Most of the studies had poor-quality methods to assess new cancer cases. Conclusions: Current evidence may suggest an association between SCT use and cancer incidence based on studies with poor-quality cancer assessment methods. However, considering the lack of demonstrated efficacy of SCT to reduce fractures, clinicians should consider discontinuing its use for osteoporosis treatment regardless of the FDA's final approval decision.

TI Clinical Results of Patellofemoral Arthroplasty
SO JOURNAL OF ARTHROPLASTY
LA English
DT Article
DE knee arthroplasty; patellofemoral arthroplasty
ID total knee arthroplasty; arthritis; prosthesis; design
AB Isolated patellofemoral arthritis can be a disabling condition that can be challenging to treat. Patients with symptoms recalcitrant to conservative measures are considered for total or partial knee arthroplasty. This retrospective study reports the results of patellofemoral arthroplasty at a single center using a variety of implant designs. Thirty patients (37 knees) with isolated patellofemoral disease treated with patellofemoral arthroplasty with a minimum of one year follow-up were evaluated. The majority of patients were female (83%) and the underlying diagnosis was osteoarthritis in 98% of knees. Reported follow-up averaged 31 months. Average Knee Society Pain, Functional, and Clinical Scores improved from pre-op to most recent follow-up. Two complications (5.4%) required intervention. One patient was converted to a total knee arthroplasty secondary to patella instability. (C) 2013 Published by Elsevier Inc.

TI Effect of implanted bisphosphonate-enriched cement on the trabecular microarchitecture of bone in a rat model using micro-computed tomography
SO INTERNATIONAL ORTHOPAEDICS
LA English
DT Article
ID in-vitro; pamidronate; fixation; histomorphometry; osteoarthritis; osteoporosis; osteoclasts; allograft; surface
AB Bisphosphonates (BPs) are antiresorptive drugs typically used to inhibit bone resorption. The latest reports show that BPs play an important role in not only achieving better bone mineral density but also in improving bone microarchitecture. The mechanism of action of the BPs is complex and multifactorial. We tried to determine whether there are any changes in the microarchitectural bone structure during local use of BP (Pamifos 60). The aim of this study was to see if BP-enriched cement used in rat models had positive effects on bone formation. Research was performed on 40 adult male Wistar rats that were divided into four groups: two control groups and two experimental groups. Rats in the experimental groups were implanted with BP-enriched cement into the bone, while the control group rats were implanted with clean bone cement (without BP). Micro-computed tomography was applied for the investigation of trabecular microarchitecture of the proximal physis of the tibial bone in all animals three and six weeks after surgery. In all microCT images variables such as bone volume

density (BV/TV), trabecular thickness (TbTh), trabecular separation (TbSp) and trabecular number (TbN) were used to describe trabecular bone morphometry. The major finding of this study is that using BP-enriched cement results in distinct changes in bone microarchitecture. We showed that local use of pamidronate (Pamifos 60) in orthopaedic cement had a positive effect on bone formation. It significantly changed three variables. We noticed increasing bone volume fraction and trabecular thickness together with decreasing trabecular separation. In this paper we demonstrate the efficacy of using BP-enriched cement in vitro in the tibiae of rats. Our most significant finding based on micro-CT picture analysis allows us to start further work on more suitable applications of BP-enriched cement in humans. We believe that future successful experiments will facilitate potential use of BP-enriched cement in clinical applications.

TI Bone loss at subchondral plate in knee osteoarthritis patients with hypertension and type 2 diabetes mellitus
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE Osteoarthritis; Subchondral plate; Microstructure; Hypertension; Type 2 diabetes mellitus
ID blood-pressure; risk-factors; osteoblasts; disease; cartilage; hip; osteoporosis; chondrocytes; association; progression
AB Objectives: This study aimed to characterize subchondral bone damages of knee osteoarthritis (OA) patients in presence of the comorbidities, i.e., hypertension and type 2 diabetes mellitus (T2DM). Methods: A total of 43 patients with advanced stage of primary knee OA were recruited, and tibial plateau specimens were collected during surgery with informed consent. The specimens were processed for

microCT and histological examination to assess the severity of subchondral bone damages. The presence of the comorbid disease, e.g., hypertension and T2DM, and the data on covariates, such as the age, gender and body mass index (BMI), were taken into account in a multi-variable linear regression model to explore the potential effect of the comorbidities on subchondral bone damages in knee OA after adjusting the covariates. Results: As compared to 15 subjects without the comorbidities, significant bone loss was observed at subchondral plate in 28 knee OA patients with hypertension and T2DM, in terms of the lower bone mineral density (BMD) (P = 0.034) and higher porosity (P = 0.032) on the medial portion of tibial plateau. After adjusting the age, gender and BMI, the presence of hypertension or T2DM was included in a regression model to explain in part the decreased BMD (r(2) = 0.551, P = 0.004) and increased porosity (r(2) = 0.545, P = 0.003) at subchondral plate in knee OA. Conclusion: Our findings suggest the biological link between bone loss at subchondral bone plate in knee OA and the comorbid diseases, i.e., hypertension and T2DM, which prompt the needs for a large-scale cohort study to confirm the causality. TI EXTENDED REPORT Efficacy and safety of strontium ranelate in the treatment of knee osteoarthritis: results of a double-blind, randomised placebo-controlled trial
SO ANNALS OF THE RHEUMATIC DISEASES
LA English
DT Article
ID postmenopausal women; glucosamine sulfate; chondroitin sulfate; subchondral bone; progression; 2-year; osteoporosis; radiographs; promotes; sequence
AB Background Strontium ranelate is currently used for osteoporosis. The international, double-blind, randomised, placebo-controlled Strontium ranelate Efficacy in Knee OsteoarthrItis triAl evaluated its effect on radiological progression of knee osteoarthritis. Methods Patients with knee osteoarthritis (Kellgren and Lawrence grade 2 or 3, and joint space width (JSW) 2.5-5 mm) were randomly allocated to strontium ranelate 1 g/day (n = 558), 2 g/day (n = 566) or placebo (n = 559). The primary endpoint was radiographical change in JSW (medial tibiofemoral compartment) over 3 years versus placebo. Secondary endpoints included radiological progression, Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) score, and knee pain. The trial is registered (ISRCTN41323372). Results The intention-to-treat population included 1371 patients. Treatment with strontium ranelate was associated with smaller degradations in JSW than placebo (1 g/day: -0.23 (SD 0.56) mm; 2 g/day: -0.27 (SD 0.63) mm; placebo: -0.37 (SD 0.59) mm); treatment-placebo differences were 0.14 (SE 0.04), 95% CI 0.05 to 0.23, $p < 0.001$ for 1 g/day and 0.10 (SE 0.04), 95% CI 0.02 to 0.19, $p = 0.018$ for 2 g/day. Fewer radiological progressors were observed with strontium ranelate ($p < 0.001$ and $p = 0.012$ for 1 and 2 g/day). There were greater reductions in total WOMAC score ($p = 0.045$), pain subscore ($p = 0.028$), physical function subscore ($p = 0.099$) and knee pain ($p = 0.065$) with strontium ranelate 2 g/day. Strontium ranelate was well tolerated. Conclusions Treatment with strontium ranelate 1 and 2 g/day is associated with a significant effect on structure in patients with knee osteoarthritis, and a beneficial effect on symptoms for strontium ranelate 2 g/day.

TI Strontium ranelate reduces the progression of experimental dog osteoarthritis by inhibiting the expression of key proteases in cartilage and of IL-1β in the synovium
SO ANNALS OF THE RHEUMATIC DISEASES
LA English

DT Article
ID nitric-oxide synthase; subchondral bone; knee; recommendations; osteoporosis; osteoblasts; resorption; reduction; collagen
AB Objective To explore the disease-modifying effect, under therapeutic conditions, of strontium ranelate (SrRan) on the progression of joint structural changes and on the major pathophysiological pathways in an experimental osteoarthritis dog model. Methods Dogs underwent sectioning of the anterior cruciate ligament, and 4 weeks after surgery received oral treatment of SrRan 25, 50 or 75 mg/kg per day, or placebo for 12 weeks. Methods included macroscopy, picrosirius red staining, histology, subchondral bone histomorphometry, quantitative PCR, and ELISA for CTX-II level in serum. Strontium plasma and synovial fluid levels were also measured. Results At steady state, strontium blood exposures were within the clinical therapeutic range of osteoarthritis patients and correlated with strontium concentrations in synovial fluid. SrRan treatment significantly reduced the osteoarthritis cartilage lesions at all doses tested ($p <= 0.05$). Significantly better preservation of the collagen network was also found in SrRan-treated dogs at 50 and 75 mg/kg per day ($p=0.03$). The osteoarthritis subchondral bone thickening observed in osteoarthritis-placebo dogs was significantly reduced by SrRan at 50 mg/kg per day ($p=0.02$). The increased gene expression levels of MMP-1, MMP-13 and cathepsin K in osteoarthritis cartilage were all significantly reduced by SrRan at 75 mg/kg per day ($p <= 0.03$) as were, in osteoarthritis synovium, IL-1 beta at 50 and 75 mg/kg per day ($p=0.05$) and MMP-3 at all doses tested ($p <= 0.02$). The serum level of CTX-II was reduced ($p <= 0.04$) by SrRan at 16 weeks in dogs treated with 50 and 75 mg/kg per day. Conclusions This study is the first to demonstrate in vivo in an animal model that SrRan reduced the progression of osteoarthritis structural changes. The inhibition of several key proteases as well as IL-1 beta may have contributed to the beneficial effect of SrRan.

TI Partial and complete retirement due to ill-health among mature age Australians
SO PUBLIC HEALTH
LA English
DT Article
DE Retirement; Middle aged; Chronic disease; Rural area
ID labor-force participation; gradual retirement; older workers; population; employment; impact; cancer; rates
AB Objectives: An ageing population requires governments to keep older people working longer and delay early retirement. This paper investigates the extent to

which common health problems and geographical location are associated with full and partial early retirement among mature-age Australians. Study design: Cross sectional. Methods: Multinomial logistic regression analysis of self-reported data of 21,719 women and 16,393 men from the 45 and Up Study. Outcome measure: retirement status. Results: Women who reported ever having been told by a doctor that they had a stroke, cancer (except melanoma and skin and breast cancer), osteoarthritis, depression, osteoporosis, thrombosis, or anxiety were more likely to be fully retired due to ill-health compared to those without these health problems. Those who reported ever having been told by a doctor that they had depression, breast cancer or osteoarthritis were more likely to be partially retired due to ill-health than those without these health problems. Men who reported ever having been told by a doctor that they had cancer, heart disease, anxiety or depression were more likely to be fully or partially retired due to ill-health than those without these health problems. Men who reported having had a stroke, diabetes, thyroid problems, osteoarthritis or osteoporosis were more likely to be fully retired due to ill-health compared to those without these health problems. Men and women living outside major cities were more likely to be fully retired due to ill-health. Men from outer regional areas were also more likely to be partially retired due to ill-health. Conclusions: To reduce early retirement due to ill-health, health practitioners, governments and employers should address targeted health problems, particularly in areas outside capital cities. TI A systematic approach to magnetic resonance imaging evaluation of epiphyseal lesions
SO MAGNETIC RESONANCE IMAGING
LA English
DT Article
DE Epiphyseal lesions; Subchondral insufficiency fracture; Osteochondral lesion; Transient osteoporosis; Giant cell tumor; Clear cell chondrosarcoma; Eosinophilic granuloma; Osteomyelitis; Avascular necrosis; Magnetic resonance imaging; Chemical shift imaging; Diffusion weighted imaging
ID clear-cell chondrosarcoma; radiologic-pathological correlation; subchondral insufficiency fracture; bone-marrow involvement; tumor-like conditions; femoral-head; chemical-shift; osteochondritis-dissecans; eosinophilic granuloma; avascular necrosis
AB Magnetic Resonance Imaging (MRI) is the preferred modality of choice to image epiphyseal lesions. It provides excellent soft tissue resolution and extent of disease. A wide spectrum of tumor and tumor like lesions can involve the epiphysis. Early and accurate diagnosis as well as appropriate management of epiphyseal lesions is critical as these conditions may lead to disabling complications such as, limb length discrepancy, angular or joint surface deformities and secondary osteoarthritis. In this article, we discuss the role of conventional sequences, such as T1W, fluid sensitive T2W and intravenous (IV) Gadolinium enhanced sequences as well as the additional value of problem solving MRI sequences such as, chemical shift and diffusion weighted imaging. Based on the imaging findings on various MRI sequences and lesion characteristics, a systematic approach directed to the diagnoses of epiphyseal lesions is presented and discussed. MRI features of clinically and biopsy proven examples of the epiphyseal lesions, such as osteomyelitis, intra-osseous abscess, infiltrative malignancy, metastases, transient osteoporosis, subchondral insufficiency fracture, avascular necrosis, osteochondral fracture, osteochondritis dissecans, eosinophilic granuloma and geode are demonstrated. Using this systematic approach, the reader will be able to better characterize epiphyseal lesions with a potential to positively affect patient management. (C) 2013 Elsevier Inc. All rights reserved.

DT Article
DE Locomotive syndrome; Lumbar spine; Musculoskeletal disease; Quality of life; Visual analogue scale
ID pain evaluation questionnaire; low-back-pain; postmenopausal women; vertebral fractures; european foundation; spinal mobility; natural-history; osteoarthritis; knee; osteoporosis
AB The Japanese Orthopaedic Association (JOA) has proposed the term "locomotive syndrome" (LS) to designate a condition in individuals with musculoskeletal disease in high-risk groups who are highly likely to require nursing care. The present study investigated the influence of LS on the quality of life (QOL)

of a community-living population. A total of 386 subjects a parts per thousand yen 50 years of age were enrolled in the study. Those whose scores on the 25-question Geriatric Locomotive Function Scale were a parts per thousand yen16 were defined as having LS. Participants answered the JOA Back Pain Evaluation Questionnaire (JOABPEQ) and visual analogue scales (VAS) for low back pain, leg pain, leg numbness, and left and right knee pain; the Roland Morris Disability Questionnaire (RDQ); and the Short Form 36 (SF-36). We compared the scores on the three QOL measures between subjects diagnosed with and without LS. There were 62 people defined as having LS. Subjects with LS scored significantly lower on the JOABPEQ and SF-36 than those without LS. They also had significantly higher scores on the five VASs and the RDQ compared with those without LS. We found that LS strongly impacted QOL and the scores from the VASs. LS appears to be a useful concept for screening subjects who are experiencing a lowered QOL due to musculoskeletal diseases, especially degenerative lumbar diseases and knee osteoarthritis.

TI Collagen hydrolysate based collagen/hydroxyapatite composite materials
SO JOURNAL OF MOLECULAR STRUCTURE
LA English
DT Article
DE pH influence; Collagen hydrolysate; Scaffold; Bone grafts; Composite material
ID in-vitro; hydroxyapatite; bone; scaffolds; nanocomposites; stimulation; temperature; gelatin; ph
AB The aim of this study was to study the influence of collagen hydrolysate (HAS) on the formation of ternary collagen-hydrolysate/hydroxyapatite composite materials (COLL-HAS/HA). During the precipitation process of HA, a large amount of brushite is resulted at pH = 7 but, practically pure HA is obtained at pH >= 8. The FTIR data reveal the duplication of the most important collagen absorption bands due to the presence of the collagen hydrolysate. The presence of collagen hydrolysate is beneficial for the management of bone and joint disorders such as osteoarthritis and osteoporosis. (C) 2012 Elsevier B.V. All rights reserved.

aflatoxin-b1
AB Mycotoxins are secondary metabolites produced by several fungi contaminating crops. In several countries, the maximum permitted levels of mycotoxins are found in foodstuffs and feedstuffs. The common strategy of mycotoxin analysis involves extraction, clean-up and quantification by chromatography. In this paper, we analyzed the reasons of underestimation of ochratoxin A (OTA) content in wine, and overestimation of OTA in wheat, depending on the pH of the clean-up step and the simultaneous presence of citrinin (CIT). We demonstrated that the increase of pH by adding polyethylene glycol (PEG) to wine led to an underestimation of OTA by conversion of OTA into open ring ochratoxin A OP-OA. In comparing three methods of extraction and clean-up for the determination of OTA and CIT in wheat(i) an inter-laboratory validated method for OTA in cereals using immunoaffinity column clean-up (IAC) and extraction by acetonitrile/water; (ii) a validated method using IAC and extraction with 1% bicarbonate Na; and (iii) an in-house validated method based on acid liquid/liquid extractionwe observed an overestimation of OTA after immunoaffinity clean-up when CIT is also present in the sample, whereas an underestimation was observed when OTA was alone. Under neutral and alkaline conditions, CIT was partially recognized by OTA antibodies.

TI Aging, obesity, and multimorbidity in women 50 years or older: a population-based study
SO MENOPAUSE-THE JOURNAL OF THE NORTH AMERICAN MENOPAUSE SOCIETY
LA English
DT Article
DE Multimorbidity; Women; Obesity; Aging
ID chronic diseases; health-care; self-report; prevalence; disability; agreement; education; patterns; impact
AB Objective: This study aims to evaluate multimorbidity and its associated factors in Brazilian women aged 50 years or older. Methods: This is a cross-sectional, population-based study using self-reports. A total of 622 women aged 50 years or older were included. Multimorbidity was defined as two or more of the following morbidities: hypertension, osteoarthritis, cataracts, diabetes mellitus, osteoporosis, glaucoma, chronic bronchitis or asthma, urinary incontinence, cancer, myocardial infarction, stroke, and pulmonary emphysema. Sociodemographic, clinical, and

behavioral factors were evaluated. Data were analyzed using chi(2) test and Fisher's exact test, and Poisson multiple regression analysis was performed. Prevalence ratios and their 95% CIs were calculated. Results: In this sample, 15.8% of participants reported no morbidities, whereas 26% reported having one morbid condition and 58.2% reported multimorbidity. With respect to morbidities, 55.9% of women reported having hypertension, 33.8% reported having osteoarthritis, 24.5% reported having cataracts, 22.7% reported having diabetes, 21.3% reported having osteoporosis, 9.9% reported having glaucoma, 9.2% reported having bronchitis, 8.9% reported having urinary incontinence, and 6.8% reported having cancer, whereas 4.8% reported having had a myocardial infarction, 2.7% reported having had a stroke, and 1.8% reported having pulmonary emphysema. Multiple regression analysis showed that for each additional year of life, women increased their likelihood of multimorbidity by 3% (95% CI, 1.02-1.04). Furthermore, for each point increase (kg/m(2)) in their body mass index, women also increased their likelihood of multimorbidity by 3% (95% CI, 1.02-1.04). Conclusions: Multimorbidity is principally associated with aging and obesity.

TI Risk factors for falls in a longitudinal population-based cohort study of Japanese men and women: The ROAD Study
SO BONE
LA English
DT Article
DE Falls; Longitudinal study; Pain; Osteoarthritis; Physical performance
ID dwelling elderly-people; osteoporotic fractures; physical performance; back-pain; knee osteoarthritis; vertebral fractures; lumbar spondylosis; muscle strength; association; balance
AB The objective of this study was to clarify the associations of physical performance and bone and joint diseases with single and multiple falls in Japanese men and women using a population-based longitudinal cohort study known as Research on Osteoarthritis/osteoporosis Against Disability (ROAD). A total of 452 men and 896 women were analyzed in the present study (mean age, 63.9 years). A questionnaire was used to assess the number of falls during the 3-year follow-up. Grip strength, 6-m walking time, and chair stand time were measured at baseline. Knee osteoarthritis (OA) and lumbar spondylosis were defined as Kellgren Lawrence = 2, 3 or 4. Vertebral fracture (VFx) was assessed with the Japanese Society of Bone and Mineral Research criteria. Osteoporosis was defined by bone mineral density using dual energy X-ray absorptiometry based on World Health Organization criteria. Knee and lower back pain were estimated by an interview. During a 3-year follow-up, 79 (17.4%) men and 216 (24.1%) women reported at least one fall, and 54(11.9%) men and 111 (12.4%) women reported multiple falls. Knee pain was a risk factor for multiple falls in women, but not in men. VFx tended to be associated with multiple falls in women, but not in men. A longer 6-m walking time was a risk factor for multiple falls in women, whereas a longer chair stand time was a risk factor for multiple falls in men. We found gender differences in risk factors for falls. (C) 2012 Elsevier Inc. All rights reserved.

TI Age-dependent decrease in the chondrogenic potential of human bone marrow mesenchymal stromal cells expanded with fibroblast growth factor-2
SO CYTOTHERAPY
LA English
DT Article
DE aging; bone marrow; chondrocytes; differentiation; mesenchymal stromal cells
ID stem-cells; donor variation; differentiation; osteoarthritis; osteoporosis; cultures; consequences; progenitors; expansion; number
AB Background aims. Human bone marrow mesenchymal stromal cells are useful in regenerative medicine for various diseases, but it remains unclear whether the aging of donors alters the multipotency of these cells. In this study, we examined age-related changes in the chondrogenic, osteogenic and adipogenic potential of mesenchymal stromal cells from 17 donors (25-81 years old), including patients with or without systemic vascular diseases. Methods. All stem cell lines were

expanded with fibroblast growth factor-2 and then exposed to differentiation induction media. The chondrogenic potential was determined from the glycosaminoglycan content and the SOX9, collagen type 2 alpha 1 (COL2A1) and aggrecan (AGG) messenger RNA levels. The osteogenic potential was determined by monitoring the alkaline phosphatase activity and calcium content, and the adipogenic potential was determined from the glycerol-3-phosphate dehydrogenase activity and oil red 0 staining. Results. Systemic vascular diseases, including arteriosclerosis obliterans and Buerger disease, did not significantly affect the trilineage differentiation potential of the cells. Under these conditions, all chondrocyte markers examined, including the SOX9 messenger RNA level, showed age-related decline, whereas none of the osteoblast or adipocyte markers showed age-dependent changes. Conclusions. The aging of donors from young adult to elderly selectively decreased the chondrogenic potential of mesenchymal stromal cells. This information will be useful in stromal cell based therapy for cartilage-related diseases.

TI Increased Levels of Interleukin 34 in Serum and Synovial Fluid Are Associated with Rheumatoid Factor and Anticyclic Citrullinated Peptide Antibody Titers in Patients with Rheumatoid Arthritis
SO JOURNAL OF RHEUMATOLOGY
LA English
DT Article
DE INTERLEUKIN 34; RHEUMATOID ARTHRITIS; RHEUMATOID FACTOR; ANTICYCLIC CITRULLINATED ANTIBODIES; OSTEOPOROSIS
ID osteopetrotic op/op mice; disease-activity; t-cells; joint destruction; langerhans cells; bone loss; osteoclastogenesis; criteria; rankl; classification
AB Objective. Interleukin 34 (IL-34) is a recently discovered cytokine that binds macrophage colony-stimulating factor (M-CSF) receptor. Rheumatoid arthritis (RA) is characterized by increased osteoclastogenesis. To identify the significance of IL-34 in RA, the IL-34 concentration was measured in serum and synovial fluid (SF). Methods. IL-34 concentrations were measured in serum from patients with RA (n = 113), patients with osteoarthritis (OA; n = 56), and controls (n = 36), and in SF isolated from patients with RA (n = 36) or OA (n = 24). Correlations between serum IL-34 levels and clinical features in RA were assessed. The levels of IL-1 beta, IL-6, IL-17 alpha, interferon-gamma-induced protein 10, receptor activator of nuclear factor kappa B ligand (RANKL), and Dickkopf-1 were also measured. Results. Patients with RA had a higher mean serum level of IL-34 than did patients with OA and controls (188.0 +/- 550.3, 36.6 +/- 38.0, and 49.1 +/- 78.5 pg/ml, respectively). Similarly, SF IL-34 concentration was higher in patients with RA than in those with OA. IL-34 levels were positively associated with IL-6 levels in serum from patients with RA and OA. SF IL-34 concentration correlated significantly with IL-6 and RANKL levels only in RA. The serum level of IL-34 was not correlated with systemic osteoporosis and radiographic joint damage in RA. IL-34 levels in the serum from patients with RA were positively correlated with rheumatoid factor and anticyclic citrullinated peptide antibody titers (r = 0.282 and 0.491, respectively). Conclusion. Circulating IL-34 levels in RA correlated with autoantibody production. Further investigations of localized and systemic effects of IL-34 are warranted to elucidate RA pathogenesis.

TI The Relationship between Osteoarthritis and Osteoporosis in Patients with Primary Generalized Osteoarthritis
SO TURKISH JOURNAL OF RHEUMATOLOGY
LA English
DT Article
DE Bone mineral density; osteoarthritis; osteoporosis
ID bone-mineral density; radiographic knee osteoarthritis; postmenopausal women; osteo-arthritis; iliac crest; elderly men; hip; hand; fracture; femur
AB Objectives: This study aims to examine the relationship between primary generalized osteoarthritis (OA) and bone mineral density (BMD) and to investigate whether OA patients have a higher BMD value than healthy individuals. Patients and methods: The study population consisted of 80 postmenopausal female

patients (mean age 58.95 +/- 4.63 years) who suffered from hand OA with Heberden's nodes, while the control group consisted of 80 postmenopausal female patients (mean age 57.62 +/- 5.39) without symptomatic OA and Heberden's nodes. The patients were age-matched. Blood biochemistry, thyroid function tests and bone turnover markers (serum calcium, phosphorus, alkaline phosphatase, osteocalcin, and urine deoxypyridinoline) and 25-hydroxyvitamin D3 [25(OH)D3] levels of the participants were measured. A comparison was made between the two groups with regard to BMD levels, lateral thoracolumbar X-rays, and anteroposterior radiographs of the pelvis, knees, and hands. The evaluation of the radiographs was based on the Kellgren-Lawrence scale. The lumbar and femoral BMD levels in both groups were measured in g/cm(2) with dual-energy X-ray absorptiometry. Results: The 25(OH)D3 value of the OA group was significantly higher than the control group, indicating a statistically significant difference. The lumbar spine BMD levels were statistically higher in the control group compared with the OA group, however, there were no significant differences in the hip BMD values and lumbar spine T scores between the groups. Conclusion: Our study results suggest that primary generalized OA is not protective against osteoporosis.

TI Prompt Analgesic Effect of Antihistaminic Diphenhydramine Ointment on Bone-Joint-Muscle Pain as Assessed by Skin Impedance
SO PHARMACOLOGY
LA English
DT Article
DE Pain; Analgesic; Skin impedance; Diphenhydramine; Indomethacin; Histamine
ID cell-adhesion molecule-1; nerve-mast cell; histidine-decarboxylase; calcium paradox; bisphosphonates etidronate; double-blind; histamine; mice; interleukin-1; disease
AB Pain is sensed, transmitted, and modified via a variety of mediators and their receptors. Histamine is a well-known mediator of pain. In addition to their antagonistic effects against histamine, classical antihistaminics possess, to various degrees, antimuscarinergic, antiserotonergic, antiadrenergic, local anesthetic, membrane-stabilizing and other pharmacologic actions. Although there have been many attempts to use classical antihistaminics as analgesics and/or analgesic adjuvants, the appearance of non-steroidal anti-inflammatory drugs discouraged such efforts. Here, we compared the analgesic effect of an ointment containing 1%

diphenhydramine (a typical first-generation antihistaminic drug) with that of indomethacin (a typical non-steroidal anti-inflammatory drug) in elderly patients with osteoarthritis and/or osteoporosis who complained of bone-joint-muscle pain. Analgesic effects were evaluated by measuring skin impedance and by subjective pain assessments (using a visual recording system) before and after ointment application. Diphenhydramine ointment exerted a prompt and marked analgesic effect that lasted for several hours, as assessed by either skin impedance or subjective pain evaluation. In contrast, the analgesic effect of indomethacin ointment was marginal, and significant only an hour or more later than that of diphenhydramine. These results suggest that diphenhydramine ointment may be useful for the relief of the bone-joint-muscle pains that are common in elderly subjects. Copyright (C) 2013 S. Karger AG, Basel

TI Lumbar Disc Degeneration in Osteoporotic Men: Prevalence and Assessment of the Relation with Presence of Vertebral Fracture
SO JOURNAL OF RHEUMATOLOGY
LA English
DT Article
DE FRACTURE; MALE; OSTEOPOROSIS; OSTEOARTHRITIS; PREVALENCE; SPINE
ID bone-mineral density; low-back-pain; radiographic osteoarthritis; postmenopausal women; spine; epidemiology; population; progression; hip; association
AB Objective. The relationship between osteoarthritis (OA) and osteoporosis (OP) remains controversial. An inverse relationship between spine OA and the presence of prevalent vertebral fractures has been shown in osteoporotic women. Our objective was to assess this relationship in osteoporotic men. Methods. All the patients had OP based on densitometric data and were aged >= 65 years. Spine

radiographs were performed according to a standardized procedure. Vertebral fractures were assessed from T4 to L4 by a semiquantitative method. Disc degenerative changes were assessed by the presence and severity of osteophytes and disc narrowing at levels T12-L1 to L5-S1. Logistic regression was used to study the relationship between the presence of vertebral fracture and lumbar disc degeneration. Results. The study included 261 osteoporotic men. The prevalence of vertebral fractures was 26.4% (69/261). At least 1 osteophyte was found in 91.6% (239/261) of patients, and at least 1 disc space narrowing in 63.5% (165/260). The prevalence of at least 1 osteophyte and/or at least 1 disc space narrowing was similar in patients with and those without vertebral fracture. No relationship was found between the presence and/or the severity of osteophytes and disc narrowings and the presence of prevalent vertebral radiographic fractures. Conclusion. In osteoporotic men, the prevalence of lumbar spine degeneration is high. There is no relationship between lumbar disc degeneration and the presence of vertebral fracture in osteoporotic men.

TI Differences in osteogenic and apoptotic genes between osteoporotic and osteoarthritic patients
SO BMC MUSCULOSKELETAL DISORDERS
LA English
DT Article
DE Human bone; Osteoporosis; Osteogenesis; Apoptosis; Microstructural
ID primary hip osteoarthritis; osteoblast differentiation; trabecular bone; cell-death; expression; disease; ligand; deficiency; increases; osterix
AB Background: Osteoporosis is a metabolic disorder characterized by a reduction in bone mass and deterioration in the microarchitectural structure of the bone, leading to a higher risk for spontaneous and fragility fractures. The main aim was to study the differences between human bone from osteoporotic and osteoarthritic patients about gene expression (osteogenesis and apoptosis), bone mineral density, microstructural and biomechanic parameters. Methods: We analyzed data from 12 subjects: 6 with osteoporotic hip fracture (OP) and 6 with hip osteoarthritis (OA), as the control group. All subjects underwent medical history, analytical determinations, densitometry, histomorphometric and biochemical study. The expression of 86 genes of osteogenesis and 86 genes of apoptosis was studied in pool of bone samples from patients with OP and OA by PCR array. Results: We observed that most of the genes of apoptosis and osteogenesis show a decrease in gene expression in the osteoporotic group in comparison with the osteoarthritic group. The histomorphometric study shows a lower bone quality in the group of patients with hip fractures compared to the osteoarthritic group. Conclusions: The bone tissue of osteoporotic fracture patients is more fragile than the bone of OA patients. Our results showed an osteoporotic bone with a lower capacities for differentiation and osteoblastic activity as well as a lower rate of apoptosis than osteoarthritic bone. These results are related with structural and biochemical parameters.

TI Effects of Cysteine Proteases on the Structural and Mechanical Properties of Collagen Fibers
SO JOURNAL OF BIOLOGICAL CHEMISTRY
LA English
DT Article
ID rat tail tendon; atomic-force microscopy; i collagen; cathepsin-k; decorin; glycosaminoglycans; fibrils; complex; proteoglycan; organization
AB Excessive cathepsin K (catK)-mediated turnover of fibrillar type I and II collagens in bone and cartilage leads to osteoporosis and osteoarthritis. However, little is known about how catK degrades compact collagen macromolecules. The present study is aimed to explore the structural and mechanical consequences of collagen fiber degradation by catK. Mouse tail type I collagen fibers were incubated with either catK or non-collagenase cathepsins. Methods used include scanning electron microscopy, protein electrophoresis, atomic force microscopy, and tensile strength testing. Our study revealed evidence of proteoglycan network degradation, followed by the progressive disassembly of macroscopic collagen fibers into primary structural elements by catK. Proteolytically released GAGs are involved in the generation of collagenolytically active catK-GAG complexes as shown by AFM. In addition to their structural disintegration, a decrease in the tensile properties of fibers was observed due to the action of catK. The Young's moduli of untreated collagen fibers versus catK-treated fibers in dehydrated conditions were 3.2 +/- 0.68 GPa and 1.9 +/- 0.65 GPa, respectively. In contrast, cathepsin L, V, B, and S revealed no collagenase activity, except the disruption of proteoglycan-GAG interfibrillar bridges, which slightly decreased the tensile strength of fibers.

TI Trabecular Homogeneity Index Derived From Plain Radiograph to Evaluate Bone Quality
SO JOURNAL OF BONE AND MINERAL RESEARCH
LA English
DT Article
DE CT SCAN; DXA; HOMOGENEITY INDEX; RADIOGRAPH; STRUCTURE ANALYSIS
ID texture analysis; mineral density; postmenopausal women; fracture load; 3-dimensional microarchitecture; hip osteoarthritis; proximal femur; osteoporosis; association; microdamage
AB Radiographic texture analysis has been developed lately to improve the assessment of bone architecture as a determinant of bone quality. We validate here an algorithm for the evaluation of trabecular homogeneity index (HI) in the proximal femur from hip radiographs, with a focus on the impact of the principal compressive system of the trabecular bone, and evaluate its correlation with femoral strength, bone mineral density (BMD), and volumetric trabecular structure parameters. A semiautomatic custom-made algorithm was applied to calculate the HI in the femoral neck and trochanteric areas from radiographs of 178 femoral bone specimens (mean age 79.3 +/- 10.4 years). Corresponding neck region was selected in CT scans to calculate volumetric parameters of trabecular structure. The site-specific BMDs were assessed from dual-energy X-ray absorptiometry (DXA),

and the femoral strength was experimentally tested in side-impact configuration. Regression analysis was performed between the HI and biomechanical femoral strength, BMD, and volumetric parameters. The correlation between HI and failure load was R-2=0.50; this result was improved to R-2=0.58 for cervical fractures alone. The discrimination of bones with high risk of fractures (load <3000N) was similar for HI and BMD (AUC=0.87). Regression analysis between the HIs versus site-specific BMDs yielded R-2=0.66 in neck area, R-2=0.60 in trochanteric area, and an overall of R-2=0.66 for the total hip. Neck HI and BMD correlated significantly with volumetric structure parameters. We present here a method to assess HI that can explain 50% of an experimental failure load and determines bones with high fracture risk with similar accuracy as BMD. The HI also had good correlation with DXA and computed tomography-derived data. (c) 2013 American Society for Bone and Mineral Research.

TI Subchondral osteopenia and accelerated bone remodelling post-ovariectomy - a possible mechanism for subchondral microfractures in the aetiology of spontaneous osteonecrosis of the knee?
SO JOURNAL OF ANATOMY
LA English
DT Article
DE bone turnover; osteonecrosis; osteoporosis; ovariectomy; remodelling

ID compact-bone; biomechanical property; ovariectomized ewes; mineral density; l3 vertebra; ovine model; turnover; osteoporosis; sheep; osteoarthritis
AB Osteopenia and subchondral microfractures are implicated in the aetiology of spontaneous osteonecrosis of the knee (SPONK). The ovine tibia shows significant alterations of the trabecular architecture within the subchondral bone of the medial tibial plateau post-ovariectomy (OVX), including reduced trabecular bone volume fraction. We hypothesise that accelerated subchondral bone resorption may also play a role in increasing microfracture risk at this site. Twenty-two sheep were examined in this study; 10 of the sheep underwent OVX, while the remainder (n = 13) were kept as controls (CON). Five fluorochrome dyes were administered intravenously at 12-week intervals via the jugular vein to both groups, to label sites of bone turnover. These animals were then killed at 12 months post-operatively. Bone turnover was significantly increased in the OVX group in both trabecular bone (2.024 vs. 1.047 no. mm-2; P = 0.05) and within the subchondral bone plate (4.68 vs. 0.69 no. mm-2; P < 0.001). In addition to the classically described turnover visible along trabecular surfaces, we also found visual evidence of intra-trabecular osteonal remodelling. In conclusion, this study shows significant alterations in bone turnover in both trabecular bone and within the subchondral bone plate at 1 year post-OVX. Remodelling of trabecular bone was due to both classically described hemi-osteonal and intra-trabecular osteonal remodelling. The presence of both localised osteopenia and accelerated bone remodelling within the medial tibial plateau provide a possible mechanism for subchondral microfractures in the aetiology of SPONK. Further utilisation of the OVX ewe may be useful for further study in this field.

TI A 26-week repeated dose toxicity study of Xian-ling-gu-bao in Sprague-Dawley rats
SO JOURNAL OF ETHNOPHARMACOLOGY
LA English
DT Article
DE Xian-ling-gu-bao; Repeated dose toxicity; No-observed-adverse-effect level
ID postmenopausal
AB Ethnopharmacological relevance: Xian-ling-gu-bao (XLGB) is a traditional Chinese prescription commonly used to treat osteoporosis, osteoarthritis, aseptic bone necrosis, climacteric syndrome, and bone fracture. However, there is limited toxicological information available on XLGB in preclinical animal model studies. It has also been recently reported that XLGB may be related to liver injury in humans. Aim of study: This study was designed to determine the potential toxic effects of XLGB, particularly hepatotoxicity, in Sprague-Dawley rats following oral administration for up to 26 weeks. Materials and methods: Male and female rats were administered XLGB by oral gavage at doses of 0, 100, 300, and 1000 mg/kg for 26 weeks followed by a recovery period of 4 weeks. Clinical signs, body weight, food consumption, ophthalmology, hematology, coagulation, serum chemistry, urinalysis, bone mineral density, hormone concentration, organ weights and histopathology were examined at the end of 13- and 26-week dosing period as well as after the recovery period. Results: Neither hepatotoxicity nor any other toxic effects were observed in the XLGB treated rats at doses up to 1000 mg/kg for 26 weeks except for a slight increase in the organ weight of the uterus in female rats at doses higher than 300 mg/kg on week 26. Conclusions: In this study, we found the no-observed-adverse-effect level (NOAEL) for XLGB in Sprague-Dawley rats was 1000 mg/kg, a dose that was equivalent to 3.3 times human dose based on body surface area. TI The problem of pain in old age
SO ANNALS OF AGRICULTURAL AND ENVIRONMENTAL MEDICINE
LA English
DT Article
DE pain; people in old age; pain treatment in the elderly
AB The elderly are more susceptible to feeling pain than young people. Pain is described as a complex, subjective feeling. causing significant limitation of physical, psychical and social functioning. In the literature, there are many classifications: of pain. Considering the duration, pain may be divided into acute and chronic. Acute pain does not depend on age and lasts less than three months whereas chronic pain is more frequent with the elderly and lasts more than three months. It can be divided into nociceptive and neuropathic pain. Involutional changes progressing in the organism of an old person, combined with numerous chronic diseases occurring in old age, cause approx. 85% of the elderly to suffer from pain. Among the diseases with concurring pain, the first are diseases of the locomotor system and include: osteoporosis, osteoarthritis, and rheumatoid arthritis. Moreover, pain is an intrinsic part of malignant cancer, neuralgia shingles, and diabetic neuropathy. Pain also conceals depression and the depression intensifies the feeling of pain. Due to frequent cognitive disorders and depression, the measurement of pain in the elderly is difficult, it thus requires vast experience. To assess the pain intensity, subjective scales are used, e.g. verbal scale, score scale. To assess the qualitative and quantitative scales the following questionnaires are used: McGill-Melzak Pain Questionnaire and the Pain Assessment Form. Significant for pain assessment with people diagnosed with dementia are objective pain symptoms, namely: worsening appetite, gnashing teeth, grimaces. Pain treatment should be multimodal and include usage of both pharmacological and non-pharmacological methods. Pharmacology is the basis for pain treatment in people of old age, which should be used in the least invasive way, starting with small dosages. The pain-relieving medicine of first choice is paracetamol. In the pharmacological treatment of old people there are also non-opioid pain relieving medicine, opioids and supportive medicine. Among non-pharmacological treatments are rehabilitation and psychological therapy. In pain treatment, awareness among the elderly, their families and carers, and medical staff that the pain is not an attribute of old age; thus, it can be correctly diagnosed and treated.

TI Angiogenic factors in bone local environment
SO CYTOKINE & GROWTH FACTOR REVIEWS
LA English
DT Review
DE Bone remodeling; Angiogenesis; EGF-like; Bone remodeling compartment
ID endothelial growth-factor; osteoclast differentiation factor; colony-stimulating factor; nf-kappa-b; chick chorioallantoic membrane; activated protein-kinase; mesenchymal stem-cells; vegf-a expression; adult human bone; factor receptor
AB Angiogenesis plays an important role in physiological bone growth and

remodeling, as well as in pathological bone disorders such as fracture repair, osteonecrosis, and tumor metastasis to bone. Vascularization is required for bone remodeling along the endosteal surface of trabecular bone or Haversian canals within the cortical bone, as well as the homeostasis of the cartilage-subchondral bone interface. Angiogenic factors, produced by cells from a basic multicellular unit (BMU) within the bone remodeling compartment (BRC) regulate local endothelial cells and pericytes. In this review, we discuss the expression and function of angiogenic factors produced by osteoclasts, osteoblasts and osteocytes in the BMU and in the cartilage-subchondral bone interface. These include vascular endothelial growth factor (VEGF), basic fibroblast growth factor (bFGF), BMP7, receptor activator of NF-kappa B ligand (RANKL) and epidermal growth factor (EGF)-like family members. In addition, the expression of EGFL2, EGFL3, EGFL5, EGFL6, EGFL7, EGFL8 and EGFL9 has been recently identified in the bone local environment, giving important clues to their possible roles in angiogenesis. Understanding the role of angiogenic factors in the bone microenvironment may help to develop novel therapeutic targets and diagnostic biomarkers for bone and joint diseases, such as osteoporosis, osteonecrosis, osteoarthritis, and delayed fracture healing. TI Generation and validation of a normative, age-specific reference curve for lumbar spine trabecular bone score (TBS) in French women
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE Bone microarchitecture; DXA (dual-energy X-ray absorptiometry); Normative data curve; TBS (trabecular bone score)
ID mineral density; structural basis; caucasian women; femoral-neck; microarchitecture; fracture; population; quality; osteoporosis; menopause
AB Age-related changes in lumbar vertebral microarchitecture are evaluated, as assessed by trabecular bone score (TBS), in a cohort of 5,942 French women. The magnitude of TBS decline between 45 and 85 years of age is piecewise linear in the spine and averaged 14.5 %. TBS decline rate increases after 65 years by 50 %. This study aimed to evaluate age-related changes in lumbar vertebral microarchitecture, as assessed by TBS, in a cohort of French women aged 45-85 years. An all-comers cohort of French Caucasian women was selected from two clinical centers. Data obtained from these centers were cross-calibrated for TBS and bone mineral density (BMD). BMD and TBS were evaluated at L1-L4 and for all lumbar vertebrae combined using GE-Lunar Prodigy densitometer images. Weight, height, and body

mass index (BMI) also were determined. To validate our all-comers cohort, the BMD normative data of our cohort and French Prodigy data were compared. A cohort of 5,942 French women aged 45 to 85 years was created. Dual-energy X-ray absorptiometry normative data obtained for BMD from this cohort were not significantly different from French prodigy normative data (p = 0.15). TBS values at L1-L4 were poorly correlated with BMI (r = -0.17) and weight (r = -0.14) and not correlated with height. TBS values obtained for all lumbar vertebra combined (L1, L2, L3, L4) decreased with age. The magnitude of TBS decline at L1-L4 between 45 and 85 years of age was piecewise linear in the spine and averaged 14.5 %, but this rate increased after 65 years by 50 %. Similar results were obtained for other region of interest in the lumbar spine. As opposed to BMD, TBS was not affected by spinal osteoarthrosis. The age-specific reference curve for TBS generated here could therefore be used to help clinicians to improve osteoporosis patient management and to monitor microarchitectural changes related to treatment or other diseases in routine clinical practice.

TI Failed joint unloading implant system in the treatment of medial knee osteoarthritis
SO ARCHIVES OF ORTHOPAEDIC AND TRAUMA SURGERY
LA English
DT Article
DE KineSpring knee implant system; Unicompartmental knee arthritis; Joint preserving; Complication; Novel device
ID patient outcm; replacement
AB In the setting of end-stage osteoarthritis of the knee, total knee arthroplasty is the gold-standard treatment. Recently, a minimally invasive, joint preserving treatment option in the treatment of medial osteoarthritis of the knee has been developed. It is called the KineSpring(A (R)) (Moximed(A (R)) International GmbH, Zurich, Switzerland). The goal of this novel device is to reduce medial compartment loading without significantly affecting the loading of the lateral compartment. In this context, the current authors present a case of device failure using these new implants, which at 7 months post-op necessitated revision surgery with complete removal of the device.

AB Guidance is provided in a European setting on the assessment and treatment of postmenopausal women at risk of fractures due to osteoporosis. The International

Osteoporosis Foundation and European Society for Clinical and Economic Aspects of Osteoporosis and Osteoarthritis published guidance for the diagnosis and management of osteoporosis in 2008. This manuscript updates these in a European setting. Systematic literature reviews. The following areas are reviewed: the role of bone mineral density measurement for the diagnosis of osteoporosis and assessment of fracture risk, general and pharmacological management of osteoporosis, monitoring of treatment, assessment of fracture risk, case finding strategies, investigation of patients and health economics of treatment. A platform is provided on which specific guidelines can be developed for national use.

TI Pomegranate Use to Attenuate Bone Loss in Major Musculoskeletal Diseases: An Evidence-Based Review
SO CURRENT DRUG TARGETS
LA English
DT Review
DE Pomegranate; osteoporosis; osteoarthritis; rheumatoid arthritis
ID necrosis-factor-alpha; nf-kappa-b; healthy postmenopausal women; menopausal syndrome model; estrogen plus progestin; punica-granatum-l.; osteoblast differentiation; juice consumption; oxidative stress; fruit extract
AB This review explores the effects of pomegranate on the pathogenesis of bone loss in osteoporosis, osteoarthritis and rheumatoid arthritis. A systematic review of the literature was conducted to identify the relevant studies on pomegranate and

osteoporosis/osteoarthritis/rheumatoid arthritis. A comprehensive search was conducted in Medline and CINAHL for relevant studies published between the years 1946 to 2012. The main inclusion criteria were research articles published in English, studies had to report the association or effect of pomegranate and these bone and joint diseases: osteoporosis, osteoarthritis or rheumatoid arthritis. The literature search identified 35 potentially relevant articles, whereby 8 met the inclusion criteria. Two animal studies, two combinations of animal and in vitro studies, three in vitro studies and one human study were included in this review. All the studies reported positive effects of pomegranate extract or juice on osteoporosis, osteoarthritis and rheumatoid arthritis. This evidence-based review highlighted the potential of pomegranate extract being used for treating bone loss in osteoporosis, osteoarthritis and rheumatoid arthritis. Further studies are required to identify the active ingredients and molecular mechanisms before controlled human observational studies are conducted to provide stronger evidence.

TI Osteoporosis and Orthopedic Surgery: Effect of Bone Health on Total Joint Arthroplasty Outcome
SO CURRENT RHEUMATOLOGY REPORTS

LA English
DT Article
DE Osteoporosis; Orthopedic surgery; Joint arthroplasty; Bone health; Resurfacing total hip arthroplasty; Osteolysis; Vitamin D; Teriparatide; Denosumab; Heterotopic ossification
ID total knee arthroplasty; vitamin-d status; mineral density; heterotopic ossification; bisphosphonate use; implant fixation; fracture risk; hip; osteoarthritis; women
AB Osteoporosis is a common condition. As the population ages, more patients with osteoporosis will require orthopedic procedures, including arthroplasty. Adverse outcomes are more likely for patients with osteoporosis requiring orthopedic procedures, for example those with intraoperative fractures, periprosthetic osteolysis with implant migration, and postoperative periprosthetic fractures. Cemented prosthetic hip replacements may be more successful among patients with poor bone quality. Femoral neck fracture is a concern during hip resurfacing among patients with osteoporosis. Vitamin D deficiency is common among patients undergoing joint arthroplasty and the ideal vitamin D level for joint arthroplasty has yet to be determined. Both bisphosphonates and teriparatide may aide successful osteointegration among patients undergoing noncemented joint arthroplasty. Focusing on bone health perioperatively should result in better outcomes for orthopedic procedures.

TI Parathyroid hormone [1-34] improves articular cartilage surface architecture and integration and subchondral bone reconstitution in osteochondral defects in vivo
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE PTH [1-34]; PTH1R; Osteochondral defect; Cartilage repair; Subchondral bone
ID full-thickness defects; autologous chondrocyte implantation; cell-based repair; igf-i; experimental-model; osteoarthritis; osteoporosis; rabbit; knee; pth
AB Objective: The 1-34 amino acid segment of the parathyroid hormone (PTH [1-34]) mediates anabolic effects in chondrocytes and osteocytes. The aim of this study was to investigate whether systemic application of PTH [1-34] improves the

repair of non-osteoarthritic, focal osteochondral defects in vivo. Design: Standardized cylindrical osteochondral defects were bilaterally created in the femoral trochlea of rabbits (n = 8). Daily subcutaneous injections of 10 mu g PTH [1-34]/kg were given to the treatment group (n = 4) for 6 weeks, controls (n = 4) received saline. Articular cartilage repair was evaluated by macroscopic, biochemical, histological and immunohistochemical analyses. Reconstitution of the subchondral bone was assessed by micro-computed tomography. Effects of PTH [1-34] on synovial membrane, apoptosis, and expression of the PTH receptor (PTH1R) were determined. Results: Systemic PTH [1-34] increased PTH1R expression on both, chondrocytes and osteocytes within the repair tissue. PTH [1-34] ameliorated the macro- and microscopic aspect of the cartilaginous repair tissue. It also enhanced the thickness of the subchondral bone plate and the microarchitecture of the subarticular spongiosa within the defects. No significant correlations were established between these coexistent processes. Apoptotic levels, synovial membrane, biochemical composition of the repair tissue, and type-I/II collagen immunoreactivity remained unaffected. Conclusions: PTH [1-34] emerges as a promising agent in the treatment of focal osteochondral defects as its systemic administration simultaneously stimulates articular cartilage and subchondral bone repair. Importantly, both time-dependent mechanisms of repair did not correlate significantly at this early time point and need to be followed over prolonged observation periods. TI Is there any association between leptin levels and bone mineral density in haemophiliac men?
SO ARCHIVES OF MEDICAL SCIENCE
LA English
DT Article
DE haemophilia; arthropathy; osteoporosis; osteopenia; leptin
ID healthy postmenopausal women; serum leptin; biochemical markers; body-composition; key role; mass; osteoporosis; differentiation; osteoarthritis; testosterone
AB Introduction: Conflicting data exist regarding the role of leptin in bone metabolism. The purpose of the present study was to investigate serum leptin concentrations in male patients with haemophilia A and B, a disease known to be associated with low bone mass. Material and methods: Eighty-one male patients, aged 45.4 +/- 15 years, were screened. Bone mineral density (BMD) was measured by dual-energy X-ray absorptiometry (DXA) in lumbar spine (LS), femoral neck (FN) and total hip (TH). Results: Low bone mass was diagnosed in 20 patients (24.7%). Serum leptin concentrations were strongly associated with body weight (r(s) = 0.457, p = 0.0001) and body mass index (BMI) (r(s) = 0.491, p = 0.0001). In unadjusted analysis leptin was inversely associated with BMD in LS (r(s) = -0.255, p

= 0.023), but not in FN and TH (r(s) = -0.205, p = 0.068 and r(s) = -0.191, p = 0.090, respectively). However, after adjusting for BMI and body weight, leptin was inversely associated with BMD in FN (F-1,F-76 = 7.727, p = 0.007, beta = -0.371, Delta R-2 = 0.089) and TH (F-1,F-76 = 4.533, p = 0.036, beta = -0.290, Delta R-2 = 0.054), but not in LS (F-1,F-75 = 2.076, p = 0.154, beta = -0.202, Delta R-2 = 0.026). No association was found between age, presence of HBV, HCV or HIV infection or alkaline phosphatase and leptin levels. Conclusions: Our study showed a negative association between circulating leptin levels and bone mass in males, independently of body weight and BMI.

TI Preliminary report on a study of health-related quality of life in patients with rheumatoid arthritis
SO RHEUMATOLOGY INTERNATIONAL
LA English
DT Article
DE Rheumatoid arthritis; Health-related quality of life; SF-36
ID survey sf-36; reliability; validity; association; depression; disability; mortality; tests
AB There are studies about health-related quality of life (HRQoL) in patients with rheumatoid arthritis (RA), but few studies prospectively assessed HRQoL. The main purpose of this study was to analyze HRQoL in patients hospitalized due to RA exacerbation and observed over a planned 2-year follow-up in an outpatient setting. The study involved 42 women and 9 men, at mean age of 62.5 years (SD

+/- A 12.6). The mean duration of the study was 22-23 months. The HRQoL analysis was performed using the SF-36 survey. At the beginning of the study, basic data on age, sex, selected biochemical (ESR, CRP, GFR, hemoglobin, plasma albumin, plasma protein), and clinical parameters (the duration of RA, VAS, DAS28, BMI, the presence of cardiovascular disease, diabetes, osteoporosis, osteoporotic fractures, osteoarthritis, neoplasm) were collected. Questionnaires were completed at the beginning and end of the study. Statistically significant reductions in HRQoL scores were observed in social functioning (SF; 0.42 vs 0.32, P < 0.05), whereas role-emotional health (RE; 0.48 vs 0.59, P < 0.05) and mental health (MH; 0.47 vs 0.54, P < 0.05) scores were increased. A decrease in the SF was positively correlated with the lack of osteoporosis at baseline (r = 0.35, P > 0.02). An increase in the MH was inversely correlated with BMI (r = -0.31, P < 0.05), and the level of hemoglobin (r = -0.32, P < 0.028) and positively correlated with the presence of osteoarthritis at baseline (r = 0.29, P < 0.05). In RA patients, dimensions of HRQoL as SF, RE, and MH could change within 2 years and these changes could be related to comorbidities. Although preliminary findings are promising, further studies are needed.

TI RANKL/OPG Ratio and DKK-1 Expression in Primary Osteoblastic Cultures from Osteoarthritic and Osteoporotic Subjects
SO JOURNAL OF RHEUMATOLOGY
LA English
DT Article
DE OSTEOBLASTS; OSTEOPOROSIS; OSTEOARTHRITIS; WNT SIGNALING; RANKL/OPG
ID kappa-b ligand; receptor activator; osteoclast differentiation; hip osteoarthritis; in-vitro; bone; osteoprotegerin; cells; dickkopf-1; vitamin-d-3
AB Objective. To evaluate the expression of Dicickopf-1 protein factor (DICK-1), DKK-2, and beta-catenin, components of the Wnt pathway, in human osteoarthritic (OA) and osteoporotic (OP) osteoblasts and to correlate it to cell metabolic activity, proliferation, and receptor activator of nuclear factor-kappa B ligand/osteoprotegerin (RANKL/OPG) expression. Methods. Primary human osteoblast cultures were obtained from healthy, OA, and OP donors. In each cell population we evaluated DICK-1, DKK-2, nonphosphorylated beta-catenin and RANKL/OPG expression, osteocalcin and alkaline phosphatase (ALP) synthesis, and cell proliferation, both in basal condition and after vitamin D3 stimulation. Results. DICK-1 and DICK-2 showed opposite patterns of expression in OA and OP osteoblasts. The RANKL/OPG ratio was significantly higher in the OP group because of a greater expression of RANKL, whereas it was significantly lower in the OA

group because of a higher expression of OPG. Treatment with vitamin D3 increased the RANKL/OPG ratio and DKIC-2 expression and reduced DICK-1 expression in each cell population, but did not affect beta-catenin levels. Both osteooalcin and ALP production and cell proliferation were enhanced in OA cells and reduced in the OP ones. Conclusion. These data confirm that OA and OP are characterized by opposite bone changes, consisting of reduced bone remodeling processes with increased osteoblast activity in OA, and enhanced bone resorptive activity with reduction of osteoblast metabolism in OP, and suggest that the Wnt pathway is involved in the pathogenesis of both diseases.

TI QCT bone mineral density responses to 1 year of oral bisphosphonate after total knee replacement for knee osteoarthritis
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE Bisphosphonate; BMD; QCT; Total knee arthroplasty
ID postmenopausal osteoporosis; official positions; fracture risk; arthroplasty; women; therapy; hip; alendronate; cohort; pain
AB Bone mineral density (BMD) declined in more than half (53.7%) of post-total knee arthroplasty (TKA) patients (44 of the 82) after 1 year of oral bisphosphonate treatment, and that this decline was significant in bilateral TKA patients. TKA has proven to be an extremely successful procedure in terms of improving ambulatory function. However, the effects of such improvements in ambulatory function and of bisphosphonate on axial BMD have not been established. The purpose of this study was to determine the effect of 1 year of oral bisphosphonate in postmenopausal patients that have undergone TKA and to identify factors related to BMD changes using lumbar spine quantitative computed tomography (QCT). Eighty-two postmenopausal women that underwent primary TKA for knee osteoarthritis and who received once-weekly oral alendronate 70 mg for 12 months after TKA were enrolled. The effect of 1 year of oral bisphosphonate treatment post-TKA and the factors related to general lumbar spine BMD changes by using QCT were determined. Some 53.7% of patients (44 of the 82) experienced an average lumbar spine QCT BMD decline of -6 mg/ml (range -15 to -0.5 mg/ml) after 1 year of oral bisphosphonate treatment, whereas the remaining 38 patients (46.3%) experienced an average increase of 6.8 mg/ml (range 0.6 to 15.7 mg/ml). Logistic and linear regression analysis showed that bilateral TKA was significantly related to a BMD decline ($p < 0.05$). Other factors, such as, age, body mass index, number of comorbidities, and Knee Society scores were not found to be significantly related to BMD response. BMD declined in more than half (53.7%) of the patients after bisphosphonate treatment, and that this decline was significant in bilateral TKA patients. We believe that reduced mobility during rehabilitation was probably responsible for these BMD reductions.

ID gluten-free diet; arthritis; bone; osteoporosis; children
AB Background and Aim: To evaluate presence of sero-negative spondyloarthritis (SpA) in celiac disease (CD) patients, and whether compliance with a gluten free diet (GFD) improved arthritis manifestations in these patients. Methods: We undertook a prospective, questionnaire based, cross-sectional cohort study to evaluate the presence or absence of SpA simultaneously in both CD and non-CD cohorts. Results: 356/590 (60.3%) patients with CD participated in this study. 99% had diagnosis confirmed by a diagnostic test (79% small bowel biopsy, 19.8% blood test, 3.9% stool test). Approximately 131 (37%) cases of arthritis were reported in CD patients. Of the 6/356 CD patients with seronegative spondyloarthritides, four had sacroiliitis, two ankylosing spondylitis, and one psoriatic arthritis, compared to one ankylosing spondylitis and five psoriatic arthritis in non-CD. Osteoarthritis (89 vs 59, P = 0.93) was the most common diagnosis reported by respondents. More CD patients with diarrhea (94%) and anemia (81%) improved on GFD, compared to arthritis symptoms (30%). Autoimmune thyroiditis (10.6% vs 0.4%), insulin dependent diabetes mellitus (IDDM) (2.2% vs 1.7%), systemic Lupus erythematosus (SLE) (1.1% vs 0), and psoriasis (12.9% vs 5.5%) occurred more frequently in CD patients. The prevalence of Crohn's disease, ulcerative colitis, Sjogren's syndrome, primary biliary cirrhosis, and primary sclerosing cholangitis was around 1% each. Univariate Logistic regression analysis showed <= high school education (odds ratio [OR] 2.01, P < 0.003), age >= 60 years (OR 4.13, P < 0.001), and osteoporosis (OR 2.78, P < 0.001) to be significantly associated with report of arthritis in CD patients. Conclusion: We did not find a high rate of SpA in CD patients. In contrast, increased rates of autoimmune thyroiditis, SLE, IDDM, and psoriasis were seen in CD.

ID bone-mineral density; necrosis-factor-alpha; fracture risk; ankylosing-spondylitis; women; osteoprotegerin; interleukin-6; pathogenesis; expression; cytokines
AB Osteoporosis (OP) commonly occurs in the setting of inflammatory arthritis, whereas there is an inverse relationship with osteoarthritis (OA). We review the recent updates in epidemiology and pathophysiology of OP relating to several arthridities. In ankylosing spondylitis, lateral lumbar spine dual x-ray absorptiometry is better at detecting osteoporosis compared with the AP view and patients receiving treatment with anti-tumor necrosis factor medications had lower levels of bone turnover markers. With regard to rheumatoid arthritis, anticitrullinated peptide positivity without clinical arthritis as well as higher levels of interleukin-6 is associated with decreased bone mineral density and polymorphisms in the vitamin D receptor in RA patients may predispose to OP. With regard to OA, results from the Global Longitudinal Study of Osteoporosis in Women study and several radiological studies suggest that differences in the distribution of bone mass at the femoral neck may account for the inverse relationship of OA and OP, and several studies suggest that OA and OP have opposing cytokine and bone metabolism marker profiles.

TI Osteoporosis Risk Prediction for Bone Mineral Density Assessment of Postmenopausal Women Using Machine Learning
SO YONSEI MEDICAL JOURNAL
LA English
DT Article
DE Screening; machine learning; risk assessment; clinical decision tools; support vector machines
ID support vector machines; self-assessment tool; fracture risk; prevalence; diagnosis; classification
AB Purpose: A number of clinical decision tools for osteoporosis risk assessment have been developed to select postmenopausal women for the measurement of bone mineral density. We developed and validated machine learning models with the aim of more accurately identifying the risk of osteoporosis in postmenopausal women compared to the ability of conventional clinical decision tools. Materials and Methods: We collected medical records from Korean postmenopausal women based on the Korea National Health and Nutrition Examination Surveys. The training data set was used to construct models based on popular machine learning algorithms such as support vector machines (SVM), random forests, artificial neural networks (ANN), and logistic regression (LR) based on simple surveys. The machine learning models were compared to four conventional clinical decision tools: osteoporosis self-assessment tool (OST), osteoporosis risk assessment instrument (ORAI), simple calculated osteoporosis risk estimation (SCORE), and osteoporosis index of risk (OSIRIS). Results: SVM had significantly better area under the curve (AUC) of the receiver operating characteristic than ANN, LR, OST, ORAL SCORE, and OSIRIS for-the training set. SVM predicted osteoporosis risk with an AUC of 0.827, accuracy of 76.7%, sensitivity of 77.8%, and specificity of 76.0% at total hip, femoral neck, or lumbar spine for the testing set The significant factors selected by SVM were age, height, weight, body mass index, duration of menopause, duration of breast feeding, estrogen therapy, hyperlipidemia, hypertension, osteoarthritis, and diabetes mellitus. Conclusion: Considering various predictors associated with low bone density, the machine learning methods may be effective tools for identifying postmenopausal women at high risk for osteoporosis.

TI Quantitative computed tomography assessment of bone mineral density after 2 years' oral bisphosphonate treatment in postmenopausal osteoarthritis patients who underwent total knee arthroplasty
SO JOURNAL OF INTERNATIONAL MEDICAL RESEARCH
LA English
DT Article
DE Total knee arthroplasty; TKA; quantitative computed tomography; QCT; bisphosphonate; alendronate; bone mineral density; BMD
ID women; osteoporosis; prevalence; fractures; therapy; risk; hip
AB Objectives: To identify the effects of two years' oral bisphosphonate (alendronate) treatment in patients who underwent total knee arthroplasty (TKA); to determine whether significant responses seen after the first year of treatment changed during the second year. Additionally, the study tried to identify factors relating to bone mineral density (BMD) changes. Methods: This was a prospective 2-year follow-up study of a previous 1-year report of postmenopausal women with knee osteoarthritis who underwent primary unilateral or staged bilateral TKA, after which they received 70 mg alendronate orally once-weekly. BMD was measured using quantitative computed tomography (QCT) on lumbar vertebrae at baseline (pre-TKA) and at 12 and 24 months. Factors associated with BMD changes were determined by regression analysis. Results: Sixty-one patients entered the second year and continued treatment for >= 24 months. Mean vertebral QCT BMDs at baseline and after 12 and 24 months' alendronate treatment were 71.8 mg/ml (41.9-97.5 mg/m1), 69.3 mg/ml (31.4-103.9 mg/m1), and 72.7 mg/m1 (33.1-136.1 mg/m1), respectively. Patients undergoing bilateral TKA and who had more severe OA at baseline (bilateral severe [grade 4] OA) had a lower BMD response after 2 years' bisphosphonate treatment, compared with patients with less severe unilateral knee OA who underwent unilateral TKA.Improvements were, however, seen compared with year I levels. Low BMI was associated with BMD nonresponse. Conclusions: Patients with bilateral severe OA (grade 4) requiring bilateral knee

replacement are at greater risk of nonresponse after 2 years' oral alendronate treatment. A longer duration of treatment may be necessary in these patients.

TI In vitro and in vivo angiogenic activity of osteoarthritic and osteoporotic osteoblasts is modulated by VEGF and vitamin D3 treatment
SO REGULATORY PEPTIDES
LA English
DT Article
DE Angiogenesis; Chorioallantoic membrane; Osteoarthritis; Osteoporosis; Vitamin D3
ID endothelial growth-factor; skeletal development; expression; cells; differentiation; bone; osteogenesis; activation; mechanisms; migration
AB Vascular Endothelial Growth Factor (VEGF) is a potent angiogenic factor, which

also regulates bone remodeling. Osteoblasts not only respond to VEGF stimulation, but also express and synthesize this factor. The present study was aimed to evaluate in vitro differences in VEGF production and expression of cultured human osteoblastic cells derived from healthy donors and from subjects affected by osteoarthritis and osteoporosis, under basal conditions than after vitamin D-3, and to investigate the angiogenic activity of culture media obtained by these cells in chick embryo chorioallantoic membrane (CAM) assay. The results showed that normal and pathological osteoblasts produce and express VEGF and 1,25 dihydroxy-vitamin D-3 treatment increases protein and m-RNA VEGF levels. In addition culture media of pathological osteoblasts induce a strong angiogenic response, greater than observed with culture medium of normal cells, suggesting the involvement of osteoblast-derived VEGF in the pathogenesis of bone diseases.

TI Bone mineralization is elevated and less heterogeneous in adults with type 2 diabetes and osteoarthritis compared to controls with osteoarthritis alone
SO BONE
LA English
DT Article
DE Bone mineralization density distribution (BMDD); Type 2 diabetes; Osteoporosis; Quantitative backscattered electron imaging; Bone quality
ID backscattered electron images; density distribution; trabecular bone; fracture risk; iliac crest; osteoporotic fractures; matrix mineralization; mechanical-property; biochemical markers; cortical bone
AB Purpose: The purpose of this study was to determine whether trabecular bone mineralization differed in adults with type 2 diabetes compared to adults without type 2 diabetes. Methods: Proximal femur specimens were obtained following a total hip replacement procedure from men and women >= 65 years of age with and without type 2 diabetes. A scanning electron microscope was used for quantitative backscattered electron imaging (qBEI) analysis of trabecular bone

samples from the femoral neck. Gray scale images (pixel size=5.6 mu m(2)) were uploaded to Image! software and gray level (GL) values were converted to calcium concentrations (weight [wt] % calcium [Ca]) using data obtained with energy dispersive X-ray spectrometry. The following bone mineralization density distribution (BMDD) outcomes were collected: the weighted mean bone calcium concentration (Ca-MEAN), the most frequently occurring bone calcium concentration (Ca-PEAK) and mineralization heterogeneity (Ca-WIDTH). Differences between groups were assessed using the Student's t-test for normally distributed data and Mann-Whitney U-test for non-normally distributed data. An alpha value of <0.05 was considered significant. Results: Thirty-five Caucasian participants were recruited (mean [standard deviation, SD] age, 75.5 [6.5] years): 14 adults with type 2 diabetes (years since type 2 diabetes diagnosis, 13.5 [7.4] years) and 21 adults without type 2 diabetes. In the adults with type 2 diabetes, bone Ca-MEAN was 4.9% greater (2036 [0.98] wt.% Ca versus 19.40 [1.07] wt.% Ca, p = 0.015) and Ca-WIDTH was 9.4% lower (median [interquartile range] 3.55 [2.99-4.12] wt.% Ca versus 3.95 [0.71] wt% Ca, p<0.001) compared to controls. There was no between-group difference in Ca-PEAK (21.12 [0.97] wt% Ca for type 2 diabetes versus 20.44 [1.30] wt.% Ca for controls, p = 0.121). Conclusion: The combination of elevated mean calcium concentration in bone and lower mineralization heterogeneity in adults with type 2 diabetes may have deleterious effects on the biomechanical properties of bone. These microscopic alterations in bone mineralization, which may be mediated by suppressed bone remodeling, further elucidate higher fracture risk in adults with type 2 diabetes. TI Comparison of gait and pathology outcomes of three meniscal procedures for induction of knee osteoarthritis in sheep
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE Osteoarthritis; Meniscus; Sheep; Animal model
ID plateau leveling osteotomy; arthroscopic partial meniscectomy; ground reaction forces; in-vivo kinematics; articular-cartilage; tibial plateau; matrix metalloproteinases; medial meniscectomy; stifle joint; aggrecan
AB Objective(s): Meniscectomy (MX) of sheep induces a well-established animal model of human osteoarthritis (OA). This study compared the clinical (lameness) and pathological outcomes of unilateral, complete medial MX vs two less traumatic and more easily performed meniscal destabilisation procedures. Methods: Four-year old wethers (n = 6/group) underwent sham operation, cranial pole release (CPR), mid-body transection (MBT) or total MX of the medial meniscus. Joints were assessed for gross pathology (cartilage erosion and osteophytes), histomorphometry, two histopathology scoring methods (modified Mankin-type and Pritzker score), and immunohistology for ADAMTS- and MMP-cleaved neoepitopes, at 12 weeks post-op. Ground reaction forces (GRFs) were determined by force plate in a subset (n = 4/group) at baseline, 2.5, 8, and 12 weeks post-op. Results: Gross pathology scores of operated groups differed significantly from sham animals ($P < 0.05$) but not from each other, though qualitative differences were noted: CPR sheep developed more cranial and focal lesions, while MBT and MX joints showed more widespread lesions and osteophyte formation. Similarly, histopathology scores were significantly elevated vs sham but did not differ between operated groups at $P < 0.05$, except for a trend for lower tibial cartilage histopathology in MBT consistent with the immunohistologic pattern of reduced aggrecanase-cleavage neoepitope in that model. CPR sheep developed less femoral subchondral sclerosis, suggesting some residual biomechanical effect from the destabilised but intact meniscus. Few significant differences were noted between operated groups in force plate analyses, though gait abnormalities appeared to be least in CPR sheep, and most persistent (>12 weeks) in MBT animals. Conclusion: The well-validated ovine MX model and the simpler meniscal destabilisation procedures resulted in broadly similar joint pathology and

lameness. Meniscal CPR or MBT, as easier and more clinically relevant procedures, may represent preferred models for the induction of OA and evaluation of potential disease-modifying therapies. (C) 2012 Osteoarthritis Research Society International. Published by Elsevier Ltd. All rights reserved.

DT Review
ID quality-of-life; randomized controlled-trial; obstructive pulmonary-disease; chronic heart-failure; cardiovascular risk-factors; improves standing balance; knee extensor strength; bone-mineral density; older-adults; blood-pressure
AB Tai Chi Chuan (Tai Chi) is a Chinese traditional mind-body exercise and recently, it becomes popular worldwide. During the practice of Tai Chi, deep diaphragmatic breathing is integrated into body motions to achieve a harmonious balance between body and mind and to facilitate the flow of internal energy (Qi). Participants can choose to perform a complete set of Tai Chi or selected movements according to their needs. Previous research substantiates that Tai Chi has significant benefits to health promotion, and regularly practicing Tai Chi improves aerobic capacity, muscular strength, balance, health-related quality of life,

and psychological well-being. Recent studies also prove that Tai Chi is safe and effective for patients with neurological diseases (e. g., stroke, Parkinson's disease, traumatic brain injury, multiple sclerosis, cognitive dysfunction), rheumatological disease (e. g., rheumatoid arthritis, ankylosing spondylitis, and fibromyalgia), orthopedic diseases (e. g., osteoarthritis, osteoporosis, low-back pain, and musculoskeletal disorder), cardiovascular diseases (e. g., acute myocardial infarction, coronary artery bypass grafting surgery, and heart failure), chronic obstructive pulmonary diseases, and breast cancers. Tai Chi is an aerobic exercise with mild-to-moderate intensity and is appropriate for implementation in the community. This paper reviews the existing literature on Tai Chi and introduces its health-promotion effect and the potential clinical applications.

DT Review
DE subchondral bone; articular cartilage; osteoarthritis; osteoporosis; bone agents
ID anterior cruciate ligament; radiographic knee osteoarthritis; estrogen replacement therapy; subchondral trabecular bone; reduces cartilage degeneration; meniscectomized guinea-pig; articular-cartilage; salmon-calcitonin; mineral density; strontium ranelate

AB Background: Osteoarthritis (OA) joints display relevant microstructure alterations associated to an increase in remodeling at subchondral bone, which supports its crucial role in OA pathogenesis. Despite this, the treatment of knee OA patients with antiresorptive drugs has given discordant results, suggesting the existence of a particular patient subset with good response to halting high subchondral remodeling. Objective: To identify an OA phenotype that may obtain major benefit from therapy with bone-acting agents. Methods: A systematic review of the literature was performed by searching the Medline and PubMed databases from 1990 to April 2013 using the following keywords: subchondral bone, articular cartilage, and osteoarthritis in various combinations with bone agents, bone mineral density, and scintigraphy. Results: Early animal and human studies provided the rationale for the beneficial use of bone agents on OA cartilage damage. Several bone-acting agents have reduced low back pain and likely spondylosis progression. Recently, strontium ranelate has been reported to exert both structural and clinical benefits in knee OA patients with radiological progression. However, other antiresorptives have shown divergent results. Human studies suggest that these contradictory results may be due to the lack of well-defined OA phenotypes and an accurate methodology to recruit and follow up these patients. Conclusions: A particular subset of postmenopausal patients with high remodeling and/or low subchondral bone density may benefit from the treatment with bone-acting agents hindering OA progression. This OA population could be identified with the simultaneous use of subchondral bone dual-energy X-ray absorptiometry and scintigraphy. (C) 2014 Elsevier Inc. All rights reserved.

TI Epigenetics and methylation in the rheumatic diseases
SO SEMINARS IN ARTHRITIS AND RHEUMATISM
LA English
DT Review
DE Epigenetics; Methylation; EWAS; Autoimmune diseases; Rheumatic diseases
ID systemic-lupus-erythematosus; epigenome-wide association; dynamic dna methylation; t-cells; osteoarthritic chondrocytes; ankylosing-spondylitis; genetic contribution; norwegian twins; down-regulation; arthritis
AB Objectives: Rheumatic diseases encompass a wide range of conditions of poorly characterized etiopathology, many having both genetic and environmental susceptibility factors. Epigenetic studies are providing new insights into disease pathogenesis. Recent rheumatology literature related to DNA methylation studies-both epigenome-wide and candidate gene-are discussed, as well as methodological issues. Method: A PubMed search for articles published until April 2013 was conducted using the following keywords: ("methylation" OR "epigenetics") AND ("rheumatoid arthritis" OR "lupus" OR "autoimmune disease" OR "osteoporosis" OR "osteoarthritis" OR "musculoskeletal disorder") and EWAS. The reference lists of identified articles were searched for further articles. Results: Several genome-wide methylation studies have been reported recently, mostly in autoimmune rheumatic diseases. Overall, these studies have identified methylation

signatures in disease, clustering of subgroups as well as new and known epigenetic associations. Methodological issues, small sample sizes and reduced coverage of methylation assays render many results preliminary. Conclusions: There have been a number of epigenetic advances in rheumatic diseases recently. The new technologies and emerging field of epigenome-wide association will provide novel perspectives in disease etiology, diagnosis, classification, and therapy. (C) 2014 Elsevier Inc. TI Risk Factors for Falls in Older Korean Adults: The 2011 Community Health Survey
SO JOURNAL OF KOREAN MEDICAL SCIENCE
LA English
DT Article
DE Accidental Falls; Elderly People; Risk Factors; Koreans
ID recurrent falls; prevalence; seniors; home; associations; hypotension; men
AB Falls are a major health problem for elderly populations worldwide. We analyzed data from the 2011 Korean Community Health Survey to identify potential risk factors for falls in a representative population-based sample of community-dwelling older Korean adults. Risk factors for falls were assessed by multivariate survey logistic regression models. The prevalence of falls was 36.5% in males and 63.5% in females. Age and female sex were associated with a higher risk of falls. Similarly, living alone, living in an urban area, poor self-rated health, and high stress were associated with a high risk of falls. Subjects with diabetes mellitus, stroke, osteoarthritis, osteoporosis, urinary incontinence, cataracts, or depression had a high risk of falls. However, subjects with hypertension were at low risk for falls. In conclusion, age, female sex, marital status, residence location, self-rated

health, stress, and several chronic conditions were significantly associated with the risk for falls in the older Korean adults. Our findings suggest that these risk factors should be addressed in public health policies for preventing falls.

TI Methodological challenges in the use of hip-specific composite outcomes: linking measurements from hip fracture trials to the International Classification of Functioning, Disability and Health Framework
SO ARCHIVES OF ORTHOPAEDIC AND TRAUMA SURGERY
LA English
DT Article
DE Outcomes; Education; Osteoporosis; Hip fracture; Practice management; Health policy
ID quality-of-life; femoral-neck fractures; randomized-trials; end-points; replacement; issue; osteoarthritis; arthroplasty; icf; recommendations
AB The prevalence of hip-specific outcome measures in randomized trials reflects what directs our outcome assessment following a hip fracture. The present study provides an overview on the most commonly-used hip-specific outcome instruments used for postoperative assessment of hip fracture with respect to their covered contents. This can facilitate the selection of appropriate items for specific purposes in clinical as well as research settings. We used the International Classification of Functioning, Disability and Health (ICF) model to distinguish concepts within the instrument. All items from the questionnaires were categorized into one of three categories using the ICF linking rules for a standardized approach. The hip-specific composites measures were also compared to other types of prevalent measures: generic and patient-based instruments. All of the items in the instruments could be mapped to the ICF. We report the highest frequency of ICF activity and participation (71 %) within the Harris hip score (HHS) which is similar to the frequency of ICF content found in the generic measures (82 %). Hip-specific composites focused mostly on walking and moving long and short distances, while in patient-reported measures there was a concentration on the concept of sensation of pain and pain in body parts. The prevalent use of the HHS, over the other hip-specific instruments, could be attributed to its likeness in concept to other generic measures. The dominance of the ICF category of activity and participation reflects what is important to clinicians treating a hip fracture. Composite scores remain problematic as they cut across different ICF concepts. As

long as the popularity of composite scoring systems continues, an overall score may not represent the true patient preferences and concerns in clinical trials. Future studies could apply the results from this study for the creation of an ICF category-based item banking or investigators could operationalize the ICF categories within these candidate measures for specific interventions.

TI Cervical Vertebral Trabecular Bone Mineral Density in Great Danes With and Without Osseous-Associated Cervical Spondylomyelopathy
SO JOURNAL OF VETERINARY INTERNAL MEDICINE
LA English
DT Article
DE Cervical spine; Computed tomography; Dog; Osteoarthritis; Wobbler syndrome
ID quantitative computed-tomography; degenerative joint disease; x-ray absorptiometry; induced osteoporosis; lumbar spine; dogs; mri; osteoarthritis;

features; ct
AB BackgroundGreat Danes (GDs) with osseous-associated cervical spondylomyelopathy (CSM) have osteoarthritis (OA) of the cervical vertebrae. OA is often associated with increases in bone mineral density (BMD) in people and dogs. Hypothesis/ObjectivesTo compare the trabecular BMD of the cervical vertebrae between clinically normal (control) GDs and GDs with osseous-associated CSM by using computed tomography (CT). We hypothesized that the vertebral trabecular BMD of CSM-affected GDs would be higher than that of control GDs. AnimalsClient-owned GDs: 12 controls, 10 CSM affected. MethodsProspective study. CT of the cervical vertebral column was obtained alongside a calibration phantom. By placing a circular region of interest at the articular process joints, vertebral body, pedicles, and within each rod of the calibration phantom, trabecular BMD was measured in Hounsfield units, which were converted to diphosphate equivalent densities. Trabecular BMD measurements were compared between CSM-affected and control dogs, and between males and females within the control group. ResultsDifferences between CSM-affected and control dogs were not significant for the articular processes (mean=-39; P=.37; 95% CI: -102 to 24), vertebral bodies (mean=-62; P=.08; 95% CI: -129 to 6), or pedicles (mean=-36; P=.51; 95% CI: -105 to 33). Differences between female and male were not significant. Conclusions and Clinical ImportanceThis study revealed no difference in BMD between control and CSM-affected GDs. Based on our findings no association was detected between cervical OA and BMD in GDs with CSM.

TI Osteoporosis Assessment Questionnaire-Physical Function (OPAQ-PF): a psychometrically validated osteoporosis-targeted patient reported outcome measure of daily activities of physical function
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE OPAQ-PF; Osteoporosis; Outcomes assessment; Patient reported outcomes; Physical function; Psychometrics
ID quality-of-life; vertebral fractures; european foundation; women; responsiveness; sf-36
AB The purpose of this study was to evaluate the measurement properties of the Osteoporosis Assessment Questionnaire-Physical Functioning (OPAQ-PF). Based on

this study, the OPAQ-PF has confirmed unidimensionality and acceptable reliability, construct validity, and sensitivity to change in a recent fracture/no recent fracture osteoporosis sample. Dimensionality was established through exploratory and confirmatory factor analysis. Patients completed three patient reported outcome (PRO) measures and four performance-based measures (PBMs) at baseline to enable an evaluation of construct validity. Patients without a recent fracture completed the OPAQ-PF 2 weeks after baseline to enable an evaluation of test-retest reliability. Ability to detect change and interpretation of change were investigated following completion of the OPAQ-PF 12 and 24 weeks postbaseline by patients with a recent fracture. A prospective psychometric validation study in 144 postmenopausal women, with moderate to severe osteoporosis, 37 of whom had experienced a recent fragility fracture (< 6 weeks). Unidimensionality was established for the OPAQ-PF by factor analysis. The OPAQ-PF had good internal consistency (alpha = 0.974) and test-retest reliability (mean intraclass correlation coefficient (ICC) 0.993. The OPAQ-PF differentiated between patients with/without recent fracture, and by severity of osteoarthritis; it correlated strongly with hypothesized-related scales and PBMs ($r > 0.3$, $p < 0.001$). Ability to detect change was established with high correlations between changes in OPAQ-PF score and changes in global concept scores in recent fracture patients (r a parts per thousand yenaEuro parts per thousand 0.6, 24-week change). Effect size of change on OPAQ-PF score increased by level of global change ($p < 0.001$). Anchor-based methods identified an OPAQ-PF change of 10 at an individual patient level and 20 at a group level as meaningful to patients. The OPAQ-PF has confirmed unidimensionality and acceptable reliability, construct validity, and sensitivity to change in a recent fracture/no recent fracture osteoporosis sample.

TI Cross-sectional and longitudinal associations between systemic, subchondral bone mineral density and knee cartilage thickness in older adults with or without radiographic osteoarthritis
SO ANNALS OF THE RHEUMATIC DISEASES

LA English
DT Article
ID articular-cartilage; quantitative mri; surface-area; volume; osteoporosis; progression; incident; women; multicenter; compartment
AB Objectives To investigate cross-sectional and longitudinal associations between systemic bone mineral density (BMD), subchondral BMD (sBMD) and knee cartilage thickness in older adults with or without radiographic osteoarthritis (ROA). Methods A prospective cohort of 158 randomly selected subjects (mean 63 years, 48% women) including 69 non-ROA and 89 ROA subjects were studied at baseline and 2.7 years later. Knee cartilage thickness was semi-automatically determined from T1-weighted fat-suppressed MRI. Knee cartilage volume was measured from MRI. Systemic BMD and sBMD were measured by dual-energy X-ray absorptiometry (DXA). Results Cross-sectionally, total body, total hip, spine BMD and/or lateral tibial sBMD were significantly and positively associated with femoral, lateral tibial and/or patellar cartilage thickness in subjects with ROA after adjustment for potential confounders. Longitudinally, a high total body BMD was associated with an increase in femoral cartilage thickness (beta: 0.33 mm/g/cm(2), 95% CI 0.13 to 0.53); a high spine BMD was associated with increases in femoral and lateral tibial cartilage thickness (beta: 0.25 mm/g/cm(2), 95% CI 0.10 to 0.41; and beta: 0.18 mm/g/cm(2), 95% CI: 0.01 to 0.34, respectively) and a high medial tibial sBMD was associated with an increase in medial tibial cartilage thickness (beta: 0.45 mm/g/cm(2), 95% CI 0.02 to 0.89) in subjects with ROA. In contrast, there were no significant associations between baseline systemic BMD, sBMD and cartilage volume loss, nor were there associations between BMD and cartilage thickness in subjects without ROA. Conclusions Both systemic and subchondral BMD are positively associated with increased cartilage thickness in subjects with ROA, suggesting BMD may play a protective role against cartilage loss in knee OA.

TI Discrepancy in bone mineral densities at different skeletal sites in hip osteoarthritis patients
SO MODERN RHEUMATOLOGY
LA English
DT Article
DE Bone mineral density; Dual energy X-ray absorptiometry; Osteoarthritis of the hip; Quantitative ultrasonography
ID quantitative ultrasound; femoral-neck; osteoporosis; quality; age; replacement; population; osteopenia; bearing
AB Objective. Increased femoral neck bone mineral density (BMD) in a hip with osteoarthritis (OA) has been previously reported, however, it is possible that increased BMD at sites other than the hip joint is influenced by the disease process of OA. Therefore, we measured BMD at locations different from the hip joint and determined whether higher BMD was also observed at these different skeletal sites in hip OA patients. Methods. We measured BMD in 68 women (average age 61.0 years) scheduled to undergo total hip arthroplasty for end-stage OA and 100 healthy women (average age 60.9 years) as age-matched controls. BMD at the lumbar spine, radius, and calcaneus was measured by dual-energy X-ray absorptiometry (DXA). Moreover, we measured speed of sound (SOS), broadband ultrasound attenuation (BUA), and stiffness index of the calcaneus by quantitative ultrasonography (QUS). Results. BMD obtained by DXA at the lumbar spine and radius was significantly higher in hip OA patients than in controls. However, at the calcaneus, no significant differences were observed between the groups in BMD obtained by DXA. SOS, BUA, and stiffness index obtained by QUS were significantly lower in the OA group than in controls. Conclusion. Higher BMDs of the spine and radius suggest that the incidence of osteoporosis is inversely associated with the incidence of OA. However, it remains unclear whether lack of difference in BMD

and lower SOS, BUA, and stiffness index of the calcaneus in the OA group was secondary to the effect walking disturbance resulting from hip pain. Our data suggest that hip OA patients have higher BMD than healthy women, and that inactivity or immobilization caused by hip OA may reduce BMD in the lower limb.

posttranslational histone modifications
ID histone deacetylase inhibitors; mesenchymal stem-cells; promotes osteoblast differentiation; kappa-b ligand; dna methylation biomarkers; osteogenic differentiation; gene-expression; receptor activator; lineage commitment; osteocalcin gene
AB Epigenetics refers to the study of mechanisms able to influence gene expression in a stable and potentially heritable manner without altering the DNA sequence. These mechanisms include posttranslational histone modifications, miRNA-mediated post-transcriptional regulation and DNA methylation. The accumulation of molecular errors over time resulting, at least partly, in the alteration of normal epigenetic patterns is being widely associated with aging. Epigenetic processes are also considered important mechanisms through which environmental and stochastic stressors promote numerous pathologies in humans. It is, therefore, reasonable to expect that several complex multi-factorial late-onset disorders, like osteoporosis and osteoarthritis, could have a strong epigenetic component. The focal point of all skeletal pathologies is the deregulation of bone remodeling, mediated by bone-forming osteoblasts and bone-resorbing osteoclasts. In order to keep both processes in balance, the activity, differentiation and apoptosis of both cell types have to be tightly regulated. In particular, the differentiation of osteoblasts and osteoclasts is accompanied by profound changes in gene expression. It has been shown that histone deacetylation and DNA methylation negatively regulate the expression of several genes associated with different stages of osteoblast differentiation; however, several miRNAs promote osteoblastogenesis. Furthermore, inactivating mutations in the miRNA coding regions could be associated with the pathogenesis of osteoporosis. The aim of this review is to highlight the role of epigenetic mechanisms in bone remodeling and bone homeostasis, so as to implicate their diagnostic and therapeutic potential in skeletal diseases.

TI Genetic Polymorphisms of Interleukin-1 Alpha and the Vitamin D Receptor in Mexican Mestizo Patients with Intervertebral Disc Degeneration
SO INTERNATIONAL JOURNAL OF GENOMICS
LA English
DT Article
ID resonance-imaging changes; low-back-pain; risk-factors; functional polymorphism; lumbar spine; association; disease; osteoporosis; osteoarthritis; susceptibility
AB Intervertebral disc degeneration (IDD) is the most common diagnosis in patients with back pain, a leading cause of musculoskeletal disability worldwide. Several conditions, such as occupational activities, gender, age, and obesity, have been associated with IDD. However, the development of this disease has strong genetic determinants. In this study, we explore the possible association between rs1800587 (c.-949C>T) of interleukin-1 alpha (IL1A) and rs2228570 (c.2T>V) and rs731236 (c.1056T>C) of vitamin D receptor (VDR) gene polymorphisms and the development of IDD in northwestern Mexican Mestizo population. Gene polymorphisms were analyzed by polymerase chain reaction followed by restriction fragment length polymorphism, in two groups matched by age and gender: patients with symptomatic lumbar IDD (n = 100) and subjects with normal lumbar-spine MRI-scans (n = 100). Distribution of the mutated alleles in patients and controls was 27.0% versus 28.0% (P = 0.455) for T of rs1800587 (IL1A); 53.0% versus 58.0% (P = 0.183) for V of rs2228570 (VDR); and 18.0% versus 21.0% (P = 0.262) for C of rs731236 (VDR). Our results showed no association between the studied polymorphisms and IDD in this population. This is the first report on the contribution of gene polymorphisms on IDD in a Mexican population.

TI Prevention of diseases after menopause
SO CLIMACTERIC
LA English
DT Article
DE PREVENTION; MENOPAUSE; OBESITY; CARDIOVASCULAR; OSTEOPOROSIS; COGNITION; DEMENTIA; CANCER; HORMONAL THERAPY
ID coronary-heart-disease; hormone replacement therapy; body-mass index; osteoporosis-related fractures; cardiovascular risk-factors; conjugated equine estrogen; breast-cancer incidence; postmenopausal women; alzheimers-disease; waist circumference
AB Women may expect to spend more than a third of their lives after menopause. Beginning in the sixth decade, many chronic diseases will begin to emerge, which will affect both the quality and quantity of a woman's life. Thus, the onset of menopause heralds an opportunity for prevention strategies to improve the quality of life and enhance longevity. Obesity, metabolic syndrome and diabetes, cardiovascular disease, osteoporosis and osteoarthritis, cognitive decline, dementia and depression, and cancer are the major diseases of concern. Prevention strategies at menopause have to begin with screening and careful assessment for risk factors, which should also include molecular and genetic diagnostics, as these become available. Identification of certain risks will then allow directed therapy. Evidence-based prevention for the diseases noted above include lifestyle management, cessation of smoking, curtailing excessive alcohol consumption, a healthy diet and moderate exercise, as well as mentally stimulating activities. Although the most recent publications from the follow-up studies of the Women's Health Initiative do not recommend menopause hormonal therapy as a prevention strategy, these conclusions may not be fully valid for midlife women, on the basis of the existing data. For healthy women aged 50-59 years, estrogen therapy decreases coronary heart disease and all-cause mortality; this interpretation is entirely consistent with results from other randomized, controlled trials and observational studies. Thus. as part of a comprehensive strategy to prevent chronic disease after menopause, menopausal hormone therapy, particularly estrogen therapy may be considered as part of the armamentarium.

DT Article
DE MRI; Microfracture; Ankle; Osteochondritis dissecans (OCD); Bone marrow edema (BME)
ID bone-marrow edema; autologous chondrocyte transplantation; normal hyaline cartilage; articular-cartilage; arthroscopic microfracture; reparative tissue; t2 assessment; lesions; knee; osteoarthritis
AB To quantitatively evaluate cartilage repair after microfracture (MF) for ankle osteochondritis dissecans (OCD) using MRI and analyse correlations between MRI and clinical outcome. Forty-eight patients were recruited and underwent MR imaging, including 3D-DESS, T2-mapping and T2-STIR sequences, and completed American Orthopaedic Foot and Ankle Society (AOFAS) scoring. Thickness index, T2 index of repair tissue (RT) and volume of subchondral bone marrow oedema (BME) were calculated. Subjects were divided into two groups: group A (3-12 months post-op), and group B (12-24 months post-op). Student's t test was used to

compare the MRI and AOFAS score between two groups and Pearson's correlation coefficient to analyse correlations between them. Thickness index and AOFAS score of group B were higher than group A ($P < 0.001$, $P < 0.001$). T2 index and BME of group B were lower than group A ($P < 0.001$, $P = 0.012$). Thickness index, T2 index and BME were all correlated with AOFAS score ($r = 0.416$, $r = -0.475$, $r = -0.353$), but BME was correlated with neither thickness index nor T2 index. Significant improvement from MF can be expected on the basis of the outcomes of quantitative MRI and AOFAS score. MRI was correlated with AOFAS score. BME is insufficient as an independent predictor to evaluate repair quality, but reduction of BME can improve the patient's clinical outcome. aEuro cent Patients with unstable ankle OCD had satisfactory clinical outcome after MF. aEuro cent Quantitative MRI correlates with clinical outcome after MF for ankle OCD. aEuro cent The reduction of subchondral BME will improve the patient's clinical outcome. aEuro cent Quantitative MRI can monitor the process of cartilage repair over time.

TI Identical subchondral bone microarchitecture pattern with increased bone resorption in rheumatoid arthritis as compared to osteoarthritis
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE Rheumatoid arthritis; Osteoarthritis; Microarchitecture; Bone remodeling; Cyst
ID marrow edema; periarticular osteoporosis; knee osteoarthritis; articular-cartilage; osteocyte density; cancellous bone; femoral-head; joint; cysts; pathogenesis
AB Objectives: To analyze the differences in microarchitecture and bone remodeling of subchondral bone in femoral heads from patients with rheumatoid arthritis (RA) and osteoarthritis (OA). Designs: Peri-articular bone samples, including subchondral trabecular bone (STB) and deeper trabecular bone (DTB) were extracted from the load-bearing region of femoral heads from 20 patients with RA and 40 patients with OA during hip replacement surgery. Micro-CT, histomorphometry and backscatter scanning electron microscopy (BSEM) were performed to assess microarchitecture and bone histology parameters. Results: In both RA and OA, STB showed more sclerotic microarchitecture and more active bone remodeling, compared to DTB. RA and OA showed similar microarchitecture characteristics in both STB and DTB, despite STB in RA exhibiting higher bone resorption. In addition, there was no difference in the frequency of bone cysts in STB between RA and OA. In STB, the trabecular bone surrounding subchondral bone cysts (Cys-Tb) was more sclerotic than the trabecular bone found distant to cysts (Peri-Tb), with a higher level of bone remodeling. Both Cys-Tb region and Peri-Tb region were detected to have similar microarchitectural and bone remodeling characteristics in RA and OA. Conclusions: Apart from higher bone resorption in the general subchondral bone of RA samples, the periarticular bone exhibited similar microarchitectural and bone remodeling characteristics in RA and OA. TI Value of biomarkers in osteoarthritis: current status and perspectives
SO POSTGRADUATE MEDICAL JOURNAL
LA English
DT Review
ID synovial-fluid levels; c-reactive protein; biochemical markers; knee osteoarthritis; radiographic osteoarthritis; ctx-ii; rheumatoid-arthritis; biological markers; aggrecan fragments; proteomic analysis
AB Osteoarthritis affects the whole joint structure with progressive changes in cartilage, menisci, ligaments and subchondral bone, and synovial inflammation. Biomarkers are being developed to quantify joint remodelling and disease progression. This article was prepared following a working meeting of the European Society for Clinical and Economic Aspects of Osteoporosis and Osteoarthritis convened to discuss the value of biochemical markers of matrix metabolism in drug development in osteoarthritis. The best candidates are generally molecules or molecular fragments present in cartilage, bone or synovium and may be specific to one type of joint tissue or common to them all. Many currently investigated biomarkers are associated with collagen metabolism in cartilage or bone, or aggrecan metabolism in cartilage. Other biomarkers are related to non-collagenous proteins, inflammation and/or fibrosis. Biomarkers in osteoarthritis can be categorised using the burden of disease, investigative,

prognostic, efficacy of intervention, diagnostic and safety classification. There are a number of promising candidates, notably urinary C-terminal telopeptide of collagen type II and serum cartilage oligomeric protein, although none is sufficiently discriminating to differentiate between individual patients and controls (diagnostic) or between patients with different disease severities (burden of disease), predict prognosis in individuals with or without osteoarthritis (prognostic) or perform so consistently that it could function as a surrogate outcome in clinical trials (efficacy of intervention). Future avenues for research include exploration of underlying mechanisms of disease and development of new biomarkers; technological development; the 'omics' (genomics, metabolomics, proteomics and lipidomics); design of aggregate scores combining a panel of biomarkers and/or imaging markers into single diagnostic algorithms; and investigation into the relationship between biomarkers and prognosis.

TI Sonographic pattern of fetal head descent: relationship with duration of active second stage of labor and occiput position at delivery
SO ULTRASOUND IN OBSTETRICS & GYNECOLOGY
LA English
DT Article
DE intrapartum ultrasound; labor; persistent occiput posterior; second stage; three-dimensional
ID intrapartum translabial ultrasound; transperineal ultrasound; prolonged 2nd-stage; posterior position; station; progression; mode; women; angle
AB Objectives The objectives of this study were firstly to assess the longitudinal changes of various sonographic parameters of fetal head progression in relation to length of active second stage of labor, and secondly to compare ultrasound findings obtained longitudinally among fetuses with persistent occiput posterior (OP) vs those with persistent occiput anterior (OA) position. Methods From a series of nulliparous low-risk women at term attending the labor ward of our university hospital, transperineal ultrasound volumes were prospectively acquired at the beginning of the active second stage (T1) and at 40-min intervals thereafter until delivery (T2, T3). Sonographic parameters were derived from offline analysis of each volume, including the angle of progression (AoP), progression distance (PD), head-symphysis distance (HSD), head direction (HD) and midline angle. These parameters were compared between patients who delivered within 60 min from the beginning of the active second stage of labor (early delivery) and those who remained undelivered by that time (late delivery). Fetal head position was determined from stored digital images of transabdominal examinations performed at the beginning of the active second stage. Comparison was performed between fetuses with OA and those with persistent OP position at delivery. Results Spontaneous vaginal delivery was achieved in 58 (81.7%) cases, whereas vacuum

extraction and Cesarean section were performed in eight (11.3%) and five (7.0%) cases, respectively. Delivery was achieved within 60 min from the beginning of the active second stage in 44 (62.0%) patients. In the early vs late delivery groups, measurements of AoP, HSD and PD at T1 were significantly different (AoP, 143.9 +/- 20.5 degrees vs 125.3 +/- 15.0 degrees, P < 0.001; HSD, 14.8 +/- 4.5mm vs 20.9 +/- 5.8 mm, P < 0.001; PD, 44.0 +/- 14.1 vs 35.0 +/- 13.1 mm, P = 0.008). On logistic regression analysis of data obtained at T1, maternal body mass index, oxytocin administration, neonatal birth weight and HSD appeared to predict independently duration of the active second stage. Among fetuses delivering in the OP position (n = 10, 13.5%), Cesarean delivery was significantly more common than in those delivering in the OA position (n = 5 (50.0%) vs n = 2 (3.1%), P = 0.001). Women with persistent OP position compared with OA showed a significantly different AoP at T1 (122 +/- 17 degrees vs 138 +/- 20 degrees, P = 0.016), HD and HSD at T1 (HD, 112 +/- 17mm vs 86 +/- 19 mm, P < 0.001; HSD, 16.5 +/- 5.4mm vs 22.8 +/- 6.6 mm, P = 0.008) and at T2 (HD, 120 +/- 16 vs 82 +/- 27 mm, P = 0.008; HSD, 12.6 +/- 3.4mm vs 18.5 +/- 5.4 mm, P = 0.038). Conclusions AoP, PD and HSD are significantly different between patients undergoing delivery before or after 60 min from the beginning of the active second stage of labor. Ultrasound parameters are among the significant predictors of duration of the active second stage. Moreover, in fetuses persisting in the OP position vs those delivering in the OA position, fetal head progression seems to differ at early phases of the active second stage. Copyright (C) 2014 ISUOG. TI Exercise habits during middle age are associated with lower prevalence of sarcopenia: the ROAD study
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE Elderly; Epidemiology; Exercise; Physical performance; Sarcopenia
ID bioelectrical-impedance analysis; skeletal-muscle mass; older men; epidemiology; definition; predictors; healthy; cohort; adults
AB The present cross-sectional study investigated the prevalence of sarcopenia and clarified its associated factors in 1,000 elderly participants of Japanese population-based cohorts. Exercise habit in middle age was associated with low prevalence of sarcopenia in older age, suggesting that it is a protective factor against sarcopenia in older age. The present study investigated the prevalence of sarcopenia using the European Working Group on Sarcopenia in Older People (EWGSOP) definition, and clarified the association of sarcopenia with physical performance in the elderly participants of Japanese population-based cohorts of the Research on Osteoarthritis/osteoporosis Against Disability (ROAD) study. We enrolled 1,000 participants (aged a parts per thousand yen65 years) from the second visit of the ROAD study who had completed assessment of handgrip strength, gait speed, and skeletal muscle mass measured by bioimpedance analysis. Presence of sarcopenia was determined according to the EWGSOP algorithm. Information collected included exercise habits in middle age. Prevalence of sarcopenia was 13.8 % in men and 12.4 % in women, and tended to be significantly higher according to increasing age in both sexes. Factors associated with sarcopenia, as determined by logistic regression analysis, were chair stand time

(odds ratio [OR], 1.09; 95 % confidence interval [CI], 1.04-1.14), one-leg standing time (OR, 0.97; 95 % CI, 0.96-0.99), and exercise habit in middle age (OR, 0.53; 95 % CI, 0.31-0.90). Exercise habit in middle age was associated with low prevalence of sarcopenia in older age. Furthermore, linear regression analysis revealed that exercise habits in middle age were significantly associated with grip strength (P < .001), gait speed (P < .001), and one-leg standing time (P = .005) in older age. This cross-sectional study suggests that exercise habit in middle age is a protective factor against sarcopenia in older age and effective in maintaining muscle strength and physical performance in older age.

TI What about strontium ranelate in osteoarthritis? Doubts and securities
SO MODERN RHEUMATOLOGY
LA English
DT Review
DE Disease modifying osteoarthritis drugs; Osteoarthritis; Strontium ranelate
ID estrogen replacement therapy; knee osteoarthritis; subchondral bone; double-blind; ctx-ii; cartilage; efficacy; disease; sulfate; safety
AB Osteoarthritis (OA) is the most common disabling joint disease worldwide and its treatment is based on a combination of non-pharmacological and pharmacological modalities. Commonly prescribed OA medications include symptomatic drugs (non-steroidal anti-inflammatory drugs, analgesics, locally administered corticosteroids, viscosupplementation) and new compounds that are potentially able to reduce or stop the disease progression, called "Disease Modifying Osteoarthritis Drugs (DMOADs)". Strontium ranelate (SR) is an anti-osteoporotic treatment that increases bone formation, while decreasing bone resorption and it potentially acts as a new DMOAD. The objective of this review is to summarize the currently available information on clinical effects and mechanism of action of SR in OA. We have examined two post hoc analysis conducted on the large, randomized Treatment of Peripheral Osteoporosis study and the double-blind, randomized, controlled trial about SR in knee OA. Furthermore, we analyzed three studies in animal models and two in vitro experiments to better understand the mechanism of action of SR in OA. The available data demonstrate that SR could be considered a new promising symptomatic and disease-modifying agent in the treatment of OA and was safe and well tolerated. Additionally, there is a need for further investigations to establish the optimal dosage and to better clarify the mechanism of action of SR in OA.

DT Article
DE Atypical femoral fracture (AFF); Osteoporosis; Lower limb alignment; Femorotibial angle (FTA); Bisphosphonate
ID postmenopausal women; bisphosphonate use; american society; femur fractures; bone turnover; task-force; osteoarthritis; polymyositis
AB Purpose: Atypical femoral fractures (AFFs) are stress-related fractures that are speculated to associate with long-term treatment with bisphosphonates for osteoporosis. A history of AFF is a high risk factor for the development of a subsequent AFF in the same location of the contralateral femur, suggesting that a patient's individual anatomical factor(s) are related to the fracture site of AFFs. In this study, we investigated the radiographs of fourteen AFFs (four bilateral fractures

among ten patients) treated at six hospitals associated with our university between 2005 and 2010. The fracture site and standing femorotibial angle (FTA), which reflects the mechanical axis of the lower limb, were measured on weight-bearing lower limb radiographs. The fracture site and FTA of patients with typical femoral fractures (TFF) were compared to those of patients with AFFs. The correlations were examined using Spearman's rank correlation coefficients. The fracture locations in the femora were almost the same in the patients with bilateral AFFs. There was a positive correlation between the fracture site and the standing FTA in the patients with AFFs (r = 0.82, 95% confidence interval; 0.49 to 0.94), indicating that the larger the standing FTA (varus alignment), the more distal the site of the fracture in the femur. The FTA of the patients with atypical diaphyseal femoral fracture were significantly larger compared to that of those with not only atypical subtrochanteric fractures but also TFFs. In conclusion, the fracture sites of AFFs are associated with the standing lower limb alignment, while those of TFFs are not. (C) 2014 Elsevier Inc. All rights reserved.

TI Association between "loco-check" and EuroQol, a comprehensive instrument for assessing health-related quality of life: a study of the Japanese general population
SO JOURNAL OF ORTHOPAEDIC SCIENCE
LA English
DT Article
ID low-back-pain; postmenopausal women; vertebral fractures; european foundation; locomotive syndrome; spinal mobility; osteoarthritis; osteoporosis; knee; impact
AB The concept of "locomotive syndrome" (LS) was proposed by the Japanese Orthopaedic Association (JOA) in 2007 to refer to the risk of elderly individuals becoming bedridden because of reduced function of locomotive organs, for example muscles, bones, and joints. The purpose of this study was to clarify the association between LS screening results based on "loco-check" and health-related quality of life (HRQoL) assessed by use of EuroQol. Four-hundred and forty-two Japanese subjects (183 males and 259 females) were evaluated for LS and HRQoL

by use of "loco-check," EuroQol-5 dimensions (EQ-5D), and EuroQol-VAS (EQ-VAS). If the subjects answered "yes" to one or more of the seven items of "loco-check," they were assigned to a locomotive syndrome suspected group (L group). If they answered "no" to all seven items, they were assigned to a locomotive syndrome not suspected group (NL group). We investigated the association between the screening LS results obtained by use of "loco-check" and HRQoL status determined by use of EQ-5D utility value and EQ-VAS score. LS was suspected among 39.6 % of the subjects on the basis of "loco-check." In univariate analysis, significantly higher age, higher female-to-male ratio, and more reduced HRQoL were observed in the L group than in the NL group, according to EQ-5D and EQ-VAS. Logistic regression analysis showed that EQ-5D utility value and EQ-VAS score were associated with LS and the difference was statistically significant. Furthermore, correlations were found between the number of items with a "yes" answer on "loco-check", EQ-5D, or EQ-VAS. That is, a larger number of items with a "yes" answer on "loco-check" was associated with reduced HRQoL assessed by use of EQ-5D and EQ-VAS. We demonstrated that a finding of LS on the basis of "loco-check" is significantly associated with EQ-5D utility value and EQ-VAS score, and that a population identified as having LS by use of "loco-check" also had reduced HRQoL. Furthermore, it is speculated that the severity of reduced HRQoL because of locomotive dysfunction can be determined by use of "loco-check".

AB Disorders of the skeleton are one of the most common causes of chronic pain and long-term physical disability in the world. Chronic skeletal pain is caused by a remarkably diverse group of conditions including trauma-induced fracture, osteoarthritis, osteoporosis, low back pain, orthopedic procedures, celiac disease, sickle cell disease and bone cancer. While these disorders are diverse, what they share in common is that when chronic skeletal pain occurs in these disorders, there are currently few therapies that can fully control the pain without significant unwanted side effects. In this review we focus on recent advances in our knowledge concerning the unique population of primary afferent sensory nerve fibers that innervate the skeleton, the nociceptive and neuropathic mechanisms that are involved in driving skeletal pain, and the neurochemical and structural changes that can occur in sensory and sympathetic nerve fibers and the CNS in chronic skeletal pain. We also discuss therapies targeting nerve growth factor or sclerostin for treating skeletal pain. These therapies have provided unique insight into the factors that drive skeletal pain and the structural decline that occurs in the aging skeleton. We conclude by discussing how these advances have changed our understanding and potentially the therapeutic options for treating and/or preventing chronic pain in the injured, diseased and aged skeleton.

TI A REPORT FROM THE AMERICAN SOCIETY FOR BONE AND MINERAL RESEARCH

2014 ANNUAL MEETING (SEPTEMBER 12-15-HOUSTON, TEXAS, USA)
SO DRUGS OF TODAY
LA English
DT Article
DE Osteoporosis; Osteoarthritis; Fractures; Metastatic bone disease
AB Although the weather was very Texas-unlike, with fog, clouds and even intense rain, the George R. Brown Convention Center in Houston was the site for this year's annual meeting of the American Society for Bone and Mineral Research, where investigators from across the world came to present the latest findings in bone science. Four days of oral and poster presentations encompassing over 1,500 papers discussing a great variety of subjects including preclinical and clinical research aimed at improving the treatment of bone diseases such as osteoporosis and other forms of bone frailty.

TI Mediolateral Subchondral Tibial Bone Mineral Density Difference Does Not Predict Osteoarthritis Progression
SO ORTHOPEDICS
LA English
DT Article
ID knee osteoarthritis; osteoporosis; health; women
AB Data on the relationship between osteoporosis and osteoarthritis are conflicting. Most studies report "snapshot" prevalences, and there are few studies evaluating localized knee bone mineral density (BMD) measurements with respect to subsequent osteoarthritis progression. The authors hypothesize that increased mediolateral difference of the proximal tibial BMD may predict progression of knee osteoarthritis. In this study, 246 female volunteers were followed up prospectively over 2 years. Baseline BMD measurements of bilateral proximal (subchondral) tibiae were performed, and the mediolateral BMD ratio was calculated. Precision studies were performed on healthy volunteers to validate the technique. The patients were divided into osteoarthritis progressors and non-progressors based on Kellgren-Lawrence radiographic criteria at 2-year follow-up. Patients who were taking bisphosphonates or who had a history of inflammatory, infectious, or metabolic bone disease and previous hip and knee surgery were excluded. Demographic data, calcium supplementation, physical activity, baseline knee radiographs, and radiographs at 2-year follow-up were obtained. The study was adequately powered to detect an effect size of 0.4. There were 121 progressors and 125 non-progressors. Mean mediolateral BMD ratio was 1.02 among the progressors and 1.01 among the non-progressors (t=0.632, P=.528). Potential confounders were equally distributed among both groups. The data suggest that

there is no link between proximal tibial BMD ratio and progression of knee osteoarthritis.

TI Comparison of bone tissue trace-element concentrations and mineral density in

osteoporotic femoral neck fractures and osteoarthritis
SO CLINICAL INTERVENTIONS IN AGING
LA English
DT Article
DE osteoporosis; trace elements; calcium; magnesium; zinc
ID hip-replacement surgery; postmenopausal osteoporosis; zinc; magnesium; poland; joint; pathogenesis; plasma; copper; femur
AB Purpose: This study examined the role of trace elements in osteoporosis by comparing the trace-element concentrations in bone and the radiographic bone density and bone mineral density (BMD) of patients with osteoporotic femur fractures and osteoarthritis. Patients and methods: The study enrolled 30 patients operated on for proximal femoral fractures after falls, and another 30 patients undergoing hip arthroplasty at the same center for hip osteoarthritis. Bone samples were obtained during the surgical procedures. The density of the bone samples was assessed using computed tomography and the Hounsfield scale. The levels of Ca(II), Mg(II), and other trace elements in the bone samples were determined using flame atomic absorption spectrometry and inductively coupled plasma mass spectrometry. In addition, BMD, Z-scores, and T-scores were measured in the unaffected hips of all patients using dual-energy X-ray absorptiometry. Results: Magnesium (1,908 +/- 507 versus 2,540 +/- 435, P<0.05), calcium (10.4 +/- 3.5 versus 13.9 +/- 3.7, P<0.05), and zinc (2,342 +/- 1,252 versus 3,145 +/- 1,604, P<0.05) mu g g(-1), levels were significantly lower in the bone samples in the fracture group. The groups did not differ in the other biochemical parameters. All dual-energy X-ray absorptiometry findings were significantly worse in the fracture group than in the osteoarthritis group. However, the groups did not differ in femoral neck density assessed radiologically using the Hounsfield scale. The following parameters were negatively correlated with age: magnesium, r=-0.436, P<0.001; calcium, r=-0.331, P=0.01; T-score, r=-0.381, P=0.003; Z-score, r=-0.267, P=0.043; and BMD, r=-0.365, P=0.004. Conclusion: Ca(II), Mg(II), and Zn(II) appear to play important roles in bone breakdown/synthesis. Further studies of the roles of trace elements in the etiology and treatment of osteoporosis are warranted. We found decreased bone levels of Ca, Mg, and Zn in patients with osteoporotic fractures compared to subjects with osteoarthritis.

TI Structure Modeling of the Glenoid: Relevance to Shoulder Arthroplasty
SO JOURNAL OF ORTHOPAEDIC RESEARCH
LA English
DT Article
DE glenoid; total shoulder arthroplasty; shape modeling; glenoid prosthesis; surgical instrumentation
ID computed-tomography; component; osteoarthritis; replacement; version; shape; reconstruction; instability; surgery; anatomy
AB We applied shape modeling and principal component analysis (PCA) to discover glenoid bone structural relationships relevant to improving glenoid prosthesis features, fixation, and instrumentation. Knowledge of external bone morphology guides prosthesis shape and positioning, while internal bone morphology and bone density influence fixation. CT-based modeling defined nonarthritic glenoid subchondral bone surface and internal structure. First and second principal shape components were related to size and density. Reproducible structural parameters and glenoid feature relationships were discovered. Subchondral bone surface was approximated by a circle inferiorly and a triangle superiorly with the circle's center at a reproducible point along a superior-inferior line. Glenoid vault's maximum depth was at the circle's center, and the highest bone density was in posterior glenoid. Glenoid subchondral bone surface version varied from superior to inferior, but not by sex or side. Male subchondral bone surfaces were larger and more retroverted. Even if subchondral bone surfaces are deformed by arthritis, glenoid morphology can be identified by extra-articular landmarks, permitting location of the glenoid center and scapular orientation (glenoid version). Knowledge obtained from this study directs design of novel prosthesis features and instrumentation for use without pre-op CT or computer aided surgery. (c) 2014 Orthopaedic Research Society. TI Factors associated with fall-related fractures in Parkinson's disease
SO PARKINSONISM & RELATED DISORDERS
LA English
DT Article
DE Fall-related fractures; Idiopathic Parkinson's disease; Risk factors
ID osteoporosis; specificity; sensitivity; prediction; diagnosis; dementia; scale
AB Purpose: Fall-related fracture is one of the most disabling features of idiopathic Parkinson's disease (PD). A better understanding of the associated factors is needed to predict PD patients who will require treatment. Methods: This prospective study enrolled 100 adult idiopathic PD patients. Stepwise logistic regressions were used to evaluate the relationships between clinical factors and fall-related fracture. Results: Falls occurred in 56 PD patients, including 32 with fall-related fractures. The rate of falls in the study period was 2.2 +/- 1.4 per 18 months. The percentage of osteoporosis was 34% (19/56) and 11% in PD patients with and without falls, respectively. Risk factors associated with fall-related fracture were sex, underlying knee osteoarthritis, mean Unified Parkinson's Disease Rating Scale score, mean Morse fall scale, mean Hoehn and Yahr stage, and exercise habit. By stepwise logistic regression, sex and mean Morse fall scale were independently associated with fall-related fracture. Females had an odds ratio of 3.8 compared to

males and the cut-off value of the Morse fall scale for predicting fall-related fracture was 72.5 (sensitivity 72% and specificity 70%). Discussion: Higher mean Morse fall scales (>72.5) and female sex are associated with higher risk of fallrelated fractures. Preventing falls in the high-risk PD group is an important safety issue and highly relevant for their quality of life. (C) 2013 Elsevier Ltd. All rights reserved.

TI Incidence of certified need of care in the long-term care insurance system and its risk factors in the elderly of Japanese population-based cohorts: The ROAD study
SO GERIATRICS & GERONTOLOGY INTERNATIONAL
LA English
DT Article
DE activities of daily living; certification of need of care (youkaigo-nintei); disability; long-term care insurance system; prospective cohort study
ID body-mass index; radiographic knee osteoarthritis; disability; association; predictor; health; age
AB AimTo examine the incidence of certified need of care in the national long-term care insurance (LTCI) system, and to determine its risk factors in the elderly of Japanese population-based cohorts of the Research on Osteoarthritis/Osteoporosis Against Disability (ROAD) study. MethodsOf the 3040 participants in the baseline examination of the ROAD study, we enrolled 1773 (699 men, 1074 women) aged 65years or older who were not certified as in need of care level elderly at baseline. Participants were followed for incident certification of need of care in the LTCI system. Associated factors in the baseline examination with occurrence were determined by multivariate Cox proportional hazards regression analysis. Muscle dysfunction was defined in accordance with the European Working Group on Sarcopenia in Older People algorithm for screening sarcopenia. ResultsA total of 54 men and 115 women were certified as in need of care level elderly during the

average 4.0-year follow up. The incidence was 2.0 and 2.5 per 100 person-years in men and women, respectively. Identified risk factors were region, age, body mass index <18.5 or 27.5kg/m(2), grip strength, knee extension torque, usual gait speed, chair stand time and muscle dysfunction. ConclusionsBoth underweight and obesity, as well as low muscle strength and physical ability, are risk factors for certification of need of care. Considering muscle dysfunction is a risk factor for occurrence, screened individuals are recommended to receive early intervention programs regardless of muscle volume. Geriatr Gerontol Int 2014; 14: 695-701.

TI Prevalence of hallux valgus and risk factors among Japanese community dwellers
SO JOURNAL OF ORTHOPAEDIC SCIENCE
LA English
DT Article
ID randomized controlled-trial; foot pain; knee osteoarthritis; elderly persons; heberdens nodes; osteo-arthrosis; older persons; disability; women; association
AB To investigate the prevalence and severity of radiographically detected hallux valgus (HV) as well as associated risk factors among Japanese residents of Miyagawa, a mountain village located in the center of Mie Prefecture. The height, weight and body mass index (BMI) of 403 participants (male n = 135, female n = 268) recruited from among the residents of Miyagawa Village, Japan aged a parts per thousand yen65 years were measured, and baseline data, including age, sex and medical history were obtained from interviews and questionnaires. Knee osteoarthritis (KOA) was determined from radiographs of the feet and knees, and osteoporosis was determined by measuring bone mineral density. Hallux valgus, defined as angulation of the big toe at the first metatarsophalangeal joint of > 20A degrees, was classified as: mild (20A degrees aEuro"30A degrees), moderate (30A degrees aEuro"40A degrees) or severe (> 40A degrees). Risk factors for HV were calculated using multivariate logistic regression analysis that included age, sex, obesity (BMI a parts per thousand yen25), KOA, osteoporosis, Heberden's nodes and low back pain as variables. The overall prevalence of definite radiographic HV was 22.8 % (184/806), and mild, moderate and severe HV was found in 66.3, 27.2 and 6.5 % of the participants, respectively. Hallux valgus was found in at least one foot in 120 (29.8 %) of the participants and the prevalence significantly differed between females with and without HV and KOA (odds ratios: 2.54 and 1.71, respectively). The prevalence of definite radiographic HV was 29.8 %. Female sex and KOA were significantly associated with increased risk for radiographic HV.

TI Aging and Oxidative Stress Reduce the Response of Human Articular Chondrocytes to Insulin-like Growth Factor 1 and Osteogenic Protein 1
SO ARTHRITIS & RHEUMATOLOGY
LA English
DT Article
ID factor-i; proteoglycan synthesis; matrix synthesis; cartilage; osteoarthritis; expression; stimulation; homeostasis; senescence; survival
AB Objective. To determine the effects of aging and oxidative stress on the response of human articular chondrocytes to insulin-like growth factor 1 (IGF-1) and osteogenic protein 1 (OP-1). Methods. Chondrocytes isolated from normal articular cartilage obtained from tissue donors were cultured in alginate beads or monolayer. Cells were stimulated with 50-100 ng/ml of IGF-1, OP-1, or both. Oxidative stress was induced using tert-butyl hydroperoxide. Sulfate incorporation was used to measure proteoglycan synthesis, and immunoblotting of cell lysates was performed to analyze cell signaling. Confocal microscopy was performed to measure nuclear translocation of Smad4. Results. Chondrocytes isolated from the articular cartilage of tissue donors ranging in age from 24 years to 81 years demonstrated an age-related decline in proteoglycan synthesis stimulated by IGF-1 and IGF-1 plus OP-1. Induction of oxidative stress inhibited both IGF-1- and OP-1-stimulated proteoglycan synthesis. Signaling studies showed that oxidative stress inhibited IGF-1-stimulated Akt phosphorylation while increasing phosphorylation of ERK, and that these effects were greater in cells from older donors. Oxidative stress also increased p38 phosphorylation, which resulted in phosphorylation of Smad1 at the Ser(206) inhibitory site and reduced nuclear accumulation of Smad1. Oxidative stress also modestly reduced OP-1-stimulated nuclear translocation of Smad4. Conclusion. These results demonstrate an age-related reduction in the response of human chondrocytes to IGF-1 and OP-1, which are 2 important anabolic factors in cartilage, and suggest that oxidative stress may be a contributing factor by altering IGF-1 and OP-1 signaling.

DT Article
DE Osteoarthritis; Bone density; Synovitis; Inflammation; Osteoporosis
ID lifetime food restriction; high-fat diet; knee osteoarthritis; adipose-tissue; mechanical-property; mice; obesity; bone; alignment; body
AB Chronic adipose tissue inflammation and its associated adipokines have been linked to the development of osteoarthritis (OA). It has been shown that caloric restriction may decrease body mass index and adiposity. The objectives of this study were to investigate the effect of lifelong caloric restriction on bone morphology, joint inflammation, and spontaneously occurring OA development in aged mice. C57BL/NIA mice were fed either a calorie-restricted (CR) or ad libitum (AL) diet starting at 14 weeks of age. All mice were sacrificed at 24 months of age. Adipose tissue and knee joints were then harvested. Bone parameters of the joints were analyzed by micro-CT. OA and joint synovitis were determined using histology and semiquantitative analysis. Lifelong caloric restriction did not alter the severity of OA development in C57BL/NIA aged mice, and there was no difference in the total joint Mankin score between CR and AL groups ($p=0.99$). Mice also exhibited similar levels of synovitis ($p=0.54$). The bone mineral density of the femur and the tibia was comparable between the groups with a small increase in cancellous bone volume fraction in the lateral femoral condyle of the CR group compared with the AL group. Lifelong caloric restriction did not alter the incidence of OA or joint synovitis in C57BL/NIA mice, indicating that a reduction of caloric intake alone was not sufficient to prevent spontaneous age-related OA. Nonetheless, early initiation of CR continued throughout a life span did not negatively impact bone structural properties.

TI Extracorporeal shockwave therapy in osteoporotic osteoarthritis of the knee in rats: an experiment in animals
SO ARTHRITIS RESEARCH & THERAPY
LA English
DT Article
ID bone-mineral density; subchondral bone; chondrocyte apoptosis; articular-cartilage; shows; rabbits; damage; hip; progression; expression
AB Introduction: This study investigated the effectiveness of extracorporeal shockwave therapy (ESWT) in osteoporotic (OP) osteoarthritis (OA) of rat knee. Methods: Fifty-six rats were divided into seven groups including sham, OA, OP, OA + OP, OA + ESWT, OP + ESWT, and OA + OP + ESWT groups. The evaluations included gross pathology, bone mineral density (BMD), micro-computed tomography (micro-CT) scan, bone-strength test, histopathologic examination, and immunohistochemical analysis. Results: On gross pathology, group OA + OP showed larger areas of osteoarthritic changes than did groups OA and OP, as compared with the sham group. BMD and bone strength significantly decreased in groups OA, OP, and OA + OP relative to the sham group, and ESWT significantly improved BMD and bone-strength changes. On micro-CT scan, the subchondral plate thickness significantly decreased, and the bone porosity increased in groups OA, OP, and OA + OP, and ESWT significantly improved the changes in subchondral-plate thickness and bone porosity. In histopathologic examination, Mankin score and safranin O score significantly increased in groups OA and group OA + OP, but not in group OP relative to the sham group, and ESWT significantly

improved the changes. In immunohistochemical analysis, Dickkopf-1 (DKK-1) significantly increased, but vessel endothelial growth factor (VEGF), proliferating cell nuclear antigen (PCNA), and bone morphogenetic protein 2 (BMP-2) decreased in groups OA, OP, and OA + OP relative to the sham group, and ESWT significantly reversed the changes. Conclusions: Osteoporosis increased the severity of cartilage damage in osteoarthritis of the knee. ESWT showed effectiveness in the reduction of osteoporotic osteoarthritis of the knee in rats.

TI Ultrasonographic assessment of the femoral cartilage in osteoarthritis patients with and without osteoporosis
SO AGING CLINICAL AND EXPERIMENTAL RESEARCH
LA English
DT Article
DE Osteoarthritis; Osteoporosis; Femoral cartilage; Ultrasound; Bone mineral density
ID bone-mineral density; knee osteoarthritis; spine osteoarthritis; fractures; rotterdam; exercise; validity; volume; women; risk
AB Background The relationship between osteoporosis (OP) and osteoarthritis (OA) is yet unclear. Aim To evaluate the possible effect of OP on the femoral cartilage thickness in female patients with knee OA. Materials and methods Eighty patients with a diagnosis of knee OA were enrolled. Forty subjects who also had OP comprised Group I and the remaining 40 OA subjects comprised Group II. Antero-posterior knee radiographs were obtained in standing position and they were evaluated according to Kelgren-Lawrence (K-L) grading scale. Femoral cartilage evaluations were performed using a linear array US probe (7-12 MHz). In addition, ultrasonographic femoral cartilage grading was also performed for each

knee. Results Left knee scores pertaining to both gradings were found to be lower (p = 0.02, p = 0.04, respectively) in Group I when compared with those of Group II. The two grading scores were positively correlated for both knees-statistically significant only for the right side (r = 0.727, p = 0.01). No significant difference was found between the groups in terms of femoral cartilage thicknesses (all p = 0.05). Discussion Ultrasonographic and roentgenographic gradings were consistent and patients with OP had lower scores for both gradings. On the other hand, the presence of OP did not seem to have any effect on cartilage thickness measurements. Conclusions To the best knowledge of the authors, this study is the first to have explored the impact of OP on OA using US in the literature.

TI Decomposition of in vivo spatially offset Raman spectroscopy data using multivariate analysis techniques
SO JOURNAL OF RAMAN SPECTROSCOPY
LA English
DT Article
DE SORS; multivariate curve resolution; BTEM; bone; in vivo
ID entropy minimization btem; fiberoptic array; turbid media; subsurface; fluorescence; spectra; probe
AB The decomposition of spatially offset Raman spectra for complex multilayer systems, such as biological tissues, requires advanced techniques such as multivariate analyses. Often, in such situations, the decomposition methods can reach their limits of accuracy well before the limits imposed by signal-to-noise ratios. Consequently, more effective reconstruction methods could yield more accurate results with the same data set. In this study we process spatially offset Raman spectroscopy (SORS) data with three different multivariate techniques (band-target entropy minimization (BTEM), multivariate curve resolution and parallel factor analysis (PARAFAC)) and compare their performance when analysing a spectrally challenging plastic model system and an even more challenging problem, the analysis of human bone transcutaneously in vivo. For the in vivo measurements, PARAFAC's requirement of multidimensional orthogonal data is addressed by recording SORS spectra both at different spatial offsets and at different anatomical points, the latter providing added dimensionality through the variation of skin/soft tissue thickness. The BTEM and PARAFAC methods performed the best on the plastic system with the BTEM more faithfully reconstructing the major Raman bands and PARAFAC the smaller more heavily overlapped features. All three methods succeeded in reconstructing the bone spectrum from the transcutaneous data and gave good figures for the phosphate-to-carbonate ratio (within 2% of excised human tibia bone); the PARAFAC gave the most accurate figure for the mineral-to-collagen ratio (20% less than excised human tibia bone). Previous studies of excised bones have shown that certain bone diseases (such as osteoarthritis, osteoporosis and osteogenesis imperfecta) are accompanied by compositional abnormalities that can be detected with Raman spectroscopy, the utility of a technique which could reconstruct bone spectra accurately is manifest. The results have relevance on the use of SORS in general. (c) 2014 Crown copyright.

TI Self-reported quality of care for older adults from 2004 to 2011: a cohort study
SO AGE AND AGEING
LA English
DT Article
DE quality of care; geriatrics; epidemiology; older people
ID medical-record; performance; indicators; outcm; england; pay
AB Background: little is known about changes in the quality of medical care for older adults over time. Objective: to assess changes in technical quality of care over 6 years, and associations with participants' characteristics. Design: a national cohort survey covering RAND Corporation-derived quality indicators (QIs) in face-to-face structured interviews in participants' households. Participants: a total of 5,114 people aged 50 or more in four waves of the English Longitudinal Study of Ageing. Methods: the percentage achievement of 24 QIs in 10 general medical and geriatric clinical conditions was calculated for each time point, and associations with participants' characteristics were estimated using logistic regression. Results: participants were eligible for 21,220 QIs. QI achievement for geriatric conditions (cataract, falls, osteoarthritis and osteoporosis) was 41% [95% confidence interval (CI): 38-44] in 2004-05 and 38% (36-39) in 2010-11. Achievement for general medical conditions (depression, diabetes mellitus, hypertension, ischaemic heart disease, pain and cerebrovascular disease) improved from 75% (73-77) in 2004-05 to 80% (79-82) in 2010-11. Achievement ranged from 89% for cerebrovascular disease to 34% for osteoarthritis. Overall achievement was lower for participants who were men, wealthier, infrequent alcohol drinkers, not obese and living alone. Conclusion: substantial system-level shortfalls in quality of care for geriatric conditions persisted over 6 years, with relatively small and inconsistent variations in quality by participants' characteristics. The relative lack of variation by participants' characteristics suggests that quality improvement interventions may be more effective when directed at healthcare delivery systems rather than individuals.

TI Serum 25-Hydroxyvitamin D Level as an Independent Determinant of Quality of Life in Osteoporosis With a High Risk for Fracture
SO CLINICAL THERAPEUTICS
LA English
DT Article
DE 25(OH)D; fall; fracture; osteoporosis; QOL
ID vitamin-d status; back-pain; vertebral fractures; controlled-trial; fall prevention; older women; mortality; bone; supplementation; questionnaire
AB Background: Deteriorated quality of life (QOL) is a major problem in osteoporotic women. However, little is known regarding the determinants of QOL in patients with osteoporosis. Objective: Our aim was to explore the role of vitamin D status on QOL score in osteoporosis with high fracture risk. Methods: Patients were osteoporotic women aged >= 70 years and with >= 1 risk factor for incident fracture, namely prevalent osteoporotic fracture, bone mineral density (BMD) >-3.0 SD of young adult mean, or high bone turnover marker. Health-related QOL was assessed using the Japanese Osteoporosis Quality of Life Questionnaire (JOQOL). When patients were classified into quartiles by total QOL score). Serum 25-hydroxyvitamin D (25[OH]D) level was measured by immunoassay. Results: A total of 1585 osteoporotic women were included in the study (age range, 70-95 years). Age, body mass index, serum 25(OH)D status (low, normal, or high), bone mineral density, number of prevalent vertebral fractures, presence of hypertension, presence of osteoarthritis, and history of falls were significantly correlated with QOL quartile. Multivariate liner regression analysis indicated that low serum 25(OH)D level (<20 ng/mL) was an independent determinant of total QOL score quartile (P = 0.0055). The conventional determinants of QOL age (P < 0.0001), body mass index (P = 0.0060), number of prevalent vertebral fractures (P < 0.0001), presence of osteoarthritis (P = 0.0074), and history of fall (P = 0.0098) were also independent determinants of total QOL score. Conclusions: These results strongly suggest that low serum 25(OH)D level was a significant determinant of QOL in these osteoporotic women, independently of the conventional factors that reduce QOL. Maintenance of serum 25(OH)D levels >20 ng/mL may be required to maintain patients' QOL in osteoporosis. (C) 2014 The Authors. Published by Elsevier, Inc. All rights reserved.

TI Does hip osteoarthritis have a protective effect against proximal femoral fractures? A retrospective study
SO HIP INTERNATIONAL
LA English
DT Article
DE Hip; Osteoarthritis; Femoral neck fractures; Trochanteric fractures
ID bone-mineral density; cancellous bone; neck fracture; osteoporosis; femur; coxarthrosis; pattern; end
AB The inverse relationship between proximal femoral fracture incidence and hip osteoarthritis remains controversial. However, femoral neck fractures rarely occur in patients with hip osteoarthritis, suggesting a protective effect of osteoarthritis. We sought to determine if the severity of osteoarthritis influenced fracture type. We examined the radiographs of 190 consecutive patients treated at our institution after hip trauma. They were divided into three groups according to the outcome of

the trauma: femoral neck fracture; trochanteric fracture; and no fracture. We then analysed the severity of osteoarthritis within these groups. No relationship between the grade of hip osteoarthritis and the presence of a proximal femoral fracture was found. However, the grade of osteoarthritis was related both to the outcome of the trauma ($p<0.0001$) and to the location of the fracture ($p<0.0001$). Patients with osteoarthritis of the hip had a three-fold increased likelihood of trochanteric fracture compared to femoral neck fracture. Osteoarthritis does not protect against proximal femoral fractures, but strongly affects the location of the fracture in the proximal femur, increasing the possibility of a trochanteric location.

TI Spatholobus suberectus Inhibits Osteoclastogenesis and Stimulates Chondrogenesis
SO AMERICAN JOURNAL OF CHINESE MEDICINE
LA English
DT Article
DE Spatholobus suberectus; Osteoarthritis; Osteoporosis; Osteoclast; Matrix Metalloproteinases (MMPs)

ID human chondrocytes; in-vitro; osteoarthritis; cartilage; differentiation; expression; cytokine; collagen; receptor; model
AB This study was carried out to investigate the effect of Spatholobus suberectus Dunn (SS) on the protection of chondral defect and inhibition of osteoclastogenesis. To examine these effects, we measured the matrix metalloproteinase (MMP) levels in SW1353 chondrosarcoma cells and performed tartrate-resistant acid phosphatase (TRAP) staining in bone marrow macrophage (BMM)-derived osteoclasts. To investigate the anti-osteoarthritis (OA) effects, we assessed TNF-alpha-induced MMP-1, -3, -9 and tissue inhibitors of matrix metalloproteinase (TIMP) expression levels in SW1353 cells. We observed that SS extract significantly inhibited MMP and TIMP expression in SW1353 cells. Also, SS extract inhibited the receptor activator of nuclear factor-kappa B ligand (RANKL)-induced osteoclast differentiation. These results suggest that SS extract may have a potential in the treatment of bone loss and chondral defect by suppressing osteoclast differentiation and decreasing the expression of OA factors. Therefore, clarification of the mechanism of the action of SS extract and its active components is needed.

TI Postoperative Range of Motion Does Not Correlate with Patient Reported Outcome Scores in Asians after Total Knee Arthroplasty
SO JOURNAL OF ARTHROPLASTY
LA English
DT Article
DE range of motion; outcomes; PROMs; Asian
ID functional outcm; satisfaction; replacement; osteoarthritis; epidemiology; hip
AB Activities in Asian cultures require greater knee flexion. However, this study hypothesized that post-operative range of motion (ROM) does not correlate with

patient reported outcome scores at 2 years. 292 TKAs were evaluated at a public hospital in Singapore from January 2006 to May 2009. The relationship between ROM and outcome scores was examined using a multiple linear regression model with Generalized Estimating Equation (GEE) allowing adjustment for confounders and repeated TKAs within a patient. Analysis did not yield statistically significant results when patients' post-op ROM was correlated with outcome scores at 2 years. Lack of post op ROM does not translate into poorer outcome scores and dissatisfaction. Doctors can now counsel patients who are concerned about a lack of ROM after TKA. (C) 2014 Elsevier Inc. TI Chinese herbal prescriptions for osteoarthritis in Taiwan: analysis of national health insurance dataset
SO BMC COMPLEMENTARY AND ALTERNATIVE MEDICINE
LA English
DT Article
DE Association rule; Chinese herbal medicine; National health insurance; Osteoarthritis; Pharmaco-epidemiology; Traditional Chinese medicine
ID ovx-induced osteoporosis; bu drynaria-fortunei; knee osteoarthritis; radix-dipsaci; medicine; extract; bone; patterns; obesity; inflammation
AB Background: Chinese herbal medicine (CHM) has been commonly used for treating osteoarthritis in Asia for centuries. This study aimed to conduct a large-scale pharmaco-epidemiologic study and evaluate the frequency and patterns of CHM used in treating osteoarthritis in Taiwan. Methods: A complete database (total 22,520,776 beneficiaries) of traditional Chinese medicine (TCM) outpatient claims offered by the National Health Insurance program in Taiwan for the year 2002 was employed for this research. Patients with osteoarthritis were identified according to the diagnostic code of the International Classification of Disease among claimed visiting files. Corresponding prescription files were analyzed, and an association rule was applied to evaluate the co-prescription of CHM for treating osteoarthritis. Results: There were 20,059 subjects who visited TCM clinics for osteoarthritis and received a total of 32,050 CHM prescriptions. Subjects between 40 and 49 years of age comprised the largest number of those treated (19.2%), followed by 50-59 years (18.8%) and 60-69 years group (18.2%). In addition, female subjects used CHMs for osteoarthritis more frequently than male subjects (female: male = 1.89: l). There was an average of 5.2 items prescribed in the form of either an individual Chinese herb or formula in a single CHM prescription for osteoarthritis. Du-zhong (Eucommia bark) was the most commonly prescribed Chinese single herb, while Du-huo-ji-sheng-tang was the most commonly prescribed Chinese herbal formula for osteoarthritis. According to the association rule, the most commonly prescribed formula was Du-huo-ji-sheng-tang plus Shen-tong-zhu-yu-tang, and the most commonly prescribed triple-drug combination was Du-huo-ji-sheng-tang, Gu-sui-pu (Drynaria fortune (Kunze) J. Sm.), and Xu-Duan (Himalaya teasel). Nevertheless, further clinical trials are needed to evaluate the efficacy and safety of these CHMs for treating osteoarthritis. Conclusions: This study conducted a large scale pharmaco-epidemiology survey of Chinese herbal medicine use in OA patients by analyzing the NHIRD in Taiwan in year 2002.

TI Hip Arthrodesis with the Anterolateral Plate: An Innovating Technique for an Orphaned Procedure
SO PLOS ONE
LA English
DT Article
ID follow-up; fusion; tuberculosis; osteotomy; arthroplasty; replacement; joint

AB Background: In developing countries hip osteoarthritis constitutes a major public health issue as it is highly prevalent in all age ranges of population, including the young. It often remains untreated because of the low accessibility of total hip prostheses. Hip arthrodesis still represents a major treatment option, but, for several reasons which are discussed in this paper, is nowadays infrequently performed. By means of reporting the results of a new simple technique, using a self-devised plate, the relevancy of hip arthrodesis in this particular environment is emphasized. Methods and Findings: Our series included 35 patients with painful hip osteoarthritis who underwent a hip fusion with the anterolateral arthrodesis plate. Two of them had a concurrent femoral osteotomy for correction of a vicious position of the limb and another patient had a femoral diaphysis osteotomy and placement of a Wagner elongating device in order to proceed with a limb lengthening by callotasis. The follow-up period averaged 16,9 months (9 to 34). All hips, except two, achieved solid fusion between 6 and 15 months after surgery. One failure of fusion was in the oldest patient, who presented a loosening of plate and screws due to an advanced degree of osteoporosis; the other was in a young patient who admitted having walked on his leg too soon. Patient satisfaction was high. We concluded that this technique is reliable and effective. Conclusions: The results of this study should convince the hesitant surgeon and patient to consider hip arthrodesis an acceptable treatment option for disabling hip arthritis, compared to no treatment at all.

TI The National Hospital Discharge Survey and Nationwide Inpatient Sample: The Databases Used Affect Results in THA Research
SO CLINICAL ORTHOPAEDICS AND RELATED RESEARCH
LA English
DT Article
ID cardiovascular drugs; mortality; complications; arthroplasty; fracture; risk
AB The National Hospital Discharge Survey (NHDS) and the Nationwide Inpatient Sample (NIS) collect sample data and publish annual estimates of inpatient care in the United States, and both are commonly used in orthopaedic research. However, there are important differences between the databases, and because of these differences, asking these two databases the same question may result in different answers. The degree to which this is true for arthroplasty-related research has, to our knowledge, not been characterized. We tested the following null hypotheses: (1) there are no differences between the NHDS and NIS in patient characteristics, comorbidities, and adverse events in patients with hip osteoarthritis treated with THA, and (2) there are no differences between databases in factors associated with inpatient mortality, adverse events, and length of hospital stay after THA. The NHDS and NIS databases use different methods of data collection and weighting to provide data representative of all nonfederal hospital discharges in the United States. In 2006 the NHDS database contained 203,149 patients with hip arthritis treated with hip arthroplasty, and the NIS database included 193,879 patients. Multivariable analyses for factors associated with inpatient mortality, adverse events, and days of care were constructed for each database. We found that 26 of 42 of the factors in demographics, comorbidities, and adverse events after THA in the NIS and NHDS databases differed more than 10%. Age and days of care were associated with inpatient mortality with the NHDS and the NIS although the effect rates differ more than 10%. The NIS identified seven other factors not identified by the NHDS: wound complications, congestive heart failure, new mental disorder, chronic pulmonary disease, dementia, geographic region Northeast, acute postoperative anemia, and sex, that were associated with inpatient mortality even after controlling for potentially confounding variables. For inpatient adverse events,

atrial fibrillation, osteoporosis, and female sex were associated with the NHDS and the NIS although the effect rates differ more than 10%. There were different directions for sources of payment, dementia, congestive heart failure, and geographic region. For longer length of stay, common factors differing more than 10% in effect rate included chronic pulmonary disease, atrial fibrillation, complication not elsewhere classified, congestive heart failure, transfusion, discharge nonroutine compared with routine, acute postoperative anemia, hypertension, wound adverse events, and diabetes mellitus, whereas discrepant factors included geographic region, payment method, dementia, sex, and iatrogenic hypotension. Studies that use large databases intended to be representative of the entire United States population can produce different results, likely related to differences in the databases, such as the number of comorbidities and procedures that can be entered in the database. In other words, analyses of large databases can have limited reliability and should be interpreted with caution. Level II, prognostic study. See the Instructions for Authors for a complete description of levels of evidence.

TI Severe perineal laceration during operative vaginal delivery: the impact of occiput posterior position
SO JOURNAL OF PERINATOLOGY
LA English
DT Article
ID anal-sphincter injury; fetal head position; manual rotation; transverse positions; cesarean delivery; risk-factors; forceps; vacuum
AB OBJECTIVE: To identify risk factors for severe (third/fourth degree) perineal laceration with operative vaginal delivery (OVD, forceps or vacuum). STUDY DESIGN: Case-control study comparing singleton OVDs with or without severe laceration (n=138). RESULT: In multivariable analyses, severe perineal laceration was associated with occiput posterior (OP) position at delivery, vaginal nulliparity, use of forceps, longer period pushing in the second stage and lower gestational age, but not birth weight, labor induction or episiotomy. Among 29 OP patients at full dilation, 9/13 (69%) attempted rotations to occiput anterior (OA) were successful, and 14/16 (88%) patients in whom rotation was not attempted remained OP at delivery. Successful rotation from OP to OA was associated with fewer severe lacerations than no attempt or unsuccessful rotation (22 vs 75%, P=0.01). CONCLUSION: Severe perineal laceration during OVD is associated with OP position at delivery and is reduced threefold in patients successfully rotated from OP to OA.

TI Association of dietary intake with joint space narrowing and osteophytosis at the knee in Japanese men and women: the ROAD study
SO MODERN RHEUMATOLOGY
LA English
DT Article

DE Osteoarthritis; Knee; Diet; Cohort studies; Epidemiology
ID growth-arrest; vitamin-d; osteoarthritis; calcification; progression; hip; determinants; expression; arthritis; cartilage
AB Objective. The objective of the present study is to identify dietary nutrients associated with joint space narrowing (JSN) and osteophytosis at the knee in a population-based cohort of the Research on Osteoarthritis/osteoporosis Against Disability (ROAD) study. Methods. From the baseline survey of the ROAD study, 827 participants (305 men and 522 women) in a rural cohort were analyzed. Dietary nutrient intakes for the last month were assessed by a self-administered brief diet history questionnaire. Minimum joint space width (mJSW) and osteophyte area (OPA) in the medial compartment of the knee were measured using a knee osteoarthritis (OA) computer-aided diagnostic system. Results. In men, there were no associations of dietary nutrient intakes with mJSW or OPA. In women, vitamins K, B1, B2, B6, and C were associated with mJSW after adjustment for age, body mass index, and total energy ($p < 0.05$). Vitamins E, K, B1, B2, niacin, and B6 were significantly associated with OPA ($p < 0.05$) in women. Vitamins K, B and C may have a protective role against knee OA in women and might lead to disease-modifying treatments. Conclusions. The present study revealed that low dietary intake of vitamins K, B, and C are associated with JSN and osteophytosis in women.

TI Effects of High-Impact Training on Bone and Articular Cartilage: 12-Month Randomized Controlled Quantitative MRI Study
SO JOURNAL OF BONE AND MINERAL RESEARCH
LA English
DT Article
DE EXERCISE; OSTEOARTHRITIS; OSTEOPOROSIS; MENOPAUSE; RADIOLOGY
ID gadolinium-enhanced mri; knee osteoarthritis; postmenopausal women; controlled-trial; mineral density; risk-factors; exercise; hip; recommendations; adaptation
AB Osteoarthritis and osteoporosis often coexist in postmenopausal women. The simultaneous effect of bone-favorable high-impact training on these diseases is not well understood and is a topic of controversy. We evaluated the effects of high-impact exercise on bone mineral content (BMC) and the estimated biochemical composition of knee cartilage in postmenopausal women with mild

knee osteoarthritis. Eighty women aged 50 to 66 years with mild knee osteoarthritis were randomly assigned to undergo supervised progressive exercise three times a week for 12 months (n=40) or to a nonintervention control group (n=40). BMC of the femoral neck, trochanter, and lumbar spine was measured by dual-energy X-ray absorptiometry (DXA). The biochemical composition of cartilage was estimated using delayed gadolinium-enhanced magnetic resonance imaging (MRI) cartilage (dGEMRIC), sensitive to cartilage glycosaminoglycan content, and transverse relaxation time (T2) mapping that is sensitive to the properties of the collagen network. In addition, we evaluated clinically important symptoms and physical performance-related risk factors of falling: cardiorespiratory fitness, dynamic balance, maximal isometric knee extension and flexion forces, and leg power. Thirty-six trainees and 40 controls completed the study. The mean gain in femoral neck BMC in the exercise group was 0.6% (95% CI, -0.2% to 1.4%) and the mean loss in the control group was -1.2% (95% CI, -2.1% to -0.4%). The change in baseline, body mass, and adjusted body mass change in BMC between the groups was significant (p=0.005), whereas no changes occurred in the biochemical composition of the cartilage, as investigated by MRI. Balance, muscle force, and cardiorespiratory fitness improved significantly more (3% to 11%) in the exercise group than in the control group. Progressively implemented high-impact training, which increased bone mass, did not affect the biochemical composition of cartilage and may be feasible in the prevention of osteoporosis and physical performance-related risk factors of falling in postmenopausal women. (c) 2014 American Society for Bone and Mineral Research.

TI The independent and combined effects of intensive weight loss and exercise training on bone mineral density in overweight and obese older adults with osteoarthritis
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE Bone density; Obesity; Weight loss; Exercise; Osteoarthritis
ID hip fracture risk; knee osteoarthritis; postmenopausal women; body-weight; mass; men; diet; fat; metabolism; sarcopenia
AB Objective: To determine the effects of dietary-induced weight loss (D) and weight loss plus exercise (D + E) compared to exercise alone (E) on bone mineral density (BMD) in older adults with knee osteoarthritis (OA). Design: Data come from 284 older (66.0 +/- 6.2 years), overweight/obese (body mass index (BMI) 33.4 +/- 3.7 kg/m(2)), adults with knee OA enrolled in the Intensive Diet and Exercise for

Arthritis (IDEA) study. Participants were randomized to 18 months of walking and strength training (E; n = 95), dietary-induced weight loss targeting 10% of baseline weight (D; n = 88) or a combination of the two (D + E; n = 101). Body weight and composition (DXA), regional BMD, were obtained at baseline and 18 months. Results: E, D, and D + E groups lost 1.3 +/- 4.5 kg, 9.1 +/- 8.6 kg and 10.4 +/- 8.0 kg, respectively (P < 0.01). Significant treatment effects were observed for BMD in both hip and femoral neck regions, with the D and D + E groups showing similar relative losses compared to E (both P < 0.01). Despite reduced BMD, fewer overall participants had T-scores indicative of osteoporosis after intervention (9 at 18 months vs 10 at baseline). Within the D and D + E groups, changes in hip and femoral neck, but not spine, BMD correlated positively with changes in body weight (r = 0.21 and 0.54 respectively, both P < 0.01). Conclusions: Weight loss via an intensive dietary intervention, with or without exercise, results in bone loss at the hip and femoral neck in overweight and obese, older adults with OA. Although the exercise intervention did not attenuate weight loss-associated reductions in BMD, classification of osteoporosis and osteopenia remained unchanged. Clinical trial registration number: NCT00381290. (C) 2014 Osteoarthritis Research Society International. Published by Elsevier Ltd. All rights reserved.

TI Association of interleukin-6 gene polymorphisms with hand osteoarthritis and hand osteoporosis
SO CYTOKINE
LA English
DT Article
DE Kellgren/Lawrence; Osteophytes; Joint space narrowing; BMD; SNP
ID bone-mineral density; il-6; predictor; variants; women
AB Objective: Several genes, including IL-6 encoding pro-inflammatory cytokines, are involved in development of osteoarthritis and osteoporosis. The association of radiographic hand osteoarthritis (RHOA) and osteoporosis related phenotypes (RHOP) with polymorphisms in IL-6 has been reported inconsistently. The aim of this study was to examine the association, between RHOA and RHOP and IL-6 polymorphisms in two independent samples. Methods: Two samples: UK females, including 1440 individuals assessed for RHOA and 3470 assessed for RHOP; Chuvash pedigree including 1499 females and males were assessed for RHOP and RHOA. SNPs were genotyped in the IL-6 genomic region, and used in association analysis with RHOA and RHOP phenotypes. Results: RHOP phenotypes showed similar heritability estimates in both samples, ranging from 34.5 +/- 5.5% to 61.0 +/- 2.4%. RHOA in Chuvash had substantially lower heritability estimates compared to twins (e.g. OSP scores: 11.8 +/- 2.3% vs. 39.2 +/- 4.1%) with much higher prevalence and considerably stronger correlation with age (r = 0.811 vs. r = 0.505). RHOA in Chuvash sample may be traumatic in nature, caused by heavy and prolonged manual work related to their private farming. There were a number of statistically significant association results with both types of phenotypes. The most consistent result was obtained for JSN in both samples with SNP from the same haploblock. Their combined probability of no association was only p = 0.000003.

Additionally, there were SNPs common for both RHOA and RHOP. Conclusions: We have shown polymorphisms in IL_6 are significantly associated with RHOA and hand RHOP in two samples having different ethnicity and lifestyle. Age x environment x genes interaction appears as an important factor of RHOA manifestation and progression. (C) 2014 Elsevier Ltd. All rights reserved.

TI Unilateral vs Bilateral Hip Bone Mineral Density Measurement for the Diagnosis of Osteoporosis
SO JOURNAL OF CLINICAL DENSITOMETRY
LA English
DT Article
DE Bone mineral density; dual-energy X-ray absorptiometry; femur neck; osteoporosis; sensitivity and specificity
ID for-clinical-densitometry; acetabular dysplasia; official positions; fracture risk; osteoarthritis; prevalence; prediction; guidelines; rotation; japan
AB It has not been established whether unilateral or bilateral hip dual-energy X-ray absorptiometry (DXA) is preferable for the diagnosis of osteoporosis. We investigated the discordance in DXA measurements in bilateral hips to determine whether unilateral DXA is valid for osteoporosis diagnosis. The subjects were 2964 Japanese patients without a previous diagnosis of primary osteoporosis. We measured bilateral femoral bone mineral density (BMD) and calculated indices, related to the unilateral results, for predicting contralateral hip osteoporosis. A likelihood ratio (LR) of a negative test (LR [-]) of less than 0 2 was considered to exclude the diagnosis. In the normal spinal BMD group, the sensitivity of unilateral DXA for women was 27-73% and LR (-) was 0.28-0.73; the sensitivity for men was 0-50% and LR (-) was 0.51-1.00; the diagnosis of contralateral osteoporosis was not excluded. Sensitivity increased and LR (-) increased with worsening spinal BMD

status; however, LR (-) did not meet the cutoff for exclusion. We could exclude unilateral hip osteoporosis, in women only, by performing contralateral femoral DXA; this necessitated lowering the T-score cutoff from -2.5 to -2.0. Unilateral femoral DXA is not useful for excluding the diagnosis of contralateral hip osteoporosis.

TI Bone mineral density changes in the knee following anterior cruciate ligament rupture
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE Anterior cruciate ligament; Bone mineral density; Knee trauma; Osteoarthritis
ID subchondral bone; articular-cartilage; marrow lesions; canine models; osteoarthritis; injury; mri; reconstruction; osteoporosis; progression
AB Objective: The pathophysiology of anterior cruciate ligament (ACL) rupture leading to knee osteoarthritis (OA) remains largely unknown. It seems that bone loss occurs after ACL rupture. The purpose of our study was to determine bone mineral density (BMD) changes in the knee after ACL rupture during 2-year follow-up period and to compare BMD changes between the injured and healthy contralateral knee. Design: Patients were included in an observational prospective follow-up study within 6 months after ACL trauma and evaluated for 2 years. Patients were treated operatively or non-operatively. At baseline and at the one- and 2-year follow-ups, BMD was measured in six regions of the tibia and femur for both knees (medial, central, lateral) using a Dual-energy X-ray Absorptiometry (DXA) scanner. Results: One hundred forty-one patients were included, with the following characteristics: 66% were male, median age at baseline was 25.3 (inter-quartile range 11.3) years, and 63% were treated operatively. After 1 year, BMD was significantly lower in all regions of the injured knee of the operatively treated patients compared to baseline. After 2 years, BMD was significantly increased, but remained lower than the baseline levels. In all regions for all measurements, the mean BMD was significantly lower in the injured knee than in the healthy contralateral knee. Conclusions: During a 2-year follow-up period after ACL rupture, the BMD level in the injured knee was found to be lower than in the healthy contralateral knee. In operatively treated patients, the BMD decreased in the first year and increased in the second follow-up year. (C) 2013 Osteoarthritis Research Society International. Published by Elsevier Ltd. TI Three-dimensional analysis of gait in postmenopausal women with low bone mineral density
SO JOURNAL OF NEUROENGINEERING AND REHABILITATION
LA English
DT Article

DE Gait; Moment; Power; Bone mineral density; Menopause
ID quality-of-life; physical performance; muscle strength; osteoporosis; fracture; walking; mass; osteoarthritis; association; impairment
AB Background: There's lack in the literature respecting changes in the trunk and hip angles, and power profile of the lower extremities in postmenopausal women with low bone mineral density (BMD). Therefore, this study aimed to examine gait characteristics of that population, and find out which characteristics may be predictors to BMD. This may provide suitable interventions for subjects with osteoporosis. Methods: Seventeen healthy postmenopausal women and seventeen with low BMD engaged in this study. Dual X-ray Absorbiometry measured BMD at lumber (L2-4) and femoral neck. Qualysis gait analysis system assessed the gait pattern of each subject. Results: Compared to healthy peers, women with low BMD showed less trunk rotation ($p = 0.02$), hip adduction ($p = 0.005$) and extension moments ($p = 0.008$). They showed less hip power generation during early stance (H1S) ($p = 0.000$), and swing phase (H3S) ($p = 0.005$), and less hip power absorption (H2S) ($p = 0.005$). They also, showed less knee power absorption during terminal swing (K4S) ($p = 0.002$), and ankle power generation at push off (A2S) ($p = 0.000$). The ability of the gait variables to discriminate between subjects with or without osteopenia was (0.72%, $p = 0.016$) for trunk rotation, (78%, $p = 0.0004$) for hip adductor moment, (76%, $p = 0.0013$) for hip extensor moment, (87%, $p < 0.0001$) for H1S, (79%, $p = 0.0001$) for H2S, (77%, $p = 0.0008$) H3S, (81%, $p = 0.0001$) for K4S, and (93%, $p < 0.0001$) for A2S. Conclusion: Less power generation at the hip and ankle as well as, less power absorption at the hip and knee, may suggest that postmenopausal women with low BMD showed less propulsion, and stability during walking. Trunk rotation, hip adduction and extension moments, H1S, H2S, H3S, K4S, and A2S are significant predictors for low bone mass in the postmenopausal women.

TI Hip Osteoarthritis and Osteoporosis: Clinical and Histomorphometric Considerations
SO INTERNATIONAL JOURNAL OF ENDOCRINOLOGY
LA English
DT Article
ID bone-mineral density; postmenopausal women; femoral-neck; stem-cells; fracture; differentiation; angiogenesis; prevalence; expression; knee
AB Although an inverse relationship between osteoarthritis (OA) and osteoporosis (OP) has been shown by some studies, other reports supported their coexistence. To clarify this relationship, we analyzed the interplay between clinical and histomorphometric features. Bone mineral density (BMD) and histomorphometric

structure were assessed in 80 patients of four different age-matched groups undergoing hip arthroplasty for severe OA or OP-related femoral fracture. Harris Hip Score was also performed. Surgical double osteotomy of the femoral head was performed and microscopic bone slice samples analysis was performed by using a BioQuant Osteo software. Bone volume fraction (BV/TV) was lower (P < 0.01) in subjects with femoral neck fracture (20.77 +/- 4.34%) than in subjects with nonosteopenic OA (36.49 +/- 7.73%) or nonosteopenic OA (32.93 +/- 6.83%), whereas no difference was detected between subjects with femoral neck fractures and those with combined OA and OP (20.71 +/- 5.23%). Worse Harris Hip Score was found in those patients with the lowest BMD and BV/TV values. Our data support recent evidences indicating the possibility of impaired bone volume fraction in OA patients, with a high risk of developing OP, likely for their decreased mobility. Further studies are needed in order to investigate biomolecular pathway and/or growth factors involved in bone volume impairment in OA patients.

TI TBS result is not affected by lumbar spine osteoarthritis
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE Bone mineral density; BMD; DXA; TBS; Trabecular bone score; Osteoarthritis; Osteoporosis
ID trabecular bone score; x-ray absorptiometry; mineral density; osteoporotic fractures; vertebral fractures; caucasian women; microarchitecture; population; association; projection
AB The effect of lumbar osteoarthritis on bone density and trabecular bone score (TBS) was evaluated cross-sectionally and prospectively in postmenopausal women. Lumbar spine osteoarthritis was graded according to Kellgren and Lawrence grades. Lumbar osteoarthritis was found to increase lumbar spine bone density, but not TBS. Lumbar osteoarthritis overestimates lumbar bone density (areal bone mineral density (aBMD)). A new texture parameter, the TBS, has been proposed. Calculation of aBMD uses grey level value, while TBS uses grey level variation. Therefore, our hypothesis was that TBS is not influenced by lumbar spine osteoarthritis. Menopausal women participating in osteoporosis and ultrasound

(OPUS) study were included. They had an aBMD measurement of the spine and hip at baseline and 6-year visit. TBS was calculated on lumbar spine dual-energy X-ray absorptiometry (DXA) scans in an automated manner. The presence of lumbar osteoarthritis was evaluated on baseline radiographs using Kellgren and Lawrence (K&L) classification. Grades range from 0 to 4. In our study, osteoarthritis was defined by at least K&L grade 2. This study included 1,254 menopausal women (66.7 +/- 7.1 years). Among them, 727 attended the 6-year follow-up visit. Patients with lumbar osteoarthritis had an aBMD higher than those without lumbar osteoarthritis at the lumbar spine, but not at the hip. However, the aBMD significantly increased in all sites with the grade of K&L. In contrast, spine TBS was not different between patients with and without lumbar osteoarthritis ($p = 0.70$), and it was not correlated with K&L grade. Spine TBS and aBMD at all sites were negatively correlated with age ($p < 0.0001$). Body mass index was correlated positively with aBMD and negatively with spine TBS ($p < 0.0001$). The 6-year change of aBMD was significant in the hip and nonsignificant in the lumbar spine. That of TBS was significant, with a 3.3 % decrease ($p < 0.0001$), independent of K&L grade ($p = 0.28$). In postmenopausal women, lumbar osteoarthritis leads to an increase in lumbar spine aBMD. In contrast, spine TBS is not affected by lumbar osteoarthritis.

TI Association between Polymorphisms in Sclerostin, Dickkopfs and Secreted Frizzled-Related Protein Genes and Bone Mineral Density in Postmenopausal Korean Women
SO GYNECOLOGIC AND OBSTETRIC INVESTIGATION
LA English
DT Article
DE Bone density; Bone markers; Polymorphism; Wnt antagonists
ID genome-wide association; wnt signaling pathway; vitamin-d-receptor; quantitative traits; hip osteoarthritis; negative regulator; chinese women; osteoporosis; mass; osteoblasts
AB Background/Aims:The purpose of this study was to investigate the association between single nucleotide polymorphisms (SNPs) in sclerostin (SOST), dickkopf (DKK), secreted frizzled-related protein (sFRP) genes and bone mineral density (BMD) in postmenopausal Korean women. Methods:The SOST, Wnt inhibitory factor 1 (WIF1), sFRP1, sFRP2, sFRP3, sFRP4, sFRP5, DKK1, DKK2 and DKK3 polymorphisms were analyzed in 399 postmenopausal Korean women. Serum levels of bone turnover markers were measured, and BMDs at the lumbar spine and

femoral neck were also examined. Results: No significant differences in adjusted BMD at the lumbar spine and femoral neck were noted according to any single and combined polymorphisms measured in SOST, DKKs and sFRPs. However, osteoporosis at the femoral neck was 2.35 times more frequently observed in the AA genotype of the sFRP4 c.958C>A polymorphism compared to the non-AA genotype (95% CI 1.09-5.08, p = 0.03). Also, the CC genotype of the sFRP3 c.970C>G polymorphism had a higher rate of osteoporosis at the femoral neck compared to the GC geno-type (OR 8.47, 95% Cl 1.37-52.63, p = 0.049). Conclusions: Our results suggest that the sFRP3 c.970C>G and sFRP4 c.958C>A polymorphisms may be genetic factors associated with the prevalence of osteoporosis at the femoral neck in postmenopausal Korean women. TI Bone defects: Molecular and cellular therapeutic targets
SO INTERNATIONAL JOURNAL OF BIOCHEMISTRY & CELL BIOLOGY
LA English
DT Article
DE Bone disease; Mesenchymal stem cells; Histone deacetylases; Wnt pathway
ID mesenchymal stem-cells; dental-pulp; osteoblast differentiation; skeletogenesis; progenitors; disease; roles; runx2; lrp5; mass
AB Bone defects are one of the most serious pathologies that need tissue regeneration therapies. Studies on mesenchymal stem cells are changing the way we treat bone diseases. MSCs have been used for the treatment of osteogenesis imperfecta, hypophosphatasia, osteonecrosis of the femoral head, osteoporosis, rheumatoid arthritis and osteoarthritis. In this context, it is becoming ever more clear that the future of therapies will be based on the use of stem cells. In this concise review, we highlight the importance of the use of MSCs in bone diseases, focusing on the role of histone deacetylases and Wnt pathways involved in osteogenesis. A better understanding of MSC biology and osteogenesis is needed in order to develop new and targeted therapeutic strategies for the treatment of bone diseases/disorders. (C) 2014 Elsevier Ltd. DT Article
DE OA-4; osteoclast formation; osteoclastic bone resorption; osteoporosis; P38 signaling pathway
ID activated protein-kinase; nf-kappa-b; selective inhibitor; receptor activator; atpase inhibitor; gene-expression; differentiation; induction; cells
AB Osteoclasts are one of the key therapeutic targets for a variety of orthopedic diseases such as osteoporosis and osteoarthritis. In this study, we synthesized a novel compound N-(3-(cyclohexylcarbamoyl) phenyl)-1H-indole-2-carboxamide (termed as OA-4) and investigated the effects of OA-4 on the differentiation and function of osteoclasts. OA-4 markedly diminished osteoclast differentiation and osteoclast specific gene expression in a dose-dependent manner. In addition, OA-4 dose-dependently suppressed osteoclastic bone resorption. Furthermore, we found OA-4 attenuated RANKL-induced p38 phosphorylation without affecting JNK or NF-kappa B signaling pathways. Collectively, we synthesized a novel compound OA-4 which can inhibit osteoclast formation and functions via the suppression of p38 signaling pathway.

TI Further evidence of the developmental origins of osteoarthritis: results from the Hertfordshire Cohort Study
SO JOURNAL OF DEVELOPMENTAL ORIGINS OF HEALTH AND DISEASE
LA English
DT Article
DE birth weight; bone; osteoarthritis; programming
ID bone-mineral density; vitamin-d-receptor; radiographic osteoarthritis; birth-weight; knee osteoarthritis; growth; women; mass; classification; osteoporosis
AB Investigators have suggested a link between birth weight and both hand and lumbar spine osteoarthritis (OA). In this study, we sought to extend these observations by investigating relationships between growth in early life, and clinical and radiological diagnoses of OA at the hand, knee and hip, among participants from the Hertfordshire Cohort Study. Data were available for 222 men and 222 women. Clinical OA was defined based on American College of Rheumatology criteria. Radiographs were taken of the knees and hips, and graded for the presence of osteophytes and overall Kellgren and Lawrence (KL) score. Lower weight at year one was associated with higher rates of clinical hand OA (OR 1.396, 95% CI 1.05, 1.85, P = 0.021). Individuals with lower birth weights were more likely to have hip osteophytes (OR 1.512, 95% CI 1.14, 2.00, P = 0.004) and this remained robust after adjustment for confounders. Furthermore, a low weight at one year was also associated with a higher osteophyte number in the lateral compartment of the knee, after adjustment for confounders (OR 1.388, 95% CI 1.01, 1.91, P = 0.043). We have found further evidence of a relationship between early life factors and adult OA. These findings accord with previous studies.

DT Review
DE Erosive osteoarthritis; Handosteoarthritis; MRI; Osteoarthritis; Osteoporosis
ID c-reactive protein; erosive osteo-arthritis; individual radiographic features; x-ray radiogrammetry; postmenopausal women; rheumatoid-arthritis; mineral density; interphalangeal osteoarthritis; inflammatory osteoarthritis; generalized osteoarthritis

AB Hand osteoarthritis (OA) is a common disease frequently affecting middle-aged women. Prevalence estimates for OA vary widely depending on the age and sex of the population studied, the assessment tools used, and the specific joint sites analyzed OA is characterized by the degradation of articular cartilage, subchondral bone changes and osteophyte formation at the joint margins leading to joint failure. The pathogenesis of the disease and its evolution are multifactorial involving biomechanical, metabolic, hormonal, and genetic factors. Moreover, the role of inflammation has recently been advanced as pivotal in OA onset and progression. In particular, an uncommon variant of hand OA, erosive hand OA, is characterized by inflammatory and degenerative interphalangeal proximal and distal joints. The diagnosis of different types of hand OA is centered on clinical and laboratory investigations which can distinguish the peculiar aspects of these forms. Joint and bone assessments in hand OA are widely studied but there is no agreement with regard to established parameters to make a definitive diagnosis. This report focuses on the laboratory and clinimetric assessments that can be used to distinguish hand OA subtypes and addresses the debatable association with low bone mineral density in osteoporosis.

TI An algorithm recommendation for the management of knee osteoarthritis in Europe and internationally: A report from a task force of the European Society for Clinical and Economic Aspects of Osteoporosis and Osteoarthritis (ESCEO)
SO SEMINARS IN ARTHRITIS AND RHEUMATISM
LA English
DT Review
DE Algorithm; Knee osteoarthritis
ID nonsteroidal antiinflammatory drugs; placebo-controlled trials; proton-pump inhibitor; double-blind; long-term; glucosamine sulfate; oarsi recommendations; chondroitin sulfate; cardiovascular risk; hyaluronic-acid
AB Objectives: Existing practice guidelines for osteoarthritis (OA) analyze the evidence behind each proposed treatment but do not prioritize the interventions in a given sequence. The objective was to develop a treatment algorithm recommendation that is easier to interpret for the prescribing physician based on the available evidence and that is applicable in Europe and internationally. The knee was used as the model OA joint. Methods: ESCEO assembled a task force of 13 international experts (rheumatologists, clinical epidemiologists, and clinical scientists). Existing guidelines were reviewed: all interventions listed and recent evidence were retrieved using established databases. A first schematic flow chart with treatment prioritization was discussed in a 1-day meeting and shaped to the treatment algorithm. Fine-tuning occurred by electronic communication and three

consultation rounds until consensus. Results: Basic principles consist of the need for a combined pharmacological and non-pharmacological treatment with a core set of initial measures, including information access/education, weight loss if overweight, and an appropriate exercise program. Four multimodal steps are then established. Step 1 consists of background therapy, either non-pharmacological (referral to a physical therapist for realignment treatment if needed and sequential introduction of further physical interventions initially and at any time thereafter) or pharmacological. The latter consists of chronic Symptomatic Slow-Acting Drugs for OA (e.g., prescription glucosamine sulfate and/or chondroitin sulfate) with paracetamol at-need; topical NSAIDs are added in the still symptomatic patient. Step 2 consists of the advanced pharmacological management in the persistent symptomatic patient and is centered on the use of oral COX-2 selective or non-selective NSAIDs, chosen based on concomitant risk factors, with intra-articular corticosteroids or hyaluronate for further symptom relief if insufficient. In Step 3, the last pharmacological attempts before surgery are represented by weak opioids and other central analgesics. Finally, Step 4 consists of end-stage disease management and surgery, with classical opioids as a difficult-to-manage alternative when surgery is contraindicated. Conclusions: The proposed treatment algorithm may represent a new framework for the development of future guidelines for the management of OA, more easily accessible to physicians. TI Baseline bone mineral density and bone turnover in pre-operative hip and knee arthroplasty patients
SO BONE & JOINT RESEARCH
LA English
DT Article
DE Arthroplasty; Hip; Knee; Bone mineral density; BMD
ID follow-up; osteoarthritis; fracture; revision; risk
AB Aims Osteoporosis and abnormal bone metabolism may prove to be significant factors influencing the outcome of arthroplasty surgery, predisposing to complications of aseptic loosening and peri-prosthetic fracture. We aimed to investigate baseline bone mineral density (BMD) and bone turnover in patients

about to undergo arthroplasty of the hip and knee. Methods We prospectively measured bone mineral density of the hip and lumbar spine using dual-energy X-ray absorptiometry (DEXA) scans in a cohort of 194 patients awaiting hip or knee arthroplasty. We also assessed bone turnover using urinary deoxypyridinoline (DPD), a type I collagen crosslink, normalised to creatinine. Results The prevalence of DEXA proven hip osteoporosis (T-score <= -2.5) among hip and knee arthroplasty patients was found to be low at 2.8% (4 of 143). Spinal osteoporosis prevalence was higher at 6.9% (12 of 175). Sixty patients (42% (60 of 143)) had osteopenia or osteoporosis of either the hip or spine. The mean T-score for the hip was -0.34 (SD 1.23), which is within normal limits, and the mean hip Z-score was positive at 0.87 (SD 1.17), signifying higher-than-average BMD for age. The median urinary DPD/creatinine was raised in both female patients at 8.1 (interquartile range (IQR) 6.6 to 9.9) and male patients at 6.2 (IQR 4.8 to 7.5). Conclusions Our results indicate hip and knee arthroplasty patients have higher BMD of the hip and spine compared with an age-matched general population, and a lower prevalence of osteoporosis. However, untreated osteoporotic patients are undergoing arthroplasty, which may negatively impact their outcome. Raised DPD levels suggest abnormal bone turnover, requiring further investigation.

TI Adopted orphans as regulators of inflammation, immunity and skeletal homeostasis
SO SWISS MEDICAL WEEKLY
LA English
DT Review
DE inflammation; nuclear receptors; bone; macrophages; osteoblasts; osteoclasts; arthritis
ID proliferator-activated-receptor; nf-kappa-b; liver-x-receptors; collagen-induced arthritis; allergic contact-dermatitis; ppar-gamma agonists; dendritic cell-function; nuclear receptors; gene-expression; bone-marrow
AB Adopted orphan nuclear receptors, such as peroxisome proliferator-activated receptors (PPARs) and liver X receptors (LXRs), have emerged as key regulators of inflammation and immunity and likewise control skeletal homeostasis. These properties render them attractive targets for the therapy of various inflammatory and autoimmune diseases affecting the musculoskeletal system. This review summarises the current knowledge on the role of these families of receptors during innate and adaptive immunity as well as during the control of bone turnover and discuss the potential use of targeting these molecules during the treatment of chronic diseases such as osteoarthritis, rheumatoid arthritis and osteoporosis.

TI Analysis of predisposing factors in elderly people with Type II odontoid fracture
SO SPINE JOURNAL
LA English
DT Article
DE Upper cervical spine injury; Elderly; Osteoarthritis; Degenerative change; Type II odontoid fracture
ID cervical-spine injury; older; osteoarthritis; prevalence; age
AB BACKGROUND CONTEXT: Type II odontoid fracture is the most frequent individual fracture in elderly people. An older person usually sustains a Type II odontoid fracture in a fall from standing or a seated height. A relationship between osteoarthritis in the upper cervical spine and Type II odontoid fracture has been reported. However, to our knowledge, few reports have investigated statistically whether disproportionate degeneration between joints influences the susceptibility to fracture. PURPOSE: The purpose of this study was to assess predisposition to Type II odontoid fracture in the elderly. STUDY DESIGN: Retrospective review of elderly patients sustained Type II odontoid fracture and other axis fractures. PATIENT SAMPLE: Thirty-eight patients aged 65 years and older with axis fractures. OUTCOME MEASURES: Evaluation of computed tomography findings by focusing on osteoporosis and the disproportion in degeneration between each of the upper cervical joints (atlantooccipital, atlantoodontoid, and lateral atlantoaxial joints). METHODS: Seventeen patients had a Type II odontoid fracture, and 21 patients had other axis fractures. Using the computed tomography findings, we classified osteoporosis at the dens-body junction and the severity of degenerative changes in the atlantoodontoid, atlantooccipital, and lateral atlantoaxial joints as none, mild, moderate, or severe. The proportion of patients with moderate or severe osteoporosis and degenerative changes in each joint and that of patients with disproportionate degenerative changes between joints (difference in grade of >= 2 levels between joints) were compared statistically. The authors report no conflict of interest concerning the materials or methods used in this study or the findings specified in this article. RESULTS: Patients with osteoporosis and with disproportionate degenerative changes between the atlantoodontoid and lateral atlantoaxial joints were significantly more likely to have a Type II odontoid fracture than other axis fractures. These two factors were also assessed in multivariate logistic analysis. The disproportionate degenerative change between the atlantoodontoid and lateral atlantoaxial joint remained significant, even after adjusting for osteoporosis. CONCLUSIONS: Older patients with the dens fixed to the atlas because of degeneration of the atlantoodontoid joint and a smooth lateral atlantoaxial joint seem to sustain Type II odontoid fractures because, during a simple fall, the rotation of the head produces torque force on the osteoporotic dens-body junction, which acts as the rotatory center. The presence of the disproportionate osteoarthritic degeneration between the atlantoodontoid and lateral atlantoaxial joints predisposes older people to a Type II odontoid fracture.

TI Understanding risks and complications in the management of ankle fractures
SO INDIAN JOURNAL OF ORTHOPAEDICS
LA English
DT Review
DE Key words: Ankle fractures; complications; diabetes; elderly; posttraumatic ankle osteoarthirits MeSH terms: Ankle injuries; osteoarthritis; elderly; fractures; diabetes
ID posterior malleolar fractures; deep-vein thrombosis; surgical-treatment; internal-fixation; foot; thromboprophylaxis; immobilization; dislocations; reduction; diabetics
AB Ankle fracture (AF) is a common injury with potentially significant morbidity associated with it. The most common age groups affected are young active patients, sustaining high energy trauma and elderly patients with comorbidities. Both these groups pose unique challenges for appropriate management of these injuries. Young patients are at risk of developing posttraumatic osteoarthritis, with a significant impact on quality of life due to pain and impaired function. Elderly patients, especially with poorly controlled diabetes and osteoporosis are at increased risk of wound complications, infection and failure of fixation. In the most severe cases, this can lead to amputation and mortality. Therefore, individualized approach to the management of AF is vital. This article highlights commonly encountered complications and discusses the measures needed to minimize them

when dealing with these injuries.

TI The relationship between osteoarthritis and osteoporosis
SO JOURNAL OF BONE AND MINERAL METABOLISM
LA English
DT Review
DE Osteoarthritis; Osteoporosis; Relationship; Incidence; Progression
ID bone-mineral density; radiographic knee osteoarthritis; growth-factor-i; postmenopausal women; subchondral bone; hip osteoarthritis; cancellous bone; hand osteoarthritis; general-population; femoral-head
AB The relationship between osteoarthritis (OA) and osteoporosis (OP), the two most common skeletal disorders related to aging, is controversial. Previous studies suggest that OA is inversely related to OP when studied cross-sectionally and systematically. However, there are differences in the results depending on the parameter used to define OA. The purpose of this review is to analyze and summarize the literature, and derive possible answers to three key questions along with a brief introduction on underlying mechanisms: (1) Is OA correlated to a high bone mineral density (BMD)? (2) Does OA influence the progression of OP or osteoporotic fractures? (3) Does high BMD affect the incidence and progression of OA? A review of the literature suggests that OA is inversely related to OP in general when studied cross-sectionally and systematically. However, when analyzed in

individual bones, the BMD of the appendicular skeleton in OA-affected joints may decrease, particularly in the upper extremities. On whether OA influences bone loss or osteoporotic fractures, differences are observed according to the affected joints. The risk for osteoporotic fracture does not seem to decrease despite a high BMD in patients with OA, probably due to postural instability and muscle strength. Low BMD at the lumbar spine is associated with a lower incidence of knee OA although it does not arrest the progression of knee OA.

AB Introduction: Calcitonin (CT) has recently been shown to display chondroprotective effects. Here, we investigate the putative mechanisms by which CT delivers these actions. Methods: Immortalized C-28/I2 cells or primary adult human articular chondrocytes (AHAC) were cultured in high-density micromasses to investigate: (i) CT anabolic effects using qPCR and immuhistochemistry analysis; (ii) CT anti-apoptotic effects using quantitation of Bax/Bcl gene products ratio, TUNEL assay and caspase-3 expression; (iii) CT effects on CREB, COL2A1 and NFAT transcription factors. Results: CT (10(-10)-10(-8) nM) induced significant up-regulation of cartilage phenotypic markers (SOX9, COL2A1 and ACAN), with down-regulation of catabolic (MMP1 and MMP13 and ADAMTS5) gene products both in resting and inflammatory conditions. This was mirrored by an augmented production of type II collagen and accumulation of glycosaminoglycan- and proteoglycan-rich extracellular matrix in vitro. Mechanistic analyses revealed only partial involvement of cyclic AMP formation in these effects of CT. Congruently, using reporter assays for specific transcription factors, there was no indication for CREB activation, whereas the COL2A1 promoter was genuinely and directly activated by cell exposure to CT. Phenotypically, these mechanisms supported the ability of CT, whilst inactive on its own, to counteract the pro-apoptotic effects of IL-1 beta, demonstrated by TUNEL-positive staining of chondrocytes and ratio of BAX/BCL genes products. Conclusion: These data may provide a novel lead for the development of CT-based chondroprotective strategies that rely on the

engagement of mechanisms that lead to augmented chondrocyte anabolism and inhibited chondrocyte apoptosis. (C) 2014 Elsevier Inc. All rights reserved.

TI Models of care for musculoskeletal health in Australia: now more than ever to drive evidence into health policy and practice
SO AUSTRALIAN HEALTH REVIEW
LA English
DT Article
ID systematic analysis; global burden; pain; osteoarthritis; management; arthritis; injury; diseases
AB Musculoskeletal health conditions such as arthritis, osteoporosis and pain syndromes impart a profound socioeconomic burden worldwide, particularly in developed nations such as Australia. Despite the identified burden, substantial evidence-practice and care disparity gaps remain in service delivery and access that limit the potential for improved consumer outcomes and system efficiencies. Addressing these gaps requires a whole-of-sector response, supported by evidence-informed health policy. Models of care (MoCs) serve as a policy vehicle to embed evidence into health policy and guide practice through changes in service delivery systems and clinician behaviour. In Australia, MoCs for musculoskeletal health have been developed by networks of multidisciplinary stakeholders and are incrementally being implemented across health services, facilitated by dedicated policy units and clinical champions. A web of evidence is now emerging to support this approach to driving evidence into health policy and practice. Understanding the vernacular of MoCs and the development and implementation of MoCs is important to embracing this approach to health policy.

ID epidemiology; burden
AB Objectives: With this study we attempted to estimate the prevalence of

self-reported rheumatic diseases in a Portuguese population. It was also our objective to evaluate the influence of the variables sex and age on the prevalence of these diseases. Patients and Methods: The study population was comprised of 297 individuals from a total of 573 random telephone numbers selected from the city of Lisbon telephone book (landline/residents). Those 297 were the ones that agreed to answer the proposed questionnaire. Results: The prevalence value of self-reported rheumatic diseases was 26.3%. A prevalence value of self-declared osteoarthritis of 21.2% was found, 7.7% for osteoporosis, 1.3% for rheumatoid arthritis and 0.3% each for gout, systemic lupus erythematosus, Behcet's disease and fibromyalgia. An association with the variables sex and age was achieved for the total of rheumatic diseases. The same association was obtained for osteoarthritis and osteoporosis. Conclusions: This study emphasizes the good self-judgment that the inquired population has about their rheumatic diseases, and some of the obtained results are in agreement with the national and worldwide literature.

TI Prevalence of Osteoporosis in Female Patients with Advanced Knee Osteoarthritis Undergoing Total Knee Arthroplasty
SO JOURNAL OF KOREAN MEDICAL SCIENCE
LA English
DT Article
DE Bone Density; Osteoporosis; Female Knee Osteoarthritis Patient; Arthroplasty; Knee
ID bone-mineral density; body-mass index; total hip; joint replacement; risk-factors; health; population; fractures
AB This study sought to demonstrate bone mineral density (BMD) conditions in elderly female patients with knee osteoarthritis (OA) undergoing total knee arthroplasty (TKA). In addition, we sought to determine whether their BMD conditions differ from those of community-based females without knee OA. Finally we sought to determine whether clinical statuses are related to BMD in the knee OA patients. BMD conditions in 347 female patients undergoing TKA and 273 community-based females were evaluated. Additionally, comparative analyses of BMD between age and body mass index-matched knee OA groups (n=212) and the control groups (n=212) were performed. In the pre-matched knee OA group, regression analyses were performed to determine whether preoperative clinical statuses were related to BMD. Considerable prevalence of coexistent osteoporosis (31%) was found in the pre-matched knee OA patients undergoing TKA. We found no significant differences of the BMD T-scores and the prevalence of osteoporosis between the age and body mass index-matched knee OA and control groups. In the pre-matched knee OA patients, poorer preoperative clinical scores were related to poorer BMD T-scores in the proximal femur and/or lumbar spine. Our study suggests that more attention should be paid to identify and treat osteoporosis in elderly female patients with advanced knee OA undergoing TKA.

TI Early intra-articular injection of alendronate reduces cartilage changes and subchondral bone loss in rat temporomandibular joints after ovariectomy
SO INTERNATIONAL JOURNAL OF ORAL AND MAXILLOFACIAL SURGERY
LA English
DT Article
DE cartilage; subchondral bone; temporomandibular joint; osteoporosis; drug delivery
ID condyle following ovariectomy; drug-delivery; osteoarthritis; model; osteoporosis; degeneration; receptor; erosion; rabbits; mass
AB This study investigated the effects of intra-articular injection of alendronate on

the mandibular condyle in ovariectomized rats. Sixty rats were divided into five groups: ovariectomy with vehicle treatment alone, early alendronate treatment at ovariectomy, late alendronate treatment at 4 weeks after ovariectomy, sham-operation with vehicle treatment, and normal controls. The changes in cartilage and subchondral bone were evaluated by micro-computed tomography, histology, tartrate-resistant acid phosphatase (TRAP) staining, immunohistochemistry, and real-time quantitative polymerase chain reaction. Compared with late alendronate treatment, early alendronate treatment completely inhibited cartilage thickening (727.6 +/- 39.3 vs. 1013.3 +/- 51.6; P = 0.017) and improved microstructural properties of the subchondral bone, with a higher bone volume ratio (46.4 +/- 2.5 vs. 37.5 +/- 2.1; P = 0.038), trabecular thickness (47.3 +/- 1.7 vs. 34.6 +/- 1.4; P = 0.029), and trabecular number (8.5 +/- 0.6 vs. 6.2 +/- 0.3; P = 0.041) and lower trabecular separation (30.2 +/- 1.6 vs. 37.7 +/- 2.6; P = 0.034). Fewer TRAP-positive cells (4.2 +/- 0.2 vs. 6.8 +/- 0.4; P = 0.019) and a higher OPG/RANKL ratio (0.38 +/- 0.01 vs. 0.25 +/- 0.03; P = 0.043) in the subchondral bone were observed in the animals with early treatment compared to late treatment or ovariectomy/vehicle treatment. In addition, early alendronate treatment blocked the up-regulation of matrix metalloproteinase (MM?)-13 expression in the chondrocytes, whereas late alendronate treatment attenuated the up-regulation of MMP-13 expression. Our results suggest the therapeutic potential of intra-articular alendronate injection in the treatment of osteoporosis-associated temporomandibular disorders.

TI Increasing shape modelling accuracy by adjusting for subject positioning: An application to the analysis of radiographic proximal femur symmetry using data from the Osteoarthritis Initiative
SO BONE
LA English
DT Article
DE Statistical shape model; Hip morphology; Preoperative planning; Total hip arthroplasty; Osteoarthritis; Osteoporosis
ID total hip-replacement; bilateral asymmetry; progression; prediction; length; oa
AB In total hip arthroplasty, the shape of the contra-lateral femur frequently serves as a template for preoperative planning. Previous research on contra-lateral femoral symmetry has been based on conventional hip geometric measurements (which reduce shape to a series of linear measurements) and did not take the effect of subject positioning on radiographic femur shape into account. The aim of this study was to analyse proximal femur symmetry based on statistical shape models (SSMs) which quantify global femoral shape while also adjusting for differences in subject positioning during image acquisition. We applied our recently developed fully automatic shape model matching (FASMM) system to automatically segment the proximal femur from AP pelvic radiographs to generate SSMs of the proximal femurs of 1258 Caucasian females (mean age: 61.3 SD = 9.0). We used a combined SSM (capturing the left and right femurs) to identify and adjust for shape variation attributable to subject positioning as well as a single SSM (including all femurs as left femurs) to analyse proximal femur symmetry. We also calculated conventional

hip geometric measurements (head diameter, neck width, shaft width and neck-shaft angle) using the output of the FASMM system. The combined SSM revealed two modes that were clearly attributable to subject positioning. The average difference (mean point-to-curve distance) between left and right femur shape was 1.0 mm before and 0.8 mm after adjusting for these two modes. The automatic calculation of conventional hip geometric measurements after adjustment gave an average absolute percent asymmetry of within 3.1% and an average absolute difference of within 1.1 mm or 2.9 degrees for all measurements. We conclude that (i) for Caucasian females the global shape of the right and left proximal femurs is symmetric without isolated locations of asymmetry; (ii) a combined left-right SSM can be used to adjust for radiographic shape variation due to subject positioning; and (iii) adjusting for subject positioning increases the accuracy of predicting the shape of the contra-lateral hip. TI PTH [1-34]-induced alterations of the subchondral bone provoke early osteoarthritis
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE PTH [1-34]; Osteochondral unit; Early osteoarthritis; Articular cartilage; Subchondral bone; Femoral head
ID parathyroid-hormone 1-34; articular-cartilage defects; in-vivo; rabbit knee; progression; repair; model; histopathology; osteoporosis; chondrocytes
AB Objective: To test the hypothesis that changes in the subchondral bone induced by parathyroid hormone (PTH [1-34]) reciprocally affect the integrity of the articular cartilage within a naive osteochondral unit in vivo. Design: Daily subcutaneous injections of 10 mu g PTH [1-34]/kg were given to adult rabbits for 6 weeks, controls received saline. Blood samples were continuously collected to monitor renal function. The subchondral bone plate and subarticular spongiosa of the femoral heads were separately assessed by micro-computed tomography. Articular cartilage was evaluated by macroscopic. and histological osteoarthritis scoring, polarized light microscopy, and immunohistochemical determination of type-I, type-II, type-X collagen contents, PTH [1-34] receptor and caspase-3 expression. Absolute and relative extents of hyaline and calcified articular cartilage layers were measured histomorphometrically. The correlation between PTH-induced changes in subchondral bone and articular cartilage was determined. Results: PTH [1-34] enhanced volume, mineral density, and trabecular thickness within the subarticular spongiosa, and increased thickness of the calcified cartilage layer (all $P < 0.05$). Moreover, PTH [1-34] led to cartilage surface irregularities and reduced matrix staining (both $P < 0.03$). These early osteoarthritic changes correlated with and

were ascribed to the increased thickness of the calcified cartilage layer (P = 0.026) and enhanced mineral density of the subarticular spongiosa (P = 0.001). Conclusions: Modifications of the subarticular spongiosa by PTH [1-34] cause broadening of the calcified cartilage layer, resulting in osteoarthritic cartilage degeneration. These findings identify a mechanism by which PTH-induced alterations of the normal subchondral bone microarchitecture may provoke early osteoarthritis. TI Prevalence of Chronic Conditions Among Medicare Part A Beneficiaries in 2008 and 2010: Are Medicare Beneficiaries Getting Sicker?
SO PREVENTING CHRONIC DISEASE
LA English
DT Article
AB Introduction Medicare beneficiaries who have chronic conditions are responsible for a disproportionate share of Medicare fee-forservice expenditures. The objective of this study was to analyze the change in the health of Medicare beneficiaries enrolled in Part A (hospital insurance) between 2008 and 2010 by comparing the prevalence of ii chronic conditions. Methods We conducted descriptive analyses using the 2008 and 2010 Chronic Conditions Public Use Files, which are newly available from the Centers for Medicare and Medicaid Services and have administrative (claims) data on 100% of the Medicare fee-for-service

population. We examined the data by age, sex, and dual eligibility (eligibility for both Medicare and Medicaid). Results Medicare Part A beneficiaries had more chronic conditions on average in 2010 than in 2008. The percentage increase in the average number of chronic conditions was larger for dual-eligible beneficiaries (2.8%) than for nondual-eligible beneficiaries (1.2%). The prevalence of some chronic conditions, such as congestive heart failure, ischemic heart disease, and stroke/transient ischemic attack, decreased. The deterioration of average health was due to other chronic conditions: chronic kidney disease, depression, diabetes, osteoporosis, rheumatoid arthritis/osteoarthritis. Trends in Alzheimer's disease, cancer, and chronic obstructive pulmonary disease showed differences by sex or dual eligibility or both. Conclusion Analyzing the prevalence of ii chronic conditions by using Medicare claims data provides a monitoring tool that can guide health care providers and policy makers in devising strategies to address chronic conditions and rising health care costs.

TI Synthesis, Characterization and Biodistribution Studies of 125I-Radioiodinated di-PEGylated Bone Targeting Salmon Calcitonin Analogue in Healthy Rats
SO PHARMACEUTICAL RESEARCH
LA English
DT Article
DE biodistribution; HPLC; osteoporosis; radio-iodination; sCT-2(PEG-BP)
ID bisphosphonate conjugation; polyethylene-glycol; imaging agent; delivery; dosimetry; receptors; proteins
AB The objective of this study was to prepare a bisphosphonate (BP) mediated bone targeting di-PEGylated salmon calcitonin analogue sCT-2(PEG-BP) as a novel bone targeting pharmaceutical. HPLC was used for isolation of sCT-2(PEG-BP) from the reaction mixture, followed by determination of possible PEGylation sites by trypsin digestion. Stability of the compound over time, bone mineral affinity using hydroxyapatite, and biodistribution in normal rats after radiolabeling of sCT-2(PEG-BP) or control sCT with I-125 was evaluated. PEGylated sCT analogues were synthesized, and sCT-2(PEG-BP) was isolated by HPLC and confirmed by MALDI-TOF and ICP-MS. MALDI-TOF analysis of trypsinized fragments suggested Cys(1) (or Lys(11)) and Lys(18) to be the two PEGylation sites. Bone mineral affinity test showed sCT-2(PEG-BP) or I-125-sCT-2(PEG-BP) exhibited significantly increased bone mineral affinity over sCT or I-125-sCT, respectively. sCT-2(PEG-BP)

remained stable for at least 1 month. In vivo biodistribution study showed significantly increased bone retention and prolonged plasma circulation time for sCT-2(PEG-BP) compared to the control sCT. Those results support sCT-2(PEG-BP) as a promising new drug candidate for the treatment of resorptive and/or maladaptive bone conditions, such as Osteoporosis, Osteoarthritis, Rheumatoid Arthritis, Paget's disease and bone cancers.

TI Early complications of surgery in operative treatment of ankle fractures in those over 60: A review of 186 cases
SO INJURY-INTERNATIONAL JOURNAL OF THE CARE OF THE INJURED
LA English
DT Review
DE Ankle fracture; Elderly; Surgery; Outcomes; Complications
ID internal-fixation; open reduction; epidemiology; management
AB Introduction: Ankle fractures are among the most common injuries of the lower extremity encountered by orthopaedic surgeons. With increasing population age and osteoporosis, the prevalence of these fractures is expected to increase. The aim of this study was to evaluate complications and the need for revision surgery after the surgical treatment of ankle fractures in patients over 60 years of age. We report the outcomes of 186 consecutive patients who underwent operative treatment for rotational ankle fractures in our institution from 2007 to 2010. Materials and methods: Data were collected retrospectively for the purpose of this study. The outcome measures included minor complications which did not need further surgical intervention, that is, superficial wound infections, delayed wound healing, prominent implants and skin irritation, and major complications that prompted surgical intervention (due to deep wound infection, loosening of implants or loss of fixation). Medical complications were also recorded. Long-term complications (postoperative osteoarthritis) were not assessed in this study. Logistic regression analysis and Fisher's exact test were used to identify factors predicting higher risk of complications. Results: The average age was 70.67 years (standard deviation (SD) 7.40). There were 132 (71%) females and 54 (29%) males. The overall rate of complications was 21.5% with 10.8% of them being major complications prompting surgical intervention for wound washout, removal of implants and revision of fixation. Statistical analysis showed that smoking, age, diabetes, local factors (osteopaenia, peripheral neuropathy, peripheral vascular disease, lymphoedema and venous insufficiency) and modified Charlson score were significantly associated with occurrence of complications. Gender had a marginally significant effect. Coronary artery disease and fracture type (Weber classification) did not have a significant effect on the outcome. Discussion and conclusion: Our data show that surgical treatment of ankle fractures in the elderly is associated with a high rate of complications. The factors predicting a high rate of complications include smoking, age, diabetes, local factors and a higher modified Charlson score. It is important to bear the factors in mind whilst deciding whether surgical treatment should be used in the treatment of such fractures in the elderly and explains these to patients at the time of obtaining consent. Further large-scale studies are needed to validate

the predictive value of the suggested modified Charlson score. (C) 2013 Elsevier Ltd. All rights reserved.

TI Bone mineral density and association of osteoarthritis with fracture risk
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE Osteoarthritis; Fracture risk; Osteoporosis; Bone mineral density; BMI
ID radiographic knee osteoarthritis; femoral-neck; postmenopausal women; hip osteoarthritis; trabecular bone; elderly-men; osteoporosis; incident; progression; prevalence
AB Objective: High body mass index (BMI) is associated with increased risk of osteoarthritis (OA) and reduced risk of fragility fracture. However, the relationship between fragility fracture and OA remained unclear. This study sought to investigate the effect of bone mineral density (BMD) in the OA-fracture relationship. Methods: Data from 2412 women and 1452 men aged >45 years in the Dubbo Osteoporosis Epidemiology Study (DOES) were analyzed. Individuals have been followed for up to 22 years (median: 7.5 years; range: 0.1-22 years). Femoral neck BMD (FNBMD) and lumbar spine BMD (LSBMD) was measured by dual energy X-ray absorptiometry (DXA) (GE LUNAR, Madison, WI). The presence of OA was ascertained at baseline by self-reported diagnosis. The incidence of low-trauma fracture was ascertained from X-ray reports. Results: Overall, 29% of women and 26% of men had reported a diagnosis of OA. Fracture risk was significantly higher in women with OA than those without OA (Hazard ratio (HR) = 1.50; 95% confidence interval (CI), 1.28-1.76). However, the association was mainly observed in women with osteopenic BMD (HR = 1.74; 95% CI, 1.38-2.17) and normal-BMD (HR = 1.50; 95% CI, 1.06-2.13) and not in those with osteoporosis. Further analysis revealed that osteopenic women with OA had significant increase in risk of vertebral (HR = 1.85; 95% CI, 1.24-2.75) and limb fracture (HR = 2.49; 95% CI, 1.77-3.48), but not in hip fracture. In men, no comparable relationship was found before and after adjustment for covariates. Conclusion: Women with OA have an increased risk of fragility fracture, and the risk was mainly observed in non-osteoporotic group. (C) 2014 Osteoarthritis Research Society International. TI Vitamin K: Novel molecular mechanisms of action and its roles in osteoporosis
SO GERIATRICS & GERONTOLOGY INTERNATIONAL
LA English
DT Review
DE -glutamyl carboxylase; pregnane X receptor; steroid and xenobiotic receptor; vitaminK
ID gamma-carboxyglutamic acid; xenobiotic receptor sxr; coronary-heart-disease; bone-mineral density; nuclear receptor; hip-fracture; dependent carboxylation; glutamyl carboxylase; extracellular-matrix; dietary-intake
AB VitaminK is a fat-soluble vitamin, which is involved in blood coagulation mediated by maintaining the activity of coagulation factors in the liver. VitaminK also has extrahepatic actions and has been shown to prevent bone fractures in clinical studies. In addition, epidemiological studies suggest that a lack of vitaminK is associated with several geriatric diseases, including osteoporosis, osteoarthritis, dementia and arteriosclerosis. It has also been shown that vitaminK contributes to the prevention and treatment of some kinds of malignancies. Recently, we discovered a novel role for vitaminK as a ligand of the nuclear receptor, steroid and xenobiotic receptor (SXR), and its murine ortholog, pregnane X receptor (PXR). In addition to its established roles as a cofactor of -glutamyl carboxylase (GGCX) in mediating post-transcriptional modifications, vitaminK has a different mode of action mediated by transcriptional regulation of SXR/PXR target genes. Analysis of bone tissue from PXR-deficient mice showed that the bone protective effects of vitaminK are partially mediated by SXR/PXR-dependent signaling. The discoveries of a novel mode of vitaminK action have opened up new possibilities that vitaminK might be useful for prevention or treatment of a variety of diseases that affect the geriatric population. Geriatr Gerontol Int 2014; 14: 1-7.

TI Association of IL-6 G-174C polymorphism with bone mineral density
SO JOURNAL OF BONE AND MINERAL METABOLISM
LA English
DT Article
DE IL-6; Polymorphism; Bone mineral density; Osteoporosis; Caucasian elderly women
ID interleukin-6 gene polymorphism; postmenopausal women; promoter polymorphisms; knee osteoarthritis; sp1 polymorphism; japanese women; mexican women; osteoporosis; metaanalysis; variant
AB Functional polymorphisms in the promoter region of interleukin-6 (IL-6) are known to be involved in bone mineral density (BMD) and the development of

osteoporosis, but the reported results have been inconsistent. Using the meta-analysis approach, the present study is designed to provide a relatively comprehensive picture of the relationship between bone mineral density (BMD) or osteoporosis and polymorphisms in the promoter region of IL-6 (rs1800795 and rs1800796). The difference of bone mineral density (BMD) values between genotypes was examined by mean difference and 95 % confidence intervals (CIs). Association between IL-6 polymorphism and clinical osteoporosis was evaluated by pooled odds ratios (ORs) and 95 % CIs. A total of 13 articles with 11,499 subjects were included in the present study. For -174 (rs1800795), we found that individuals with the G/G genotype had a significantly lower BMD value than those with C/C genotype at femoral neck (0.02 g/cm(2), 95 % CI 0.00-0.03) (p = 0.04) and distal radius (0.01 g/cm(2), 95 %CI 0.01-0.01) (p < 0.0001). However, we did not find a statistically significant difference of BMD at the spine. When analysis was limited to postmenopausal women, similar results were obtained. We further found that the C/C genotype was associated with a reduced risk of osteoporosis compared to G/G genotype, and the pooled OR was 0.72 (95 % CI 0.54-0.95, p = 0.02). In addition, a significant relationship was found between G-634C (rs1800796) polymorphism and distal radius BMD (CC vs. GG: 0.02 g/cm(2), 95 % CI 0.01-0.03; GC vs. GG: 0.02 g/cm(2), 95 % CI 0.00-0.03) in the Asian population. These findings suggest that the CC genotype of IL-6 G-174C polymorphism may be associated with high BMD at femoral neck and distal radius and decreased risk of osteoporosis in the Caucasian population whereas G-634C polymorphism was associated with distal radius BMD in Asians.

TI Telomerase Activity in Articular Chondrocytes Is Lost after Puberty
SO CARTILAGE
LA English
DT Article
DE chondrocyte; telomerase; mesenchymal stem cells
ID mesenchymal stem-cells; age-related-changes; osteogenic protein-1; in-vivo; senescence; osteoarthritis; expression; gene; maintains; expansion
AB Objective: Telomere length and telomerase activity are important indicators of cellular senescence and replicative ability. Loss of telomerase is associated with ageing and the development of osteoarthritis. Implantation of telomerase-positive cells, chondrocytes, or stem cells expressing a normal chondrocyte phenotype is desired for cartilage repair procedures. The objective of this study was to identify at what age chondrocytes and at what passage bone marrow-derived mesenchymal stem cells (MSCs) become senescent based on telomerase activity. The effect of osteogenic protein-1 (OP-1) or interleukin-1 alpha (IL-1 alpha) treatment on telomerase activity in chondrocytes was also measured to determine the response to anabolic or catabolic stimuli. Methods: Articular cartilage was collected from horses (n = 12) aged 1 month to 18 years. Chondrocytes from prepubescent horses (< 15 months) were treated with OP-1 or IL-1 alpha. Bone marrow aspirate from adult horses was collected and cultured for up to 10 days to isolate MSCs. Telomerase activity was measured using the TeloTAGGG Telomerase PCR ELISA kit. Results: Chondrocytes from prepubescent horses were positive for telomerase activity. Treatment with IL-1 alpha resulted in a decrease in chondrocyte telomerase activity; however, treatment with OP-1 did not change telomerase activity. One MSC culture sample was positive for telomerase activity on day 2; all samples were negative for telomerase activity on day 10. Conclusions: These results suggest that chondrocytes from prepubescent donors are potentially more suitable for cartilage repair procedures and that telomerase activity is diminished by anabolic and catabolic cytokine stimulation. If MSCs are utilized in cartilage repair, minimal passaging should be performed prior to implantation.

ID quality-of-life; evidence based recommendations; eular-standing-committee; acceptable symptom state; secondary data sources; eq-5d index scores; knee osteoarthritis; cost-effectiveness; task-force; outcome measures
AB Background: General recommendations for a reference case for economic studies in rheumatic diseases were published in 2002 in an initiative to improve the comparability of cost-effectiveness studies in the field. Since then, economic evaluations in osteoarthritis (OA) continue to show considerable heterogeneity in methodological approach. Objectives: To develop a reference case specific for economic studies in OA, including the standard optimal care, with which to judge new pharmacologic and non-pharmacologic interventions. Methods: Four subgroups of an ESCEO expert working group on economic assessments (13 experts representing diverse aspects of clinical research and/or economic evaluations) were charged with producing lists of recommendations that would potentially improve the comparability of economic analyses in OA: outcome measures, comparators, costs and methodology. These proposals were discussed and refined during a face-to-face meeting in 2013. They are presented here in the format of the recommendations of the recently published Consolidated Health Economic Evaluation Reporting Standards (CHEERS) statement, so that an initiative on economic analysis methodology might be consolidated with an initiative on reporting standards. Results: Overall, three distinct reference cases are proposed, one for each hand, knee and hip OA; with diagnostic variations in the first two, giving rise to different treatment options: interphalangeal or thumb based disease for hand OA and the presence or absence of joint malalignment for knee OA. A set of management strategies is proposed, which should be further evaluated to help establish a consensus on the "standard optimal care" in each proposed reference case. The recommendations on outcome measures, cost itemisation and methodological approaches are also provided. Conclusions: The ESCEO group proposes a set of disease-specific recommendations on the conduct and reporting of economic evaluations in OA that could help the standardisation and comparability of studies that evaluate therapeutic strategies of OA in terms of costs and effectiveness. TI Bilateral differences in gait mechanics following total ankle replacement: A two year longitudinal study
SO CLINICAL BIOMECHANICS
LA English
DT Article
DE Total ankle replacement; Gait symmetry; Walking mechanics; Ankle arthritis
ID consecutive ankles; foot kinematics; walking speed; arthrodesis; arthroplasty; osteoarthritis; prostheses; fractures; arthritis; disease
AB Background: Following total ankle replacement (TAR) patients demonstrate improvements in gait. The purpose of this study was to assess the changes in gait symmetry from a pre-operative assessment through two years following TAR. Methods: Seventy-eight patients who received a primary TAR and had no contralateral pain were examined. Three-dimensional joint mechanics and ground reaction forces were collected during seven walking trials preoperatively, and 1 and 2-years post-operatively. Data was analyzed using a 2 x 3 repeated measures ANOVA to determine significant differences between limbs and across time points (alpha = 0.05). Findings: Walking speed improved from pre-operative to each post-operative time point (P<.001; ES = 1.5). Peak dorsiflexion was not changed across time or between sides, however, the dorsiflexion angle at heel strike was increased on the nonsurgical side (P = 0.049; ES = 0.32). Peak plantar flexion moment (P<.001; ES = .80), stance (P<.001; ES = .29) and step time (P<.001; ES = .41) were improved from pre-op to 1 year post-surgery on the surgical side. Step (P<.001; ES = 1.2) and stride length (P<.001; ES = 1.2) demonstrated improvements across all time points, while the weight acceptance (P<.001; ES = 27) and propulsion ground reaction forces (P<.001; ES = .22) showed improvements between pre-op and 1 year post-op. Interpretation: The results of the study indicate that the patients are able to walk faster and demonstrate an improvement in gait symmetry; however, this improvement does not return the patient to a symmetric walking pattern by 2 years post-TAR. TI Molecular evidence of osteoblast dysfunction in elderly men with osteoporotic hip fractures
SO EXPERIMENTAL GERONTOLOGY
LA English
DT Article
DE Osteoporosis; Hip fracture; Gene expression; Bone formation
ID male idiopathic osteoporosis; bone-formation; postmenopausal women; femoral-neck; osteoclast differentiation; trabecular bone; binding-protein; bmp antagonist; messenger-rna; osteoarthritis
AB Osteoporosis is extremely frequent in post-menopausal women; nevertheless, osteoporosis in men is also a severe and frequently occurring but often underestimated disease. Increasing evidence links bone loss in male idiopathic osteoporosis and age related osteoporosis to osteoblast dysfunction rather than increased osteoclast activity as seen in postmenopausal osteoporosis. The aim of this study was to investigate gene expression of osteoblast related genes and of bone architecture in bone samples derived from elderly osteoporotic men with hip fractures (OP) in comparison to bone samples from age matched men with osteoarthritis of the hip (OA). Femoral heads and adjacent neck tissue were collected from 12 men with low-trauma hip fractures and consecutive surgical hip replacement. Bone samples of age matched patients undergoing hip replacement due to osteoarthritis served as controls. One half of the bone samples was subjected to RNA extraction, reverse transcription, and real-time polymerase chain reactions. The second half of the bone samples was analyzed by static histomorphometry. From each half samples from four different regions, the central and subcortical region of the femoral head and neck, were analyzed. OP patients displayed a significantly decreased RUNX2, Osterix and SOST expression compared to OA patients. Major microstructural changes in OP bone were seen in the subcortical region of the neck and were characterized by a significant decrease of bone volume, and a significant increase of trabecular separation. In conclusion, decreased local gene expression of RUNX2 and Osterix in men with hip fractures strongly supports the concept of osteoblast dysfunction in male osteoporosis. Major microstructural changes in the trabecular structure associated with osteoporotic hip fractures in men are localized in the subcortical region of the femoral neck. (C) 2014 Elsevier Inc. TI Nanostiffness of Collagen Fibrils Extracted from Osteoarthritic Cartilage Characterized with AFM Nanoindentation
SO SOFT MATERIALS
LA English
DT Article
DE Articular cartilage; Atomic force microscopy; Collagen fibril; Nanoindentation; Stiffness
ID atomic-force microscopy; mechanical-property; nanomechanics
AB Osteoarthritis (OA) is a prevalent and deliberating joint disorder, which acts as

the leading cause for the disability and poor quality of life of the middle-age and elderly people. It is generally believed that OA is degeneration of articular cartilage. However, the debate remains on the role of subchondral bone in pathogenesis of OA. In this study, the nanostiffness of collagen fibrils from articular cartilage in patients with entirely different bone metabolism, that is, OA, osteoporosis (OP), and health, was quantitatively measured with AFM nanoindentation technique. It was found that the stiffness of individual collagen fibril from healthy cartilage was 2.67 +/- 0.12GPa under ambient condition and 11.24 +/- 0.74MPa in hydrated state respectively. The collagen fibrils were softer in osteoporosis (OP) group (ambient: 1.64 +/- 0.12GPa; hydrated: 8.59 +/- 0.59MPa). By contrast, the extracted fibrils from OA cartilages were stiffer (ambient: 4.65 +/- 0.25GPa; hydrated: 17.26 +/- 1.77MPa). The results obtained demonstrated that the collagen fibrils extracted from OA patients are stiffer than those from healthy patients, and therefore the nanomechanical characterization of extracted collagen fibrils may be a promising way for early diagnosis of OA.

TI Gender-differences in disease distribution and outcome in hospitalized elderly: Data from the REPOSI study
SO EUROPEAN JOURNAL OF INTERNAL MEDICINE
LA English
DT Article
DE Elderly; Sex-gender difference; In-hospital mortality; Disease distribution
ID coronary-heart-disease; quality-of-life; womens health; cardiovascular-disease; postmenopausal women; antidepressant use; depression; risk; epidemiology; population
AB Background and purpose: Women live longer and outnumber men. On the other hand, older women develop more chronic diseases and conditions such as arthritis, osteoporosis and depression, leading to a greater number of years of living with disabilities. The aim of this study was to describe whether or not there are gender differences in the demographic profile, disease distribution and outcome in a population of hospitalized elderly people. Methods: Retrospective observational study including all patients recruited for the REPOSI study in the year 2010. Analyses are referred to the whole group and gender categorization was applied. Results: A total of 1380 hospitalized elderly subjects, 50.5% women and 49.5% men, were considered. Women were older than men, more often widow and living alone or in nursing homes. Disease distribution showed that malignancy, diabetes, coronary artery disease, chronic kidney disease and chronic obstructive pulmonary disease were more frequent in men, but hypertension, osteoarthritis, anemia and depression were more frequent in women. Severity and comorbidity indexes according to the Cumulative Illness Rating Scale (CIRS-s and CIRS-c) were higher in men, while cognitive impairment evaluated by the Short Blessed Test (SBT), mood disorders by the Geriatric Depression Scale (GDS) and disability in daily life measured by Barthel Index (BI) were worse in women. In-hospital and 3-month mortality rates were higher in men. Conclusions: Our study showed a gender dimorphism in the demographic and morbidity profiles of hospitalized elderly people, emphasizing once more the need for a personalized process of healthcare.

TI Acrylic Bone Cements: The Role of Nanotechnology in Improving Osteointegration and Tunable Mechanical Properties
SO JOURNAL OF BIOMEDICAL NANOTECHNOLOGY
LA English
DT Review
DE Acrylic Bone Cement; Vertebroplasty; Kyphoplasty; Osteointegration; Mechanical Behavior; Biocompatibily; Bone Tissue Engineering
ID vertebral compression fractures; in-vitro release; percutaneous vertebroplasty; carbon nanotubes; particle-size; total hip; antibacterial activity; hydroxyapatite cement; physical-property; gentamicin release
AB Nanotechnology is an extremely powerful emerging technology, which is expected to have a substantial impact on biomedical technology, especially in tissue engineering and drug delivery. The use of nanocompounds and nanoparticles in the synthesis of improved bone cements to be applied in vertebroplasty/kyphoplasty and arthroplasty, is of great interest due to the increasing incidence of osteoporosis and osteoarthritis. This review reports new advances in the development of acrylic bone cements, using different radio-opalescent nanomaterials taking into consideration their influence on the mechanical behavior and biocompatibility of the resulting acrylic bone cement. Furthermore, other non-radiopaque nanoparticles capable of mechanically reinforcing the bone cement as well as induce osteointegration, are also reviewed.

Additionally, nanoparticles used to improve the controlled release of antibiotics contained in acrylic bone cements are briefly described.

TI Evaluation of Physical Performance Level as a Fall Risk Factor in Women with a Distal Radial Fracture
SO JOURNAL OF BONE AND JOINT SURGERY-AMERICAN VOLUME
LA English
DT Article
ID hand grip strength; quality-of-life; hip fracture; follow-up; forearm fractures; older-women; osteoporosis; men; disability; prevention
AB Background: Decreased physical performance has been associated with an increased risk of falls and fragility hip fractures. The purpose of our study was to compare physical performance measures and fall risk factors in middle-aged and elderly patients with recent distal radial fractures relative to age-matched control patients. Methods: We prospectively recruited forty postmenopausal women over

fifty years of age who sustained a distal radial fracture due to a fall and forty age-matched controls without a recent history of falls. We excluded those patients with cognitive impairment, neuromuscular diseases, or other chronic conditions affecting muscle function. We compared the two groups for the level of physical performance and other risk factors of a fall. Other known risk factors assessed were low body mass index; osteoarthritis; arrhythmia; depression; visual disturbance; hypotension; use of antihypertensive drugs, sedatives, hypnotics, or antidepressants; and use of four or more medications. Results: There was no significant difference in the Short Physical Performance Battery summary score between the two groups. However, when patients with distal radial fracture were compared with control patients, significantly lower scores were observed for chair stand ($p = 0.034$) and grip strength (adjusted for hand dominance) ($p = 0.038$). Conclusions: This study suggests that overall physical performance level is not different between women with a distal radial fracture and those without a distal radial fracture. Differences in chair stand test scores and grip strength may imply an early subtle decrease in physical performance level in patients with distal radial fracture.

TI Orthography facilitates vocabulary learning for children with autism spectrum disorders (ASD)
SO QUARTERLY JOURNAL OF EXPERIMENTAL PSYCHOLOGY
LA English
DT Article
DE Orthography; Reading; Vocabulary; Word learning; Autism spectrum disorder
ID word-recognition; picture; sleep; consolidation; information; impairment; deficits; ability; speech; skills
AB This study investigated the extent to which children with autism spectrum disorders (ASD) can use orthography to facilitate vocabulary learning, as is the case for typically developing (TD) children. Forty-one children aged 7-12 years, 20 with a formal diagnosis of ASD and 21 TD peers, were taught 16 low-frequency concrete science words, such as "breccia". Half of the stimuli had the written word presented alongside a picture of the target item (orthography present: OP) while the remaining items were taught with orthography absent (OA). During the learning phase, eye movements were recorded; there were no group differences in the time spent fixating the written form. Production, comprehension, and recognition of orthographic forms of new words were assessed immediately after learning and again after a 24-hour delay. The vocabulary learning of both groups was facilitated by the presence of orthography. Overall, the groups did not differ in comprehension of new words or recognition of new orthographic forms, although the children with ASD demonstrated superior phonological learning (as measured by a picture naming task) relative to TD peers. Additionally, both groups retained

or increased new knowledge after 24 hours. The results suggest that presenting the written form during oral vocabulary teaching will enhance learning and provide a mechanism for children with ASD to increase word knowledge despite potential limitations in social learning.

TI Accuracy of spinal curvature assessed by a computer-assisted device and anthropometric indicators in discriminating vertebral fractures among individuals with back pain
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE Lumbar kyphotic angle (LKA); Osteoporosis; Rib-pelvis distance (RPD); Thoracic kyphotic angle (TKA); Vertebral fracture; Wall-occiput distance (WOD)
ID thoracic kyphosis; compression fractures; postmenopausal women; osteoporosis; prevalence; deformity; mobility; lordosis; distance; posture
AB This study examined the accuracy of thoracic and lumbar kyphotic angles as well as anthropometric indicators for discriminating patients with vertebral fracture among Japanese women > 50 years old with back pain. Along with region-specific kyphotic angles and anthropometric indicators, the combination of thoracic and lumbar kyphotic angles offered the highest accuracy. Vertebral fractures have been associated with thoracic kyphosis. However, reports on lumbar kyphotic changes in association with vertebral fracture are scarce. This study investigated the accuracy of thoracic kyphotic angle (TKA) and lumbar kyphotic angle (LKA) measurements as well as anthropometric indicators (wall-occiput distance (WOD) and rib-pelvis distance (RPD)) in discriminating patients with vertebral fracture. Lateral radiographs of the spine were obtained in 70 postmenopausal Japanese women who visited an orthopedic clinic with low back pain (mean age, 76.2 +/- 9.0 years). Radiographic vertebral fracture was diagnosed using quantitative measurement according to Japanese criteria. Osteoarthritis (OA) was defined as Kellgren-Lawrence (KL) grade 3 or higher. TKA and LKA were measured using SpinalMouseA (R). WOD and RPD were also measured. At least one vertebral fracture was present in 49 subjects (70 %). Women with vertebral fractures showed significant increases in LKA, TKA + LKA, and WOD and decreases in RPD. Logistic regression analysis showed significant association between TKA + LKA and vertebral fracture independent of the presence of OA. Receiver operating characteristic analysis revealed that TKA was useful for discriminating thoracic fractures (area under the curve (AUC), 0.730) and LKA was useful for lumbar fractures (AUC, 0.691). The combination of TKA + LKA offered the highest accuracy for detecting thoracic, lumbar, and any vertebral fractures, with AUCs of 0.779, 0.728, and 0.783, respectively. WOD and RPD showed low-to-moderate accuracies for thoracic, lumbar, and any vertebral fractures. Assessment of spinal kyphosis by SpinalMouseA (R) as well as anthropometric indicators proved useful in discriminating subjects with vertebral fractures. These convenient and radiation-free methods could contribute to early diagnosis of vertebral fractures and subsequent appropriate treatment, thus preventing additional osteoporotic

fractures.

TI Pain Conditions Ranked by Healthcare Costs for Members of a National Health Plan
SO PAIN PRACTICE
LA English
DT Article
DE chronic pain; acute pain; back pain; osteoarthritis; cost drivers; claims analysis
ID osteoporosis; obesity; hip; antidepressants; osteoarthritis; prevention; patterns; back
AB Healthcare resource utilization (HCRU) and associated costs specific to pain are a growing concern, as increasing dollar amounts are spent on pain-related conditions. Understanding which pain conditions drive the highest utilization and cost burden to the healthcare system would enable providers and payers to better target conditions to manage pain adequately and efficiently. The current study focused on 36 noncancer chronic and 14 noncancer acute pain conditions and measured the HCRU and costs per member over 365days. These conditions were

ranked by per-member costs and total adjusted healthcare costs to determine the most expensive conditions to a national health plan. The top 5 conditions for the commercial line of business were back pain, osteoarthritis (OA), childbirth, injuries, and non-hip, non-spine fractures (adjusted annual total costs for the commercial members were $119 million, $98 million, $69 million, $61 million, and $48 million, respectively). The top 5 conditions for Medicare members were OA, back pain, hip fractures, injuries, and non-hip, non-spine fractures (adjusted annual costs for the Medicare members were $327 million, $218 million, $117 million, $82 million, and $67 million, respectively). The conditions ranked highest for both per-member and total healthcare costs were hip fractures, childbirth, and non-hip, non-spine fractures. Among these, hip fractures in the Medicare member population had the highest mean cost per member (adjusted per-member cost was $21,058). Further examination specific to how pain is managed in these high-cost conditions will enable providers and payers to develop strategies to improve patient outcomes through appropriate pain management.

TI Remission Over 3 Years in Patients with Paget Disease of Bone Treated with a Single Intravenous Infusion of 5 mg Zoledronic Acid
SO CALCIFIED TISSUE INTERNATIONAL
LA English
DT Article
DE Paget disease of bone; Bisphosphonate; Zoledronic acid; Treatment; Remission
ID bisphosphonates; persistence; adherence; profile
AB Using data from the Belgian Paget's Disease Registry of 142 patients treated with a 5 mg intravenous infusion of zoledronic acid, we examined disease remission over 3 years in 98 patients with Paget disease of bone (PDB) seen in routine practice. Median age was 76 years, most patients (60.2 %) were male, and all were Caucasian. Median time since PDB diagnosis was 11.5 years, few patients

(5.1 %) had a family history of PDB, and 32.6 % had received prior bisphosphonate and/or other treatments. The most common pagetic locations were pelvis, spine, femur, tibia, and skull. The most common symptoms included pain, impaired mobility, bone deformities, and joint disease: 36.7 % of patients had comorbid osteoarthritis and 16.3 % comorbid osteoporosis. Response rates were 93.3 % at 1 year, 89.5 % at 2 years, and 91.6 % at 3 years, statistically similar to an extension study of the original zoledronic acid trials. Twenty-one patients experienced a relapse over the 3-year period at a median of 20.7 months posttreatment; of these, 13 regained remission by the end of the observation period. Relapse was not associated with osteoarthritis, osteoporosis, or other comorbidities. Safety data were similar to those reported elsewhere. In summary, in this somewhat frailer sample of patients with PDB, effectiveness and safety data were similar to those observed in the original trial populations. These findings, which are the first on the use of zoledronic acid for PDB in routine clinical practice, underscore the therapeutic benefits and relative safety of zoledronic acid in the management of PDB in "real-world'' clinical settings.

TI Therapeutic application of mesenchymal stem cells in bone and joint diseases
SO CLINICAL AND EXPERIMENTAL MEDICINE
LA English
DT Review
DE Mesenchymal stem cells (MSCs); Osteoarthritis (OA); Osteogenesis imperfecta (OI); Osteoporosis; Osteonecrosis of the femoral head (ONFH); Rheumatoid arthritis (RA)
ID collagen-induced arthritis; marrow stromal cells; severe osteogenesis imperfecta; mediated gene-therapy; femoral-head; rheumatoid-arthritis; cartilage defects; progenitor cells; adipose-tissue; induced osteonecrosis
AB Mesenchymal stem cells (MSCs), the non-hematopoietic progenitor cells, are multi-potent stem cells from a variety of tissues with the capability of self-renewal, proliferation, differentiation into multi-lineage cell types, as well as anti-inflammatory and immunomodulatory. These properties make MSCs an ideal source of cell therapy in bone and joint diseases. This review describes the advances of animal study and preliminary clinical application in the past few years, related to MSC-based cell therapy in the common bone and joint diseases, including osteoarthritis, rheumatoid arthritis, osteoporosis, osteonecrosis of the femoral head and osteogenesis imperfecta. It highlights the promising prospect of MSC in clinical application of bone and joint diseases.

TI An Ex Vivo Model in Human Femoral Heads for Histopathological Study and Resonance Frequency Analysis of Dental Implant Primary Stability
SO BIOMED RESEARCH INTERNATIONAL
LA English
DT Article
ID bone-density; computerized-tomography; biomechanical aspects; surgical techniques; insertion torque; quality; quotient; values
AB Objective. This study was designed to explore relationships of resonance frequency analysis (RFA)-assessed implant stability (ISQ values) with bone

morphometric parameters and bone quality in an ex vivo model of dental implants placed in human femoral heads and to evaluate the usefulness of this model for dental implant studies. Material and Methods. This ex vivo study included femoral heads from 17 patients undergoing surgery for femoral neck fracture due to osteoporosis (OP) (n = 7) or for total prosthesis joint replacement due to severe hip osteoarthrosis (OA) (n = 10). Sixty 4.5 x 13 mm Dentsply Astra implants were placed, followed by RFA. CD44 immunohistochemical analysis for osteocytes was also carried out. Results. As expected, the analysis yielded significant effects of femoral head type (OA versus OA) ($P < 0.001$), but not of the implants ($P = 0.455$) or of the interaction of the two factors ($P = 0.848$). Bonferroni post hoc comparisons showed a lower mean ISQ for implants in decalcified (50.33 +/- 2.92) heads than in fresh (66.93 +/- 1.10) or fixated (70.77 +/- 1.32) heads (both $P < 0.001$). The ISQ score (fresh) was significantly higher for those in OA (73.52 +/- 1.92) versus OP (67.13 +/- 1.09) heads. However, mixed linear analysis showed no significant association between ISQ scores and morphologic or histomorphometric results ($P > 0.5$ in all cases), and no significant differences in ISQ values were found as a function of the length or area of the cortical layer (both $P > 0.08$). Conclusion. Although RFA-determined ISQ values are not correlated with morphometric parameters, they can discriminate bone quality (OP versus OA). This ex vivo model is useful for dental implant studies.

TI Bovine Collagen Peptides Compounds Promote the Proliferation and Differentiation of MC3T3-E1 Pre-Osteoblasts
SO PLOS ONE
LA English
DT Article
ID alkaline-phosphatase; antioxidant activity; bone; expression; cells; hydrolysate; disease; rats; mineralization; gelatin
AB Objective: Collagen peptides (CP) compounds, as bone health supplements, are known to play a role in the treatment of osteoporosis. However, the molecular mechanisms of this process remain unclear. This study aimed to investigate the effects of bovine CP compounds on the proliferation and differentiation of MC3T3-E1 cells. Methods: Mouse pre-osteoblast cell line MC3T3-E1 subclone 4 cells were treated with bovine CP compounds. Cell proliferation was analyzed by MTT assays and the cell cycle was evaluated by flow cytometry scanning.

Furthermore, MC3T3-E1 cell differentiation was analyzed at the RNA level by real-time PCR and at the protein level by western blot analysis for runt-related transcription factor 2 (Runx2), a colorimetric p-nitrophenyl phosphate assay for alkaline phosphatase (ALP), and ELISA for osteocalcin (OC). Finally, alizarin red staining for mineralization was measured using Image Software Pro Plus 6.0. Results: Cell proliferation was very efficient after treatment with different concentrations of bovine CP compounds, and the best concentration was 3 mg/mL. Bovine CP compounds significantly increased the percentage of MC3T3-E1 cells in G(2)/S phase. Runx2 expression, ALP activity, and OC production were significantly increased after treatment with bovine CP compounds for 7 or 14 days. Quantitative analyses with alizarin red staining showed significantly increased mineralization of MC3T3-E1 cells after treatment with bovine CP compounds for 14 or 21 days. Conclusions: Bovine CP compounds increased osteoblast proliferation, and played positive roles in osteoblast differentiation and mineralized bone matrix formation. Taking all the experiments together, our study indicates a molecular mechanism for the potential treatment of osteoarthritis and osteoporosis.

TI A Survey of Physiotherapists' Experience Using Outcome Measures in Total Hip and Knee Arthroplasty
SO PHYSIOTHERAPY CANADA
LA English
DT Article
DE hip arthroplasty; knee arthroplasty; outcome assessment; survey
ID performance-based tests; international classification; physical function; patient concerns; clinical-trials; health-care; osteoarthritis; rehabilitation; replacement; disability
AB Purpose: To identify physiotherapists' familiarity with and experience using outcome measures (OMs) along the care continuum for patients undergoing total joint arthroplasty (TJA) of the hip and knee. Views on future use and barriers were also captured. Methods: A stratified random sample of physiotherapists in one Canadian province completed a questionnaire about 19 standardized and clinically feasible OMs. Analyses included descriptive statistics and chi-square and McNemar tests to compare use of OMs for clinical decision making and program evaluation. Results: Of 694 physiotherapists surveyed, 298 (43%) responded. Of these, 172 (58%) treated TJA clients and completed the full questionnaire. A majority worked in public practice settings and >1 care phase (e.g., pre-op, acute, rehab). All physiotherapists reported using >1 OM and having greater experience using performance-based measures than patient-reported OMs. OMs were used more often for clinical decision making than for program evaluation. Dissatisfaction with available tools was evident from respondents' comments. Several barriers to using OMs were identified in varied clinical settings and care phases. Conclusions: While

physiotherapists use a variety of OMs along the TJA continuum, there remain challenges to routine use across clinical settings, care phases, and patient sub-groups.

TI Moving from evidence to practice: Models of care for the prevention and management of musculoskeletal conditions
SO BEST PRACTICE & RESEARCH IN CLINICAL RHEUMATOLOGY
LA English
DT Article
DE Model of care; Policy; Musculoskeletal; Arthritis; Osteoporosis; Pain; Injury; Evidence; Implementation
ID fracture liaison services; minimal trauma fracture; evidence based recommendations; chronic disease management; eular-standing-committee; quality-of-life; low-back-pain; rheumatoid-arthritis; self-management; knee osteoarthritis
AB With musculoskeletal conditions now identified as the second highest cause of the morbidity-related global burden of disease, models of care for the prevention and management of disability related to musculoskeletal conditions are an imperative. Musculoskeletal models of care aim to describe how to operationalise evidence-based guidelines for musculoskeletal conditions and thus support implementation by clinical teams and their health systems. This review of models of care for musculoskeletal pain conditions, osteoarthritis, rheumatoid arthritis, osteoporosis and musculoskeletal injuries and trauma outlines health system and local implementation strategies to improve consumer outcomes, including supporting access to multidisciplinary teams, improving access for vulnerable populations and levering digital technologies to support access and self-management. However, the challenge remains of how to inform health system decision-makers and policy about the human and fiscal benefits for broad implementation across health services. Recommendations are made for potential solutions, as well as highlighting where further evidence is required. (C) 2014 Elsevier Ltd. All rights reserved.

TI Acute total hip replacement for acetabular fractures: A systematic review of the literature
SO INJURY-INTERNATIONAL JOURNAL OF THE CARE OF THE INJURED
LA English
DT Review
DE Acute total hip replacement; Immediate total hip replacement; Acetabular fracture; Walking ability; Weight-bearing
ID internal-fixation; arthroplasty; management; reduction
AB Introduction: Immediate total hip replacement (THR) in patients with acetabular fractures is controversial because of concerns about high complication rates. The current article is a systematic review of the literature on the use of acute THR for the treatment of acetabular fractures. Materials and methods: This systematic review included studies published in English between 1992 and 2012 of subjects with acetabular fracture undergoing immediate THR. Outcomes of interest included indications; clinical assessment, including walking ability; comparison with control

group; associated procedures, and rate of complications, such as loosening or revision surgery. Results: This review identified six studies, of which only one included a control group. Acute THR was associated with satisfying outcomes with regard to clinical assessment and walking ability. The comparative study assessed the difference between acute THR and delayed THR in acetabular fractures: improved outcomes were observed in the delayed THR group, although the differences between the two groups were not statistically significant. Discussion: According to data reported in the literature, acute primary THR can be successful in patients with poor bone quality, combined acetabular and femoral neck fractures, or pathological fractures and concurrent osteoarthritis of the hip. Relative indications include old age, delayed presentation, substantial medical comorbidities, and pathologic obesity. Clinical outcomes with acute THR were similar to those with delayed THR. Although the results reported in the six studies reviewed here were satisfying overall, there is limited evidence in this area in the existing literature and future prospective investigations are required. Conclusion: Data reported in the literature indicate that immediate THR can be successful in appropriately selected elderly patients or patients with extensive osteoporosis, combined acetabular and femoral neck fractures or pathological fractures. There is currently a limited evidence base for THR in patients with acetabular fractures; therefore, physicians' practice and expertise are the most useful tools in clinical practice. TI Linear signal hyperintensity adjacent to the subchondral bone plate at the knee on T2-weighted fat-saturated sequences: imaging aspects and association with structural lesions
SO SKELETAL RADIOLOGY
LA English
DT Article
DE Magnetic resonance imaging; Knee; Subchondral bone; Tibial menisci; Insufficiency fracture
ID marrow edema syndrome; transient osteoporosis; articular-cartilage; mr; osteoarthritis; intensity; echo
AB To describe the association between linear T2 signal abnormalities in the subchondral bone and structural knee lesions. MR studies of patients referred for the evaluation of knee pain were retrospectively evaluated and 133 of these patients presented bone marrow edema pattern (BMEP) (study group) and while 61 did not (control group). The presence of linear anomalies of the subchondral bone on T2-weighted fat-saturated sequences was evaluated. The findings were correlated to the presence of structural knee lesions and to the duration of the patient's symptoms. Histologic analysis of a cadaveric specimen was used for anatomic correlation. Linear T2 hyperintensities at the subchondral bone were present in 41 % of patients with BMEP. None of the patients in the control group presented this sign. When a subchondral linear hyperintensity was present, the prevalence of radial or root tears was high and that of horizontal tears was low (71.4 and 4.8 %, respectively). Sixty-nine percent of the patients with a subchondral insufficiency fracture presented a subchondral linear hyperintensity. It was significantly more prevalent in patients with acute or sub-acute symptoms (p <

0.0001). The studied linear T2 hyperintensity is located at the subchondral spongiosa and can be secondary to local or distant joint injuries. Its presence should evoke acute and sub-acute knee injuries. This sign is closely related to subchondral insufficiency fractures and meniscal tears with a compromise in meniscal function.

AB This consensus article reviews the diagnosis and treatment of osteoporosis in geriatric populations. Specifically, it reviews the risk assessment and intervention thresholds, the impact of nutritional deficiencies, fall prevention strategies, pharmacological treatments and their safety considerations, the risks of sub-optimal treatment adherence and strategies for its improvement. This consensus article reviews the therapeutic strategies and management options for the treatment of osteoporosis of the oldest old. This vulnerable segment (persons over 80 years of age) stands to gain substantially from effective anti-osteoporosis treatment, but the under-prescription of these treatments is frequent. This report is the result of an ESCEO (European Society for Clinical and Economic Aspects of Osteoporosis and Osteoarthritis) expert working group, which explores some of the reasons for this and presents the arguments to counter these beliefs. The risk assessment of older individuals is briefly reviewed along with the differences between some intervention guidelines. The current evidence on the impact of nutritional deficiencies (i.e. calcium, protein and vitamin D) is presented, as are strategies to prevent falls. One possible reason for the under-prescription of pharmacological treatments for osteoporosis in the oldest old is the perception that anti-fracture efficacy requires long-term treatment. However, a review of the data shows convincing anti-fracture efficacy already by 12 months. The safety profiles of these pharmacological agents are generally satisfactory in this patient segment provided a few precautions are followed. These patients should be considered for particular consultation/follow-up procedures in the effort to convince on the benefits of treatment and to allay fears of adverse drug reactions, since poor adherence is a major problem for the success of a strategy for osteoporosis and limits cost-effectiveness.

TI Prevalence and progression of radiographic ossification of the posterior longitudinal ligament and associated factors in the Japanese population: a 3-year follow-up of the ROAD study
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE Bone mineral density; Diffuse idiopathic skeletal hyperostosis; Ossification of posterior longitudinal ligament of cervical spine; Plasma pentosidine; Prevalence; Progression
ID bone-mineral density; glycation end-product; body-mass index; cervical-spine; plasma pentosidine; renal-failure; risk; opll; collagen; dish
AB The prevalence of radiographic cervical ossification of the posterior longitudinal ligament (OPLL) in 1,562 Japanese from a population-based cohort was 1.9 %. The presence of OPLL showed a significant association with the femoral neck bone mineral density (BMD), presence of diffuse idiopathic skeletal hyperostosis (DISH) and plasma pentosidine levels. Only one new case of radiographic OPLL was detected, but OPLL progressed in all affected subjects. The purpose of this study was to clarify the prevalence and progression of radiographic OPLL and the associated factors, using the population-based cohort Research on Osteoarthritis/osteoporosis Against Disability (ROAD). In the ROAD study, 1,690 participants underwent X-ray examination of the entire spine and both knees. Radiographic OPLL, lumbar spondylosis, knee osteoarthritis and DISH were diagnosed by a single, well-experienced orthopaedic surgeon. An interviewer-administered questionnaire and tests for anthropometric measurements were administered, and the BMDs of the lumbar spine and proximal femur were determined. A new OPLL case was considered if heterotopic ossification in the posterior longitudinal ligament was absent at baseline but present during follow-up. Progression was defined as an increase in the maximum length or width of the ossification at follow-up over that at baseline. Radiographic OPLL was detected in 30 (17 men, 13 women) of 1,562 individuals who underwent X-ray examination of the cervical spine (prevalence = 1.9 %). Its prevalence was significantly higher in men than in women ($p = 0.007$), but no association with age was observed. In a logistic regression analysis, OPLL showed a significant association with the femoral neck BMD, presence of DISH and plasma pentosidine levels. Only one new case of radiographic OPLL was detected, but OPLL progressed in all affected subjects. This population-based study clarified the prevalence of radiographic OPLL in the Japanese population as well as its progression. OPLL

showed significant association with plasma pentosidine levels, BMD and DISH.

TI Association of knee osteoarthritis with onset and resolution of pain and physical functional disability: The ROAD study
SO MODERN RHEUMATOLOGY
LA English
DT Article
DE Knee joint; Osteoarthritis; Epidemiology; Longitudinal studies

ID radiographic osteoarthritis; united-states; bone-marrow; prevalence; cohort; population; validation; arthritis; symptoms; health
AB Objectives. To examine the onset and resolution of pain and physical functional disability using Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) and their association with knee osteoarthritis (OA) in the longitudinal large-scale population of the nationwide cohort study, Research on Osteoarthritis/osteoporosis Against Disability (ROAD). Methods. Subjects from the ROAD study who had been recruited during 2005-2007 were followed up 3 years later. A total of 1,578 subjects completed the WOMAC questionnaire at baseline and follow up, and the onset and resolution rate of pain and physical functional disability were examined. We also examined the association of onset of pain and physical functional disability and their resolution with severity of knee OA as well as age, body-mass index and grip strength. Results. After a 3.3-year follow-up, the onset rate of pain was 35.0% and 35.3% in men and women, respectively, and the onset rate of physical functional disability was 38% and 40%, respectively. Resolution rate of pain was 20.3% and 26.2% in men and women, respectively, and resolution rate of physical functional disability was 16% and 14% in men and women, respectively. Knee OA was significantly associated with onset and resolution of pain and physical functional disability in women, but there was no significant association of knee OA with onset of pain and resolution of physical functional disability in men. Conclusions. The present longitudinal study revealed the onset rate of pain and physical functional disability as well as their resolution, and their association with knee OA.

TI Dynamics of femoral bone remodelling in well fixed total hip arthroplasty. A 20-year follow-up of 20 hips
SO HIP INTERNATIONAL
LA English
DT Article
DE Arthroplasty; Remodelling; Cemented; Cortical thinning
ID muller straight stem; x-ray absorptiometry; mineral density; women; osteoporosis; prostheses; bmd
AB The aim of our study was to investigate the dynamics of cortical thinning around well fixed cemented Muller straight stems without osteolysis at different time periods during long term follow-up. We investigated patients operated on for

osteoarthritis with a cemented Muller straight stem, all with more than 15 years follow-up and no radiological signs of osteolysis. Cortical thinning in 20 THA hips (19 patients) followed for a mean of 20 (16 to 22) years was measured medially and laterally at six levels from the first postoperative, five, 10 years and the last follow-up x-rays. Sixty percent of observed cortical thinning occurred during the first five postoperative years, which was more evident proximally. We conclude that significantly greater cortical bone loss occurs around cemented Muller straight stems during the first five years, than is seen subsequently. We feel that this is a non-pathological process mainly related to the Muller straight stem.

TI Impact of Aging on the Regenerative Properties of Bone Marrow-, Muscle-, and Adipose-Derived Mesenchymal Stem/Stromal Cells
SO PLOS ONE
LA English
DT Article
ID stem-cells; stromal cells; in-vitro; chondrogenic differentiation; proliferation rate; cartilage repair; tissue; age; transcription; enrichment
AB Mesenchymal stem/stromal cells (MSCs) are promising cell sources for regenerative therapies due to their multipotency and ready availability, but their application can be complicated by patient-specific factors like age or illness. MSCs have been investigated for the treatment of many musculoskeletal disorders, including osteoarthritis and osteoporosis. Due to the prevalence of these diseases in older populations, researchers have studied how aging affects MSC properties and have found that proliferation and differentiation potential are impaired. However, these effects have never been compared among MSCs isolated from multiple tissue sources in the same, healthy donor. Revealing differences in how MSCs are affected by age could help identify an optimal cell source for musculoskeletal therapies targeting older patients. MSCs were isolated from young and old rabbit bone marrow, muscle, and adipose tissue. Cell yield and viability were quantified after isolation procedures, and expansion properties were assessed using assays for proliferation, senescence, and colony formation. Multipotency was also examined using lineage-specific stains and spectrophotometry of metabolites. Results were compared between age groups and among MSC sources. Results showed that MSCs are differentially influenced by aging, with bone marrow-derived stem cells having impaired proliferation, senescence, and chondrogenic response, whereas muscle-derived stem cells and adipose-derived stem cells exhibited no negative effects. While age reduced overall cell yield and adipogenic potential of all MSC populations, osteogenesis and clonogenicity remained unchanged. These findings indicate the importance of age as a factor when designing cell-based therapies for older patients.

TI Subchondral insufficiency fractures and spontaneous osteonecrosis of the knee may not be related to osteoporosis
SO ARCHIVES OF OSTEOPOROSIS
LA English
DT Article
DE Insufficiency fracture; Spontaneous osteonecrosis of the knee (SONK); Osteopenia; Osteoarthritis; Osteoporosis
AB A Summary The term insufficiency fracture implies inadequate bone and is applied to some subchondral knee magnetic resonance images. We reviewed bone

mineral density, body mass index, meniscal extrusion, comorbidities, and demographics in 32 knee insufficiency fracture patients. Only five were osteoporotic. Meniscal extrusion was predominant. Purpose The literature supports systemic osteoporosis as a risk fracture for spontaneous osteonecrosis of the knee (SONK). SONK is also called a subchondral insufficiency fracture. Recognizing that insufficiency fracture and SONK are related, we designed this retrospective study to determine if knee subchondral insufficiency fractures were associated with osteoporosis based on bone mineral density. Methods Based on magnetic resonance imaging findings, 32 patients were diagnosed as having an insufficiency fracture by an orthopaedic surgeon with magnetic resonance imaging confirmation by a musculoskeletal radiologist. We reviewed body mass index, age, sex, comorbidities, demographics, and bone mineral density using both T-scores and Z-scores. Results The average age was 70, and only five patients were osteoporotic. Twenty-six of the 32 patients were female. The average age-related Z-score was 1 standard deviation above normal. Conclusions We conclude that osteoporosis is not the underlying cause of this disorder in the majority of patients.

TI Prevalence of radiographic hip osteoarthritis is increased in high bone mass
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE Osteoarthritis; Osteoporosis; DXA; Radiology; Epidemiology
ID mineral density; knee osteoarthritis; elderly-men; women; risk; incident; standardization; osteoporosis; definitions; individuals
AB Objective: Epidemiological studies have shown an association between increased bone mineral density (BMD) and osteoarthritis (OA), but whether this

represents cause or effect remains unclear. In this study, we used a novel approach to investigate this question, determining whether individuals with High Bone Mass (HBM) have a higher prevalence of radiographic hip OA compared with controls. Design: HBM cases came from the UK-based HBM study: HBM was defined by BMD Z-score. Unaffected relatives of index cases were recruited as family controls. Age-stratified random sampling was used to select further population controls from the Chingford and Hertfordshire cohort studies. Pelvic radiographs were pooled and assessed by a single observer blinded to case-control status. Analyses used logistic regression, adjusted for age, gender and body mass index (BMI). Results: 530 HBM hips in 272 cases (mean age 62.9 years, 74% female) and 1702 control hips in 863 controls (mean age 64.8 years, 84% female) were analysed. The prevalence of radiographic OA, defined as Croft score >= 3, was higher in cases compared with controls (20.0% vs 13.6%), with adjusted odds ratio (OR) [95% CI] 1.52 [1.09, 2.11], P = 0.013. Osteophytes (OR 2.12 [1.61, 2.79], P < 0.001) and subchondral sclerosis (OR 2.78 [1.49, 5.18], P = 0.001) were more prevalent in cases. However, no difference in the prevalence of joint space narrowing (JSN) was seen (OR 0.97 [0.72, 1.33], P = 0.869). Conclusions: An increased prevalence of radiographic hip OA and osteophytosis was observed in HBM cases compared with controls, in keeping with a positive association between HBM and OA and suggesting that OA in HBM has a hypertrophic phenotype. TI Production of a polyclonal antibody against osteogenic protein-1, and its role in the diagnosis of osteoarthritis
SO SINGAPORE MEDICAL JOURNAL
LA English
DT Article
DE osteoarthritis; osteogenic protein-1; sandwich ELISA; synovial fluid
ID age-related-changes; fluid
AB INTRODUCTION Osteoarthritis (OA) is a progressive degenerative disorder of the articular cartilage. Available diagnostic radiography has been poorly associated with the progress and severity of this clinical disease. As osteogenic protein-1 (OP-1) has been identified as a bone morphogenetic protein with a major role in cartilage repair, we aimed to evaluate its potential role in the diagnosis of OA. METHODS This was an experimental study conducted at the Department of Biochemistry, Sikkim Manipal Institute of Medical Sciences, India. Polyclonal antibodies (i. e. anti-OP-1[f]) were raised against OP-1 in mice, and subsequently used in a sandwich enzyme-linked immunosorbent assay (ELISA) to detect the presence of OP-1 in the synovial fluids of 75 osteoarthritic patients. For the purpose of correlation, the radiographic assessments of the knees of the 75 patients were graded using the Kellgren-Lawrence scoring system. RESULT The polyclonal antibody (i. e. anti-OP-1[f]) raised against OP-1 was able to detect the

presence of OP-1 in the synovial fluids of all the osteoarthritic patients via sandwich ELISA. The level of the OP-1 was found to be much higher than the reference range and correlated positively with the severity of OA (r = 0.24; p = 0.04). CONCLUSION Our study shows that the polyclonal antibody, anti OP-1(f), could be used for the immunodiagnosis of osteoarthritis via sandwich ELISA.

TI The role of dietary protein and vitamin D in maintaining musculoskeletal health in postmenopausal women: A consensus statement from the European Society for Clinical and Economic Aspects of Osteoporosis and Osteoarthritis (ESCEO)
SO MATURITAS
LA English
DT Article
DE Musculoskeletal health; Menopause; Osteoporosis; Sarcopenia; Prevention; Physical exercise
ID hormone replacement therapy; randomized controlled-trial; muscle mass sarcopenia; essential amino-acids; frail elderly-people; bone-mineral density; skeletal-muscle; older-adults; resistance exercise; physical performance
AB From 50 years of age, postmenopausal women are at an increased risk of developing sarcopenia and osteoporosis as a result of deterioration of musculoskeletal health. Both disorders increase the risk of falls and fractures. The risk of developing sarcopenia and osteoporosis may be attenuated through healthy lifestyle changes, which include adequate dietary protein, calcium and vitamin D intakes, and regular physical activity/exercise, besides hormone replacement therapy when appropriate. Protein intake and physical activity are the main anabolic stimuli for muscle protein synthesis. Exercise training leads to increased muscle mass and strength, and the combination of optimal protein intake and exercise produces a greater degree of muscle protein accretion than either intervention alone. Similarly, adequate dietary protein intake and resistance exercise are important contributors to the maintenance of bone strength. Vitamin D helps to maintain muscle mass and strength as well as bone health. These findings suggest that healthy lifestyle measures in women aged >50 years are essential to allow healthy ageing. The European Society for Clinical and Economic Aspects of Osteoporosis and Osteoarthritis (ESCEO) recommends optimal dietary protein intake of 1.0-1.2 g/kg body weight/d with at least 20-25 g of high-quality protein at each main meal, with adequate vitamin D intake at 800 IU/d to maintain serum 25-hydroxyvitamin D levels >50 nmol/L as well as calcium intake of 1000 mg/d, alongside regular physical activity/exercise 3-5 times/week combined with protein intake in close proximity to exercise, in postmenopausal women for prevention of age-related deterioration of musculoskeletal health. DT Article
DE Sp1; Protein phophatase 2A; CYP1A1; Aryl hydrocarbon receptor
ID aryl-hydrocarbon receptor; dioxin receptor; caco-2 cells; cancer cells; hepg2 cells; gene; activation; expression; element; phosphorylation
AB The aryl hydrocarbon receptor (AhR) is a transcription factor that is activated by either 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) or omeprazole (OP). Activated AhR can induce CYP1A1 transcription by binding to the xenobiotic responsive element (XRE). However, the mechanism of activation of the CYP1A1 promoter region is poorly understood. Previous reports showed that Sp1 could bind to a GC-rich region near the CYF'1A1 promoter. This study sought to clarify the function of Sp1 in CYP1A1 transcription. Phosphorylation of Sp1 at Ser-59 (pSer-59) was previously reported to be closely related to transcriptional regulation. We used a site-specific phospho-antibody to show that treatment with TCDD or OP drastically reduced the level of pSer-59 in Sp1 from HepG2 cells. This reduction was too much, we hypothesized that the reduced phosphorylation level resulted from activation of phosphatase activity. Given that pSer-59 is dephosphorylated by PP2A, we examined the effect of a PP2A inhibitor, okadaic acid (OA), on pSer-59 and transcription of CYP1A1. The results showed that OA blocked dephosphorylation of Ser-59 and drastically inhibited transcription of CYP1A1. Similar results were obtained after knockdown of PP2A. Treatment with OA had no effect on the expression of AhR, its nuclear translocation, or its ability to bind to the XRE. Furthermore, dephosphorylation of SO at Ser-59 was not affected by knockdown of AhR. These results indicate that the signals from TCDD or OP caused PP2A-mediated dephosphotylation of Sp1 at Ser-59 and induced CYP1A1 transcription. This signaling pathway was independent of the AhR-mediated pathway. (C) 2013 Elsevier B.V. All rights reserved.

TI A multicenter observational study on the role of comorbidities in the recurrent episodes of benign paroxysmal positional vertigo
SO AURIS NASUS LARYNX

DT Article
DE BPPV; Vertigo; Hypertension; Diabetes; Osteoarthrosis; Osteoporosis; Otolaryngology; Comorbidity; Neurology; Elderly
ID postural restrictions; hearing-loss; depression; prevalence; nystagmus; otoconia
AB Objective: Primary objective of this study was to find a statistical link between the most worldwide comorbidities affecting the elderly population (hypertension, diabetes, osteoarthrosis, osteoporosis and depression) and recurrent episodes of BPPV. Secondary objective was defining possible "groups of risk" for people suffering recurrent positional vertigo related to the presence of a well documented comorbidity. Methods: This was an observational, cross-sectional, multicenter, spontaneous, non-pharmacological study. The data of 1092 patients suffering BPPV evaluated in 11 different Departments of Otolaryngology, Otoneurology and Neurology, referring Centers for positional vertigo evaluation, were retrospectively-collected. Results: Regarding evaluated comorbidities (hypertension, diabetes, osteoarthrosis, osteoporosis and depression), data analysis showed the presence of at least one comorbid disorder in 216 subjects (19.8%) and 2 or more in 408 subjects (37.4%). Moreover there was a statistical significant difference between the number of comorbidities and the number of recurrences, otherwise said as comorbidity disorders increased the number of relapses increased too. Conclusion: The presence of a systemic disease may worsen the status of the posterior labyrinth causing a more frequent otolith detachment. This condition increases the risk for patients suffering BPPV to have recurrent episodes, even if correctly managed by repositioning maneuvers. The combination of two or more of aforementioned comorbidities further increases the risk of relapsing BPPV, worsened by the presence of osteoporosis. On the basis of this results it was possible to define "groups of risk" useful for predicting BPPV recurrence in patients with one or more comorbidity. (C) 2013 Published by Elsevier Ireland Ltd.

TI Microstructural trabecular bone from patients with osteoporotic hip fracture or osteoarthritis: Its relationship with bone mineral density and bone remodelling

markers
SO MATURITAS
LA English
DT Article
DE Osteoarthritis; Osteoporosis; Microstructural trabecular bone; Biomechanical trabecular bone, Bone mineral density; Bone turnover markers
ID postmenopausal women; cancellous bone; femoral-head; risk; microarchitecture; difference; fragility; damage
AB Osteoporosis (OP) and osteoarthritis (OA) are the most prevalent musculoskeletal disorders in the elderly but the relationship between them is unclear. The purposes of this study are to analyze the bone turnover markers (BTM), bone mineral density (BMD) and the structural and mechanical properties of trabecular bone in patients with OP and OA, and to explore the relationship between these two diseases. We studied 12 OP patients and 13 OA patients. We analyzed BTM (beta-CrossLaps and PINP), BMD and microstructural and biomechanical parameters (micro-CT). Our results were: OP group has higher levels of beta-CrossLaps and lower BMD at the femoral neck. Also, OP patients have a decreased volume of trabecular bone and less trabecular number, with architecture showing prevalence of rod-like trabeculae and worse connectivity than OA patients. The biomechanical parameters were worse in OP patients. BMD was correlated with almost all the structural and biomechanical parameters. Moreover, beta-CrossLaps was negatively correlated with hip BMD and with bone surface density and positively with trabecular separation. BTM, BMD and bone microstructural changes in osteoporosis are opposite to those of OA. These findings justify a less resistant bone with higher risk of fragility fractures in OP patients. These histomorphometric and biomechanical changes may be suspected by measuring of BMD and beta-CrossLaps levels. (C) 2014 Elsevier Ireland Ltd. All rights reserved.

TI Vitamin D receptor gene polymorphisms and risk of osteoarthritis: A meta-analysis
SO EXPERIMENTAL BIOLOGY AND MEDICINE
LA English
DT Article
DE Vitamin D receptor; meta-analysis; polymorphism; osteoarthritis
ID bone-mineral density; postmenopausal women; knee osteoarthritis; hip osteoarthritis; radiographic osteoarthritis; disc degeneration; association; osteoporosis; alleles; disease
AB The vitamin D receptor (VDR) gene polymorphisms have been reported to be involved in the development of many musculoskeletal disorders, including osteoarthritis (OA). However, results were inconsistent and there is no definite conclusion regarding the association between any VDR polymorphism and the risk of OA. In this study, we conducted a meta-analysis to determine whether BsmI, TaqI, and ApaI polymorphisms in the VDR gene are associated with OA susceptibility. Literature research was performed using PubMed and EMBASE databases. Studies illustrating the association between the three VDR polymorphisms and OA were included, and their qualities were assessed using Newcastle-Ottawa scale. Eight eligible studies, recruiting 1626 cases and 2024 controls were identified. Their methodological qualities were generally good, with scores ranging from 6 to 8 points. However, throughout all summary analyses, which were performed for multiple categories and on four contrasts (allele contrast, contrast of homozygotes, recessive and dominant models), none of the VDR BsmI, TaqI, and ApaI gene polymorphisms were found to be significantly associated with the risk of OA. On the other hand, there was no significant publication bias. Results from this meta-analysis suggested that the VDR BsmI, TaqI, and ApaI gene polymorphisms might not be important predictors of OA. More studies further investigating these associations, especially taking into account of gene-gene, gene-environment interactions, and other confounding factors are warranted.

TI The association of fatigue, comorbidity burden, disease activity, disability and gross domestic product in patients with rheumatoid arthritis. Results from 34 countries participating in the Quest-RA programme
SO CLINICAL AND EXPERIMENTAL RHEUMATOLOGY
LA English
DT Article
DE QUEST-RA; rheumatoid arthritis; fatigue; comorbidity; disease activity

ID subclinical atherosclerosis; prevalence; impact; pain
AB Objective The aim is to assess the prevalence of comorbidities and to further analyse to which degree fatigue can be explained by comorbidity burden, disease activity, disability and gross domestic product (GDP) in patients with rheumatoid arthritis (RA). Methods Nine thousands eight hundred seventy-four patients from 34 countries, 16 with high GDP (>24.000 US dollars [USD] per capita) and 18 low-GDP countries (<24.000 USD) participated in the Quantitative Standard monitoring of Patients with RA (QUEST-RA) study. The prevalence of 31 comorbid conditions, fatigue (0-10 cm visual analogue scale [VAS] [10 worst]), disease activity in 28 joints (DAS28), and physical disability (Health Assessment Questionnaire score MAW) were assessed. Univariate and multivariate linear regression analyses were performed to assess the association between fatigue and comorbidities, disease activity, disability and GDP. Results Overall, patients reported a median of 2 comorbid conditions of which hypertension (31.5%), osteoporosis (17.6%), osteoarthritis (15.5%) and hyperlipidaemia (14.2%) were the most prevalent. The majority of comorbidities were more common in high-GDP countries. The median fatigue score was 4.4 (4.8 in low-GDP countries and 3.8 in high-GDP countries, $p<0.001$). In low-GDP countries 25.4% of the patients had a high level of fatigue (>6.6) compared with 23.0% in high-GDP countries ($p<0.001$). In univariate analysis, fatigue increased with increasing number of comorbidities, disease activity and disability in both high- and low-GDP countries. In multivariate analysis of all countries, these 3 variables explained 29.4% of the variability, whereas GDP was not significant. Conclusion Fatigue is a widespread problem associated with high comorbidity burden, disease activity and disability regardless of GDP.

TI Radiographic and clinical results after surgically treated tibial plateau fractures at three and twenty two years postsurgery
SO INTERNATIONAL ORTHOPAEDICS
LA English
DT Article
DE Tibial plateau fractures; Follow-up studies; Osteoarthritis; Fracture fixation; Radiography
ID follow-up; condylar fractures; operative treatment; trabecular pattern; bone loss; osteoporosis; index; calcaneum; arthritis; knee
AB Purpose We examined the development of osteoarthritis (OA) and post-traumatic bone loss after surgery for tibial plateau fractures (TPF). Methods Patients who had participated in previous follow-up (FU) examinations after TPF and primary reduction and internal fixation were re-evaluated. At the first FU, a median of three years after the accident (short-term FU), the patients underwent functional assessments and standardised X-rays to grade radiological OA and

post-traumatic bone loss. At the second FU, a median of 22 years after the accident (long-term FU), 30 patients were available. An identical protocol was applied, and additional investigations [Knee Injury and Osteoarthritis Outcome Score (KOOS) and magnetic resonance imaging (MRI) of the injured knee] were performed. Results When the subjective and objective results at first FU were compared with those of the second FU for the same patients, deterioration of symptoms, signs and radiological OA was noted; however, ten patients had no OA even after the long-term FU. Some patients developed post-traumatic bone loss. In 13 of 31 knees, there was little or no radiological evidence of bone loss at the second FU. Conclusions The short-term FU examination results after TPF have little prognostic value for the individual patient, as good results may deteriorate over the long run; however, there were some knees with no OA at the long-term FU. This is the first report focusing on post-traumatic bone loss after TPF.

TI Cohort Profile: The Namwon Study and the Dong-gu Study
SO INTERNATIONAL JOURNAL OF EPIDEMIOLOGY
LA English
DT Article
ID intima-media thickness; aged 50 years; genetic association analysis; nutrition examination survey; cumulative smoking exposure; cardiovascular risk-factors; carotid-artery structure; korea national-health; bone-mineral density; knee osteoarthritis
AB These two cohorts were designed to examine the increasing burden of chronic diseases among Korean populations. The studies investigated determinants for stroke, osteoporosis, dementia and cancer among middle-aged and elderly Korean populations. The Namwon Study baseline survey was performed between 2004 and 2007 (n = 10 667), and followed up 4 years later (n = 8157, follow-up rate = 76.5%). The baseline survey of the Dong-gu Study was administered over 2007-2010 (n = 9260), and will be followed up between 2014 and 2015. Questionnaires included

assessment of cognitive function, psychiatric health and lifestyle factors. Clinical examinations, biochemical tests and genotyping focused on evaluating the determinants of target diseases and their intermediate phenotypes. Potential collaborators will be invited to contact the chief investigators.

TI Effects of tibolone on osteoarthritis in ovariectomized rats: Association with nociceptive pain behaviour
SO EUROPEAN JOURNAL OF PAIN
LA English
DT Article

ID anterior cruciate ligament; estrogen replacement therapy; low-calcium diet; postmenopausal women; knee osteoarthritis; cartilage turnover; induced arthritis; receptor-alpha; bone mass; expression
AB Background To investigate the role of the synthetic steroid tibolone in the progression of osteoarthritis (OA) and in nociceptive behaviour in an experimental rat model of OA and ovariectomy (OVX)-induced osteoporosis. Methods OA was induced in Wistar rats by anterior cruciate ligament transection (ACLT) of the right knee. Osteoporosis was induced by bilateral OVX. Groups of animals were subjected to ACLT, OVX, sham or OVX + ACLT. In addition, two groups were subjected to OVX + ACLT surgeries and were orally administered 0.1 or 0.5 mg tibolone every other day for 14 consecutive weeks, starting 6 weeks after surgery. Nociceptive behaviours (secondary mechanical allodynia and weight-bearing distribution of the hind paws) were analysed prior to and every 3 weeks after surgery up to 24 weeks. At 24 weeks, histopathological studies were performed on the cartilage and synovial membranes of the knee joints, and bone metabolism was assessed by measuring serum concentrations of calcium, phosphorus and alkaline phosphatase. Results Rats undergoing ACLT or OVX + ACLT surgeries showed obvious OA changes in the joints. Animals subjected to ACLT + OVX and treated with tibolone had significantly less cartilage degeneration and synovitis and showed improved nociceptive tests compared with animals undergoing ACLT + OVX surgeries alone. OVX increased the severity of the ACLT-induced OA changes. There was a significant increase in serum alkaline phosphatase in the tibolone-treated ACLT + OVX groups. Conclusions Treatment with tibolone attenuated the development of OA, concomitantly reduced nociception and increased serum alkaline phosphatase in ACLT + OVX rats.

TI Bone mineral density in patients with destructive arthrosis of the hip joint
SO JOURNAL OF BONE AND MINERAL METABOLISM
LA English
DT Article
DE Bone mineral density (BMD); Dual-energy X-ray absorptiometry (DXA); Osteoarthritis of the hip; Rapidly destructive arthrosis
ID subchondral insufficiency fracture; early mri findings; femoral-head; rapid

destruction; osteoarthritis; osteoporosis; coxarthrosis; replacement; acetabulum; age
AB Recent reports have shown the existence of subchondral insufficiency fracture in rapidly destructive arthrosis of the hip joint (RDA), and the findings suggest that osteopenia is related to the pathogenesis of the rapid progression of this disease. Therefore, we measured bone mineral density (BMD) in RDA patients. We measured BMD of the lumbar spine, radius, and calcaneus using dual-energy X-ray absorptiometry in 19 patients with RDA and 75 with osteoarthritis of the hip (OA) and compared BMD at different skeletal sites between RDA and OA patients. No significant differences were observed in BMD of the lumbar spine, ultradistal radius, mid-radius, and calcaneous between the RDA and OA groups. Our data suggest that RDA is not accompanied by generalized osteoporosis. Factors other than generalized bone status, for example, BMD around the affected hip joint before destruction, need to be analyzed to elucidate the pathophysiological mechanism of RDA.

TI Vitamin D deficiency in anesthesia department caregivers at the end of winter
SO ACTA ANAESTHESIOLOGICA SCANDINAVICA
LA English
DT Article
ID d insufficiency; health; assays
AB Background: To test whether the vitamin D status of anesthesia department caregivers practicing at high Northern latitudes is compatible with current recommendations, the 25-hydroxyvitamin D (25(OH) D) levels of caregivers at hospitals in Iceland (64 degrees 08' N) and in Wisconsin (43 degrees 07' N) were compared at the end of winter. Methods: Anesthesia department faculty and resident physicians, non-physician anesthetists, and critical care nurses completed a questionnaire, and provided blood samples for analysis of 25(OH) D by reverse-phase high performance liquid chromatography. Results: One hundred and six participants in Iceland and 124 participants in Wisconsin were enrolled. No difference in mean serum 25(OH) D levels between Iceland [70.53 nmol/l, standard deviation (SD) 30.87 nmol/l] and Wisconsin (70.0 nmol/l, SD 30.0 nmol/l) was observed. In Iceland and Wisconsin, 25(OH) D levels below 25 nmol/l were observed in 4.7% and 4.0%, below 50 nmol/l in 34.9% and 25.0%, and below 75

nmol/l in 56.6% and 61.3% of caregivers, respectively. Conclusions: 25(OH) D levels below the 50 nmol/l (20 ng/ml) threshold recommended by the Institute of Medicine and the European Society for Clinical and Economic Aspects of Osteoporosis and Osteoarthritis, and below the 75 nmol/l (30 ng/ml) threshold recommended by The Endocrine Society, are highly prevalent among anesthesia caregivers working at two Northern hospitals at the end of winter who may otherwise not meet criteria to be tested. Anesthesia and critical care providers may wish to determine their 25(OH) D levels and use effective, safe, and low cost supplementation to target a 25(OH) D level compatible with optimal health. TI Goal-directed treatment of osteoporosis in Europe
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE BMD; Bone marker; FRAX; Management strategy; Osteoporosis; Target-to-treat; Treat-to-target
ID bone-mineral density; vertebral fracture risk; american-diabetes-association; parathyroid-hormone 1-34; postmenopausal women; rheumatoid-arthritis; hip fracture; raloxifene treatment; strontium ranelate; blood-pressure
AB Despite the proven predictive ability of bone mineral density, Fracture Risk Assessment Tool (FRAXA (R)), bone turnover markers, and fracture for osteoporotic fracture, their use as targets for treatment of osteoporosis is limited.
Treat-to-target is a strategy applied in several fields of medicine and has recently become an area of interest in the management of osteoporosis. Its role in this setting remains controversial. This article was prepared following a European Society for Clinical and Economic Aspects of Osteoporosis and Osteoarthritis (ESCEO) working group meeting convened under the auspices of the International Osteoporosis Foundation (IOF) to discuss the feasibility of applying such a strategy in osteoporosis in Europe. Potential targets range from the absence of an incident fracture to fixed levels of bone mineral density (BMD), a desired FRAXA (R) score, a specified level of bone turnover markers or indeed changes in any one or a combination of these parameters. Despite the proven predictive ability of all of these variables for fracture (particularly BMD and FRAX), their use as targets remains limited due to low sensitivity, the influence of confounders and current lack of evidence that targets can be consistently reached. ESCEO considers that it is not currently feasible to apply a treat-to-target strategy in osteoporosis, though it did identify a need to continue to improve the targeting of treatment to those at higher risk (target-to-treat strategy) and a number of issues for the research agenda. These include international consensus on intervention thresholds and

definition of treatment failure, further exploration of the relationship between fracture and BMD, and FRAX and treatment efficacy and investigation of the potential of short-term targets to improve adherence.

DT Article
ID idiopathic skeletal hyperostosis; mineral density; knee osteoarthritis; hip osteoarthritis; spinal involvement; elderly-men; enthesopathy; osteoporosis; cartilage; women
AB Objective. Previous studies of skeletal remains have suggested that both enthesophytes and osteophytes are manifestations of an underlying bone-forming tendency. A greater prevalence of osteophytes has been observed among individuals with high bone mass (HBM) compared with controls. This study was undertaken to examine the possible interrelationships between bone mass, enthesophytes, and osteophytes in a population of individuals with extreme HBM. Methods. Cases of HBM (defined according to bone mineral density [BMD] Z scores on dual x-ray absorptiometry) from the UK-based HBM study were compared with a control group comprising unaffected family members and general population controls from the Chingford and Hertfordshire cohort studies. Pelvic radiographs from cases and controls were pooled and evaluated, in a blinded manner, by a single observer, who performed semiquantitative grading of the radiographs for the presence and severity of osteophytes and enthesophytes (score range 0-3 for each). Logistic regression analysis was used to identify significant associations, with a priori adjustment for age, sex, and body mass index. Results. In this study, 226 radiographs from HBM cases and 437 radiographs from control subjects were included. Enthesophytes (grade > 1) and moderate enthesophytes (grade > 2) were more prevalent in HBM cases compared with controls (adjusted odds ratio [OR] 3.00 [95% confidence interval (95% CI) 1.96-4.58], P < 0.001 for any enthesophyte; adjusted OR 4.33 [95% CI 2.67-7.02], P < 0.001 for moderate enthesophytes). In the combined population of cases and controls, the enthesophyte grade was positively associated with BMD at both the total hip and lumbar spine (adjusted P for trend < 0.001). In addition, a positive association between osteophytes and enthesophytes was observed; for each unit increase in enthesophyte grade, the odds of any osteophyte being present were increased >2-fold (P < 0.001). Conclusion. Strong interrelationships were observed between osteophytes, enthesophytes, and HBM, which may be helpful in defining a distinct subset of patients with osteoarthritis characterized by excess bone formation.

TI Joint bleeding in factor VIII deficient mice causes an acute loss of trabecular bone and calcification of joint soft tissues which is prevented with aggressive factor replacement
SO HAEMOPHILIA
LA English
DT Article
DE bone density; factor VIII; haemarthrosis; joint degradation; microCT; mineralization
ID long-term prophylaxis; hemophilic arthropathy; mineral density; mouse model; hemarthrosis; cartilage; disease; protein; osteoarthritis; osteoporosis
AB While chronic degenerative arthropathy is the main morbidity of haemophilia, a very high prevalence of low bone density is also seen in men and boys with haemophilia. This study investigates bone degradation in the knee joint of haemophilic mice resulting from haemarthrosis and the efficacy of aggressive treatment with factor VIII in the period surrounding injury to prevent bone pathology. Skeletally mature factor VIII knock-out mice were subjected to knee joint haemorrhage induced by puncture of the left knee joint capsule. Mice received either intravenous factor VIII treatment or placebo immediately prior to injury and at hours 4, 24, 48, 72 and 96 after haemorrhage. Mice were killed 2-weeks after injury and the joint morphology and loss of bone in the proximal tibia was assessed using microCT imaging. Quantitative microCT imaging of the knee joint found acute bone loss at the proximal tibia following injury including loss of trabecular bone volumetric density and bone mineral density, as well as trabecular connectivity density, number and thickness. Unexpectedly, joint injury also resulted in calcification of the joint soft tissues including the tendons, ligaments, menisci and cartilage. Treatment with factor VIII prevented this bone and soft tissue degeneration. Knee joint haemorrhage resulted in acute changes in adjacent bone including loss of bone density and mineralization of joint soft tissues. The rapid calcification and loss of bone has implications for the initiation and progression of osteoarthritic degradation following joint bleeding.

TI Vitamin K and musculoskeletal health in postmenopausal women
SO MOLECULAR NUTRITION & FOOD RESEARCH
LA English
DT Review
DE Bone; Cartilage; Osteoarthritis; Osteoporosis; Vitamin K
ID bone-mineral density; matrix gla protein; osteocalcin-deficient mice; circulating levels; gene-expression; undercarboxylated osteocalcin; osteoporotic fractures; knee osteoarthritis; biochemical markers; hand osteoarthritis
AB Aside from its important role in blood clotting, vitamin K is an important dietary factor in regulating bone and cartilage mineralization. The vitamin K requirements to maintain musculoskeletal health may be more than the current recommendations and subclinical vitamin K deficiency may be involved in the pathogenesis of osteoporosis and osteoarthritis. Observational studies suggest that diets low in vitamin K are associated with increased risk of fractures and osteoarthritis in older adults. However, so far randomized controlled trials of vitamin K supplementation in Caucasian populations have not shown clinically significant improvements in bone mineral density at major skeletal sites. Supplementation with vitamin K may reduce the risk of fractures, but this conclusion comes from clinical trials with methodological limitations. At this time, only one randomized controlled trial has examined the effect of vitamin K supplementation on radiographic hand osteoarthritis and found no overall effect. Large well-designed randomized controlled trials are needed to compare the efficacies of vitamin K1 and K2 on fractures and osteoarthritis among older adults. In summary, currently there is not enough evidence to recommend the use of vitamin K supplements for the prevention of bone loss, fractures, or osteoarthritis in postmenopausal women.

TI Osteoblast ontogeny and implications for bone pathology: an overview
SO CELL AND TISSUE RESEARCH
LA English
DT Review
DE Osteoblasts; Bone; Osteoblasts ontogeny; Mesenchymal stemcell; Bone pathology
ID mesenchymal stem-cells; subchondral bone; stromal cells; osteogenic differentiation; gene-expression; regulatory role; amniotic-fluid; growth-factors; transcription; receptor
AB Osteoblasts are specialized mesenchyme-derived cells accountable for bone synthesis, remodelling and healing. Differentiation of osteoblasts from mesenchymal stem cells (MSC) towards osteocytes is a multi-step process strictly controlled by various genes, transcription factors and signalling proteins. The aim of this review is to provide an update on the nature of bone-forming osteoblastic

cells, highlighting recent data on MSC-osteoblast-osteocyte transformation from a molecular perspective and to discuss osteoblast malfunctions in various bone diseases. We present here the consecutive stages occurring in the differentiation of osteoblasts from MSC, the transcription factors involved and the role of miRNAs in the process. Recent data concerning the pathogenic mechanisms underlying the loss of bone mass and architecture caused by malfunctions in the synthetic activity and metabolism of osteoblasts in osteoporosis, osteogenesis imperfecta, osteoarthritis and rheumatoid arthritis are discussed. The newly acquired knowledge of the ontogeny of osteoblasts will assist in unravelling the abnormalities taking place during their differentiation and will facilitate the prevention and/or treatment of bone diseases by therapy directed against altered molecules and mechanisms.

TI Pulsed Electromagnetic Fields Partially Preserve Bone Mass, Microarchitecture, and Strength by Promoting Bone Formation in Hindlimb-Suspended Rats
SO JOURNAL OF BONE AND MINERAL RESEARCH
LA English
DT Article
DE PULSED ELECTROMAGNETIC FIELDS; DISUSE; HINDLIMB UNLOADING; THREE-POINT BENDING TEST; BONE TURNOVER; WNT/LRP5/beta-CATENIN SIGNALING
ID affects osteoclast formation; hormone replacement therapy; trabecular architecture; knee osteoarthritis; osteoporosis; stimulation; model; sclerostin; disuse; alendronate
AB A large body of evidence indicates that pulsed electromagnetic fields (PEMF), as a safe and noninvasive method, could promote in vivo and in vitro osteogenesis. Thus far, the effects and underlying mechanisms of PEMF on disuse osteopenia and/or osteoporosis remain poorly understood. Herein, the efficiency of PEMF on osteoporotic bone microarchitecture, bone strength, and bone metabolism, together with its associated signaling pathway mechanism, was systematically investigated in hindlimb-unloaded (HU) rats. Thirty young mature (3-month-old), male Sprague-Dawley rats were equally assigned to control, HU, and HU + PEMF groups. The HU + PEMF group was subjected to daily 2-hour PEMF exposure at 15 Hz, 2.4 mT. After 4 weeks, micro-computed tomography (mu CT) results showed that PEMF ameliorated the deterioration of trabecular and cortical bone microarchitecture. Three-point bending test showed that PEMF mitigated HU-induced reduction in femoral mechanical properties, including maximum load, stiffness, and elastic modulus. Moreover, PEMF increased serum bone formation markers, including osteocalcin (OC) and N-terminal propeptide of type 1 procollagen (P1NP); nevertheless, PEMF exerted minor inhibitory effects on bone resorption markers, including C-terminal crosslinked telopeptides of type I collagen (CTX-I) and tartrate-resistant acid phosphatase 5b (TRAcP5b). Bone histomorphometric analysis demonstrated that PEMF increased mineral apposition rate, bone formation rate, and osteoblast numbers in cancellous bone, but PEMF caused no obvious changes on osteoclast numbers. Real-time PCR showed that PEMF promoted tibial gene expressions of Wnt1, LRP5, beta-catenin, OPG, and OC, but did not alter RANKL, RANK, or Sost mRNA levels. Moreover, the inhibitory effects of PEMF on disuse-induced osteopenia were further confirmed in 8-month-old mature adult HU rats. Together, these results demonstrate that PEMF alleviated disuse-induced bone loss by promoting skeletal anabolic activities, and imply that PEMF might become a potential biophysical treatment modality for disuse osteoporosis. (c) 2014 American Society for Bone and Mineral Research.

TI Designing a strategy to implement optimal conservative treatments in patients with knee or hip osteoarthritis in orthopedic practice: a study protocol of the BART-OP study

SO IMPLEMENTATION SCIENCE
LA English
DT Article
DE Osteoarthritis; Hip; Knee; Conservative treatment; Implementation strategy; Barriers and facilitators
ID stepped-care strategy; clinical-practice; eular recommendations; management; practitioners; guidelines; interview; adults
AB Background: National and international evidence-based guidelines for hip and knee osteoarthritis recommend to start with (a combination of) conservative treatments, followed by surgical intervention if a patient does not respond sufficiently to conservative treatment options. Despite these recommendations, there are strong indications that conservative treatments are not optimally used in orthopedic practice. Our study aims to quantify the use of conservative treatments in Dutch orthopedic practice and to explore the barriers and facilitators for the use of conservative treatments that should be taken into account in a strategy to improve the embedding of conservative treatments in hip and knee osteoarthritis in orthopedic practice. Methods: This study consists of three phases. First, current use of conservative treatments in patients with hip and knee osteoarthritis will be explored using an internet-based survey among at least 100 patients to identify the underused conservative treatments. Second, barriers and facilitators for the use of conservative treatments in orthopedic practice will be identified using semi-structured interviews among 10 orthopedic surgeons and 5 patients. The interviews will be followed by an internet-based survey among approximately 450 orthopedic surgeons and at least 100 patients in which the identified barriers and facilitators will be ranked by importance. Finally, an implementation strategy will be developed based on the results of the previous phases using intervention mapping. Discussion: The developed strategy is likely to result in an optimal and standardized use of conservative treatment options in hip and knee osteoarthritis in orthopedic practice, because it is focused on identified barriers and facilitators. In addition, the results of this study can be used as an example for optimizing the use of conservative care in other patient groups. In a subsequent study, the developed implementation strategy will be assessed on its effectiveness, feasibility and costs.

TI Osteoarthritis of the Second Metatarsophalangeal Joint Associated With Hallux Valgus Deformity
SO FOOT & ANKLE INTERNATIONAL
LA English
DT Article
DE degenerative osteoarthritis; hallux valgus; second metatarsophalangeal joint
ID freibergs-disease; foot
AB Background: Hallux valgus is speculated to increase the load on the second metatarsophalangeal (MTP) joint, possibly inducing degenerative osteoarthritis. In addition, the severity of arthritis may be correlated with the severity of hallux valgus. This study evaluated the association of arthritis of the second MTP joint in hallux valgus patients and the relationship between arthritis of the second MTP joint and hallux valgus deformity. Methods: A total of 382 patients (509 feet) underwent surgery for symptomatic hallux valgus deformities by the 2 senior authors (KTL, YUP) from November 2011 to December 2012. A total of 54 patients (61 feet), all female, were included in the osteoarthritis (OA) group. The rest were assigned to the nonosteoarthritis (NOA) group. There were 328 patients (448 feet) consisting of 16 men and 432 women. Osteoarthritis patients were then evaluated and classified according to joint space narrowing (JSN) and osteophyte (OP) formation. A statistical analysis was conducted to compare the 2 groups in terms of their hallux valgus angle (HVA), intermetatarsal angle (IMA), distal metatarsal articular angle (DMAA), hypermobility of the first metatarsal ray, the length of the second metatarsal bone, and the length ratio of the first and second metatarsal bones. Correlation coefficients were calculated to compare the severity of hallux valgus and the degree of osteoarthritis of the second MTP joint. Results: The IMA of the OA group was 16.2 +/- 2.9 degrees, and that of the NOA group was 15.4 +/- 3.3 degrees (P = .034, Mann-Whitney U test). The DMAA of the OA group was 18.2 +/- 8.3 degrees, and that of the NOA group was 16.1 +/- 8.0 degrees (P = .029, Mann-Whitney U test). There were no significant differences between the 2 groups in terms of the HVA, hypermobility, the length of the second metatarsal bone, and the length ratio of the second and first metatarsal bones. In the OA group, there was a positive correlation between the HVA and the degree of osteoarthritis (osteophyte formation) (gamma = 0.278, P = .030). In addition, there was a positive correlation between the IMA and the degree of osteoarthritis (. = 0.284 [JSN], 0.327 [OP] for the HVA, P = .026 [JSN],.010 [OP]). However, there was no significant difference between hypermobility and the degree of osteoarthritis (P =.356 [JSN],.635 [OP], Mann-Whitney U test). Furthermore, there were no positive correlations between the DMAA, the length of the second metatarsal bone, and the metatarsal length ratio. Conclusion: Our study demonstrated a positive correlation between HVA, IMA, and osteoarthritis of the second MTP joint. Other studies will be needed to determine the factors that are responsible for this correlation.

TI Septal aperture aetiology: still more questions than answers
SO FOLIA MORPHOLOGICA
LA English
DT Article
DE septal aperture; subtrochlear foramen; musculoskeletal stress markers; humeral robusticity; skeletal material
ID musculoskeletal stress markers; standardized scoring method; coronoid-olecranon septum; supratrochlear foramen; occupational stress; muscle markers; humerus; population; bone; age
AB Many theories have been suggested in order to explain the aetiology of septal aperture. The influence of genes, the size and shape of ulna processes, joint laxity, bone robusticity, osteoarthritis, and osteoporosis has been discussed; however, the problem has not yet been solved. The aim of the study was to examine the correlations between musculoskeletal stress markers, humeral robusticity and septal aperture. Additionally, the frequency of septal aperture according to sex, age, and skeletal side had been analysed. The skeletal material had come from a medieval cemetery in Cedynia, Poland. Skeletons of 201 adults (102 males, 99 females) had been examined and septal aperture had been scored. Six muscle attachment sites of upper limb bones had been analysed. Humeral robusticity had been calculated by use of the humeral robusticity index. The frequency of septal aperture among the population from Cedynia is 7.5%. There are no differences in septal aperture prevalence between males and females, the skeletal sides or age groups. In the analysed material, males with less developed muscle markers of right upper bones proved a higher predictable rate in having septal aperture (R = -0.34). On the left bones and among females, the converse correlation had also been found, but it is not statistically significant. The correlation between septal aperture and humeral robusticity is converse, yet small and insignificant. These results can confirm the theory of joint laxity and suggest that stronger bones (heavier muscles, more robust bones) increase joint tightness, and therefore protect the humeral lamina from septal aperture formation. But this theory needs a further detailed analysis.

TI A genome-wide association study of copy-number variation identifies putative loci associated with osteoarthritis in Koreans
SO BMC MUSCULOSKELETAL DISORDERS
LA English
DT Article
DE Osteoarthritis; Copy number variation; OA risk gene; TNKS; CA10
ID susceptibility locus; bone; disease; polymorphism; mechanisms; periostin; genetics; women; gdf5
AB Background: OA is a complex disease caused by environmental and genetic risk factors. The purpose of this study is to identify candidate copy number variations (CNVs) associated with OA. Methods: We performed a genome-wide association study of CNV to identify potential loci that confer susceptibility to or protection from OA. CNV genotyping was conducted using NimbleGen HD2 3 x 720K comparative hybridization array and included samples from 371 OA patients and 467 healthy controls. The putative CNV regions identified were confirmed with a

TaqMan assay. Results: We identified six genomic regions associated with OA encompassing CNV loci. None of six loci had previously been reported in genome-wide association studies with OA, although a genetic analysis suggested that they have functional effects. The protein product of a candidate risk gene for obesity, TNKS, targets Wnt inhibition, and this gene was significantly associated with hand and knee OA. Copy number deletion on TNKS was associated with a 1.37-fold decreased risk for OA. In addition, CA10, which shows a strong association with osteoporosis, was also significant in our study. Copy number deletion on this gene was associated with a 1.69-fold decreased risk for OA. Conclusion: We identified several CNV loci that may contribute to OA susceptibility in Koreans. Further functional investigations of these genes are warranted to fully characterize their putative association.

TI Reproducibility and Diagnostic Accuracy of Kellgren-Lawrence Grading for Osteoarthritis Using Radiographs and Dual-Energy X-ray Absorptiometry Images
SO JOURNAL OF CLINICAL DENSITOMETRY
LA English
DT Article
DE Bone mineral density; DXA; Kellgren-Lawrence; osteoarthritis; osteoporosis
ID hip osteoarthritis; reliability; kappa
AB Advances in image quality from modern dual-energy X-ray absorptiometry (DXA) scanners now allow near radiograph-like quality images at a low radiation

dose. This opens potential new applications for the use of DXA scanners to study other musculoskeletal conditions, such as osteoarthritis, which is often investigated by visual assessment of radiographs. Together, osteoporosis and osteoarthritis are the 2 most common musculoskeletal conditions, both of which primarily affect older people. The aim of this study was to determine whether Kellgren-Lawrence grading of DXA images can be used to grade hip osteoarthritis as effectively as radiographs. People who had attended for recent pelvic radiographs underwent DXA of hips (50 hips from 25 people) using a GE Healthcare iDXA scanner. Three observers assigned Kellgren-Lawrence grades to each image, and grading was repeated at least 1 week apart. Intraobserver and interobserver reliability for radiographs and DXA images were calculated using quadratic-weighted kappa (QWK). People were recalled 12 months later, and the tests were repeated with both the radiograph and DXA scans taken within 2 weeks of each other. Hip DXA intraobserver reproducibility achieved a QWK range of 0.88-0.95 and interobserver reproducibility of 0.85-0.88, similar to QWK from hip radiographs. Intraobserver reliability between subject-matched radiograph and iDXA images revealed QWK ranging between 0.80 and 0.88. Reproducibility of hip osteoarthritis grading using DXA was comparable with that of radiographs in this study and similar to repeatability scores previously published in literature. Given the lower radiation dose and the opportunity to simultaneously investigate osteoporosis, DXA presents an attractive imaging option for osteoarthritis.

TI Therapeutic effects of OP-1 on metal wear particle induced osteoblasts injury in vitro
SO INTERNATIONAL JOURNAL OF CLINICAL AND EXPERIMENTAL MEDICINE
LA English
DT Article
DE Bone morphogenetic pritein-7; osteoblast formation; cobalt wear particles
ID total joint arthroplasty; total hip; bmp-7; osteoarthritis; cartilage; replacement; progression; impact
AB Aseptic lossening is a main reason for the revision of total joint arthroplasty. Metal-wear particles induced deregulation of bone resorption or formation has been considered as the major process of aseptic lossening. Osteogenic protein-1 (OP-1) can be used to improve bone formation. However, such effect is not clearly understood after the metal-wear particles injury. Here, we investigated the molecular mechanisms by which OP-1 regulates the activity of bone formation and anti-inflammatory after injury. Results showed that OP-1 increased cell viability and bone formation ability of impaired osteoblast cells at 72 hours after being injured

by cobalt particles. Pathway analyses revealed that both mRNA and protein levels of Smad1 and Smad5 were significantly increased upon the treatment of OP-1 in the cell injury model. Similarly, runt-related transcription factor 2 (Runx2) was also significantly upregulated in the OP-1 treated cells. Moreover, treatment with OP-1 inhibited the secretion of interleukin 6 (IL-6), tumor necrosis factor alpha (TNF-a), and IL-18 in cobalt impaired cells. Collectively, these results suggest that OP-1 could inhibit cobalt particles induced cell injury by activating Smad1, Smad5, and Runx2, and such procedure is accompanied by anti-inflammatory reaction.

TI Limb Alignment, Subluxation, and Bone Density Relationship in the Osteoarthritic Varus Knee
SO JOURNAL OF KNEE SURGERY
LA English
DT Article
DE knee; arthroplasty; subluxation; angulation
ID mineral density; proximal tibia; computed-tomography; arthroplasty; deformity; severity; osteoporosis; progression; component; condyle
AB Lower limb alignment, tibiofemoral (TF) subluxation, and bone density changes around the knee are significant factors related to the development of knee osteoarthritis (OA) and have great impact on its severity. The relation of each factor to knee OA was evaluated separately in previous studies; however, few studies have attempted to integrate their respective effects. The purpose of this study was to determine if an identifiable interaction exists between coronal limb alignment, TF subluxation, and bone density in the development of knee OA. A total of 120 patients with symptomatic, varus knee OA, with preoperative standing anteroposterior (AP) hip-to-ankle radiographs and a computed tomographic scan of the knee, were included in this study. Overall mechanical lower extremity alignment, and TF subluxation were measured on the AP radiographs, while trabecular bone density (TBD) wasmeasured in four regions of interest for both the tibial plateau and distal femur in all patients. The patients were stratified into the following four cohorts: (A) high subluxation, high angulation; (B) high subluxation, low angulation; (C) low subluxation, high angulation; and (D) low subluxation, low angulation. The mean TBD in group B was significantly higher than in groups C and D ($p = 0.003$ and 0.03, respectively). In addition, themeanTBD in group A was significantly higher than in group C. This study highlights the relationship between limb alignment, knee subluxation, and bone density in the osteoarthritic knee. These preliminary results present a proof-of-principle, that bone mineral density affects the degree of coronal alignment and TF subluxation in OA.

TI Analysis of the Content of Cadmium and Zinc in Parts of the Human Hip Joint
SO BIOLOGICAL TRACE ELEMENT RESEARCH
LA English
DT Article
DE Cadmium; Zinc; Hip joint; Bone; AAS

ID femur head; bone; lead; exposure; tissue; metals; osteoporosis; accumulation; metabolism; fractures
AB Cadmium is an element with proven direct and indirect toxic effects on bones. Zinc affects the content of cadmium in the human body. These elements show antagonistic interactions. The aim of the research was to determine the levels of cadmium and zinc in the hip joint tissues and interactions between these elements. The study group consisted of 91 subjects, 66 women and 25 men. The tissues were obtained intraoperatively during hip endoprosthetic surgery. The levels of cadmium and zinc were assayed by the atomic absorption spectrophotometry (AAS) method. The analysis of the content of cadmium and zinc in different parts of the hip joint, i.e., articular cartilage, cortical bone, and cancellous bone of the femoral head as well as the articular capsule and a fragment of the cancellous bone taken from the intertrochanteric region of the femoral bone showed significant differences. The cancellous bone was found to have the highest potential to accumulate the elements studied, whereas part of the articular capsule the lowest. Higher levels of cadmium and zinc were observed in samples obtained from men. Patients with bone fractures had higher cadmium content than those with osteoarthritis. The study on the content of cadmium and zinc in the tissues of the hip joint is one of the primary research biomonitoring.

TI Disease-modifying effect of strontium ranelate in a subset of patients from the Phase III knee osteoarthritis study SEKOIA using quantitative MRI: reduction in bone marrow lesions protects against cartilage loss
SO ANNALS OF THE RHEUMATIC DISEASES
LA English
DT Article
ID placebo-controlled trial; double-blind; postmenopausal osteoporosis; joint replacement; clinical symptoms; volume loss; progression; risk; drug; osteoblasts
AB Objective To explore, using MRI, the disease-modifying effect of strontium ranelate (SrRan) treatment on cartilage volume loss (CVL) and bone marrow lesions (BMLs) in a subset of patients from a Phase III clinical trial in knee wosteoarthritis (OA) (SrRan Efficacy in Knee OsteoarthrItis triAl (SEKOIA)). Material and methods Patients with primary symptomatic knee OA were randomised to receive either SrRan 1 g/day or 2 g/day or placebo (SEKOIA study). A subset of these patients had MRIs at baseline, 12, 24 and 36 months to assess the knee cartilage volume and BMLs. Missing values were imputed and the analyses were adjusted according to Bonferroni. Results In this MRI subset, the distribution of patients (modified intention-to-treat; n=330) was 113, 105 and 112 for SrRan 1 g/day, 2 g/day and placebo, respectively. The groups were fairly balanced at baseline regarding demographics, clinical symptoms or imaging characteristics. Treatment with SrRan 2 g/day significantly decreased CVL on the plateaus at 12 (p=0.002) and 36 (p=0.003) months compared with placebo. Of note, in the medial femur and plateau, SrRan 1 g/day, but not SrRan 2 g/day, had more CVL than placebo. In patients with BML in the medial compartment at baseline, the BML score at 36 months was decreased in both treatment groups compared with the placebo group

(SrRan 1 g/day, p=0.002 and SrRan 2 g/day p=0.001, respectively), and CVL significantly decreased with SrRan 2 g/day (p=0.023) in the plateau compared with placebo. Conclusions In knee OA patients, treatment with SrRan 2 g/day was found to have beneficial effects on structural changes by significantly reducing CVL in the plateau and BML progression in the medial compartment.

TI Satellite Cells CD44 Positive Drive Muscle Regeneration in Osteoarthritis Patients
SO STEM CELLS INTERNATIONAL
LA English
DT Article
ID femoral-neck; stem-cells; osteoporosis; bmp2
AB Age-related bone diseases, such as osteoarthritis and osteoporosis, are strongly associated with sarcopenia and muscle fiber atrophy. In this study, we analyzed muscle biopsies in order to demonstrate that, in osteoarthritis patients, both osteophytes formation and regenerative properties of muscle stem cells are related to the same factors. In particular, thanks to immunohistochemistry, transmission electron microscopy, and immunogold labeling we investigated the role of BMP-2 in muscle stem cells activity. In patients with osteoarthritis both immunohistochemistry and transmission electron microscopy allowed us to note a higher number of CD44 positive satellite muscle cells forming syncytium. Moreover, the perinuclear and cytoplasmic expression of BMP-2 assessed by in situ molecular characterization of satellite cells syncytia suggest a very strict correlation between BMP-2 expression and muscle regeneration capability. Summing up, the higher BMP-2 expression in osteoarthritic patients could explain the increased

bone mineral density as well as decreased muscle atrophy in osteoarthrosic patients. In conclusion, our results suggest that the control of physiological BMP-2 balance between bone and muscle tissues may be considered as a potential pharmacological target in bone-muscle related pathology.

TI Comparison of microstructural and mechanical properties of trabeculae in femoral head from osteoporosis patients with and without cartilage lesions: a case-control study
SO BMC MUSCULOSKELETAL DISORDERS
LA English
DT Article
DE Osteoporosis; Osteoarthritis; Mechanical properties; Microstructure
ID human articular-cartilage; hip osteoarthritis; cancellous bone; subchondral bone; postmenopausal women; knee osteoarthritis; european guidance; in-vitro; diagnosis; fracture
AB Background: Degeneration of cartilage will change load distribution, affecting bone remodeling progress and trabecular structure and strength. However, in human primary osteoporosis, whether cartilage lesions would also affect properties beneath trabecular bone remains unknown. In this study, we explored the differences in local trabecular properties between osteoporosis patients with and without cartilage lesions. Methods: Eighteen pairs of femoral heads with and without cartilage lesions in a weight-bearing area were collected from senile femoral neck fracture patients. The Mankin score and glycosaminoglycan (GAG) content were used to evaluate the severity of the cartilage lesions. Micro-CT and compression tests were used to obtain structural and mechanical characteristics of each trabecular column. Multivariate linear regression was performed to evaluate the association between mechanical parameters and the degree of cartilage lesion. Results: In osteoporosis patients with cartilage lesions, the bone volume fraction (BV/TV) and trabecular thickness (Tb.Th) of the trabecular column were significantly higher than that of osteoporotic control patients (all $P < 0.05$), while the Young's modulus was lower ($P = 0.024$). Multivariable linear regression indicated that in both groups, bone mineral density (BMD) significantly correlated with Young's modulus (all $P < 0.05$). While in patients with cartilage lesion, GAG content was also correlated with Young's modulus (standardized coefficient 0.443, $P < 0.01$). Conclusions: Osteoporosis patients with cartilage lesions exhibited a weaker mechanical property of trabeculae. The intimate association of cartilage lesions and impairment of trabecular mechanical properties indicate that cartilage and trabeculae belong to an interdependent functional unit. Previously proposed adaptive mechanisms in osteoarthritis might also be applicable to the progression

of osteoporosis.

TI Serum levels of 25-hydroxyvitamin D and the occurrence of musculoskeletal diseases: a 3-year follow-up to the road study
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE 25-Hydroxyvitamin D; Epidemiology; Incidence; Osteoarthritis; Osteoporosis; Population-based cohort study
ID vitamin-d status; knee osteoarthritis; japanese men; hip osteoarthritis; risk-factors; osteoporosis; association; cohort; adults; women
AB Assessment of serum 25-hydroxyvitamin D levels in association with the occurrence of musculoskeletal diseases using a population-based cohort study design revealed that serum 25-hydroxyvitamin D levels could predict the occurrence of osteoporosis at the femoral neck within 3 years, but not the occurrence of knee osteoarthritis or lumbar spondylosis. The aim of this study is to clarify the association between serum 25-hydroxyvitamin D (25D) levels and occurrence of osteoporosis and osteoarthritis in the general population. The Research on Osteoarthritis/Osteoporosis Against Disability study, a large-scale population-based cohort study, was performed during 2005-2007. Serum 25D levels were measured in 1,683 participants. Of these, 1,384 individuals (81.9 %) completed a second follow-up survey 3 years later. Osteoporosis was defined according to World Health Organization criteria, in which osteoporosis is diagnosed by T-scores of bone mineral density (BMD) that are 2.5 standard deviations (SD) less than normal BMD. Knee osteoarthritis and lumbar spondylosis

were defined as Kellgren-Lawrence grade a parts per thousand yen2, using paired X-ray films. Cumulative incidences were determined according to changes in measurements using World Health Organization criteria for osteoporosis or Kellgren-Lawrence grades for osteoarthritis between the baseline and second survey. The mean (SD) serum 25D level of the 1,384 participants in both surveys was 23.4 ng/mL (6.5). The annual cumulative incidences of osteoporosis at L2-4 and the femoral neck were 0.76 and 1.83 %/year, respectively. The incidences of knee osteoarthritis and lumbar spondylosis were 3.3 and 11.4 %/year, respectively. After adjusting for potential associated factors, logistic regression analyses revealed that the odds ratio for the occurrence of femoral neck osteoporosis significantly decreased as serum 25D levels increased (+1 SD; odds ratio 0.67; 95 % confidence interval 0.49-0.92; p = 0.014). Higher serum 25D levels may prevent the occurrence of osteoporosis at the femoral neck, but not knee osteoarthritis, lumbar spondylosis, or osteoporosis at L2-4.

TI Fragility Fractures in Patients with Rheumatoid Arthritis and Osteoarthritis Compared with the General Population
SO JOURNAL OF RHEUMATOLOGY
LA English
DT Article
DE RHEUMATOID ARTHRITIS; OSTEOARTHRITIS; FRACTURES; EPIDEMIOLOGY; OSTEOPOROSIS
ID bone-mineral density; knee osteoarthritis; hip osteoarthritis; risk; osteoporosis; association; register
AB Objective. To determine the rate ratios of hip and distal radius fractures in patients with rheumatoid arthritis (RA), hip osteoarthritis (OA), and knee OA. Methods. Cohort study using healthcare data (1998-2012) covering the entire population of the Skane region of Sweden. Results. We found an increased rate of

hip fracture in both female [standardized fracture rate ratio (SFR) 1.54, 95% CI 1.40-1.70] and male patients with RA (SFR 1.81, 95% CI 1.51-2.17). The hip fracture rate in female OA was reduced by 10-20%, and trochanteric fracture tended to have a higher rate ratio compared with the cervical. Conclusion. The 50-80% increased rate of hip fracture adds to the total burden of RA while the shifted distribution of cervical/trochanteric fractures in OA is in support of subchondral bone alterations.

TI Effects of ultrasound on estradiol level, bone mineral density, bone biomechanics and matrix metalloproteinase-13 expression in ovariectomized rabbits
SO EXPERIMENTAL AND THERAPEUTIC MEDICINE
LA English
DT Article
DE ultrasound therapy; estradiol; osteoporosis; osteoarthritis; matrix metalloproteinase-13
ID intensity pulsed ultrasound; hormone replacement therapy; distraction osteogenesis; estrogen deficiency; articular-cartilage; promoter activity; ii collagen; osteoarthritis; chondrocytes; osteoporosis
AB The aim of the present study was to observe the effect of ultrasound (US) on estradiol level, bone mineral density (BMD), bone biomechanics and matrix metalloproteinase-13 (MMP-13) expression in ovariectomized (OVX) rabbits. A total of 28 virgin New Zealand white rabbits were randomly assigned into the following groups: Control (control group), ovariectomy (OVX group), ovariectomy with ultrasound therapy (US group) and ovariectomy with estrogen replacement therapy group (ERT group). At 8 weeks after ovariectomy, the US group received ultrasound treatment while the ERT group were orally treated with conjugated estrogens, and the control and OVX groups remained untreated. The estradiol level, BMD and bone biomechanics, cartilage histology and the MMP-13 expression were analyzed after the intervention. The results indicate that the US treatment increased estradiol level, BMD and bone biomechanical function. Furthermore, the US treatment appeared to improve the recovery of cartilage morphology and decreased the expression of MMP-13 in OVX models. Furthermore, the results suggest that 10 days of US therapy was sufficient to prevent the reduction of estradiol, BMD and bone biomechanical function, to protect osteoarthritis cartilage structure, and to reduce MMP-13 transcription and expression in OVX rabbits. Therefore, US treatment may be a potential treatment for postmenopausal osteoarthritis and osteoporosis.

TI Quantitative morphometric patterns in cartilage and bone from the humeral heads of end-stage osteoarthritis patients
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE Shoulder; Arthritis; Osteoporosis; Morphometry; Micro-computed tomography; Magnetic resonance imaging
ID micro-computed tomography; subchondral bone; mineral density; articular-cartilage; glenohumeral relationships; rheumatoid-arthritis; osteoporosis; thickness; association; shoulder
AB Objective: The purpose of this work is to investigate in a quantitative manner, the gross and regional structural patterns in cartilage and bone from the humeral head of end-stage OA patients, with the goal of identifying patterns of disease. Since the prevalence of primary OA of the shoulder is increasing as the population ages and the non-traumatic degenerative changes leading to this disease are poorly understood, a site-specific morphometric analysis speaks to the structure-function remodelling relationship of the pathological anatomy. Methods: Humeral heads were harvested from twenty-one patients undergoing shoulder arthroplasty for end-stage primary OA. The samples were scanned with micro-computed tomography and magnetic resonance imaging (MRI), and registered to provide reconstructed 3D datasets of the cartilage, cortical and trabecular bone tissues. Gross visual examination of the datasets allowed samples

to be classified as OA-like, osteoporosis (OP)-like or OA/OP-like. Results: Volumes of interest (VOI) separating the OA-like samples into five distinct regions showed positive correlations between bone and cartilage morphometric parameters; specifically in areas where more cartilage has been lost, the underlying subchondral cortical bone was more porous and thicker, while the subchondral trabecular bone was more dense, including more connections and trabeculae. These differences were site-specific, where the central humeral head saw the greatest destruction of cartilage and bone sclerosis, followed by the anterior aspects. Conclusion: The ability to correlate bone and cartilage changes is valuable, as these structural cuesmay allow a more targeted diagnostic approach and a better classification of the disease, leading to improved therapies. TI Inhibition of differentiation and function of osteoclasts by dimethyl sulfoxide (DMSO)
SO CELL AND TISSUE RESEARCH
LA English
DT Article
DE DMSO; Osteoclasts; RANKL; RAW 264.7 cells; Osteoporosis
ID musculoskeletal disorders; cryopreservation; cells; bone; osteoarthritis; diseases; tissue
AB Dimethyl sulfoxide (DMSO) is an FDA-approved organosulfur solvent that is reported to have therapeutic value in osteoarthritis and osteopenia. DMSO is used as a cryoprotectant for the cryopreservation of bone grafts and mesenchymal stem cells which are later used for bone repair. It is also used as a solvent in the preparation of various scaffolds used for bone tissue engineering purposes. DMSO has been reported to inhibit osteoclast formation in vitro but the mechanism involved has remained elusive. We investigated the effect of DMSO on osteoclast differentiation and function using a conventional model system of RAW 264.7 cells. The differentiation of RAW 264.7 cells was induced by adding 50 ng/ml RANKL and the effect of DMSO (0.01 and 1 % v/v) on RANKL-induced osteoclastogenesis was investigated. Addition of 1 % DMSO significantly inhibited RANKL-induced formation of TRAP+, multinucleated, mature osteoclasts and osteoclast late-stage precursors (c-Kit(-) c-Fms(+) Mac-1(+) RANK(+)). While DMSO did not inhibit proliferation per se, it did inhibit the effect of RANKL on proliferation of RAW 264.7 cells. Key genes related to osteoclast function (TRAP, Integrin alpha V beta 3, Cathepsin K and MMP9) were significantly down-regulated by DMSO. RANKL-induced expression of RANK gene was significantly reduced in the presence of DMSO. Our data, and reports from other investigators, that DMSO enhances osteoblastic differentiation of mesenchymal stem cells and also prevents bone loss in ovarietcomized rats, suggest that DMSO has tremendous potential in the treatment of osteoporosis and bone diseases arising from uncontrolled activities of the osteoclasts.

TI Mapping trabecular disconnection "hotspots" in aged human spine and hip
SO BONE
LA English
DT Article
DE Cancellous bone disconnection; Fracture site microarchitecture; Ageing vertebra; Ageing femur; Osteoporosis; Osteoarthritis
ID vertebral cancellous bone; mechanical-property; regional-variations; disc degeneration; femoral-head; fracture; mass; men; osteoporosis; architecture
AB Trabecular bone disconnection is an independent factor in age-related skeletal failure where real termini (ReTm; rare in youth) may cause weakness disproportionate to tissue loss, yet their structural contribution at vulnerable locations remains uncertain. ReTm (previously recorded at the iliac crest) were mapped in "normal" aged vertebral bodies (T11-L5 autopsy; 20 females, 10 males) and corresponding proximal femora (autopsy; 10 females). Results were compared with biomechanically failed femora from orthopaedic subjects aged >58 yr (osteoporosis OP, 10 females; osteoarthritis OA, 10 females). A novel direct 2D/3D histological method was applied to large, thick (300 mu m) slices superficially silver-stained to separate ReTm (unstained) from apparent termini (planar artefacts, brown). Light microscope field co-ordinates enabled ReTm mapping and statistical testing relative to i) sex, ii) tissue sector and iii) slicing plane. In men ReTm populations were small and random while in women they were large and sector-specific. In vertebrae they clustered anterior/superior being rare posterior/inferior; in the femoral head they concentrated distal/superior and also near the fovea, being fewer distal/inferior. A distribution polarity was evident with 100% more ReTm observed transversely (i.e., on tensile-related cross struts) than longitudinally (i.e., on compression-related vertical struts). Their numbers rose in OP (BV/TV < 14%, microCT) and in OA (BV/TV > 14%), remaining polarised and sector-specific in OP only. Comparative experimentation by marrow elution of an OP animal model demonstrated "floating segments" as a possible outcome. Conclusions were supported statistically that trabecular disconnection "hotspots" at vulnerable locations are sex- and sector-specific, mainly transaxial, and subject to disease modulation. ID bone-mineral density; postmenopausal women; articular-cartilage; wnt; osteoarthritis; gene; mice; sost; osteoporosis; inhibition
AB Sclerostin is a cysteine-knot glycoprotein product of the SOST gene, predominately expressed by osteocytes, that is a regulator of osteoblastic bone formation. When sclerostin binds to its low-density lipoprotein receptor-related proteins 5 and 6 on the cell membrane of osteoblasts, it inhibits canonical Wnt/beta-catenin signaling and reduces osteoblastic bone formation. Sclerostin was first identified in the study of two rare autosomal recessive disorders, sclerosteosis and van Buchem disease, which are associated with absent or reduced levels of sclerostin. Although homozygote patients with these disorders have serious adverse clinical consequences due to excessive bone growth, heterozygote patients have a normal phenotype, high bone mass, and very low risk of fractures. This has led to the concept that downregulation of sclerostin might be effective in the treatment of osteoporosis. Several humanized monoclonal antibodies to sclerostin, including romosozumab and blosozumab, are now in clinical development. Preliminary data show that these agents result in a transient increase in bone formation markers, a sustained decrease in bone resorption markers, and a robust increase in bone mineral density. If any of these agents are found to reduce fracture risk with a favorable safety profile, it will expand the options for osteoanabolic therapy for patients at high risk for fractures.

DT Article
ID mesenchymal stem-cells; oxidative stress; rheumatoid-arthritis; intraarticular injection; replicative senescence; osteosarcoma cells; life-span; differentiation; expression; apoptosis
AB Background and purpose - We reviewed the current state of research on microRNAs in age-related diseases in cartilage and bone. Methods - PubMed searches were conducted using separate terms to retrieve articles on (1) the role of microRNAs on aging and tissue degeneration, (2) specific microRNAs that influence

cellular and organism senescence, (3) microRNAs in age-related musculoskeletal conditions, and (4) the diagnostic and therapeutic potential of microRNAs in age-related musculoskeletal conditions. Results - An increasing number of studies have identified microRNAs associated with cellular aging and tissue degeneration. Specifically in regard to frailty, microRNAs have been found to influence the onset and course of age-related musculoskeletal conditions such as osteoporosis, osteoarthritis, and posttraumatic arthritis. Both intracellular and extracellular microRNAs may be suitable to function as diagnostic biomarkers. Interpretation - The research data currently available suggest that microRNAs play an important role in orchestrating age-related processes and conditions of the musculoskeletal system. Further research may help to improve our understanding of the complexity of these processes at the cellular and extracellular level. The option to develop microRNA biomarkers and novel therapeutic agents for the degenerating diseases of bone and cartilage appears to be promising.

DT Review
DE patient report outcomes; outcome measures; systematic review; systemic lupus erythematous
ID quality-of-life; patient-reported outcm; activity questionnaire; cultural-adaptation; validation; damage; portuguese; spanish; index
AB Objective. Patient reported outcomes (PROs) are relevant in rheumatology. Variable accessibility and validity of commonly used PROs are obstacles to homogeneity in evidence synthesis. The objective of this project was to provide a comprehensive library of "validated PROs". Methods. A launch meeting with rheumatologists, PROs methodological experts, and patients, was held to define the library's aims and scope, and basic requirements. To feed the library we performed systematic reviews on selected diseases and domains. Relevant information on PROs was collected using standardised data collection forms based on the COSMIN checklist. Results. The EULAR Outcomes Measures Library (OML), whose aims are to provide and to advise on PROs on a user-friendly manner albeit based on scientific grounds, has been launched and made accessible to all. PROs currently included cover any domain and, are generic or specifically target to the following diseases: rheumatoid arthritis, osteoarthritis, spondyloarthritis, low back pain, systemic lupus erythematosus, gout, osteoporosis, juvenile idiopathic arthritis, and fibromyalgia. Up to 236 instruments (106 generic and 130 specific) have been identified, evaluated, and included. The systematic review for SLE, which yielded 10 specific instruments, is presented here as an example. The OML website includes, for each PRO, information on the construct being measured and the extent of validation, recommendations for use, and available versions; it also contains a glossary on common validation terms. Conclusion. The OML is an in progress library led by rheumatologists, related professionals and patients, that will help to better understand and apply PROs in rheumatic and musculoskeletal diseases.

TI Association of Severe Disc Degeneration With All-Cause Mortality and Abdominal Aortic Calcification Assessed Prospectively in Older Men Findings of a Single-Center Prospective Study of Osteoporosis in Men
SO ARTHRITIS & RHEUMATOLOGY
LA English
DT Article
ID population-based cohort; hand osteoarthritis; follow-up; cardiovascular-disease; knee osteoarthritis; lumbar spine; risk-factors; back-pain; minos; atherosclerosis
AB Objective. To assess the association of disc degeneration with all-cause mortality and with the severity and rate of progression of abdominal aortic calcification (AAC) in older men. Methods. Men >50 years of age (n = 766) underwent lateral spine radiography and blood collection and were monitored prospectively. We assessed the association of disc degeneration with all-cause mortality (at 10 years), AAC severity (at baseline), and AAC progression (at 7.5 years). Results. After adjustment for confounders, including AAC, the total overall grade score for AAC predicted all-cause mortality (hazard ratio [HR] 1.20 per SD increase [95% confidence interval (95% CI) 1.01-1.43]). The highest tertile of the total overall grade score was associated with higher mortality rates (39.3/1,000 person-years for a score of >8 versus 20.9/1,000 person-years for a score of 0-8; adjusted HR 1.47 [95% CI 1.05-2.06]). The odds of severe AAC (score of >5) increased with the total disc space narrowing score (adjusted HR 1.44 per SD [95% CI 1.11-1.87]). The highest tertile of the total disc space narrowing score was associated with higher odds of severe AAC (adjusted HR 2.42 versus the lowest tertile [95% CI 1.24-4.73]). The probability of long-term AAC stability decreased with an increasing total osteophyte score (adjusted HR 0.66 per SD [95% CI 0.49-0.88]). The highest tertile of the total osteophyte score was associated with a lower probability of AAC stability (adjusted HR 0.35 versus the lowest tertile [95% CI 0.18-0.71]). Conclusion. Older men with severe disc degeneration have greater AAC severity, faster AAC progression, and higher all-cause mortality rates.

ID network metaanalysis; chondroitin sulfate; glucosamine sulfate; hip; placebo; viscosupplementation; management
AB Despite the near concurrent publication by influential scientific organizations, there are important differences in interpretation of the evidence base and the conclusions derived from the recent Osteoarthritis Research Society International (OARSI) guidelines for the management of knee osteoarthritis, the American College of Rheumatology (ACR) guidelines (concerning also hip and hand osteoarthritis) and the algorithm recommendations by the European Society for Clinical and Economic Aspects of Osteoporosis and Osteoarthritis (ESCEO). This is particularly evident for the drug class of symptomatic slow-acting drugs in osteoarthritis. In this paper, we highlight these differences and try to understand where they derive from, proposing an evidence-based interpretation.

TI Bone mineral density is not associated with musculoskeletal pain in postmenopausal Korean women aged aparts per thousandyen50 years
SO CLINICAL RHEUMATOLOGY
LA English
DT Article
DE Bone mineral density; Kellgren-Lawrence; Osteoarthritis; Osteoporosis; Pain; Postmenopausal women
ID ovariectomy-induced hyperalgesia; quality-of-life; back-pain; knee osteoarthritis; osteoporosis; alendronate; prevalence; calcitonin; teriparatide; innervation
AB Although many studies reported improvement of back pain after osteoporosis treatment, there is insufficient evidence to determine whether osteoporosis is painful. We investigated whether bone mineral density correlated with musculoskeletal pain in postmenopausal Korean women aged a parts per thousand yen50 years. Data for postmenopausal women aged a parts per thousand yen50 years were obtained from the fifth Korea National Health and Nutrition Examination Survey database. Demographics, Kellgren-Lawrence grade, and numeric rating scale for pain in the hip and knee joints, presence of back pain, and activity level were analyzed. Only subjects with dual-energy X-ray absorptiometry scans and hip and knee radiographs were included. Those with malignancy, pain medication use, or a history of fragility fractures were excluded. After univariate analysis, multiple linear regression analysis was performed to examine the significant factors correlated with the degree of hip and knee pain. Binary logistic regression analysis was performed to identify factors significantly associated with the presence of back pain. In total, 387 women were included in the data analysis. Age ($p = 0.005$) was the only significant factor correlated with the intensity of hip pain, while Kellgren-Lawrence grade ($p < 0.001$) was the only significant factor correlated with knee pain intensity in multiple regression analysis. Binary logistic regression analysis showed that age ($p = 0.002$) was the only significant factor associated with the presence of back pain. Musculoskeletal pain was not affected by or associated with the bone mineral density (BMD) of the affected body part in postmenopausal Korean women aged a parts per thousand yen50 years after adjusting for the degree of osteoarthritis.

TI Can We Identify Patients with High Risk of Osteoarthritis Progression Who Will Respond to Treatment? A Focus on Epidemiology and Phenotype of Osteoarthritis
SO DRUGS & AGING
LA English
DT Article
ID radiographic knee osteoarthritis; evidence based recommendations; subchondral bone turnover; eular-standing-committee; task-force; hand osteoarthritis; cartilage

damage; obese women; weight-loss; field mri
AB Osteoarthritis is a syndrome affecting a variety of patient profiles. A European Society for Clinical and Economic Aspects of Osteoporosis and Osteoarthritis and the European Union Geriatric Medicine Society working meeting explored the possibility of identifying different patient profiles in osteoarthritis. The risk factors for the development of osteoarthritis include systemic factors (e.g., age, sex, obesity, genetics, race, and bone density) and local biomechanical factors (e.g., obesity, sport, joint injury, and muscle weakness); most also predict disease progression, particularly joint injury, malalignment, and synovitis/effusion. The characterization of patient profiles should help to better orientate research, facilitate trial design, and define which patients are the most likely to benefit from treatment. There are a number of profile candidates. Generalized, polyarticular osteoarthritis and local, monoarticular osteoarthritis appear to be two different profiles; the former is a feature of osteoarthritis co-morbid with inflammation or the metabolic syndrome, while the latter is more typical of post-trauma osteoarthritis, especially in cases with severe malalignment. Other biomechanical factors may also define profiles, such as joint malalignment, loss of meniscal function, and ligament injury. Early- and late-stage osteoarthritis appear as separate profiles, notably in terms of treatment response. Finally, there is evidence that there are two separate profiles related to lesions in the subchondral bone, which may determine benefit from bone-active treatments. Decisions on appropriate therapy should be made considering clinical presentation, underlying pathophysiology, and stage of disease. Identification of patient profiles may lead to more personalized healthcare, with more targeted treatment for osteoarthritis.

TI Sarcopenia: a histological and immunohistochemical study on age-related muscle impairment
SO AGING CLINICAL AND EXPERIMENTAL RESEARCH
LA English
DT Article
DE Sarcopenia; BMP4; Osteoporosis; Osteoarthritis; Satellite stem cells; Myostatin
ID skeletal-muscle; fragility fractures; bone; mass; osteoporosis; dysfunction; diseases; cells; beta
AB Background Sarcopenia and osteoporosis increase the risk of bone fracture in the elderly due to the loss of muscle mass and the decrease in bone mineral density. Myostatin and Bone Morphogenetic Proteins (BMPs) are important molecules involved in muscle mass homeostasis. Aim In this study, we investigated the role of BMP4 and myostatin in the pathophysiogenesis of sarcopenia related to osteoporosis and osteoarthritis. Methods Muscle atrophy, BMP4 and myostatin expression were evaluated in 27 biopsies of osteoarthritic (OA) women and 27 biopsies from osteoporotic (OP) group by immunohistochemical reaction. Muscle stem cell niches were investigated by transmission electron microscopy analysis.

Results Myostatin and BMP4 expression was evaluated by counting the number of positive fibers on 25 high-power field. We found that OA muscle biopsies showed a significantly higher number of BMP4-positive fibers (37.35 +/- 5.63) as compared with muscle of OP patients (9.60 +/- 1.57). Unlike BMP4 expression, the number of myostatin-positive fibers in OP patients (33.95 +/- 4.10) was significantly higher compared to OA group (13.86 +/- 1.68). The ultrastructural analysis of BMP4-positive tissues displayed the presence of a high rate of satellite cells both single or as syncytium giving proof of muscle regeneration capability. Discussion Our results indicated that sarcopenia and osteoporosis shared an impairment of metabolic activity. Conversely, the molecular mechanisms of OA seem to inhibit the onset of an age-related sarcopenia. Conclusion The characterization of molecular mechanisms underlying the bone-muscle crosstalk could open new therapeutic perspectives in elderly diseases.

TI Medical Gains of Chondroitin Sulfate Upon Fucosylation
SO CURRENT MEDICINAL CHEMISTRY
LA English
DT Article
DE Carbohydrate-based drug discovery; carbohydrate-based drug development; chondroitin sulfate; fucosylation; fucosylated chondroitin sulfate; glycosaminoglycans
ID depolymerized holothurian glycosaminoglycan; sea-cucumber; anticoagulant activity; fucose branches; physicochemical characteristics; antithrombotic mechanisms; polysaccharide account; echinoderm; muscle; dhg
AB Chondroitin sulfate (CS) is a glycosaminoglycan (GAG) composed of alternating N-acetyl galactosamine and glucuronic acid units within disaccharide building blocks. CS is a key functional component in proteoglycans of cartilaginous tissues. Owing to its numerous biological roles, CS is widely explored in the pharmaceutical market as nutraceutical ingredient commonly utilized against arthritis, osteoarthrosis, and sometimes osteoporosis. Tissues like shark cartilage and bovine trachea are common sources of CS. Nonetheless, a new CS type has been introduced and investigated in the last few decades in what regards its medical potentials. It is named fucosylated chondroitin sulfate (FucCS). This less common CS type is isolated exclusively from the body wall of sea cucumbers. The presence of fucosyl branching units in the holothurian FucCS gives to this unique GAG, therapeutic properties in various pathophysiological systems which are inexistent in the common CS explored in the market. Examples of these systems are

coagulation, thrombosis, hemodialysis, atherosclerosis, cellular growth, angiogenesis, fibrosis, tumor growth, inflammation, viral and protozoan infections, hyperglycemia, diabetes-related pathological events and tissue damage. This report aims at describing the medical benefits gained upon fucosylation of CS. Clinical prospects of these medical benefits are also discussed herein.

TI Does osteophytosis at the knee predict health-related quality of life decline? A 3-year follow-up of the ROAD study
SO CLINICAL RHEUMATOLOGY
LA English
DT Article
DE Epidemiology; Longitudinal Studies; Osteoarthritis; Pain; WOMAC
ID individual radiographic features; osteoarthritis index; patellofemoral joint; hip osteoarthritis; united-states; association; prevalence; cohort; population; arthritis
AB The objective of the present longitudinal study was to clarify whether osteophytosis and joint space narrowing predict quality of life (QOL) decline using a longitudinal population-based cohort of the Research on Osteoarthritis/osteoporosis Against Disability (ROAD) study. The present study analyzed 1,525 participants who completed the radiographic examination at baseline and questionnaires regarding QOL at a 3-year follow-up (546 men and 979 women; mean age, 67.0 +/- 11.0 years). This study examined the associations of osteophyte area (OPA) and minimum joint space width (mJSW) in the medial compartment of the knee at baseline with pain and physical functional disability measured by the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC). OPA and mJSW in the medial compartment of the knee were measured using a knee osteoarthritis (OA) computer-aided diagnosis system. Overall, OPA independently predicted physical functional disability after 3 years of follow-up.

When analyzed in men and women separately, OPA, rather than mJSW, was an independent predictor for pain and physical functional disability after 3 years of follow-up in men. OPA, rather than mJSW, also predicted worsening of pain in men during the 3-year follow-up, whereas in women, mJSW, rather than OPA, predicted worsening of pain. In conclusion, the present longitudinal study using a large-scale population from the ROAD study found gender differences in the association of osteophytosis and joint space narrowing with pain and physical functional disability.

TI Bone and cartilage characteristics in postmenopausal women with mild knee radiographic osteoarthritis and those without radiographic osteoarthritis
SO JOURNAL OF MUSCULOSKELETAL & NEURONAL INTERACTIONS
LA English
DT Article
DE Osteoarthritis; Bone Strength; Kellgren and Lawrence Grade; Quantitative MRI; Postmenopausal Women
ID gadolinium-enhanced mri; mineral density; articular-cartilage; osteo-arthritis; hip; osteoporosis; expression; association; population; patterns
AB Objectives: To evaluate the association between radiographically-assessed knee osteoarthritis and femoral neck bone characteristics in women with mild knee radiographic osteoarthritis and those without radiographic osteoarthritis. Methods: Ninety postmenopausal women (mean age [SD], 58 [4] years; height, 163 [6] cm; weight, 71 [11] kg) participated in this cross-sectional study. The severity of radiographic knee osteoarthritis was defined using Kellgren-Lawrence grades 0=normal (n=12), 1=doubtful (n=25) or 2=minimal (n=53). Femoral neck bone mineral content (BMC), section modulus (Z), and cross-sectional area (CSA) were measured with DXA. The biochemical composition of ipsilateral knee cartilage was estimated using quantitative MRI measures, T2 mapping and dGEMRIC. The associations between radiographic knee osteoarthritis grades and bone and cartilage characteristics were analyzed using generalized linear models. Results: Age-, height-, and weight-adjusted femoral neck BMC (p for linearity=0.019), Z (p for linearity=0.033), and CSA (p for linearity=0.019) increased significantly with higher knee osteoarthritis grades. There was no linear relationship between osteoarthritis grades and knee cartilage indices. Conclusions: Increased DXA assessed hip bone strength is related to knee osteoarthritis severity. These results are hypothesis driven that there is an inverse relationship between osteoarthritis and osteoporosis. However, MRI assessed measures of cartilage do not discriminate mild radiographic osteoarthritis severity.

TI Total hip arthroplasty for acute acetabular fractures: a review of the literature
SO EXPERT REVIEW OF MEDICAL DEVICES
LA English
DT Review
DE acetabulum; acute; arthroplasty; fracture; hip
ID reduction internal-fixation; low-friction arthroplasty; elderly-patients; heterotopic ossification; older population; risk-factors; dislocations; replacement; management; classification

AB There have been many advances in the treatment of acetabular fractures; however, the role of total hip arthroplasty (THA) as part of acute fracture management is not well-defined. The indications to acutely manage an acetabular fracture with THA include patients who were older than 65 years of age, who had extensive intra-articular comminution, impaction of the acetabular dome, a displaced-impacted femoral neck fracture, presented with severe osteopenia or osteoporosis, or preexisting osteoarthritis. Implant survivorship and clinical outcomes were favorable with low complications when managing an acetabular fracture with THA. THA may be an effective option for treating acetabular fractures in appropriately selected patients.

TI Does primary total knee arthroplasty for acute knee joint fracture maintain autonomy in the elderly? A retrospective study of 21 cases
SO ORTHOPAEDICS & TRAUMATOLOGY-SURGERY & RESEARCH
LA English
DT Article
DE Knee; Joint fracture; Total knee arthroplasty; Osteoporosis; Peri-articular
ID tibial plateau fractures; distal femoral fractures; femur fractures; fixation; management; mortality; injury; old
AB INTRODUCTION: Due to poor results and failure encountered in osteosynthesis of peri-articular fracture of the knee, arthroplasty may be suggested to osteopenic elderly subjects. All osteosynthesis techniques entail loss of independence and are associated with elevated mortality. No studies definitively establish better management of such fractures. HYPOTHESIS: Total arthroplasty provides better autonomy after peri-articular fracture of the knee. MATERIAL AND METHOD: Seventy-nine patients aged over 65years were operated on for peri-articular fracture of the knee between April 2008 and March 2013. In 21 cases, treated by a single surgeon, total knee arthroplasty was performed in view of osteopenia or osteoarthritis. Mean age was 79years (range, 68-96years). There were 10 distal femoral and 11 proximal tibial fractures. Mean follow-up was 31months (range, 9-68months). Cases of pathologic fracture, failed osteosynthesis and non-operative management were excluded. All patients showed severe osteopenia on radiology and half already had advanced osteoarthritis. RESULTS: One-year mortality was 14%. At last follow-up, the revision rate was 9.5%. Fifteen patients were followed up. Mean Parker score fell from 7.2 (range, 2-9) preoperatively to 4.6 (range, 0-9) at last follow-up, indicating loss of independence. At follow-up, mean IKS score was 116.6 (range, 0-192) with mean IKS knee score of 78.4 (range, 0-100) and IKS

function score of 38.2 (range, 0-100). Mean Oxford score was 36/60 (range, 18-53). Global IKS and IKS function scores were significantly better in case of ASA-2 than ASA-3 ($P<0.05$). There was no difference between femoral and tibial fractures in terms of IKS or Oxford score or loss of independence. DISCUSSION: Total knee arthroplasty can be considered for peri-articular fracture of the knee in osteopenic geriatric patients. Although surgical revision was less frequent than after osteosynthesis and resumption of weight-bearing was immediate, autonomy was still impaired. Mortality was comparable to other reports. TI Selective glucocorticoid receptor modulator compound A, in contrast to prednisolone, does not induce leptin or the leptin receptor in human osteoarthritis synovial fibroblasts
SO RHEUMATOLOGY
LA English
DT Article
DE leptin; glucocorticoids; compound A; osteoarthritis; synovial fibroblast
ID rheumatoid-arthritis; knee osteoarthritis; mice; expression
AB Objective. Glucocorticoids are powerful anti-inflammatory compounds that also induce the expression of leptin and leptin receptor (Ob-R) in synovial fibroblasts through TGF-beta signalling and Smad1/5 phosphorylation. Compound A (CpdA), a selective glucocorticoid receptor agonist, reduces inflammation in murine arthritis models and does not induce diabetes or osteoporosis, thus offering an improved risk: benefit ratio in comparison with glucocorticoids. Due to the detrimental role of leptin in OA pathogenesis, we sought to determine whether CpdA also induced leptin and Ob-R protein expression as observed with prednisolone. Methods. Human synovial fibroblasts and chondrocytes were isolated from the synovium and

cartilage of OA patients after joint surgery. The cells were treated with prednisolone, TGF-beta 1, TNF-alpha and/or CpdA. Levels of leptin, IL-6, IL-8, MMP-1 and MMP-3 were measured by ELISA and expression levels of Ob-R phospho-Smad1/5, phospho-Smad2, alpha-tubulin and glyceraldehyde 3-phosphate dehydrogenase were analysed by western blotting. Results. CpdA, unlike prednisolone, did not induce leptin secretion or Ob-R protein expression in OA synovial fibroblasts. Moreover, CpdA decreased endogenous Ob-R expression and down-regulated prednisolone-induced leptin secretion and Ob-R expression. Mechanistically, CpdA, unlike prednisolone, did not induce Smad1/5 phosphorylation. CpdA, similarly to prednisolone, down-regulated endogenous and TNF-alpha-induced IL-6, IL-8, MMP-1 and MMP-3 protein secretion. The dissociative effect of CpdA was confirmed using chondrocytes with no induction of leptin secretion, but with a significant decrease in IL-6, IL-8, MMP-1 and MMP-3 protein secretion. Conclusion. CpdA, unlike prednisolone, did not induce leptin or Ob-R in human OA synovial fibroblasts, thereby demonstrating an improved risk: benefit ratio.

TI LOCAL ORIGINS IMPART CONSERVED BONE TYPE-RELATED DIFFERENCES IN HUMAN OSTEOBLAST BEHAVIOUR
SO EUROPEAN CELLS & MATERIALS
LA English
DT Article
DE In vitro; human osteoblasts; shoulder arthroplasty; vasculature; subchondral; trabecular; cortical; osteogenic differentiation
ID in-vitro; subchondral bone; trabecular bone; transcription factor; prostaglandin e-2; cortical bone; growth-factor; cells; differentiation; expression
AB Osteogenic behaviour of osteoblasts from trabecular, cortical and subchondral bone were examined to determine any bone type-selective differences in samples from both osteoarthritic (OA) and osteoporotic (OP) patients. Cell growth, differentiation; alkaline phosphatase (TNAP) mRNA and activity, Runt-related transcription factor-2 (RUNX2), SP7-transcription factor (SP7), bone sialoprotein-II (BSP-II), osteocalcin/bone gamma-carboxyglutamate (BGLAP), osteoprotegerin (OPG, TNFRSF11B), receptor activator of nuclear factor-kappa beta ligand (RANKL, TNFSF11) mRNA levels and proangiogenic vascular endothelial growth factor-A (VEGF-A) mRNA and protein release were assessed in osteoblasts from paired humeral head samples from age-matched, human OA/OP (n = 5/4) patients. Initial outgrowth and increase in cell number were significantly faster ($p < 0.01$) in subchondral and cortical than trabecular osteoblasts, in OA and OP, and this bone type-related differences were conserved despite consistently faster growth in OA. RUNX2/SP7 levels and TNAP mRNA and protein activity were, however, greater in trabecular than subchondral and cortical osteoblasts in OA and OP. BSP-II levels were significantly greater in trabecular and lowest in cortical osteoblasts in both OA and OP. In contrast, BGLAP levels showed divergent bone type-selective behaviour; highest in osteoblasts from subchondral origins in OA and trabecular origins in OP. We found virtually identical bone type-related differences, however, in TNFRSF11B:TNFSF11 in OA and OP, consistent with greater potential for paracrine effects on osteoclasts in trabecular osteoblasts. Subchondral osteoblasts (OA) exhibited highest VEGF-A mRNA levels and release. Our data indicate that human osteoblasts in trabecular, subchondral and cortical bone have inherent, programmed diversity, with specific bone type-related differences in growth, differentiation and pro-angiogenic potential in vitro.

TI Exercise as medicine - evidence for prescribing exercise as therapy in 26 different chronic diseases
SO SCANDINAVIAN JOURNAL OF MEDICINE & SCIENCE IN SPORTS
LA English
DT Article
DE physical activity; physical training; type 2 diabetes; cardiovascular; cancer; neuropsychiatric
ID quality-of-life; chronic heart-failure; polycystic ovarian syndrome; randomized controlled-trial; low-back-pain; cardiovascular risk-factors; time physical-activity; dependent diabetes-mellitus; resting blood-pressure; density-lipoprotein cholesterol
AB This review provides the reader with the up-to-date evidence-based basis for prescribing exercise as medicine in the treatment of 26 different diseases: psychiatric diseases (depression, anxiety, stress, schizophrenia); neurological diseases (dementia, Parkinson's disease, multiple sclerosis); metabolic diseases (obesity, hyperlipidemia, metabolic syndrome, polycystic ovarian syndrome, type 2 diabetes, type 1 diabetes); cardiovascular diseases (hypertension, coronary heart disease, heart failure, cerebral apoplexy, and claudication intermittent); pulmonary diseases (chronic obstructive pulmonary disease, asthma, cystic fibrosis); musculo-skeletal disorders (osteoarthritis, osteoporosis, back pain, rheumatoid arthritis); and cancer. The effect of exercise therapy on disease pathogenesis and symptoms are given and the possible mechanisms of action are discussed. We have interpreted the scientific literature and for each disease, we provide the reader with our best advice regarding the optimal type and dose for prescription of exercise.

AB A Summary In this study, we propose a novel method for accurate trabeculae extraction from human femoral heads using 3D-printing techniques and compare spatial deviation errors between this novel method and the conventional method. We found that spatial deviation errors, which indicate inaccuracy and unreliability, were significantly higher with the conventional method. Introduction Assessment of structural and mechanical properties of local bone is important in the study of pathological changes associated with musculoskeletal degenerative diseases. However, the widely used visual extraction method (VIS) for trabecular columns showed large deviations from veridicality, referred to as spatial deviation errors (SDE). Here, we propose a novel method for accurately locating and trephining trabeculae using a 3D-printed (3DP) positioning device and also evaluate the SDE of the VIS. Methods Twenty femoral heads were obtained from osteoporotic patients, and the trabecular columns were extracted from the principal compressive trabeculae by VIS (n = 10) or the 3DP (n = 10) method. Morphological, structural, and mechanical properties were compared between both groups along with the recorded errors in spatial deviation. Results Compared with the 3DP group, the average angle of central axis deflection in the VIS group was significantly greater; SDE in the VIS group was 26.1, 8.8, 4.1, 9.8, 7.2, 8.1, and 10.1 % greater for bone mineral density, bone volume/tissue volume ratio, trabecular thickness, trabecular number, Young's modulus, yield strength, and ultimate strength. Conclusion In this study, a high degree of SDE was demonstrated in the VIS, which indicates that the conventional technique is unreliable. Additionally, accurate sample fabrication and credible quantitative analysis of local trabeculae among individuals can be achieved with the aid of computed tomography and the 3DP device, thus providing a more objective method for researching musculoskeletal degenerative diseases and possibly a better clinical understanding of these disorders.

TI Prevalence of diffuse idiopathic skeletal hyperostosis (DISH) of the whole spine and its association with lumbar spondylosis and knee osteoarthritis: the ROAD study
SO JOURNAL OF BONE AND MINERAL METABOLISM
LA English
DT Article
DE Prevalence; Diffuse idiopathic skeletal hyperostosis; Knee osteoarthritis; Lumbar spondylosis; ROAD study
ID posterior longitudinal ligament; metabolic syndrome; risk-factors; population; ossification; manifestations; fractures; hungary; insulin
AB We aimed to assess the prevalence of diffuse idiopathic skeletal hyperostosis (DISH) and its association with lumbar spondylosis (LS) and knee osteoarthritis (KOA) using a population-based cohort study entitled Research on Osteoarthritis/osteoporosis Against Disability (ROAD). In the baseline ROAD study, which was performed between 2005 and 2007, 1,690 participants in mountainous and coastal areas underwent anthropometric measurements and radiographic examinations of the whole spine (cervical, thoracic, and lumbar) and both knees. They also completed an interviewer-administered questionnaire. Presence of DISH was diagnosed according to Resnick criteria, and LS and KOA were defined as Kellgren-Lawrence (KL) grade a parts per thousand yen3. Among the 1,690 participants, whole-spine radiographs of 1,647 individuals (97.5 %; 573 men, 1,074 women; mean age, 65.3 years) were evaluated. Prevalence of DISH was 10.8 % (men 22.0 %, women 4.8 %), and was significantly higher in older participants (presence of DISH 72.3 years, absence of DISH 64.4 years) and mainly distributed at the thoracic spine (88.7 %). Logistic regression analysis revealed that presence of DISH was significantly associated with older age [+1 year, odds ratio (OR): 1.06, 95 % confidence interval (CI): 1.03-1.14], male sex (OR: 5.55, 95 % CI: 3.57-8.63), higher body mass index (+1 kg/m(2), OR: 1.08, 95 % CI: 1.02-1.14), presence of LS (KL2 vs KL0: 1, OR: 5.50, 95 % CI: 2.81-10.8) (KL a parts per thousand yen3 vs KL0: 1, OR:

4.09, 95 % CI: 2.08-8.03), and presence of KOA (KL a parts per thousand yen3 vs KL0: 1, OR: 1.89, 95 % CI: 1.14-3.10) after adjusting for smoking, alcohol consumption, and residential area (mountainous vs coastal). This cross-sectional population-based study clarified the prevalence of DISH in general inhabitants and its significant association with LS and severe KOA.

TI The experimental osteoporosis in sheep - clinical approach
SO POLISH JOURNAL OF VETERINARY SCIENCES
LA English
DT Article
DE osteoporosis; animal model; indentation; mapping of elements; mechanical examinations; glucocorticosteroids
ID ovariectomy; model
AB The implementation of new methods of oseoporotic therapy requires tests on an animal model. One of the best is the sheep, whose numerous advantages over other models are described in the literature. The aim of this study was induction of osteoporosis using steroids and ovariorectomy methods in sheep and description of the change in parameters with regard to healthy sheep. The study was

performed on female "merino" breed sheep divided into three groups: Negative control (NC) healthy animals, positive control (PC) ovariorectomised animals and steroid group (SC) where methylprednisolone was implemented. Blood tests, diagnostic arthroscopy, quantitative computed tomography and X-Ray micro-tomography of bone were carried out. Blood tests revealed a decreased level of estrogens, progesterone and increased parathormone and cortisol levels in the SC group. A decrease in bone turnover markers and an increase in bone resorption markers in all groups were also noted. Diagnostic arthroscopy revealed osteoarthrosis in PC and SC groups. Radiological density tests showed a slight decrease in PC and NC groups whereas there was more than a triple decrease in SC. Results obtained from microCT showed quickly developing osteoporosis in the SC group, which is reflected in numerous parameters analysed in this study. The best effects for osteoporosis induction were obtained using ovariorectomised sheep with methylprednisolone injections.

TI Primary cup stability in THA with augmentation of acetabular defect. A comparison of healthy and osteoporotic bone
SO ORTHOPAEDICS & TRAUMATOLOGY-SURGERY & RESEARCH
LA English
DT Article
DE Arthroplasty; Replacement; Hip prosthesis; Bone cements; Osteoporosis
ID total hip-arthroplasty; revision arthroplasty; knee arthroplasty; implant design; femoral-head; follow-up; osteoarthritis; reconstruction; micromotions; replacement
AB Background context: Reconstruction of acetabular defect has been advocated as standard procedure in total hip arthroplasty. The presence of bony defects at the acetabulum is viewed as a cause of instability and acetabular wall augmentation is often used without proper consideration of surrounding bone density. The initial cup-bone stability is, however, a challenge and a number of studies supported by clinical follow-ups of patients suggested that if the structural graft needs supporting more than 50% of the acetabular component, a reconstruction cage device spanning ilium to ischium should be preferred to protect the graft and provide structural stability. This study aims to (1) investigate the relationship between cup motion and bone density and (2) quantify the re-distribution of stress at the defect site after augmentation. Hyphotesis: Paprosky type I or II, acetabular defects, when reconstructed with bone screws supported by bioabsorbable calcified triglyceride bone cement are significantly less effective for osteoporotic bone than healthy bone. Materials and methods: Acetabular wall defects were reconstructed on six cadaveric subjects with bioabsorbable calcified triglyceride bone cement using a re-bar technique. Data of the specimen with higher bone density was used to validate a Finite Element Model. Values of bone apparent density ranging from healthy to osteoporotic were simulated to evaluate (1) the cup motion, through both displacement and rotation, (2) and the von Mises stress distribution. Results: Defect reconstruction with bone screws and bioabsorbable calcified triglyceride bone cement results in a re-distribution of stress at the defect site. For a reduction of 65% in bone density, the cup displacement was similar to a healthy bone for loads not exceeding 300 N, as load progressed up to 1500 N, the reconstructed defect showed increase of 99 mu m (128%) in displacement and of 0.08 degrees in rotation angle. Conclusions: Based on the results, we suggest that an alternative solution to wall defect augmentation with bone screws supported by bioabsorbable calcified triglyceride bone cement, be used for osteoporotic bone.

TI Characterization of Bone Perfusion by Dynamic Contrast-Enhanced Magnetic Resonance Imaging and Positron Emission Tomography in the Dunkin-Hartley Guinea Pig Model of Advanced Osteoarthritis
SO JOURNAL OF ORTHOPAEDIC RESEARCH
LA English
DT Article
DE Osteoarthritis; PET; MRI; subchondral bone; perfusion
ID f-18 fluoride-ion; subchondral bone; articular-cartilage; intraosseous pressure; avascular necrosis; blood-flow; pet; hip; histomorphometry; abnormality
AB This study characterizes changes in subchondral bone circulation in OA and examines relationships to bone structure and cartilage degeneration in Dunkin-Hartley guinea pigs. We have used dynamic contrast-enhanced MRI (DCE-MRI) and PET, with pharmacokinetic modeling, to characterize subchondral bone perfusion. Assessments are made of perfusion kinetics and vascular permeability by MRI, and blood volume and flow, and radionuclide incorporation into bone, by PET. These parameters are compared to cartilage lesion severity and bone histomorphometry. Assessments of intraosseous thrombi are made morphologically. Prolonged signal enhancement during the clearance phase of MRI correlated with OA severity and suggested venous stasis. Vascular permeability was not increased indicating that transvascular migration of contrast agent was not responsible for signal enhancement. Intraosseous thrombi were not observed. Decreased perfusion associated with severe OA was confirmed by PET and was associated with reduced radionuclide incorporation and osteoporosis. MRI and PET can be used to characterize kinetic parameters of circulation in OA and correlate them with subchondral bone metabolism of interest to the pathophysiology of OA. The significance of these observations may lie in alterations induced in the expression of cytokines by OA osteoblasts that are related to bone remodeling and cartilage breakdown. TI Bone mineral density distribution in the proximal femur and its relationship to morphologic factors in progressed unilateral hip osteoarthritis
SO JOURNAL OF BONE AND MINERAL METABOLISM
LA English
DT Article
DE Osteoarthritis of the hip; Bone mineral density; Dual energy X-ray absorptiometry
ID femoral-neck; postmenopausal women; fracture risk; osteoporosis; reliability; geometry; men
AB Although an adverse relationship between osteoporosis and osteoarthritis (OA) has been reported, it remains controversial. In most previous reports of OA, bone mineral density (BMD) changes in the subtrochanteric region have not been clarified, whilst BMD of the femoral neck and trochanteric region has been well investigated. In our current study, we investigated the BMD ratio compared to the contralateral side in the whole proximal femurs of hip OA patients. We aimed to clarify the morphologic factor that may influence these BMD ratios. We performed dual energy X-ray absorptiometry (DEXA) analysis of 69 hip joints from unilateral progressed OA cases. The minimum joint space, center edge angle, Sharp angle, acetabular head index, neck-shaft angle, and leg length discrepancy were also measured as radiographic factors. The correlation between BMD ratio and radiographic morphologic factors was then evaluated by logistic regression. The BMD ratio was higher in the femoral neck than in the distal region. In terms of radiographic factors, the neck-shaft angle was revealed to influence the decreased BMD ratio in the distal subtrochanteric part, whilst the leg length discrepancy and Sharp angle showed a relationship with the increased BMD ratio in the proximal neck region. The discrepancy in the BMD ratio between the femoral neck and the distal subtrochanteric region in the proximal femur is influenced by several morphologic factors.

TI Impact of Dietary Habits and Physical Activity on Bone Health among 40 to 60 Year Old Females at Risk of Osteoporosis in India
SO ECOLOGY OF FOOD AND NUTRITION
LA English
DT Article
DE risk factors; osteoporosis; BMD
ID hip fracture risk; protein-intake; milk intake; prospective cohort; controlled-trial; mineral density; elderly-people; vitamin-k; metaanalysis; women
AB Osteoporosis is a disorder of bones with increasing risk among women. However, a number of modifiable factors can help in combating this disorder. Present study examined the relationship of diet and physical activity and risk of

osteoporosis through biochemical tests, bone mass density (BMD) scores, and standard questionnaires. Genetic risk for osteoporosis, presence of osteoarthritis, and thyroid problems were found among 8%, 7%, and 3% of participants, respectively; and 78% had onset of menopause between 47 to 55 years of age. Results revealed that less intake of proteins, minerals, and diverse fruit and vegetable consumption was significantly ($p <= 0.05$; 0.01) correlated with decreased BMD score and serum calcium. It was concluded that adequate intake of varied fruits and vegetables, good protein, habit of daily physical activity, adequate sun exposure, and dietary calcium, may play a promising role in decreasing the risk of osteoporosis among women of this age group.

TI Factors affecting bone mineral density in postmenopausal women
SO ARCHIVES OF OSTEOPOROSIS
LA English
DT Article
DE Bone mineral density; Postmenopausal; Menopause; Obesity; Physical activity; Education; Parity
ID body-mass index; risk-factors; physical-activity; osteoporotic fractures; knee osteoarthritis; metabolic syndrome; elderly-men; prevalence; association; parity
AB This study aimed to determine the relationship between bone mineral density (BMD) and demographic, biochemical, and clinical features according to BMD

measurement sites. The results indicated that BMD correlates negatively with menopause duration, parity, and history of fractures but positively correlates with obesity, physical activity, education, and serum ferritin. Purpose/Introduction Osteoporosis (OP) is an important cause of morbidity and mortality in the elderly people. The impacts of various factors on bone mineral density (BMD) differ across diverse population. We hypothesized that the influences of factors which affect BMD vary according to BMD measurement sites. The aim of this study was to determine the relationship between BMD in the femoral neck (FN) and lumbar spine (LS) with some common clinical, demographic, and biochemical parameters in postmenopausal women. Methods In this cross-sectional case-control study, all postmenopausal women of the Amirkola Health and Ageing Project (AHAP) who performed bone densitometry were included. BMD at FN and LS was measured by DXA method. Data regarding clinical, demographic, and biochemical characteristics were provided. OP was diagnosed by the International Society for Clinical Densitometry criteria. Pearson correlation and multivariate regression analyses with simultaneous adjustment were performed to determine relationship. Results Five hundred thirty-seven women with mean age of 67.9 +/- 6.7 years and mean menopause duration (MD) of 15.8 +/- 5.1 years were studied. MD correlated negatively with FNBMD and LS-BMD g/cm(2) (r=-0.405, p=0.001 and r=-0.217, p=0.001). Body mass index (BMI) correlated positively with FN and LS-BMD g/cm(2) (r=0.397, p=0.001 and r=0.311, p=0.001). The association of MD with risk of FN-OP was stronger than LS-OP. Obesity and metabolic syndrome (MS) and higher serum ferritin reduced the risk of OP at both LS and FN similarly, whereas the impacts of parity, prior fracture, high level of education, and physical activity were significantly different across BMD measurement sites. Conclusion The results of this study indicated a significant association between OP and MD, obesity, parity, MS, history of fracture, serum ferritin, level of education, and physical activity. However, the direction and the strength of association varied across BMD measurement sites.

AB Osteoarthritis (OA) is a heterogeneous disorder. The goals of this review are (1) To stimulate use of standardized nomenclature for OA that could serve as building blocks for describing OA and defining OA phenotypes, in short to provide unifying disease concepts for a heterogeneous disorder; and (2) To stimulate establishment of ROAD (Risk of OA Development) and ROAP (Risk of OA Progression) tools analogous to the FRAX (TM) instrument for predicting risk of fracture in osteoporosis; and (3) To stimulate formulation of tools for identifying disease in its early preradiographic and/or molecular stages - REDI (Reliable Early Disease Identification). Consensus around more sensitive and specific diagnostic criteria for OA could spur development of disease modifying therapies for this entity that has proved so recalcitrant to date. We fully acknowledge that as we move forward, we expect to develop more sophisticated definitions, terminology and tools. (C) 2015 Osteoarthritis Research Society International. ID quantitative trait loci; single-nucleotide polymorphism; guidance molecule rgma; mineral density; knee osteoarthritis; inbred strains; fractures; resolution; complex; power
AB Background: The microstructure of trabecular bone is a composite trait governed by a complex interaction of multiple genetic determinants. Identifying these genetic factors should significantly improve our ability to predict of osteoporosis and its associated risks. Genetic mapping using collaborative cross mice (CC), a genetically diverse recombinant inbred mouse reference panel, offers a powerful tool to identify causal loci at a resolution under one mega base-pairs, with a relatively small cohort size. Here, we utilized 31 CC lines (160 mice of both sexes in total) to perform genome-wide haplotype mapping across 77,808 single-nucleotide polymorphisms (SNPs). Haplotype scans were refined by imputation with the catalogue of sequence variation segregating in the CC to suggest potential candidate genes. Trabecular traits were obtained following microtomographic analysis, performed on 10-mu m resolution scans of the femoral distal metaphysis. We measured the trabecular bone volume fraction (BV/TV), number (Tb.N), thickness (Tb.Th), and connectivity density (Conn.D). Results:

Heritability of these traits ranged from 0.6 to 0.7. In addition there was a significant (P < 0.01) sex effect in all traits except Tb.Th. Our haplotype scans yielded six quantitative trait loci (QTL) at 1 % false discovery rate; BV/TV and Tb.Th produced two proximal loci each, on chromosome 2 and 7, respectively, and Tb.N and Conn.D yielded one locus on chromosomes 8 and 14, respectively. We identified candidate genes with previously-reported functions in bone biology, and implicated unexpected genes whose function in bone biology has yet to be assigned. Based on the literature, among the genes that ranked particularly high in our analyses (P < 10(-6)) and which have a validated causal role in skeletal biology, are Avp, Oxt, B2m (associated with BV/TV), Cnot7 (with Tb.N), Pcsk6, Rgma (with Tb.Th), Rb1, and Cpb2 (with Conn.D). Other candidate genes strongly suggested by our analyses are Sgcz, Fgf20 (associated with Tb.N), and Chd2 (with Tb.Th). Conclusion: We have demonstrated for the first time genome-wide significant association between several genetic loci and trabecular microstructural parameters for genes with previously reported experimental observations, as well as proposing a role for new candidate genes with no previously characterized skeletal function.

TI The clinical use of vitamin D metabolites and their potential developments: a position statement from the European Society for Clinical and Economic Aspects of Osteoporosis and Osteoarthritis (ESCEO) and the International Osteoporosis Foundation (IOF)
SO ENDOCRINE
LA English
DT Article
DE Calcidiol; Calcifediol; Cholecalciferol; Calcitriol; Alfacalcidol; Eldecalcitol
ID biologically-active metabolite; intestinal calcium-transport; bone-mineral density; serum 25-hydroxyvitamin d; d analog; d supplementation; postmenopausal women; double-blind; oral 25-hydroxycholecalciferol; creatinine clearance
AB Several compounds are produced along the complex pathways of vitamin D-3 metabolism, and synthetic analogs have been generated to improve kinetics and/or vitamin D receptor activation. These metabolites display different chemical properties with respect to the parental or native vitamin D-3, i.e., cholecalciferol, which has been, so far, the supplement most employed in the treatment of vitamin D inadequacy. Hydrophilic properties of vitamin D-3 derivatives facilitate their intestinal absorption and their manageability in the case of intoxication because of the shorter half-life. Calcidiol is a more hydrophilic compound than parental vitamin D-3. Active vitamin D analogs, capable of binding the vitamin D receptor evoking vitamin D-related biological effects, are mandatorily employed in hypoparathyroidism and kidney failure with impaired 1 alpha-hydroxylation. They have been shown to increase BMD, supposedly ameliorating calcium absorption and/or directly affecting bone cells, although their use in these conditions is jeopardized by the development of hypercalciuria and mild hypercalcemia. Further studies are needed to assess their overall safety and effectiveness in the long-term and new intermittent regimens, especially when combined with the most effective

antifracture agents.

TI Effect of C282Y Genotype on Self-Reported Musculoskeletal Complications in Hereditary Hemochromatosis
SO PLOS ONE
LA English
DT Article
ID joint replacement surgery; genetic hemochromatosis; iron-overload; hfe gene; ferritin concentrations; increased risk; bone; arthropathy; osteoarthritis; mutations
AB Objective Arthropathy that mimics osteoarthritis (OA) and osteoporosis (OP) is considered a complication of hereditary hemochromatosis (HH). We have limited data comparing OA and OP prevalence among HH patients with different hemochromatosis type 1 (HFE) genotypes. We investigated the prevalence of OA and OP in patients with HH by C282Y homozygosity and compound heterozygosity (C282Y/H63D) genotype. Methods A total of 306 patients with HH completed a questionnaire. Clinical and demographic characteristics and presence of OA, OP and related complications were compared by genotype, adjusting for age, sex, body mass index (BMI), current smoking and menopausal status. Results In total, 266 of the 306 patients (87%) were homozygous for C282Y, and 40 (13%) were compound heterozygous. The 2 groups did not differ by median age [60 (interquartile range [IQR] 53 to 68) vs. 61 (55 to 67) years, P=0.8], sex (female: 48.8% vs. 37.5%, P=0.18) or current smoking habits (12.4% vs. 10%, P=0.3). As compared with compound heterozygous patients, C282Y homozygous patients had higher median serum ferritin concentration at diagnosis [1090 (IQR 610 to 2210) vs. 603 (362 to 950) mu g/L, P<0.001], higher median transferrin saturation [80% (IQR 66 to 91%) vs. 63% (55 to 72%), P<0.001]) and lower median BMI [24.8 (22.1 to 26.9) vs. 26.2 (23.5 to 30.3) kg/m2, P<0.003]. The overall prevalence of self-reported OA was significantly higher with C282Y homozygosity than compound heterozygosity (53.4% vs. 32.5%; adjusted odds ratio [aOR] 2.4 [95% confidence interval 1.2-5.0]), as was self-reported OP (25.6% vs. 7.5%; aOR 3.5 [1.1-12.1]). Conclusion Patients with C282Y homozygosity may be at increased risk of musculoskeletal complications of HH.

TI Role of Curcumin in Common Musculoskeletal Disorders: a Review of Current Laboratory, Translational, and Clinical Data
SO ORTHOPAEDIC SURGERY
LA English
DT Review
DE Curcumin; Osteoarthritis; Osteoporosis; Sarcoma; Turmeric
ID nf-kb activation; cells in-vitro; matrix-metalloproteinase; articular chondrocytes; rheumatoid-arthritis; receptor activator; ovariectomized rat; signaling pathway; gene-expression; united-states
AB The Indian spice turmeric, in which the active and dominant biomolecule is curcumin, has been demonstrated to have significant medicinal properties, including anti-inflammatory and anti-neoplastic effects. This promise is potentially very applicable to musculoskeletal disorders, which are common causes of physician visits worldwide. Research at the laboratory, translational and clinical levels that supports the use of curcumin for various musculoskeletal disorders, such as osteoarthritis, osteoporosis, musculocartilaginous disorders, and sarcoma is here in comprehensively summarized. Though more phase I-III trials are clearly needed, thus far the existing data show that curcumin can indeed potentially be useful in treatment of the hundreds of millions worldwide who are afflicted by these musculoskeletal disorders.

TI Analysis of the Bone MicroRNome in Osteoporotic Fractures
SO CALCIFIED TISSUE INTERNATIONAL
LA English
DT Article
DE MicroRNA; Epigenetics; Osteoporosis; Fractures; Osteoblasts
ID osteogenic differentiation; epigenetic mechanisms; stem-cells; expression; metaanalysis; genetics; mirnas
AB Osteoporosis causes important morbidity among elderly individuals. Fragility fractures, and especially hip fractures, have a particularly negative impact on the patients' quality of life. The role of epigenetic mechanisms in the pathogenesis of many disorders is increasingly recognized, yet little is known about their role in non-malignant bone disorders such as osteoporosis. The aim of this study was to explore the expression of miRNAs in patients with osteoporotic hip fractures. Trabecular bone samples were obtained from the femoral heads of patients undergoing replacement surgery for osteoporotic hip fractures and non-fracture controls with hip osteoarthritis. Levels of 760 miRNA were analyzed by real-time PCR. Thirteen miRNAs showed nominally significant ($p < 0.05$) differences between both groups. Six miRNAs (miR-187, miR-193a-3p, miR-214, miR518f, miR-636, and miR-210) were selected for the replication stage. These miRNAs were individually analyzed in a larger group of 38 bone samples. At this stage, we confirmed statistically significant differences across groups for mir-187 and miR-518f. The median relative expression levels of miR-187 were 5.3-fold higher in the non-fracture group ($p = 0.002$). On the contrary, miR-518f was preferentially expressed in bones from osteoporotic patients (8.6-fold higher in fractures; $p = 0.046$). In this first hypothesis-free study of the bone microRNome we found two miRNAs, miR-187, and miR-518f, differentially regulated in osteoporotic bone. Further studies are needed to elucidate the mechanisms involved in the association of these miRNAs with fractures.

TI Subchondral bone changes and chondrogenic capacity of progenitor cells from subchondral bone in the collagenase-induced temporomandibular joints

osteoarthritis rabbit model
SO INTERNATIONAL JOURNAL OF CLINICAL AND EXPERIMENTAL PATHOLOGY
LA English
DT Article
DE Subchondral bone; temporomandibular joint; osteoporosis; progenitor cells
ID mesenchymal stem-cells; articular-cartilage; sox9; differentiation; progression; gene
AB Purpose: The goals of this study were to characterize subchondral bone changes, and to determine biological activity characteristics of progenitor cell populations from subchondral bone in the collagenase-induced temporomandibular joint osteoarthritis (TMJOA) rabbit model. Greater understanding of such pathological changes occurring in TMJOA samples is critical in the future treatment modalities regarding cartilage protection and repair. Furthermore, the use of progenitor cell populations in various cartilage regeneration strategies proves to be a fruitful avenue for research and clinical applications. Materials and methods: Bone remodeling and anabolic activity of subchondral bone was evaluated by hematoxylin-eosin (H&E), Alcian blue-periodic acid-Schiff (AB-PAS) staining and immuohistochemical staining. The biological activity characteristics of progenitor cells were assessed by expressions of collagen type II, CD44, SOX-9 and MMP-9 by immunohistochemistry and Western blot analysis. Results: In most of the specimens, cartilage of the digested area displayed a reaction characterized by thickening of the cartilage cellular structure with retraction structure formation in the subchondral bone. Most of the specimens focuses on chondroid metaplasia were observed in the subchondral bone, promoting its remodeling, which could develop to endochondral ossification and increasing subchondral bone size. Meanwhile, immunohistochemistry analysis revealed that CD44 expressions in subchondral bone were most significantly increased in TMJOA at 2 weeks group ($P < 0.01$). And, at 4, 6 and 8 weeks groups, the osteochondral junction had completely disappeared by active subchondral bone remodeling, and collagen type II, CD44, SOX-9 and MMP-9 expressions in active subchondral bone region were significantly increased in TMJOA ($P < 0.05$). In addition, western blot analysis revealed that CD44 expression significantly emerged in subchondral bone region at 2 weeks group ($P < 0.01$). Meanwhile, SOX-9 expression emerged in all group, and the intensity was increased in the experimental groups ($P < 0.05$). Conclusion: Our results suggest that the beneficial activation of progenitor cells and bone marrow stem cells in subchondral bone at early stage of TMJOA played an important role on renovation and remodeling of subchondral bone.

TI Prospective multicenter study of ultrasound-based measurements of fetal head station and position throughout labor
SO ULTRASOUND IN OBSTETRICS & GYNECOLOGY
LA English
DT Article
DE fetal head position; fetal head station; LaborPro; occipitoposterior; ultrasound in labor
ID transvaginal digital examination; occiput posterior position; association
AB Objectives To assess the relationship between fetal head position and head station during labor, as measured using an ultrasound-based system, and the occurrence of occiput posterior (OP) position at delivery. Methods This was an

international prospective observational study including women who delivered between January 2009 and September 2013 in four centers: one in Brooklyn, NY, USA; one in Haifa, Israel; and two in Paris, France. We used an ultrasound-based system (LaborPro) to monitor fetal head station and position non-invasively throughout labor. We collected data on demographics, labor parameters and outcome. Results A total of 595 women were included. In 563 (94.6%) women, fetal head position at delivery was occiput anterior (OA), in 31 (5.2%) it was OP and in one (0.2%) it was occiput transverse. In 89% of pregnancies with intrapartum OP when fetal head station was above -2, the head position turned to OA at delivery; the equivalent figures were 74% and 63% OA at delivery when intrapartum OP was diagnosed at head stations of -2 to < 0, and 0 and below, respectively. Cesarean delivery was performed in 35% of pregnancies with fetal head in OP position at delivery, as opposed to 10% of those with non-OP position at delivery. On retrospective analysis, all deliveries in OP were already in OP at station -2 and below. Conclusions In this first assessment of fetal head position at delivery according to fetal head position at various station levels, our data show that 100% of OP positions at delivery were already in OP position at station -2 and below. We did not observe rotation from a non-OP to an OP position from station -2 and below. Nearly two-thirds of fetuses in OP at station 0 and below will rotate to an OA position for delivery. TI Pulsed electromagnetic fields for postmenopausal osteoporosis and concomitant lumbar osteoarthritis in southwest China using proximal femur bone mineral density as the primary endpoint: study protocol for a randomized controlled trial
SO TRIALS
LA English
DT Article
DE Menopause; Pulsed electromagnetic fields; Osteoporosis; Osteoarthritis
ID double-blind; knee osteoarthritis; indirect costs; expression; metaanalysis; reliability; cartilage; fracture; therapy; health
AB Background: Osteoporosis (OP) and osteoarthritis (OA) are prevalent skeletal disorders among postmenopausal women. Coexistence is common especially that of postmenopausal osteoporosis (PMO) and lumbar OA. An hypothesis has been raised that OP and OA might share the same pathogenic mechanism, and pulsed electromagnetic fields (PEMFs) were reported to have anti-osteoporosis and anti-osteoarthritis properties, but this suggestion was based primarily on biomarker data. Therefore, whether these two effects could take place simultaneously has not yet been investigated. This randomized controlled trial (RCT) is designed to explore the effect of PEMFs for PMO and concomitant lumbar OA. Methods/Design: The study will include PMO patients (postmenopausal women; aged between 50 and 70 years; have been postmenopausal for at least 5 years and diagnosed with OP using proximal femur T-score) with concomitant lumbar OA (patients with confounding disorders like diabetes, hypertension, hyperlipidemia, and previous fracture history, etcetera, will be excluded) will be randomly assigned to two arms: PEMFs group and sham PEMFs group. There will be 25 participants in each arm (50 in total) and the outcome assessment, including the primary endpoint (proximal femur bone mineral density), will be performed at 5 weeks, 3 months and 6 months after enrollment. Discussion: PMO and lumbar OA are prominent public health problem, especially for postmenopausal women. We hope this RCT will provide scientific evidence to primary care of the postmenopausal women regarding the use of these nonpharmaceutical, noninvasive modalities, PEMFs, in managing PMO and lumbar OA.

TI MiRNA profiling of whole trabecular bone: identification of osteoporosis-related changes in MiRNAs in human hip bones
SO BMC MEDICAL GENOMICS
LA English
DT Article
DE Osteoporosis; microRNAs; Osteoblast; Fracture; Epigenetic regulation
ID cells; expression; differentiation; transcription; homeostasis; micrornas; cartilage; disease; mir-483; gene
AB Background: MicroRNAs (miRNAs) are important regulators of gene expression, with documented roles in bone metabolism and osteoporosis, suggesting potential therapeutic targets. Our aim was to identify miRNAs differentially expressed in fractured vs nonfractured bones. Additionally, we performed a miRNA profiling of primary osteoblasts to assess the origin of these differentially expressed miRNAs. Methods: Total RNA was extracted from (a) fresh femoral neck trabecular bone

from women undergoing hip replacement due to either osteoporotic fracture (OP group, n = 6) or osteoarthritis in the absence of osteoporosis (Control group, n = 6), matching the two groups by age and body mass index, and (b) primary osteoblasts obtained from knee replacement due to osteoarthritis (n = 4). Samples were hybridized to a microRNA array containing more than 1900 miRNAs. Principal component analysis (PCA) plots and heat map hierarchical clustering were performed. For comparison of expression levels, the threshold was set at log fold change > 1.5 and a p-value < 0.05 (corrected for multiple testing). Results: Both PCA and heat map analyses showed that the samples clustered according to the presence or absence of fracture. Overall, 790 and 315 different miRNAs were detected in fresh bone samples and in primary osteoblasts, respectively, 293 of which were common to both groups. A subset of 82 miRNAs was differentially expressed (p < 0.05) between osteoporotic and control osteoarthritic samples. The eight miRNAs with the lowest p-values (and for which a validated miRNA qPCR assay was available) were assayed, and two were confirmed: miR-320a and miR-483-5p. Both were over-expressed in the osteoporotic samples and expressed in primary osteoblasts. miR-320a is known to target CTNNB1 and predicted to regulate RUNX2 and LEPR, while miR-483-5p down-regulates IGF2. We observed a reduction trend for this target gene in the osteoporotic bone. Conclusions: We identified two osteoblast miRNAs over-expressed in osteoporotic fractures, which opens novel prospects for research and therapy.

TI CLODRONATE: OLD DRUG, NEW USES
SO JOURNAL OF BIOLOGICAL REGULATORS AND HOMEOSTATIC AGENTS
LA English
DT Article
DE clodronate; osteoarthritis; extra-articular calcifications; aseptic mobilization of prosthesis
ID double-blind; knee; osteoarthritis; osteoporosis; aminobisphosphonates; bisphosphonates; inhibition; cells; women; risk
AB Clodronate (CLO) is a bisphosphonate (BP) with proved efficacy in the treatment of osteoporosis. The reason of its activity is the anti-resorptive action, which is a common characteristic of BPs. Contrary to other BPs, CLO has a relatively low

affinity for bone and a peculiar mechanism of action. CLO is effective in several diseases associated to excessive bone resorption as bone Paget's disease and CRPS type I. Moreover, there are data showing activity of CLO in the erosive osteoarthritis of the hands, in the osteoarthritis of the knees, in the treatment of extra-articular calcifications and in preventing the mobilization of knee and hip prosthesis.

TI Effect of Polycalcium, a mixture of Polycan and calcium lactate-gluconate in a 1:9 weight ratio, on rats with surgery-induced osteoarthritis
SO EXPERIMENTAL AND THERAPEUTIC MEDICINE
LA English
DT Article
DE calcium; osteoarthritis; Mankin score; beta-glucan; rat
ID aureobasidium-pullulans; beta-glucan; rheumatoid-arthritis; keratan sulfate; cartilage; model; mice; inflammation; glycosaminoglycans; osteoporosis
AB In the present study, the beneficial and synergistic effects of Polycalcium, a mixture of Polycan and calcium (Ca) lactate-gluconate in a 1:9 weight ratio, on a rat model of osteoarthritis (OA) were explored. Polycalcium (50, 100 and 200 mg/kg) was administered orally once per day for 28 days from 1 week after the OA-modeling surgery. Diclofenac sodium (2 mg/kg) was administered as a reference drug. Following the OA surgery, increases in the maximum extension angles, edematous changes in knee and capsule thickness, reductions in chondrocyte proliferation and cartilage glycosaminoglycan (GAG) levels, as well as changes in cartilage degeneration were observed. However, these OA-related symptoms were inhibited after 28 days of continuous oral treatment with Polycalcium. Anti-OA effects, including the induction of chondrocyte proliferation, were detected in the Polycalcium-treated rats and were more favorable compared with those in rats treated with Polycan or Ca lactate-gluconate alone (100 mg). Therefore, a mixture of Polycan and Ca lactate-gluconate was demonstrated to have beneficial synergistic effects on OA.

TI Using otolith shape and morphometry to identify four Alburnus species (A. chalcoides, A. escherichii, A. mossulensis and A. tarichi) in Turkish inland waters
SO JOURNAL OF APPLIED ICHTHYOLOGY
LA English
DT Article
ID sagittal otolith; stock discrimination; trachurus-trachurus; horse mackerel; atlantic; identification; fish; morphology; growth; l.
AB Asteriscus otolith shapes as well as their morphometry and shape contours were investigated in order to identify four allopatric Alburnus species: A. chalcoides (Guldenstadt, 1772) (Ordu), A. escherichii Steindachner, 1897 (Eskisehir), A.

mossulensis Heckel, 1843 (Tunceli), and A. tarichi (Guldenstadt, 1814) (Van) in Turkish inland waters. These were compared using the shape indices (form factor, roundness, circularity, ellipticity, rectangularity and aspect ratio), and the morphological characters [otolith weight (OWE), otolith length (OL), otolith width (OW), otolith perimeter (OP), and otolith area (OA)]. The overall canonical discriminant analysis (CDA) classification score was 93.8%, with the lowest score for A. escherichii (82.5%) and the highest for A. chalcoides (100%). The otolith shapes, morphology and shape contours of all sampled fish were a clear species differentiator, thereby demonstrating that the otolith shape is species-specific. The current study presents for the first time comprehensive variation information on interspecific left-right asteriscus otoliths in males and females of each Alburnus species: A. chalcoides from Ordu, A. escherichii from Eskisehir, A. mossulensis from Tunceli and A. tarichi from Van, based on a total of 307 individuals. Scanning electron microscopy (SEM) images, shape contours and other otolith characters vary within the same genus; these differences should be investigated not only in other freshwater fish species or genera but also in the same species living in different habitats. In addition, further investigation is required not only with respect to the morphometry, biometry, shape, geometry, and shape contours of the otoliths, but also regarding the genetic methods for robust identification of various sympatric and allopatric fish populations.

TI Changes in Health-Related Quality of Life After Gastric Bypass in Patients With and Without Obesity-Related Disease
SO OBESITY SURGERY
LA English
DT Article
DE Health-related quality of life; Morbid obesity; Severe obesity; Bariatric surgery; Gastric bypass; Comorbidity; SF-36; OP-scale
ID body-mass index; bariatric surgery; staging system; subjects sos; sf-36; intervention; validity
AB A substantial proportion of severely obese patients undergoing bariatric surgery have not developed disease as a consequence of obesity. Little is known about the effects of bariatric surgery on health-related quality of life (HRQL) in this patient group. In a prospective study at a public hospital, we compared HRQL in gastric bypass patients with and without obesity-related disease before and 2 years after surgery. HRQL was assessed in 232 severely obese patients before, 1 year, and 2 years after Roux-en-Y gastric bypass. We used a general HRQL questionnaire, the Short Form 36, and an obesity-specific questionnaire, the Obesity-related Problems scale. The patients were divided into two groups based on the presence of obesity-related disease (n = 146) or not (n = 86) before surgery. We defined obesity-related disease as having at least one of the following conditions: type 2 diabetes mellitus, hypertension, dyslipidemia, coronary heart disease, obstructive sleep apnea, gastroesophageal reflux disease, or osteoarthritis. Linear mixed models were used to analyze the HRQL outcomes. Before surgery, patients with no obesity-related disease reported equal HRQL compared with patients with obesity-related disease. Two years after gastric bypass, substantial improvements in all subscales of Short Form 36 and in Obesity-related Problems scale were observed in both groups, and the improvements were similar in 7 out of 8 subscales of Short Form 36 as well as for the Obesity-related Problems scale. Baseline HRQL was similar in patients with and without obesity-related disease prior to gastric bypass. After surgery, patients with no comorbidity had similar positive changes in HRQL as patients with one or several comorbidities. These findings indicate that other factors than obesity-related disease are at least as important for severely obese patients' impaired HRQL.

TI Urinary 8-iso-prostaglandin F2 as a marker of metabolic risks in the general Japanese population: The ROAD study
SO OBESITY
LA English
DT Article
ID systemic oxidative stress; low-density-lipoprotein; in-vivo; f-2-isoprostanes; isoprostanes; accumulation; hemoglobin; overweight; biomarkers; adiposity
AB ObjectiveTo determine whether 8-iso-prostaglandin F2 (8-iso-PGF2) is a reliable biomarker of the accumulation of metabolic risks [e.g., overweight, hypertension, impaired glucose tolerance (IGT), and dyslipidemia]. MethodsThis was a cross-sectional study of the baseline characteristics of a Japanese general population cohort study: Research on Osteoarthritis/Osteoporosis Against Disability (ROAD). Of 1,690 participants, 1,527 fulfilled all questionnaires and examinations. Free and conjugated urinary 8-iso-PGF2 levels and metabolic syndrome (MetS) components including blood pressure, HbA1c, total cholesterol, high-density lipoprotein cholesterol (HDL-C), and non-HDL-C were analyzed. The data were analyzed by ANCOVA, multiple regression analysis, and multinomial logistic analysis. Results8-iso-PGF2 was significantly associated with HbA1c and significantly inversely associated with total cholesterol and non-HDL-C. Notably, IGT with an HbA1c cut-off of 5.5% was significantly associated with 8-iso-PGF2 level in participants aged 50 years. Multinomial logistic regression analysis revealed 8-iso-PGF2 level was significantly associated with a greater number of MetS risks present; this association was stronger in younger participants. In participants aged 71 years, 8-iso-PGF2 was significantly associated with a greater number of MetS risks with higher IGT cut-offs. ConclusionsUrinary 8-iso-PGF2 can be a reliable marker of IGT and the accumulation of MetS risks, especially in younger people.

TI How Important Is Mode of Administration in Treatments for Rheumatic Diseases and Related Conditions?
SO CURRENT RHEUMATOLOGY REPORTS
LA English
DT Article
DE Economics; Quality of life; Mode of administration
ID willingness-to-pay; osteoporosis drug-treatment; treatment preferences; patient preferences; health-care; choice; adherence; arthritis; osteoarthritis; risk
AB Many new drugs do not offer clinical benefits over existing treatments but provide potentially more convenient modes of administration. These include how frequently a treatment is given, how it is delivered, who gives the treatment, and whether there are any associated local adverse reactions. We reviewed studies in rheumatology that ask patients and society the value they assign to these aspects of treatment in comparison to the benefits and side effects and costs. We find that mode of administration is generally valued by both patients and society, but the extent depends on the context of the disease and the study participants. Respondents with a more severe disease seem to assign less value to mode and frequency of administration, and prioritize improvement in pain and function. However, patients with chronic, but less severe, disease seem to place greater value on mode of administration. Furthermore, respondents with experience of the treatments perceived to be more inconvenient assigned lower value to more

convenient treatments. Unfortunately, we found few examples of studies that reported values in a format that could easily be incorporated into resource allocation decisions by payers.

TI Turning Bone Morphogenetic Protein 2 (BMP2) on and off in Mesenchymal Cells
SO JOURNAL OF CELLULAR BIOCHEMISTRY
LA English
DT Article
DE GENE REGULATION; TRANSCRIPTION; POST-TRANSCRIPTIONAL; MESENCHYMAl CELL; GROWTH FACTOR; MORPHOGEN; CALCIFICATION
ID in-vivo; osteoblast differentiation; regulatory elements; gene-transcription; signaling pathway; expression; wnt; stimulation; region; rna
AB The concentration, location, and timing of bone morphogenetic protein 2 (BMP2, HGNC:1069, GeneID: 650) gene expression must be precisely regulated. Abnormal BMP2 levels cause congenital anomalies and diseases involving the mesenchymal cells that differentiate into muscle, fat, cartilage, and bone. The molecules and conditions that influence BMP2 synthesis are diverse. Understandably, complex mechanisms control Bmp2 gene expression. This review includes a compilation of agents and conditions that can induce Bmp2. The currently known trans-regulatory factors and cis-regulatory elements that modulate Bmp2 expression are summarized and discussed. Bone morphogenetic protein 2 (BMP2, HGNC:1069, GeneID: 650) is a classical morphogen; a molecule that acts at a distance and whose concentration influences cell behavior. In mesenchymal cells, the concentration of BMP2 influences myogenesis, adipogenesis, chondrogenesis, and osteogenesis. Because the amount, timing, and location of BMP2 synthesis influence the allocation of cells to muscle, fat, cartilage, and bone, the mechanisms that regulate the Bmp2 gene are crucial. Key early mesodermal events that require precise Bmp2 regulation include heart specification and morphogenesis. Originally named for its osteoinductive properties, healing fractures requires BMP2. The human Bmp2 gene also has been linked to osteoporosis and osteoarthritis. In addition, all forms of pathological calcification in the vasculature and in cardiac valves involve the pro-osteogenic BMP2. The diverse tissues, mechanisms, and diseases influenced by BMP2 are too numerous to list here (see OMIM: 112261). However, in all BMP2-influenced pathologies, changes in the behavior and differentiation of pluripotent mesenchymal cells are a recurring theme. Consequently, much effort has been devoted to identifying the molecules and conditions that influence BMP2 synthesis and the complex mechanisms that control Bmp2 gene expression. This review begins with an overview of the Bmp2 gene's chromosomal neighborhood and then summarizes and evaluates known

regulatory mechanisms and inducers. J. Cell. Biochem. 116: 2127-2138, 2015. (c) 2015 Wiley Periodicals, Inc.

TI Trabecular bone score (TBS) as a new complementary approach for osteoporosis evaluation in clinical practice
SO BONE
LA English
DT Review
DE Osteoporosis; Epidemiology; Trabecular bone score (TBS); Fragility fracture; Bone mineral density; FRAX
ID finite-element-analysis; mineral density bmd; in-vivo measurement; postmenopausal women; lumbar spine; vertebral fracture; risk-factors; microarchitectural texture; white women; men
AB Trabecular bone score (TBS) is a recently-developed analytical tool that performs novel grey-level texture measurements on lumbar spine dual X-ray absorptiometry (DXA) images, and thereby captures information relating to trabecular microarchitecture. In order for TBS to usefully add to bone mineral density (BMD) and clinical risk factors in osteoporosis risk stratification, it must be independently associated with fracture risk, readily obtainable, and ideally, present a risk which is amenable to osteoporosis treatment. This paper summarizes a review of the scientific literature performed by a Working Group of the European Society for Clinical and Economic Aspects of Osteoporosis and Osteoarthritis. Low TBS is consistently associated with an increase in both prevalent and incident fractures that is partly independent of both clinical risk factors and areal BMD (aBMD) at the lumbar spine and proximal femur. More recently, TBS has been shown to have predictive value for fracture independent of fracture probabilities using the FRAX (R) algorithm. Although TBS changes with osteoporosis treatment, the magnitude is less than that of aBMD of the spine, and it is not clear how change in TBS relates to fracture risk reduction. TBS may also have a role in the assessment of fracture risk in some causes of secondary osteoporosis (e.g., diabetes, hyperparathyroidism and glucocorticoid-induced osteoporosis). In conclusion, there is a role for TBS in fracture risk assessment in combination with both aBMD and FRAX. (C) 2015 Elsevier Inc. All rights reserved.

AB Objective: To evaluate the prevalence of osteoporosis in patients awaiting total hip arthroplasty. Method: Twenty-nine patients diagnosed with hip osteoarthritis awaiting primary total arthroplasty of the hip answered WOMAC questionnaire, VAS and questions about habits, osteoporosis and related diseases. Bone mineral densitometry of the lumbar spine and hips and laboratory tests (complete blood count and examination of calcium metabolism) were performed. Weight and height were measured to calculate body mass index (BMI). The evaluated quantitative characteristics were compared between patients with and without osteoporosis using the Mann-Whitney tests. Results: Thirteen men and 16 women with a mean age of 61.5 years old, WOMAC 51.4; EVA 6.4 and BMI 27.6 were evaluated. The prevalence of osteoporosis was 20.7%, and 37.9% had osteopenia. Patients with osteoporosis were older than patients without osteoporosis (p=0.006). The mean bone mineral density of the femoral neck without hip osteoarthritis was lower than the affected side (p=0.007). Thirty-five percent of patients did not know what osteoporosis is. Of these, 30% had osteopenia or osteoporosis. Conclusion: osteoarthritis and osteoporosis may coexist and the population waiting for total hip arthroplasty should be considered at risk for the presence of osteoporosis.

TI Response of Osteoblasts to the Stimulus of Fluid Flow
SO CRITICAL REVIEWS IN EUKARYOTIC GENE EXPRESSION
LA English
DT Article
DE osteoblast; biomechanical response; fluid flow; stimulus; bone disease
ID bone morphogenetic protein-2; mesenchymal stem-cells; necrosis-factor-alpha; marrow stromal cells; human osteoarthritic osteoblasts; alkaline-phosphatase activity; fas-mediated apoptosis; growth-factor-beta; formation in-vitro; kappa-b ligand
AB Bone is an important porous tissue that supports the body, maintains calcium and phosphate homeostasis, protects vital organs, and houses bone marrow. The interaction between hydrostatic pressure and fluid phase, solid phase, cells, and vascular in bone makes bone inevitably bear baseline levels of fluid flow. Fluid flow plays an important role in regulating the proliferation, differentiation, distribution, and apoptosis of osteoblasts in bone. The effect of fluid flow on osteoblasts is dependent on time, velocity, and type. Some response of osteoblasts to fluid flow is closely related to the soluble factors secreted by the osteoblasts themselves or other types of bone cells. When the response is disordered, related bone diseases such as osteoporosis, osteoarthritis, and abnormal osteogenesis probably happen. In this article we review the current progress in the study of the response of osteoblasts to the direct and indirect stimulus of fluid flow and their roles in osteogenesis and related bone diseases.

TI Red Yeast Rice Plus Berberine: Practical Strategy for Promoting Vascular and Metabolic Health
SO ALTERNATIVE THERAPIES IN HEALTH AND MEDICINE
LA English
DT Review
ID activated protein-kinase; coronary secondary prevention;

congestive-heart-failure; fatty liver-disease; cancer incidence; cardiovascular-disease; cell-proliferation; insulin-resistance; messenger-rna; beta-blockers
AB Lovastatin, the progenitor of the statin family, is in fact a naturally occurring compound produced by the yeast Monascus purpureus. Red yeast rice (RYR), a traditional Chinese food made by fermenting rice with M purpureus, is an herbal medicine that has been used for 1200 y as a therapy for problems related to circulation and digestion. RYR contains a range of compounds known as monacolins, of which monacolin K-renamed lovastatin by pharmaceutical researchers-was found to be the most potent inhibitor of cholesterol synthesis. Standardized extracts of RYR, providing 10 mg of monacolins daily, have been shown to lower elevated low-density lipoprotein (LDL) cholesterol by approximately 20%. In a large secondary prevention trial in China, RYR was found to be markedly protective with respect to cardiovascular events and total mortality. Yet RYR very rarely induces the myopathy and hepatic damage commonly seen with prescription statin therapy. The Chinese herbal compound berberine, used to treat diabetes and congestive heart failure in China, has been shown to increase hepatic expression of LDL receptors and, hence, to lower LDL cholesterol, by extending the half-life of LDL receptor messenger ribonucleic acid (mRNA). This effect is complementary to the increased transcription of this mRNA promoted by statin therapy. Because berberine is well tolerated aside from transient gastrointestinal (GI) upset in some people and, in particular, has not been reported to cause myopathy or hepatic damage, the combination of RYR and berberine may have the potential to achieve reductions in LDL cholesterol comparable with those achieved with prescription statin therapy, but without the associated risks such as muscle damage and diabetes. Moreover, berberine, via its ability to activate adenosine monophosphate-activated kinase (AMPK), which it shares with the drug metformin, can lower triglycerides, improve metabolic syndrome, aid glycemic control in diabetics, and act directly on the vasculature to promote vascular health. It may also have the potential to reduce risk for various cancers, osteoporosis, osteoarthritis, nonalcoholic fatty-liver disease, and neurodegenerative disorders, although such predictions are highly speculative. Whereas statin therapy modestly increases risk for type 2 diabetes, berberine likely has the opposite effect. These considerations suggest that combined administration of RYR and berberine may provide a broader range of health protection than is afforded by prescription statin therapy, with lower risks for serious adverse effects compared with statins. Randomized, controlled trials (RCTs) assessing the effect of optimal intakes of RYR and berberine on serum lipids and other vascular risk factors are needed.

TI Strontium ranelate analgesia in arthritis models is associated to decreased cytokine release and opioid-dependent mechanisms
SO INFLAMMATION RESEARCH
LA English
DT Article
DE Arthritis; Cytokines; Zymosan; Pain; Strontium ranelate
ID experimental osteoarthritis; bone-resorption; pain; osteoporosis; morphine; receptor; cells; women; risk
AB Objective We investigated the anti-inflammatory activity of strontium ranelate (SR) in arthritis models. Materials and methods Rats received 1 mg zymosan (Zy) or saline intra-articularly. Other groups were subjected to anterior cruciate ligament transection in the right knee, as an osteoarthritis (OA) model, or a sham procedure. Joint pain was assessed using the articular incapacitation and paw-pressure tests. Cell influx and cytokines were measured in joint exudates. Treatment Groups received either SR (30-300 mg/kg per os) or saline. Results SR dose-dependently and significantly inhibited joint pain in both Zy and OA models, while not altering cell influx. Naloxone administration significantly reversed SR analgesia. SR

significantly reduced levels of Interleukin-1 beta and tumor necrosis factor-alpha in Zy arthritis, whereas those of cytokine-induced neutrophil chemoattractant (CINC)-1 were not altered. Conclusions SR provides analgesia in arthritis that is associated to inhibition of the release of inflammatory cytokines into inflamed joints. This effect is abrogated by administration of the opioid antagonist naloxone.

DT Article
DE Arthroplasty, replacement, hip; Osteoarthritis, hip; Aged; Quality of life; Health of the elderly
ID joint replacement; decision-making; heart-failure; outcm; knee; responsiveness; osteoporosis; fractures; arthritis; recovery
AB CONTEXT AND OBJECTIVES: Quality-of-life results have increasingly been evaluated among patients undergoing joint replacements. The objective of this study was to compare two assessment instruments for health-related quality of life (one generic and the other specific), among elderly patients undergoing total hip arthroplasty. DESIGN AND SETTING: Cross-sectional descriptive study in a reference hospital in the region of Campinas. METHODS: The subjects were 88 elderly outpatients aged 60 years or over who underwent primary total hip arthroplasty. Two instruments for assessing health-related quality of life were applied: the generic Medical Study 36-item Short-Form Health Survey (SF-36) and the specific Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC). Cronbach's alpha and the ceiling and floor effects of the instruments were evaluated. RESULTS: The scores from both instruments showed that issues of a physical nature affected these elderly people's quality of life most. The pain and stiffness dimensions of WOMAC showed ceiling effects and only the functional capacity and pain dimensions of the SF-36 did not show the ceiling effect. The SF-36 presented floor effects in the dimensions of physical and emotional aspects. Cronbach's alpha was considered satisfactory in both instruments (alpha > 0.70). CONCLUSIONS: The floor and ceiling effects that were observed suggest that these instruments may present some limitations in detecting changes to the majority of the SF-36 dimensions, except for functional capacity and pain, and to the pain and stiffness dimensions of WOMAC, when applied to elderly people with total hip arthroplasty.

TI OSTEOBLASTS WITH IMPAIRED SPREADING CAPACITY BENEFIT FROM THE POSITIVE CHARGES OF PLASMA POLYMERISED ALLYLAMINE
SO EUROPEAN CELLS & MATERIALS
LA English
DT Article
DE Osteoblast function; actin cytoskeleton; vinculin; spreading; cytochalasin D; titanium; surface modification; plasma polymerised allylamine; surface charge
ID titanium surfaces; focal adhesion; cell-adhesion; in-vitro; subchondral bone; actin; osteoarthritis; osteoporosis; mg-63; organization
AB Bone diseases such as osteoporosis, osteoarthritis and rheumatoid arthritis, impinge on the performance of orthopaedic implants by impairing bone regeneration. For this reason, the development of effective surface modifications supporting the ingrowth of implants in morbid bone tissue is essential. Our study is designed to elucidate if cells with restricted cell-function limiting adhesion processes benefit from plasma polymer deposition on titanium. We used the actin filament disrupting agent cytochalasin D (CD) as an experimental model for cells with impaired actin cytoskeleton. Indeed, the cell's capacity to adhere and spread was drastically reduced due to shortened actin filaments and vinculin contacts that were smaller. The coating of titanium with a positively charged nanolayer of plasma polymerised allylamine (PPAAm) abrogated these disadvantages in cell adhesion and the CD-treated osteoblasts were able to spread significantly. Interestingly, PPAAm increased spreading by causing enhanced vinculin number and contact length, but without significantly reorganising actin filaments. PPAAm with the monomer allylamine was deposited in a microwave-excited low-pressure plasma-processing reactor. Cell physiology was monitored by flow cytometry and confocal laser scanning microscopy, and the length and number of actin filaments was quantified by mathematical image processing. We showed that biomaterial

surface modification with PPAAm could be beneficial even for osteoblasts with impaired cytoskeleton components. These insights into in vitro conditions may be used for the evaluation of future strategies to design implants for morbid bone tissue.

TI Elastic Properties of Human Osteon and Osteonal Lamella Computed by a Bidirectional Micromechanical Model and Validated by Nanoindentation
SO JOURNAL OF BIOMECHANICAL ENGINEERING-TRANSACTIONS OF THE ASME
LA English
DT Article
DE cortical bone; osteon; lamella; micromechanics; elastic constants; nanoindentation
ID mineralized collagen fibrils; human cortical bone; indentation modulus; compact-bone; orientation; constants; yield; prediction; stiffness
AB Knowledge of the anisotropic elastic properties of osteon and osteonal lamellae provides a better understanding of various pathophysiological conditions, such as aging, osteoporosis, osteoarthritis, and other degenerative diseases. For this reason, it is important to investigate and understand the elasticity of cortical bone. We created a bidirectional micromechanical model based on inverse homogenization for predicting the elastic properties of osteon and osteonal lamellae of cortical bone. The shape, the dimensions, and the curvature of osteon and osteonal lamellae are described by appropriately chosen curvilinear coordinate systems, so that the model operates close to the real morphology of these bone components. The model was used to calculate nine orthotropic elastic constants of osteonal lamellae. The input values have the elastic properties of a single osteon. We also expressed the dependence of the elastic properties of the lamellae on the angle of orientation. To validate the model, we performed nanoindentation tests on several osteonal lamellae. We compared the experimental results with the calculated results, and there was good agreement between them. The inverted model was used to calculate the elastic properties of a single osteon, where the

input values are the elastic constants of osteonal lamellae. These calculations reveal that the model can be used in both directions of homogenization, i.e., direct homogenization and also inverse homogenization. The model described here can provide either the unknown elastic properties of a single lamella from the known elastic properties at the level of a single osteon, or the unknown elastic properties of a single osteon from the known elastic properties at the level of a single lamella.

TI Variation in the PTH2R gene is associated with age-related degenerative changes in the lumbar spine
SO JOURNAL OF BONE AND MINERAL METABOLISM
LA English
DT Article
DE Genetic; Polymorphism; PTH2R; Degenerative changes; Spine
ID bone-mineral density; elderly-women; parathyroid-hormone; follow-up; fracture; osteoporosis; osteoarthritis; intermittent; pthr1; risk
AB In the elderly, degenerative changes in the lumbar spine are common, contributing to falsely elevated bone mineral density (BMD) values. The parathyroid hormone (PTH) system plays an important role in the regulation of bone turnover and we explore the hypothesis that polymorphisms (SNPs) within genes in this pathway (PTH, PTHLH, PTH1R and PTH2R) contribute to degenerative manifestations of the spine in elderly women. The study included 1,004 Swedish women aged 75 years from the population-based OPRA cohort who attended follow-up at 5 and 10 years. Lumbar spine BMD was assessed by dual energy X-ray absorptiometry (DXA) and each individual vertebra was evaluated visually on the

DXA image for apparent degenerative manifestations. Six SNPs in PTH and 3 SNPs each in PTH1R, PTH2R and PTHLH were analysed. Among women with degenerative manifestations at the lumbar spine, there was an over-representation at baseline of those carrying the PTH2R SNP rs897083 A-allele (p = 0.0021; odds ratio 1.5 95 % CI 1.2-2.0) and across the duration of follow-up (p = 0.0008). No association was observed between degenerative manifestations and variation in the other genes. None of the PTH hormone system genes were associated with vertebral fracture. Variation in the PTH2R gene (Chr2q34, rs897083) may contribute to the age-associated degenerative manifestations that develop at the lumbar spine.

TI Calcitonin suppresses intervertebral disk degeneration and preserves lumbar vertebral bone mineral density and bone strength in ovariectomized rats
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE Biomechanics; Intervertebral disk degeneration; Micro-computed tomography; Osteopenia; Salmon calcitonin
ID low-back-pain; postmenopausal women; salmon-calcitonin; grading system; matrix; osteoarthritis; expression; osteoporosis; chondrocytes; degradation
AB We investigated the effect of calcitonin (CT) on lumbar intervertebral disk degeneration (LIDD) in rats with ovariectomy-induced osteopenia. CT protected ovariectomized rats from LIDD by, at least in part, modifying extracellular matrix metabolism of the disks and preserving the microarchitecture and biomechanical properties of adjacent vertebrae. Introduction The present study aimed to investigate the effect of CT on lumbar vertebral bone mineral density and intervertebral disk degeneration in ovariectomized (OVX) rats. Methods We first subjected 50 3-month-old female rats to either OVX (n = 30) or sham (n = 20).

Twelve weeks later, ten OVX and ten sham rats were necropsied. The remaining OVX rats began to receive either saline vehicle (OVX + V, n = 10), or salmon CT (OVX + CT, 16 IU/kg/2 days, n = 10). After 12 weeks of treatment, necropsy was conducted and bone mineral density was determined in L3-4 and L5-6 vertebrae. The microstructure and biomechanical properties of L3 vertebrae were detected by micro-computed tomography and compression test, respectively. L5-6 was also used to measure intervertebral disk height and observe intervertebral disk histological changes by Van Gieson staining and histological scores, as well as immunohistochemistry (IHC) analysis of matrix metalloprotease (MMP)-1, MMP-13, and collagen II expression. Results At 12 weeks post-OVX, OVX rats had lower BV/TV and Tb.N and higher intervertebral disk histological score than sham rats. After 24 weeks, OVX + CT rats had higher BMD, BV/TV, Tb.N, and bone biomechanical strength values than OVX + V rats. Histological analysis showed OVX + CT rats had significantly lower disk degeneration scores than OVX + V rats. IHC analysis revealed CT treatment decreased expression of MMP-1 and MMP-13 and increased expression of collagen II compared with OVX + V rats. Conclusions Our data demonstrate that CT-treated OVX rats display less intervertebral disk degeneration and favorable changes in intervertebral disk metabolism, associated with higher trabecular bone mass, better trabecular microarchitecture, and better biomechanical strength when compared to vehicle-treated OVX rats.

TI Chronic Pain, Comorbid Medical Conditions, and Associated Risk Factors in Kuwait: Gender and Nationality Differences
SO PAIN MEDICINE
LA English
DT Article
DE Chronic Pain; Medical Comorbidities; Gender Differences; Kuwait; Rehabilitation; Health Behavior
ID low-back-pain; prevalence; health; epidemiology; population; country; diseases; children; obesity; burden
AB Objective. Chronic pain is an international health problem that imposes enormous costs on societies around the world. There is good reason to suspect that chronic pain is a serious health issue in Kuwait and is associated with comorbid

medical conditions like diabetes. The aim of this study is to examine the report of pain and incidence of medical comorbidities among a large convenience sample of patients treated at a private rehabilitation center in Kuwait and to examine differences in patient groups based on age, gender, and Kuwaiti nationality. Methods. This study examined intake data from 2,103 patients treated at a rehabilitation center in Kuwait. Most of the subjects were female (55.4%) and averaged 43.3 years of age (+/- 14.5, range 18- 88). Sixty nine percent were Kuwaiti citizens and 57.9% were employed. Results. Marked differences in pain and health-related conditions were found between Kuwaiti nationals and non- Kuwaitis, with significantly increased incidences of hypertension, osteoarthritis, diabetes, asthma, osteoporosis, and cardiac and respiratory problems among the Kuwaitis (P < 0.001). Notable gender differences were also identified with women reporting more intense, widespread pain, and reporting more comorbid medical problems compared with men (P < 0.001). Conclusions. This extensive survey study that found female Kuwaitis to have a higher incidence of pain and medical comorbidities than males and non- Kuwaitis highlights the role of cultural factors in contributing to pain and comorbid medical conditions. This information is critical in organizing resources to implement adequate healthcare services and behavioral interventions in Kuwait and other Arab countries to improve pain and health-related conditions.

TI Heparin-binding epidermal growth factor-like growth factor (HB-EGF) is increased in osteoarthritis and regulates chondrocyte catabolic and anabolic activities
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE Cartilage; Growth factors; Metalloproteinases; Integrins; Bone morphogenetic proteins; Chondrocytes
ID human articular chondrocytes; activated protein-kinase; fibronectin fragments; gene-expression; cartilage; mice; stimulation; cells; membrane; mig-6
AB Objective: We determined if the epidermal growth factor receptor ligand HB-EGF is produced in cartilage and if it regulates chondrocyte anabolic or catabolic activity. Methods: HB-EGF expression was measured by quantitative PCR using RNA isolated from mouse knee joint tissues and from normal and osteoarthritis (OA) human chondrocytes. Immunohistochemistry was performed on normal and OA human cartilage and meniscus sections. Cultured chondrocytes were treated with fibronectin fragments (FN-f) as a catabolic stimulus and osteogenic protein 1 (OP-1) as an anabolic stimulus. Effects of HB-EGF on cell signaling were analyzed by immunoblotting of selected signaling proteins. MMP-13 was measured in conditioned media, proteoglycan synthesis was measured by sulfate incorporation, and matrix gene expression by quantitative PCR. Results: HB-EGF expression was increased in 12-month old mice at 8 weeks after surgery to induce OA and increased amounts of HB-EGF were noted in human articular cartilage from OA knees. FN-f stimulated chondrocyte HB-EGF expression and HB-EGF stimulated chondrocyte MMP-13 production. However, HB-EGF was not required for FN-f stimulation of MMP-13 production. HB-EGF activated the ERK

and p38 MAP kinases and stimulated phosphorylation of Smad1 at an inhibitory serine site which was associated with inhibition of OP-1 mediated proteoglycan synthesis and reduced aggrecan (ACAN) but not COL2A1 expression. Conclusion: HB-EGF is a new factor identified in OA cartilage that promotes chondrocyte catabolic activity while inhibiting anabolic activity suggesting it could contribute to the catabolic-anabolic imbalance seen in OA cartilage. TI Extracorporeal shock wave therapy in the treatment of primary bone marrow edema syndrome of the knee: a prospective randomised controlled study
SO BMC MUSCULOSKELETAL DISORDERS
LA English
DT Article
DE Bone marrow edema syndrome; Extracorporeal shock wave therapy; Knee; Conservative treatment; Magnetic resonance imaging
ID necrotic femoral heads; core decompression; transient osteoporosis; osteonecrosis; hip; expression; prostacyclin; rabbits; vegf
AB Background: The aim of this prospective study was to evaluate the effectiveness of extracorporeal shock wave therapy (ESWT) in normalizing the symptoms and imaging features of primary bone marrow edema syndrome (BMES) of the knee. Methods: This study compared the outcomes of ESWT (Group A) (n = 20) and intravenously applied prostacyclin and bisphosphonate (Group B) (n = 20) in the treatment of BMES of the knee in our department between 2011 and 2013. The Visual Analog Scale for pain (VAS, 100 mm), the Western Ontario and McMaster University Osteoarthritis Index (WOMAC), the SF-36 scores and MRI scans as well as plain radiographs were obtained before and after therapy between two groups. Results: Compared with Group B, we found greater improvement in VAS, the WOMAC Osteoarthritis Index and SF-36 score at 1, 3 and 6 months post-treatment in Group A ($P < 0.05$). Furthermore, MRI scans showed a higher incidence of distinct reduction and complete regression of bone marrow edema at 6 months in Group A (95 vs. 65 %; $P = 0.018$). The MRI at 1 year follow-up showed complete regression in all patients in Group A. However, two cases in Group B continued to normalize over the subsequent follow-up period. Conclusions: ESWT can produce

rapid pain relief and functional improvement. It may be an effective, reliable, and non-invasive technique for rapid treatment of BMES of the knee.

TI Risk factors for falls in a longitudinal cohort study of Saudi postmenopausal women: the Center of Excellence for Osteoporosis Research Study
SO MENOPAUSE-THE JOURNAL OF THE NORTH AMERICAN MENOPAUSE SOCIETY
LA English
DT Article
DE Falls; Postmenopausal women; Risk factors
ID population-based cohort; older-adults; vitamin-d; physical performance; vertebral fractures; elderly persons; japanese men; community; prevention; people
AB Objective: This study aims to identify possible risk factors for falls among Saudi postmenopausal women in a population-based study. Methods: Seven hundred seven postmenopausal women aged 50 years or older were followed in a prospective cohort study. Participant demographic characteristics, medical history, lifestyle factors, past-year history of falls, and physical activity (PA) scores were assessed. We recorded single and multiple falls, anthropometric parameters, five special physical performance tests, hormone levels, and bone mineral density measurements. Data on knee osteoarthritis (OA), lumbar spondylosis, and osteopenia were collected. Knee and lower back pain were assessed by interview, and cognition was assessed with Mini-Mental State Examination. Results: During the mean (SD) follow-up of 5.2 (1.3) years, 164 women (23.2%) reported at least one fall, of whom 73 women (10.3%) reported multiple falls. Six independent predictors of all falls were identified: PA score of 12.61 or lower (lowest quartile; odds ratio [OR], 4.10; 95% CI, 1.82-8.90); past-year history of falls (OR, 2.44; 95% CI, 2.30-2.90); age 65 years or older (OR, 2.16; 95% CI, 1.30-3.12); presence of knee OA (OR, 1.56; 95% CI, 1.03-2.34); handgrip strength of 13.88 kg or lower (lowest quartile; OR, 1.33; 95% CI, 1.09-1.64); and 8-ft walk test of 3.94 s or longer (highest quartile; OR, 1.18; 95% CI, 1.07-1.35). Conclusions: Poor PA score, past-year history of falls, age 65 years or older, presence of knee OA, poor handgrip strength, and prolonged time on the 8-ft walk test are risk factors for all falls among Saudi

postmenopausal women.

TI Pseudoachondroplasia and painful sequelae
SO AMERICAN JOURNAL OF MEDICAL GENETICS PART A
LA English
DT Article
DE dwarfism; pseudoachondroplasia; pain; bone fragility; COMP
ID multiple epiphyseal dysplasia; osteoarthritis; mutations; knee
AB Pseudoachondroplasia (PSACH) is a well-described autosomal dominant short limb dwarfing condition caused by mutations in the cartilage oligomeric matrix protein gene (COMP). The most debilitating complication of the disorder is joint pain starting in childhood, the extent and severity of which is poorly defined. The aim of this study was to fully assess the pain and identify additional clinical complications affecting those with PSACH. An online survey was distributed to individuals with PSACH. Of the 77 surveys analyzed, 83% reported chronic pain starting as early as the newborn period. Pain was most frequently reported in weight bearing joints including the knees, hips, and back, and significantly interfered with their overall quality of life. For pain relief, patients with PSACH used a wide variety of treatments. However, patients reported only a 60% resolution of pain with their current treatments. An increase in other comorbidities was not found, specifically osteoporosis was not increased. This study documents for the first time that pain is the most common presenting symptom in PSACH and is often overlooked until short stature becomes obvious. The recognition of chronic pain as one of the earliest manifestations of PSACH is important to allow for prompt diagnosis. (c) 2015 Wiley Periodicals, Inc.

TI Effects of OsteoKing on osteoporotic rabbits
SO MOLECULAR MEDICINE REPORTS
LA English
DT Article
DE micro-computerized tomography; ovariectomy; bone mineral density; osteoporosis; Heng-Gu-Gu-Shang-Yu-He-Ji; OsteoKing
ID bone-mineral density; biochemical markers; postmenopausal women; anabolic therapy; turnover; alendronate; microarchitecture; determinants; biomechanics; healthy
AB Heng-Gu-Gu-Shang-Yu-He-Ji, also known as OsteoKing, is used as a herbal Traditional Chinese Medicine for the treatment of bone disease, including femoral head necrosis and osteoarthritis. However, whether OsteoKing has anti-osteoporotic properties has remained to be elucidated. The purpose of the present study was therefore to investigate the effects of OsteoKing on ovariectomy-induced osteoporosis in rabbits. Female New Zealand white rabbits were randomly divided into an ovariectomized (OVX) group and a sham-surgery group. The rabbits in the OVX group were subjected to an ovariectomy, while the rabbits in the sham group were subjected to the removal of an area of fat near the two ovaries. Bone mineral density, mechanical properties, serum biochemical parameters and micro-architecture were examined at 150 days post-OVX to characterize the experimental animal model. Once the osteoporotic rabbit model had been established, the rabbits in the OVX group were divided into the following groups: Model group, nilestriol group and 300 and 600 mg/kg OsteoKing groups, containing 16 rabbits in each group. OsteoKing and nilestriol were administered orally. The bone mineral density, mechanical properties, serum biochemical parameters, histology and micro-architecture were examined using dual-energy X-ray absorptiometric analysis, mechanical assessments, enzyme-linked

immunosorbent assays, histopathological evaluation and micro-computerized tomography examination following 60 days and 120 days of treatment, respectively. Treatment with OsteoKing led to an elevation in the bone mineral density of the vertebra and serum phosphorus levels, reduced serum concentrations of osteocalcin, procollagen type I N-terminal peptide, tartrate-resistant acid phosphatase 5b and cross-linked N-telopeptide of type I collagen, improved mechanical properties (maximum load, stiffness and energy absorption capacity), and micro-architecture of the lumbar vertebra in the OVX osteoporotic rabbit model following treatment for 120 days. In conclusion, it was demonstrated that OsteoKing is effective in the prevention of estrogen deficiency-associated bone loss and may be a promising drug for the treatment of post-menopausal osteoporosis.

TI Subchondral insufficiency fractures of the knee: review of imaging findings
SO ACTA RADIOLOGICA
LA English
DT Review
DE Joint diseases; bone fractures; knee; magnetic resonance imaging (MRI); osteopenia
ID spontaneous osteonecrosis; femoral-head; transient osteoporosis; diagnosis; lesions; bone; sonk; hip
AB Subchondral insufficiency fracture of the knee (SIFK) is a potentially devastating disorder that may progress rapidly to osteoarthritis with articular surface collapse. It should be suspected in the appropriate clinical setting, as in early stages it is usually indistinct on initial plain radiographs and magnetic resonance imaging is required for a definitive diagnosis. Outcome of SIFK depends on several factors, including the initial subchondral fracture size, patient BMI, degree of osteopenia, as well as early diagnosis and initial treatment. The purpose of this paper is to review the clinical presentation, pathophysiology, image findings, complications and outcome of SIFK.

TI Mutual associations among musculoskeletal diseases and metabolic syndrome components: A 3-year follow-up of the ROAD study
SO MODERN RHEUMATOLOGY
LA English
DT Article
DE Incidence; Knee osteoarthritis; Lumbar spondylosis; Metabolic risk factor; Osteoporosis
ID radiographic knee osteoarthritis; body-mass index; risk-factors; diagnostic-criteria; lumbar spondylosis; diabetes-mellitus; japanese men; progression; fractures; women
AB Objective. This study aimed to assess the mutual associations between musculoskeletal diseases (knee osteoarthritis [KOA], lumbar spondylosis [LS], osteoporosis [OP]) and metabolic syndrome components (obesity [OB], hypertension [HT], dyslipidemia [DL], impaired glucose tolerance [IGT]). Methods. Of the 1,690 participants (596 men, 1,094 women) at baseline, 1,384 individuals (81.9%; 466 men, 918 women) had complete data at the first follow-up in 2008. Logistic regression analysis included the occurrence or nonoccurrence of the musculoskeletal diseases or metabolic components as the outcome variable and the remaining musculoskeletal diseases and metabolic components at baseline as explanatory variables, adjusted for age, sex, residential region, smoking, and alcohol consumption. Results. The risk of KOA occurring increased significantly with HT (odds ratio [OR], 2.57; 95% confidence interval [CI], 1.22-5.42; p = 0.013) and IGT (OR, 1.99; 95% CI, 1.07-3.70; p = 0.029). The risk of OP occurring at the lumbar spine increased with OP at the femoral neck (OR, 4.21; 95% CI 1.46-12.1; p = 0.008), and vice versa (OR, 2.19; 95% CI, 1.01-479; p = 0.047). KOA increased the risk of HT

(Kellgren-Lawrence [KL] grade=0, 1 vs. KL = 2: OR, 1.84; 95% CI, 1.09-3.12; p = 0.024) and DL (KL = 0, 1 vs. KL >= 3: OR, 1.66; 95% CI, 1.05-2.61; p = 0.029) occurring. Reciprocal relationships existed between the presence of metabolic components and the occurrence of the other metabolic components. Conclusion. Mutual relationships existed between the occurrence and presence of musculoskeletal diseases, particularly KOA, and metabolic syndrome components.

TI The effect of osteoarthritis on the regional anatomical variation of subchondral trabecular bone in the femoral head
SO CLINICAL BIOMECHANICS
LA English
DT Article
DE Femoral head; Osteopenetration; Cancellous bone characteristics; Osteoarthritis
ID cancellous bone; mechanical-property; cartilage degeneration; distributions; osteoporosis; knee
AB Background: The subchondral trabecular bone is located deep inside the articular cartilage, with the subcapital region carrying up to 70% of the diurnal loads occurring in the hip joint. This leads to severe regional anatomical variations of subchondral trabecular bone in the femoral head and the purpose of this study was to examine whether osteoarthritis affects these topographic characteristics. Methods: 60 femoral heads were harvested during hip replacement and studied by osteopenetration at 8 pre-defined angles, at a penetration rate of 1 mm/s. Twenty-eight of the donors underwent surgery due to osteoarthritis, whereas the remaining were trauma patients with hip fractures. To correlate these measurements to non-invasive data, all specimens were scanned by micro Computed Tomography (mu CT) prior to experimentation. A cross-sectional area, perpendicular to the needle penetration pathway, was analyzed and the deviations compared to the recorded osteopenetration energy. Findings: The experiments revealed significant topographical deviations in the trabeculae. These were more pronounced in the osteoarthritic samples which also required overall higher osteopenetration energy. A notable dependency of the directional bone strength to its cross-sectional characteristics was observed. Although the effect of "gender" on osteopenetration energy was proven to be significant, gender was not considered an independent variable in a regression model correlating

osteopenetration energy to 20 trabecular bone density as this did not improve the value of the adjusted R-2. Interpretation: The investigation provided refined insight into femoral head load-bearing capacity of patients suffering from osteoarthritis, as a comparison of osteoarthritic to healthy samples illustrated that subchondral trabecular bone in the femoral head region is subjected to increased remodeling and demineralization, reflected in higher osteopenetration values. TI Imaging atlas for eligibility and on-study safety of potential knee adverse events in anti-NGF studies (Part 1)
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE Imaging; Safety; aNGF; Osteoarthritis; Osteonecrosis
ID tibial plateau alignment; bone-marrow lesions; spontaneous osteonecrosis; transient osteoporosis; osteoarthritis; pain; tanezumab; joint; growth; association
AB Monoclonal antibodies that bind and inhibit nerve growth factor (NGF) have demonstrated both, good analgesic efficacy and improvement in function in patients with osteoarthritis (OA). Despite initial promising data, trials in OA had been suspended by the Federal Food and Drug Administration (FDA) due to concerns over accelerated rates of OA progression. Imaging will play a crucial role in future clinical trials to define eligibility of potential participants and to monitor safety during the course of these studies. This will require baseline and frequent follow-up radiographs of both, the index joints and other large weight bearing joints to identify subjects at risk prior inclusion and on study so treatment can be discontinued. This imaging overview in the form of an atlas describes and illustrates potential exclusionary joint imaging findings at eligibility and potential adverse joint events on radiography and magnetic resonance imaging (MRI) in studies investigating a-NGF compounds. The overarching goal of this atlas is to facilitate trial design and to promote a common language and understanding between potential expert readers. This first section of the atlas will focus on knee joint specific findings that are relevant to a-NGF studies. TI Evidence Base of Clinical Studies on Tai Chi: A Bibliometric Analysis
SO PLOS ONE
LA English
DT Article
ID aerobic capacity; elderly-people; exercise; fear
AB Background The safety and health benefits of Tai Chi mind-body exercise has been documented in a large number of clinical studies focused on specific diseases and health conditions. The objective of this systematic review is to more comprehensively summarize the evidence base of clinical studies of Tai Chi for healthcare. Methods and Findings We searched for all types of clinical studies on Tai chi in PubMed, the Cochrane Library and four major Chinese electronic databases from their inception to July 2013. Data were analyzed using SPSS17.0 software. A total of 507 studies published between 1958 and 2013 were identified, including 43 (8.3%) systematic reviews of clinical studies, 255 (50.3%) randomized clinical trials, 90 (17.8%) non-randomized controlled clinical studies, 115 (22.7%) case series and 4 (0.8%) case reports. The top 10 diseases/conditions was hypertension, diabetes, osteoarthritis, osteoporosis or osteopenia, breast cancer, heart failure, chronic obstructive pulmonary disease, coronary heart disease, schizophrenia, and depression. Many healthy participants practiced Tai Chi for the purpose of health promotion or preservation. Yang style Tai Chi was the most popular, and Tai Chi was frequently practiced two to three 1-hour sessions per week for 12 weeks. Tai Chi was used alone in more than half of the studies (58.6%), while in other studies Tai Chi was applied in combination with other therapies including medications, health education and other physical therapies. The majority of studies (94.1%) reported positive effects of Tai Chi, 5.1% studies reported uncertain effects and 0.8% studies reported negative effects. No serious adverse events related to Tai Chi were reported. Conclusions The quantity and evidence base of clinical studies on Tai Chi is substantial. However, there is a wide variation in Tai Chi intervention studied and the reporting of Tai Chi intervention needs to be improved. Further well-designed and reported studies are recommended to

confirm the effects of Tai Chi for the frequently reported diseases/conditions.

TI Effects of BIS076 in a model of osteoarthritis induced by anterior cruciate ligament transection in ovariectomised rats
SO BMC MUSCULOSKELETAL DISORDERS
LA English
DT Article
DE Osteoarthritis; BIS076; Anterior cruciate ligament transection model; Ovariectomised rats
ID bone-mineral density; knee osteoarthritis; subchondral bone; ii collagen; cartilage; inhibition; disease; osteoporosis; degradation; progression
AB Background: Osteoarthritis (OA) is the most frequent articular disease and a leading cause of disability. There is a need for effective treatments able to slow the progression of disease. Some of the available treatments are dietary supplements providing natural components. Recent studies have shown that estrogen deficiency contributes to the pathophysiological events of OA progression. Methods: We have used the anterior cruciate ligament transection model of OA in ovariectomised rats to study the effects of BIS076, a new formulation of a natural porcine cartilage extract associated with hydroxyapatite (as a source of calcium) and vitamin D-3. Cartilage degradation, proteoglycan depletion and synovitis were followed by histochemistry. Effects on bone microstructure were determined by mu CT. The levels of biomarkers in serum and inflammatory mediators in knee homogenates were measured by luminex or ELISA. Results: Oral administration of BIS076 reduced articular cartilage damage and serum levels of cartilage degradation markers C-telopeptide of type II collagen and cartilage oligomeric matrix protein, as well as matrix metalloproteinase-3. The local inflammatory response was down-regulated by BIS076 with lower production of pro-inflammatory cytokines and prostaglandin E-2 in joint tissues. In addition, BIS076 was effective on metaphyseal bone alterations as this formulation increased volumetric bone mineral density and improved bone micro-architecture. These effects were related to the modification of bone metabolism reflected by changes in bone biomarkers with reductions in the ratio receptor activator of nuclear factor.B ligand/osteoprotegerin and the levels of tartrate-resistant acid phosphatase-5b, suggesting an inhibitory activity of BIS076 on trabecular bone resorption. Conclusions: We have demonstrated the protective properties of a new formulation (BIS076) on joint lesion and bone

alterations in an experimental model of OA in ovariectomised rats. This study supports the interest of BIS076 in OA treatments.

TI Pre-operative opioid analgesia reduces clinical success of laparoscopic gastric electrical stimulation placement in patients with gastroparesis
SO SURGICAL ENDOSCOPY AND OTHER INTERVENTIONAL TECHNIQUES
LA English
DT Article
DE Gastric pacemaker; Gastric electrical stimulator (GES); Opioid analgesia; Endoscopy
ID narcotic bowel syndrome; pathophysiology; tolerance
AB Gastroparesis is a common chronic and costly disorder for which medical therapy is often unsuccessful. Gastric electrical stimulation (GES) has been used to treat refractory cases, however, response is variable and difficult to predict. This study aims to assess whether pre-operative opioid analgesics (OA) use affects clinical success of GES. Records of 128 patients who underwent laparoscopic GES placement from March 2001 to September 2012 were analyzed retrospectively. Data collected included demographics, surgical outcomes, and clinical parameters. Pre- and post-operative opioid analgesic dosing (No = 0 morphine equivalents

(ME)/day, Low = 0-40 ME/day, Mid = 41-80 ME/day, High > 80 ME/day), as well as clinical symptom assessment was collected for up to 3 years post-operatively. Clinical success was defined as (1) OA reduction of > 50 %, (2) maintenance of weight, or (3) symptom improvement. Descriptive statistics were computed for all factors. A $p < 0.05$ was considered statistically significant. Fifty-three patients were on OA pre-operatively compared to 69 patients who were not. Patients not on OA pre-operatively were less likely than those on OA pre-op group to be on OA post-operatively ($p = 0.005$); however, there were no differences in weight or symptom improvement. Sub-group analysis of the 53 patients on OA demonstrated significant improvement in clinical symptoms in the low-morphine cohort compared to the mid-morphine cohort ($p = 0.02$), and OA dosing post-operatively in the low-morphine cohort diminished significantly compared to mid- and high-morphine cohort ($p = 0.032$). There was no significant difference in weight. OA dosing pre-operatively significantly affects clinical success of GES placement. Criteria for offering GES implantation may need to take OA dosing into consideration.

TI Trabecular Bone Score: Where are we now?
SO JOINT BONE SPINE

LA English
DT Review
DE Osteoporosis; Fragility fracture; Densitometry; Bone mineral density; Trabecular Bone Score
ID mineral density; lumbar spine; primary hyperparathyroidism; osteoporotic fractures; postmenopausal women; vertebral fractures; caucasian women; white women; tbs; microarchitecture
AB The Trabecular Bone Score is a rather new index obtained at the lumbar spine at the same time as a real bone mineral density. It was developed to reflect bone microarchitecture. It was proposed to be easily used in everyday practice as a surrogate of bone strength. Our aim was to review 1. technical points such as correlations between Trabecular Bone Score and bone microarchitectural parameters, Trabecular Bone Score and bone strength, the effects of dual-energy X-ray absorptiometry image spatial resolution, age, macroarchitecture, body mass index, and osteoarthritis, on Trabecular Bone Score, and 2. evidences to use Trabecular Bone Score for separating individuals with fragility fractures from controls, predicting fragility fractures, and for longitudinally monitoring changes related to treatments. Correlations between Trabecular Bone Score and bone microarchitectural parameters vary widely across bone sites, microarchitectural parameters, and study designs. In vivo, the Trabecular Bone Score explains little of the variance in trabecular microarchitectural parameters. We emphasize that it is a texture parameter. The Trabecular Bone Score is reduced in patients with fragility fracture. Several retrospective and prospective studies have shown its discriminative ability regarding the fracture risk. When combining the areal Bone mineral Density and Trabecular Bone Score, the Trabecular Bone Score remains a predictor of fracture but not the areal Bone Mineral Density. However in prospective studies, the best predictor of fracture remains hip areal bone mineral density. Due to the lack of evidence, we recommend not to use Trabecular Bone Score for following patients treated by anti-osteoporotic drugs. (C) 2015 Societe francaise de rhumatologie. TI Population-based study of the association of osteoporosis and chronic

musculoskeletal pain and locomotive syndrome: the Katashina study
SO JOURNAL OF ORTHOPAEDIC SCIENCE
LA English
DT Article
ID quality-of-life; low-back-pain; quantitative ultrasound; knee osteoarthritis; japanese women; health; disability; prevalence; community; men
AB "Locomotive syndrome", a concept proposed by the Japanese Orthopaedic Association (JOA), refers to risk conditions among the elderly population that may lead to the need for nursing care services. The association between osteoporosis (OP) or chronic musculoskeletal pain (CMSP) and the screening results of locomotive dysfunction identified by the GLFS-25 (a 25-question geriatric locomotive function scale) has not yet been adequately investigated. Two hundred eighty-seven Japanese subjects were evaluated for locomotive dysfunction using the GLFS-25 and were also evaluated for their bone status by a quantitative ultrasound (QUS) assessment of the bone status (i.e., the measurement of the speed of sound (SOS) of the calcaneus). Furthermore, a questionnaire survey concerning CMSP persisting for 3 months or longer was given to those subjects. Statistical analyses were conducted to clarify the association between the bone status or CMSP and the screening results for locomotive dysfunction. The % young adult mean (%YAM) of the SOS was significantly lower among the 43 subjects with locomotive dysfunction identified by the GLFS-25 than in the 244 subjects without locomotive dysfunction ($p < 0.001$). Moreover, low back pain ($p < 0.01$), shoulder pain ($p < 0.05$) and knee pain ($p < 0.001$) were significantly more frequently observed in the 43 subjects with locomotive dysfunction than the 244 subjects without locomotive dysfunction. The screening results of the %YAM of the SOS was significantly associated with the population demonstrating locomotive dysfunction screened by the GLFS-25 based on the age-, gender- and BMI-adjusted analysis (OR 0.95, 95 % CI 0.91-0.98). Furthermore, the %YAM of SOS correlated with the GLFS-25 score (beta = -0.212, p = 0.001). Furthermore, low back pain (OR 2.60, 95 % CI 1.29-5.24), shoulder pain (OR 2.16, 95 % CI 1.00-4.66), and knee pain (OR 2.97, 95 % CI 1.41-6.28) were found to be associated with locomotive dysfunction based on the results of the age-, gender- and a BMI-adjusted analysis. The %YAM of the SOS was associated with the population demonstrating locomotive dysfunction which was identified using the GLFS-25, and the severity of locomotive dysfunction evaluated by the GLFS-25 was found to correlate with the %YAM of the SOS. Furthermore, low back pain, shoulder pain and knee pain were found to be associated with the screening results for locomotive dysfunction by the GLFS-25.

TI Medial Unicondylar Knee Arthroplasty Improves Patellofemoral Congruence: a Possible Mechanistic Explanation for Poor Association Between Patellofemoral

Degeneration and Clinical Outcome
SO JOURNAL OF ARTHROPLASTY
LA English
DT Article
DE unicondylar knee arthroplasty; patellofemoral joint; fixed bearing; congruence; clinical follow-up
ID follow-up; unicompartmental arthroplasty; radiological assessment; osteoarthritis-index; western-ontario; replacement; joint; minimum; subluxation; arthritis
AB The purpose was to determine the effect of medial fixed bearing unicondylar knee arthroplasty (UKA) on postoperative patellofemoral joint (PFJ) congruence and analyze the relationship of preoperative PFJ degeneration on clinical outcome. We retrospectively reviewed 110 patients (113 knees) who underwent medial UKA. Radiographs were evaluated to ascertain PFJ degenerative changes and congruence. Clinical outcomes were assessed preoperatively and postoperatively. The postoperative absolute patellar congruence angle (10.05 +/- 10.28) was significantly improved compared with the preoperative value (14.23 +/- 11.22) (P = 0.0038). No correlation was found between preoperative PFJ congruence or degeneration severity, and WOMAC scores at two-year follow up. Pre-operative PFJ congruence and degenerative changes do not affect UKA clinical outcomes. This finding may be explained by the post-op PFJ congruence improvement. (C) 2015 Elsevier Inc. TI Characteristics of hip fracture patients with and without muscle atrophy/weakness: Predictors of negative economic outcomes
SO JOURNAL OF MEDICAL ECONOMICS
LA English
DT Article
AB Objective: Hip fractures have negative humanistic and economic consequences.

Predictors and sub-groups of negative post-fracture outcomes (high costs and extensive healthcare utilization) were identified in patients with and without muscle atrophy/weakness (MAW). Methods: Truven Health MarketScan data identified patients >= 50 years old with inpatient hospitalizations for hip fracture. Patients had >= 12 months of continuous healthcare insurance prior to and following index hospitalization and no hip fracture diagnoses between 7 days and 1 year prior to admission. Predictors and sub-groups of negative outcomes were identified via multiple logistic regression analyses and classification and regression tree (CART) analyses, respectively. Results: Post-fracture 1-year all-cause healthcare costs (USD$31,430) were higher than costs for the prior year ($18,091; p<0.0001). Patients with MAW had greater post-fracture healthcare utilization and costs than those without MAW (p<0.05). Greater post-fracture costs were associated with a higher number of prior hospitalizations and emergency room visits, length of index hospitalization, Charlson Comorbidity Index (CCI), and discharge status; diagnosis of rheumatoid arthritis, osteoarthritis, or osteoporosis; and prior use of antidepressants, anticonvulsants, muscle relaxants, benzodiazepines, opioids, and oral corticosteroids (all p<0.009). High-cost patient sub-groups included those with MAW and high CCI scores. Conclusions: Negative post-fracture outcomes were associated with MAW vs no MAW, prior hospitalizations, comorbidities, and medications.

TI Protective effect of porcine placenta in a menopausal ovariectomized mouse
SO REPRODUCTION
LA English
DT Article
ID hormone replacement therapy; estrogen-receptor beta; postmenopausal women; cell-proliferation; bone-marrow; in-vitro; l-lysine; differentiation; supplementation; osteoarthritis
AB Menopause is a significant physiological phase that occurs as women's ovaries stop producing ovum and the production of estrogen declines. Human placenta and some amino acids are known to improve menopausal symptoms. In this study, we investigated that porcine placenta extract (PPE) and arginine (Arg), a main amino acid of PPE, would have estrogenic activities in ovariectomized (OVX) mice

as a menopause mouse model, human breast cancer cell line (MCF-7) cells, and human osteoblast cell line (MG-63) cells. PPE or Arg significantly inhibited the body weight and increased the vagina weight compared to the OVX mice. PPE or Arg ameliorated the vaginal atrophy in the OVX mice. The levels of 17 beta-estradiol and the activities of alkaline phosphatase (ALP) were significantly increased by PPE or Arg in the serum of OVX mice. Trabecular bone parameters such as bone mineral density and porosity were also improved by PPE or Arg in the OVX mice. In the MCF-7 and MG-63 cells, PPE or Arg significantly increased the cell proliferation, estrogen receptor beta mRNA expression, and estrogen-response elements luciferase activity. Finally, PPE or Arg increased the activations of ALP and extracellular signal-regulated kinase 1/2 in the MG-63 cells. These results indicate that PPE or Arg would have estrogenic and osteoblastic activity. Therefore, PPE or Arg may be useful as new pharmacological tools for treating menopausal symptoms including osteoporosis.

TI Recommendations for an update of the 2010 European regulatory guideline on clinical investigation of medicinal products used in the treatment of osteoarthritis and reflections about related clinically relevant outcomes: expert consensus statement
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Review
DE Osteoarthritis; Registration of drugs; Guideline
ID nonsteroidal antiinflammatory drugs; patient reported outcm; total joint replacement; slow-acting drugs; double-blind; knee osteoarthritis; glucosamine sulfate; hip osteoarthritis; symptomatic efficacy; hyaluronic-acid
AB Objective: The European Society on Clinical and Economic aspects of Osteoporosis and Osteoarthritis (ESCEO) organised a working group to evaluate the need for updating the current European guideline on clinical investigation of drugs used in the treatment of osteoarthritis (OA). Design: Areas of potential attention were identified and the need for modifications, update or clarification was examined. Proposals were then developed based on literature reviews and through a consensus process. Results: It was agreed that the current guideline overall still reflects the current knowledge in OA, although two possible modifications were identified. The first relates to the number and timing of measurements required as primary endpoints during clinical trials of symptom-relieving drugs, either drugs with rapid onset of action or slow acting drugs. The suggested modifications are intended to take into consideration the

time related clinical need and expected time response to these drugs - i.e., a more early effect for the first category in addition to the maintenance of effect, a more continuous benefit over the long-term for the latter - in the timing of assessments. Secondly, values above which a benefit over placebo should be considered clinically relevant were considered. Based on literature reviews, the most consensual values were determined for primary endpoints of both symptom-relieving drugs (i.e., pain intensity on a visual analogue scale (VAS)) and disease-modifying drugs (i.e., radiographic joint-space narrowing). Conclusions: This working document might be considered by the European regulatory authorities in a future update of the guideline for the registration of drugs in OA. (C) 2015 The Authors. DT Review
DE Bone disease; Mechanotransduction; Osteoarthritis; Osteoporosis; Osteosarcoma; Chondrosarcoma
ID superficial zone protein; cyclic tensile strain; primary cilia; articular-cartilage; mechanical-stress; growth-factor; in-vivo; osteoarthritic cartilage; chondrocyte apoptosis; transcription factors
AB The skeleton is subject to dynamic changes throughout life and bone remodeling is essential for maintenance of bone functionality. The cell populations which predominantly participate in bone and cartilage remodeling, namely osteocytes, osteoblasts, osteodasts and chondrocytes sense and respond to external mechanical signals and via a series of molecular cascades control bone metabolism and turnover rate. The aforementioned process, known as mechanotransduction, is the underlying mechanism that controls bone homeostasis and function. A wide array of cross-talking signaling pathways has been found to play an important role in the preservation of bone and cartilage tissue health. Moreover, alterations in bone mechanotransduction pathways, due to genetic, hormonal and biomechanical factors, are considered responsible for the pathogenesis of bone and cartilage diseases. Extensive research has been conducted and demonstrated that aberrations in mechanotransduction pathways result in disease-like effects, however only few signaling pathways have actually been engaged in the development of bone disease. The aim of the present review is to present these signaling molecules and cascades that have been found to be mechano-responsive and implicated in bone disease development, as revealed by research in the last five years. In addition, the role of these molecules as prognostic or diagnostic disease markers and their potential as therapeutic targets are also discussed. (C) 2015 Elsevier B.V. All rights reserved.

TI Joint space narrowing, body mass index, and knee pain: the ROAD study (OAC1839R1)

SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE Cohort study; Epidemiology; Osteoarthritis; Pain
ID quality-of-life; individual radiographic features; middle-aged women; risk-factors; bone-marrow; osteoarthritis; association; progression; cohort; impact
AB Objective: The objective of the present study was to clarify the association of joint space narrowing with knee pain in Japanese men and women using a large-scale population-based cohort of the Research on Osteoarthritis/osteoporosis Against Disability (ROAD) study. Methods: This study examined the association between minimum joint space width (mJSW) in the medial compartment and pain at the knee. mJSW was measured in the medial and lateral compartments of the knee using a knee osteoarthritis (OA) computer-aided diagnosis system. Results: From the 3040 participants in the ROAD study, the present study analyzed 2733 participants who completed the radiographic examinations and questionnaires regarding knee pain (975 men and 1758 women; mean age, 69.9 +/- 11.2 years). Subjects with lateral knee OA were excluded. After adjustment for age and Body mass index (BMI), medial mJSW, as well as medial mJSW/lateral mJSW, was significantly associated with knee pain. Sex and BMI affected the association of medial mJSW with knee pain. The threshold of medial mJSW was approximately 3 mm in men and 2 mm in women, while that of medial mJSW/lateral mJSW was approximately 60% in both men and women. BMI was found to have a distinct effect on the association of mJSW with pain. Conclusion: The present cross-sectional study using a large-scale population from the ROAD study showed that joint space narrowing had a significant association with knee pain. The thresholds of joint space narrowing for knee pain were also established.

TI Association between serum vitamin D status and health-related quality of life (HRQOL) in an older Korean population with radiographic knee osteoarthritis: data from the Korean national health and nutrition examination survey (2010-2011)
SO HEALTH AND QUALITY OF LIFE OUTCOMES
LA English
DT Article
DE Vitamin D; Quality of life; EQ-VAS; EQ-5D; Osteoarthritis; knee
ID 25-hydroxyvitamin d; d supplementation; d deficiency; physical function; disability; pain; osteoporosis; comorbidity; performance; limitations
AB Background: Vitamin D is important in bone health and its relationship with osteoarthritis has recently been reported. Both vitamin D deficiency and knee osteoarthritis are age dependent and are known to affect quality of life (QOL) in older populations. In this study, we aimed to determine the association between vitamin D status and health-related quality of life (HRQOL) in an older Korean population with knee osteoarthritis. Methods: A total of 2,165 participants aged >= 50 years with radiographic knee osteoarthritis defined as Kellgren-Lawrence (KL) grade >= 2 were selected from data from the 5th Korean National Health and Nutrition Examination Survey (KNHANES V), a representative cross-sectional nationwide survey conducted in 2010-2011. They stratified into two levels by vitamin D status (deficiency < 10 ng/dL and normal >= 10 ng/dL). HRQOL was measured using the EuroQOL visual analogue scale (EQ-VAS) and the five dimensions and summary index of the EuroQOL-5 dimension (EQ-5D). Results: The vitamin D deficiency group was more likely to report problems with mobility, self-care, and usual activities. Vitamin D deficiency was significantly associated with

poor HRQOL indicated by the lowest quartile of EQ-VAS (unadjusted odds ratio [OR] = 1.832, p = 0.006) and the lowest quartile of the EQ-5D index (unadjusted OR = 1.992, p = 0.003). Theses associations of vitamin D status with EQ-VAS and EQ-5D index were maintained after adjustment for age and sex (Model 1: OR = 1.677, p = 0.022 and OR = 1.701, p = 0.021, respectively). The significant associations of vitamin D status with EQ-VAS were maintained after adjustment for other possible covariates (Model 3: OR = 1.562, p = 0.044). Also, a trend of associations between vitamin D status and EQ-5D index were shown after adjustment for other covariates (Model3: OR = 1.681, p = 0.056). Conclusion: This is the first study to reveal that vitamin D status is independently associated with HRQOL in an older Korean population with knee osteoarthritis. Our results suggest that the maintenance of sufficient vitamin D status may be important to prevent QOL decline in older populations with knee osteoarthritis.

TI Commentary on recent therapeutic guidelines for osteoarthritis
SO SEMINARS IN ARTHRITIS AND RHEUMATISM
LA English
DT Review
DE Guidelines; Osteoarthritis treatment; NSAIDs; Hyaluronates; Glucosamine;

Chondroitin sulfate
ID knee osteoarthritis; double-blind; hyaluronic-acid; eular recommendations; oarsi recommendations; glucosamine sulfate; chondroitin sulfate; task-force; placebo; management
AB Background: Despite availability of international evidence-based guidelines for osteoarthritis (OA) management, agreement on the different treatment modalities is lacking. Method: A symposium of European and US OA experts was held within the framework of the Annual European Congress of Rheumatology to discuss and compare guidelines and recommendations for the treatment of knee OA and to reach a consensus for management, particularly for areas in which there is no clear consensus: non-pharmacological therapy; efficacy and safety of analgesics and non-steroidal anti-inflammatory drugs (NSAIDs); intra-articular (i.a.) hyaluronates (HA); and the role of chondroitin sulfate (CS) and/or glucosamine sulfate (GS). Results: All guidelines reviewed agree that knee OA is a progressive disease of the joint whose management requires non-pharmacological and pharmacological approaches. Discrepancies between guidelines are few and mostly reflect heterogeneity of expert panels involved, geographical differences in the availability of pharmacotherapies, and heterogeneity of the studies included. Panels chosen for guideline development should include experts with real clinical experience in drug use and patient management. Implementation of agreed guidelines can be thwarted by drug availability and reimbursement plans, resulting in optimal OA treatment being jeopardized, HA and symptomatic slow-acting drugs for osteoarthritis (SySADOAs) being clear examples of drugs whose availability and prescription can greatly vary geographically. In addition, primary care providers, often responsible for OA management (at least in early disease), may not adhere to clinical care guidelines, particularly for non-pharmacological OA treatment. Conclusion: Harmonization of the recommendations for knee OA treatment is challenging but feasible, as shown by the step-by-step therapeutic algorithm developed by the European Society for Clinical and Economic Aspects of Osteoporosis and Osteoarthritis (ESCEO). More easily disseminated and implemented guidance for OA treatment in the primary care setting is key to improved management of OA. (C) 2015 Elsevier Inc. All rights reserved.

TI Association of microstructural and mechanical properties of cancellous bone and their fracture risk assessment tool scores
SO INTERNATIONAL JOURNAL OF CLINICAL AND EXPERIMENTAL MEDICINE
LA English
DT Article
DE Microstructural; cancellous bone; fracture risk assessment
ID osteoporotic fractures; mineral density; women; microdamage; strength; diagnosis; age; turnover; alcohol; rats
AB This study is to investigate the association between fracture probabilities determined by using the fracture risk assessment tool (FRAX) and the microstructure and mechanical properties of femoral bone trabecula in osteoporosis (OP) and osteoarthritis (OA) patients with hip replacements. By using FRAX, we evaluated fracture risks of the 102 patients with bone replacements. Using micro CT scanning, we obtained the analysis parameters of microstructural properties of cancellous bone. Through morphometric observations, fatigue tests and compression tests, we obtained parameters of mechanical properties of cancellous bones. Relevant Pearson analysis was performed to investigate the association between the fracture probability and the microstructure and mechanical properties of femoral bone trabecula in patients. Fifteen risk factors in

FRAX were compared between OP and OA patients. FRAX hip fracture risk score and major osteoporotic in OP and OA patients were significantly different. FRAX was associated with tissue bone mineral density and volumetric bone mineral density. Our study suggests that the probabilities of major osteoporotic and hip fracture using FRAX is associated with bone mass but not with micro bone quality.

TI Factors affecting changes in the serum levels of 25-hydroxyvitamin D: a 3-year follow-up of the ROAD study
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE 25-Hydroxyvitamin D; Bone mineral density; Nutrition; Population-based cohort study; Risk factors
ID bone-mineral density; vitamin-d inadequacy; postmenopausal women; fracture risk; osteoporosis; calcium; adults; association; deficiency; cohort
AB In this 3-year population-based cohort study, among 1346 subjects, the mean annual change in the serum 25-hydroxyvitamin D levels was 7.6 %/year, which tended to increase during the 3-year period. Multivariate regression analysis indicated that the L2-4 bone mineral density and total daily energy intake were significant independent associated factors. Introduction The aim of this study was to clarify the change rate of the serum levels of 25-hydroxyvitamin D (25D) and the associated factors in a general Japanese population during a 3-year period. Methods The baseline survey of Research on Osteoarthritis/osteoporosis Against Disability study (ROAD), a large-scale population-based cohort study, was performed between 2005 and 2007, and a follow-up survey was repeated 3 years later. Among 1690 participants at baseline, the change rate of the serum 25D levels

were assessed in 1346 individuals (79.6 %; 458 men and 888 women) who completed measurements of 25D at both the baseline and follow-up examinations. The change rate was calculated, and the factors associated with the changes in the 25D levels were determined using multivariate regression analysis after adjustment for age, gender, body mass index, participated month, and regional differences at baseline. Results The mean (standard deviation) change rate of the 25D levels in all subjects was 7.6 (13.3) %/year (men, 8.2 [12.4] %/year; women, 7.3 [13.7] %/year). Multivariate regression analysis indicated that higher bone mineral density at lumbar spine L2-4 ($p = 0.05$) and total daily energy intake ($p = 0.04$) were significantly associated with the change rate of the 25D levels. Conclusions The serum levels of 25D tended to increase over the 3-year period, and higher lumbar bone mineral density and daily energy intake were found to be associated with increases in the 25D levels over time.

TI Is Zolpidem Associated with Increased Risk of Fractures in the Elderly with Sleep Disorders? A Nationwide Case Cross-Over Study in Taiwan
SO PLOS ONE
LA English
DT Article
ID hip-fractures; older-people; benzodiazepine use; insomnia; falls; behaviors; hypnotics; mortality; hospitalization; osteoporosis
AB Background We conducted a study using a case-crossover design to clarify the risk of acute effects of zolpidem and benzodiazepine on all-sites of fractures in the elderly. Design of study Case-crossover design. Methods and Materials Elderly

enrollees (n = 6010) in Taiwan's National Health Insurance Research Database with zolpidem or benzodiazepine use were analyzed for the risk of developing fractures. Results After adjusting for medications such as antipsychotics, antidepressants, and diuretics, or comorbidities such as hypertension, osteoarthritis, osteoporosis, rheumatoid arthritis and depression, neither zolpidem nor benzodiazepine was found to be associated with increased risk in all-sites fractures. Subjects without depression were found to have an increased risk of fractures. Diazepam is the only benzodiazepine with increased risk of fractures after adjusting for medications and comorbidities. Hip and spine were particular sites for increased fracture risk, but following adjustment for comorbidities, the associations were found to be insignificant. Conclusion Neither zolpidem nor benzodiazepine was associated with increased risk of all-site fractures in this case cross-over study after adjusting for medications or comorbidities in elderly individuals with insomnia. Clinicians should balance the benefits and risks for prescribing zolpidem or benzodiazepine in the elderly accordingly.

TI Variability in reference point rnicroindentation and recommendations for testing cortical bone: Location, thickness and orientation heterogeneity
SO JOURNAL OF THE MECHANICAL BEHAVIOR OF BIOMEDICAL MATERIALS
LA English
DT Article
DE Microindentation; Reference point indentation; Bone quality; Homogeneity; Femur
ID in-vivo measurement; femoral-neck; mechanical-property; microindentation; indentation; density; osteoarthritis; fractures; women; men
AB Reference Point Indentation (RPI) has been proposed as a new clinical tool to aid the diagnosis of Osteoporosis. This study has examined the performance of the tool within entire femurs to improve the understanding of the mechanical properties of bone and also to guide future RPI testing to optimize repeatability of results obtained using the technique. Human, bovine, porcine and rat femurs were indented along three longitudinal axes: anterior and posterior: medial and lateral as well as around the circumference of the femoral head and neck. Cortical and subchondral bone thickness was measured using CT and radiography. The study shows that in some samples, bone is too thin to support the high loads applied with the technique and in these cases, RPI values are highly influenced by thickness. The technique will be useful in the mid-shaft region where cortical thickness is greatest, providing previously established guidelines are followed to optimize measurement repeatability, including performing multiple measurements per sample and investigating multiple samples. The study has also provided evidence that RPI values vary significantly with test site, hence mechanical properties should not be inferred from RPI findings alone away from the test site, even within the same bone. In conclusion, RPI appears to be a useful tool for scientific investigation; however further work is required to examine the feasibility of using RPI for assessing differences between healthy and diseased bone in a clinical setting. TI Prescription patterns of Chinese herbal products for patients with fractures in Taiwan: A nationwide population-based study
SO JOURNAL OF ETHNOPHARMACOLOGY
LA English
DT Article
DE Complementary and alternative medicine; Fracture; National health insurance research database; Rhizoma Drynariae; Shu-jing-huo-xue-tang; Traditional Chinese medicine
ID drynaria-fortunei; medicine use; in-vitro; radix; extract; expression; children; model; phytochemistry; osteoarthritis
AB Ethnopharmacological relevance: Traditional Chinese medicine (TCM) has been used in the treatment of fracture for thousands of years. However, large-scale surveys examing the utilization of Chinese herbal products (CHPs) for treating fractures and their related symptoms are lacking. This study aimed to investigate the prescription patterns of CHPs among patients with fractures in Taiwan. Materials and methods: The TCM usage in patients with fractures was analyzed using a sample of one million individuals randomly selected from the National Health Insurance Research Database who were newly diagnosis with fractures in 2001-2008, with a followed-up period through 2010. Results: We identified 115,327 patients who were newly diagnosed with fractures in the study population. Among them, 4.97% (n=5731) adjunctively utilized TCM for fracture treatment. TCM users were mostly young or middle-aged, female, and resided in highly urbanized areas. With regard to the comorbidities of fractures, TCM users had a lower prevalence of coronary artery disease, chronic obstructive lung disease, diabetes mellitus, hypertension and stroke than non-TCM users, except for osteoporosis. Shu-jing-huo-xue-tang was the most frequently prescribed Chinese herbal formula, while Rhizoma Drynariae (Gu-sui-bu) was the most common single herb for patients with fractures. The CHPs were found to cover not only bone healing but also fracture-related symptoms. TCM users had lower medical expenditure for hospitalization for the first six months after incident fractures than non-TCM users (1749 +/- 2650 versus 2274 +/- 3159 US dollars, $p<0.0001$). Conclusions: Our study identified the TCM utilization for patients with fractures in Taiwan. Integration of

TCM treatment reduced the medical costs for hospitalization. Further basic research and clinical studies to investigate the mechanism and clinical efficacies of CHPs are warranted. (C) 2015 Elsevier Ireland Ltd. All rights reserved.

AB Adipose tissue has been more accepted as an active contributor to whole body homeostasis, rather than just a fat depot, since leptin, a 16 kDa protein, was discovered as the product of the obese gene in 1994. With more and more studies conducted on this hormone, it has been shown that there is a close relationship between adipose tissue and bone, which have important effects on each other. Bone is the source of many hormones, such as osteocalcin, that can affect energy metabolism and then the anabolism or catabolism of fat tissue. In contrast, the adipose tissue synthesizes and releases a series of adipokines, which are involved in bone metabolism through direct or indirect effects on bone formation and resorption. Interestingly, leptin, one of the most important cytokines derived from fat tissue, seems to account for the largest part of effects on bone, through direct or indirect involvement in bone remodeling and by playing a significant role in many bone diseases, such as osteoporosis, osteoarthritis, rheumatic arthritis, bone tumors and even fractures. In this review, we will discuss the progress in leptin research, particularly focusing on the roles of leptin in bone diseases.

TI Association between new indices in the locomotive syndrome risk test and decline in mobility: third survey of the ROAD study
SO JOURNAL OF ORTHOPAEDIC SCIENCE
LA English
DT Article
ID to-stand test; sit; disability; older
AB Background We aimed to clarify the association between new indices in a locomotive syndrome risk test and decline in mobility. Methods In the third survey of the Research on Osteoarthritis/osteoporosis Against Disability (ROAD) study, data on the indices were obtained from 1575 subjects (513 men, 1062 women) of the 1721 participants in mountainous and coastal areas. As outcome measures for decline in mobility, we used the five-times-sit-to-stand test (FTSST) and walking speed with cutoff values of 12 s and 0.8 m/s, respectively. Results We first estimated the prevalence of the indices in locomotive syndrome risk test stage 1, including two-step test score < 1.3, difficulty with one-leg standing from a 40-cm-high seat in the stand-up test, and 25-question GLFS score a parts per thousand yen7, which were found to be 57.4, 40.6, and 22.6 %, respectively. Next, we investigated the prevalence of the indices in locomotive syndrome risk test stage 2, including two-step test score < 1.1, difficulty with standing from a 20-cm-high seat using both legs in the stand-up test, and 25-question GLFS score a

parts per thousand yen16, which were found to be 21.1, 7.9, and 10.6 %, respectively. Logistic regression analysis using slow FTSST time or slow walking speed as the objective factor, and presence or absence of indices as the independent factor, after adjusting for confounders, showed all three indices in both stages 1 and 2 were significantly and independently associated with immobility. Finally, we clarified the risk of immobility according to an increasing number of indices in both stages 1 and 2 and found that the odds ratio for both slow FTSST time and slow walking speed increased exponentially. Conclusion We found that the three indices independently predicted immobility and that accumulation of indices increased the risk of immobility exponentially.

TI Can We Identify Patients with High Risk of Osteoarthritis Progression Who Will Respond to Treatment? A Focus on Biomarkers and Frailty
SO DRUGS & AGING
LA English
DT Article
ID symptomatic knee osteoarthritis; bone-marrow lesions; hip-osteoarthritis; implementing frailty; stratified medicine; clinical-practice; cartilage volume; prevalence; gene; epidemiology
AB Osteoarthritis (OA), a disease affecting different patient phenotypes, appears as an optimal candidate for personalized healthcare. The aim of the discussions of the European Society for Clinical and Economic Aspects of Osteoporosis and Osteoarthritis (ESCEO) working group was to explore the value of markers of different sources in defining different phenotypes of patients with OA. The ESCEO organized a series of meetings to explore the possibility of identifying patients who would most benefit from treatment for OA, on the basis of recent data and expert opinion. In the first meeting, patient phenotypes were identified according to the number of affected joints, biomechanical factors, and the presence of lesions in the subchondral bone. In the second meeting, summarized in the present article, the working group explored other markers involved in OA. Profiles of patients may be defined according to their level of pain, functional limitation, and presence of coexistent chronic conditions including frailty status. A considerable amount of data suggests that magnetic resonance imaging may also assist in delineating different phenotypes of patients with OA. Among multiple biochemical biomarkers identified, none is sufficiently validated and recognized to identify patients who should be treated. Considerable efforts are also being made to identify genetic and epigenetic factors involved in OA, but results are still limited. The many potential biomarkers that could be used as potential stratifiers are promising, but more research is needed to characterize and qualify the existing biomarkers and to identify new candidates.

TI Regional fat depots and their relationship to bone density and microarchitecture in young oligo-amenorrheic athletes
SO BONE
LA English
DT Article
DE Visceral fat; Marrow fat; Athletes; Oligo-amenorrhea; BMD; Microarchitecture
ID visceral fat; marrow fat; femoral-neck; trabecular bone; mineral content; strength; postmenopausal; osteoporosis; adipocytes; cells
AB Context: Various fat depots have differential effects on bone. Visceral adipose tissue (VAT) is deleterious to bone, whereas subcutaneous adipose tissue (SAT) has positive effects. Also, marrow adipose tissue (MAT), a relatively newly recognized fat depot is inversely associated with bone mineral density (BMD). Bone mass in athletes depends on many factors including gonadal steroids and muscle mass. Exercise increases muscle mass and BMD, whereas, estrogen deficiency decreases BMD. Thus, the beneficial effects of weight-bearing exercise on areal and volumetric BMD (aBMD and vBMD) in regularly menstruating (eumenorrheic) athletes (EA) are attenuated in oligo-amenorrheic athletes (OA). Of note, data regarding VAT, SAT, MAT and regional muscle mass in OA compared with EA and non-athletes (C), and their impact on bone are lacking. Methods: We used (i) MRI to assess VAT and SAT at the L4 vertebra level, and cross-sectional muscle area (CSA) of the mid-thigh, (ii) 1H-MRS to assess MAT at L4, the proximal femoral metaphysis and mid-diaphysis, (iii) DXA to assess spine and hip aBMD, and (iv) HRpQCT to assess vBMD at the distal radius (non-weight-bearing bone) and tibia (weight-bearing bone) in 41 young women (20 OA, 10 EA and 11 C 18-25 years). All athletes engaged in weight-bearing sports for >= 4 h/week or ran >= 20 miles/week. Main outcome measures: VAT, SAT and MAT at L4; CSA of the mid-thigh; MAT at the proximal femoral metaphysis and mid-diaphysis; aBMD, vBMD and bone microarchitecture. Results: Groups had comparable age, menarchal age, BMI, VAT, VAT/SAT and spine BMD Z-scores. EA had higher femoral neck BMD Z-scores than OA and C. Fat mass was lowest in OA. SAT was lowest in OA ($p = 0.048$); L4 MAT was higher in OA than EA ($p = 0.03$). We found inverse associations of (i) VAT/SAT with spine BMD Z-scores ($r = -0.42$, $p = 0.01$), (ii) L4 MAT with spine and hip BMD Z-scores ($r = -0.44$, $p = 0.01$; $r = -036$, $p = 0.02$), and vBMD of the

radius and tibia (r = -0.49, p = 0.002; r = -0.41, p = 0.01), and (iii) diaphyseal and metaphyseal MAT with vBMD of the radius (r <= -0.42, p <= -0.01) and tibia (r <= -0.34, p <= -0.04). In a multivariate model including VAT/SAT, L4 MAT and thigh CSA, spine and hip BMD Z-scores were predicted inversely by L4 MAT and positively by thigh CSA, and total and cortical radius and total tibial vBMD were predicted inversely by L4 MAT. VAT/SAT did not predict radius or tibia total vBMD in this model, but inversely predicted spine BMD Z-scores. When L4 MAT was replaced with diaphyseal or metaphyseal MAT in the model, diaphyseal and metaphyseal MAT did not predict aBMD Z-scores, but diaphyseal MAT inversely predicted total vBMD of the radius and tibia. These results did not change after adding percent body fat to the model. Conclusions: VAT/SAT is an inverse predictor of lumbar spine aBMD Z-scores, while L4 MAT is an independent inverse predictor of aBMD Z-scores at the spine and hip and vBMD measures at the distal tibia and radius in athletes and non-athletes. Diaphyseal MAT independently predicts vBMD measures of the distal tibia and radius. (C) 2015 Elsevier Inc. All rights reserved.

TI Systemic biochemical markers of joint metabolism and inflammation in relation to radiographic parameters and pain of the knee: data from CHECK, a cohort of early-osteoarthritis subjects
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE Osteoarthritis; Inflammation; Biochemical markers; Osteophytes; Joint space width
ID oligomeric matrix protein; osteophyte formation; chondroitin sulfate; hip osteoarthritis; bone-density; ctx-ii; cartilage; biomarkers; severity; tissue
AB Objective: To investigate associations of biochemical markers of joint metabolism and inflammation with minimum joint space width (JSW) and osteophyte area (OP area) of knees showing no or doubtful radiographic osteoarthritis (OA) and to investigate whether these differed between painful and non-painful knees. Design: Serum (s-) and urinary (u-) levels of the cartilage markers uCTX-II, sCOMP, sPIIANP, and sCS846, bone markers uCTX-I, uNTX-I, sPINP, and sOC, synovial markers sPIIINP and sHA, and inflammation markers hsCRP and erythrocyte sedimentation rate (ESR) were assessed in subjects from CHECK (Cohort Hip and Cohort Knee) demonstrating Kellgren and Lawrence grade <= 1 OA on knee radiographs. Minimum JSW and OP area of these knees were quantified in detail using Knee Images Digital Analysis (KIDA). Results: uCTX-II levels showed negative associations with minimum JSW and positive associations with OP area. sCOMP and sHA levels showed positive associations with OP area, but not with minimum JSW. uCTX-I and uNTX-I levels showed negative associations with minimum JSW and OP area. Associations of biochemical marker levels with minimum JSW were similar between painful and non-painful knees, associations of uCTX-II, sCOMP, and sHA with OP area were only observed in painful knees. Conclusions: In these subjects with no or doubtful radiographic knee OA, uCTX-II might not only reflect articular cartilage degradation but also endochondral ossification in osteophytes. Furthermore, sCOMP and sHA relate to osteophytes, maybe because synovitis drives osteophyte development. High bone turnover may aggravate articular cartilage loss. Metabolic activity in osteophytes and synovial tissue, but not in articular cartilage may be related to knee pain. (C) 2014 Osteoarthritis Research Society International. Published by Elsevier Ltd. TI Osthole Inhibits Proliferation and Induces Catabolism in Rat Chondrocytes and Cartilage Tissue
SO CELLULAR PHYSIOLOGY AND BIOCHEMISTRY
LA English
DT Article
DE Osthole; Chondrocytes; Proliferation; Catabolism; Cartilage tissue
ID human articular chondrocytes; human osteoarthritic cartilage; in-vitro; gene-expression; matrix metalloproteinases; activation; cells; differentiation; degradation; pathway
AB Background/Aims: Cartilage destruction is thought to be the major mediator of

osteoarthritis. Recent studies suggest that inhibition of subchrondral bone loss by anti-osteoporosis (OP) drug can protect cartilige erosion. Osthole, as a promising agent for treating osteoporosis, may show potential in treating osteoarthritis. The purpose of this study was to investigate whether Osthole affects the proliferation and catabolism of rat chondrocytes, and the degeneration of cartilage explants. Methods: Rat chondrocytes were treated with Osthole (0 mu M, 6.25 mu M, 12.5 mu M, and 25 mu M) with or without IL1-beta (10ng/ml) for 24 hours. The expression levels of type II collagen and MMP13 were detected by western Blot. Marker genes for chondrocytes (A-can and Sox9), matrix metalloproteinases (MMPs), aggrecanases (ADAMTS5) and genes implicated in extracellular matrix catabolism were evaluated by qPCR. Cell proliferation was assessed by measuring proliferating cell nuclear antigen (PCNA) expression and fluorescence activated cell sorter. Wnt7b/beta-catenin signaling was also investigated. Cartilage explants from two-week old SD rats were cultured with IL-1 beta, Osthole and Osthole plus IL-1 beta for four days and glycosaminoglycan (GAG) synthesis was assessed with toluidine blue staining and Safranine O/Fast Green FCF staining, collagen type II expression was detected by immunofluorescence. Results: Osthole reduced expression of chondrocyte markers and increased expression of MMP13, ADAMTS5 and MMP9 in a dose-dependent manner. Catabolic gene expression levels were further improved by Osthole plus IL-1 beta. Osthole inhibited chondrocyte proliferation. GAG synthesis and type II collagen were decreased in both the IL-1 beta groups and the Osthole groups, and significantly reduced by Osthole plus IL-1 beta. Conclusions: Our data suggested that Osthole increases the catabolism of rat chondrocytes and cartilage explants, this effect might be mediated through inhibiting Wnt7b/beta-catenin pathway. TI LRP receptor family member associated bone disease

SO REVIEWS IN ENDOCRINE & METABOLIC DISORDERS
LA English
DT Review
DE LRP; Wnt/beta-catenin; Bone related disease
ID osteoporosis-pseudoglioma syndrome; sclerostin antibody treatment; wnt signaling pathway; brtl/+ mouse model; osteoarthritis-susceptibility; osteogenesis imperfecta; monoclonal-antibody; mineral density; chromosome 11q; gene
AB A dozen years ago the identification of causal mutations in the low-density lipoprotein receptor-related protein 5 (LRP5) gene involved in two rare bone disorders propelled research in the bone field in totally new directions. Since then, there have been an explosion in the number of reports that highlight the role of the Wnt/beta-catenin pathway in the regulation of bone homeostasis. In this review we discuss some of the most recent reports (in the past 2 years) highlighting the involvement of the members of the LRP family (LRP5, LRP6, LRP4, and more recently LRP8) in the maintenance of bone and their implications in bone diseases. These reports include records of new single nucleotides polymorphisms (SNPs) and haplotypes that suggest variants in these genes can contribute to subtle variation in bone traits to mutations that give rise to extreme bone phenotypes. All of these serve to further support and reinforce the importance of this tightly regulated pathway in bone. Furthermore, we discuss provocative reports suggesting novel approaches through inhibitors of this pathway to treat rarer diseases such as Osteoporosis-Pseudoglioma Syndrome (OPPG), Osteogenesis Imperfecta (OI), and Sclerosteosis/Van Buchem disease. It is hoped that by understanding the role of each component of the pathway and their involvement in bone diseases that this knowledge will allow us to develop new, more effective therapeutic approaches for more common diseases such as post-menopausal osteoporosis, osteoarthritis, and rheumatoid arthritis as well as these rarer bone diseases.

TI ARTHRITIS AND OSTEOPOROSIS: PATHOGENETIC CORRELATIONS IN FUNCTION OF ARTHROPLASTY
SO JOURNAL OF BIOLOGICAL REGULATORS AND HOMEOSTATIC AGENTS
LA English
DT Article
DE arthritis; inflammation; subchondral bone; bone edema; clodronate
ID bone-mineral density; hip-arthroplasty; synovial-fluid; osteoarthritis; cartilage; knee; implantation; serum; dexa; stem
AB Osteoarthritis is being increasingly characterised as an inflammatory incoming and recurrent disease, with the specific symptoms of inflammation at every stage of the disease. With regard to the pathogenesis over time, the degenerative and inflammatory components are combined and lead to osteocartilaginous

degeneration. Such deterioration involves other joint tissues as well as the subchondral bone tissue, the suffering of which is the key event of the beginning and progression of OA; its involvement concerns the same pathogenetic mechanisms and the same chemical mediators of the chondropathy. The increase in joint inflammatory events leads to suspect the onset or the worsening of the osteometabolic disorder, which is documented by the MR as "bone edema" or as algodystrophic syndrome. The pain appears both while moving and resting and with signs of inflammation. The treatment of OA requires drugs, such as paracetamol, selective and nonselective NSAIDs and opiates, for pain control. Treatment should ensure the pharmacological control of the pain related to the osteometabolic juxta-articular alteration, through bisphosphonates, favouring those which can control bone loss, inflammation and pain.

TI Quadriceps muscle strength, radiographic knee osteoarthritis and knee pain: the ROAD study
SO BMC MUSCULOSKELETAL DISORDERS
LA English
DT Article
DE Cohort study; Epidemiology; Osteoarthritis; Pain; Muscle
ID bioelectrical-impedance analysis; dwelling elderly subjects; grip strength; skeletal-muscle; association; mass; health; cohort; japan; disability
AB Background: The objective of this study was to clarify the association of quadriceps muscle strength with knee pain using a large-scale, population-based cohort of the Research on Osteoarthritis/osteoporosis Against Disability (ROAD) study. Methods: From the 2566 subjects at the third visit of the ROAD study, the present study analyzed 2152 subjects who completed radiographic examinations and measurements of muscle strength and mass (690 men and 1462 women; mean age, 71.6 +/- 12.2 years). Knee pain was assessed by an experienced orthopedist. Knee osteoarthritis (OA) was defined according to Kellgren-Lawrence (KL) grade. Quadriceps muscle strength and muscle mass at the lower limbs were measured by the Quadriceps Training Machine (QTM-05F, Alcare Co., Ltd. Tokyo, Japan) and the Body Composition Analyzer MC-190 (Tanita Corp., Tokyo, Japan), respectively.

Results: Quadriceps muscle strength and weight bearing index (WBI: quadriceps muscle strength by weight) were significantly associated with knee pain after adjustment for age and body mass index, whereas grip strength and muscle mass at the lower limbs were not. The significant association of quadriceps muscle strength with knee pain was independent of radiographic knee OA. Conclusion: The present cross-sectional study showed an independent association of quadriceps muscle strength with knee pain.

TI Publication outcomes of the abstracts presented at the 2011 European Congress on Osteoporosis, Osteoarthritis and Musculo-Skeletal Diseases (ECCEO-IOF11)
SO ARCHIVES OF OSTEOPOROSIS
LA English
DT Article
DE Publication outcomes; ECCEO-IOF Meeting; Oral communication; Poster; Presentation format
ID society; presentations; academy; rates
AB The publication outcomes of the abstracts presented during the ECCEO-IOF

2011 reflect a high research productivity, support the robustness of the selection process conducted by the Scientific Advisory Committee and suggest that IOF-ESCEO WCO is successful in its mission to promote and disseminate research.
Background and Objective The European (now World) Congress on Osteoporosis, Osteoarthritis and Musculo-Skeletal Diseases (IOF-ESCEO WCO, formerly ECCEO-IOF) is the largest worldwide event fully dedicated to the clinical, epidemiological, translational and economic aspects of bone, joint and muscle diseases. The role of the Scientific Advisory Committee is to select abstracts for oral communication or poster presentation based on a short summary of the research. The aim of the present survey was to determine the publication rate in international peer reviewed journals of abstracts accepted at the IOF-ESCEO WCO 2011 Meeting (formerly ECCEO-IOF11), the relationship, if any, between the presentation format of the abstract and its subsequent full publication and the impact factor of the journal in which research was published. Results Of 619 abstracts accepted at the 2011 ECCEO-IOF11 annual meeting, 45 were accepted for oral communication and 574 accepted for poster presentation. In the subsequent 3 years (2011-2014), 191 abstracts were published as a full-length manuscript (30.9 %). The publication rate was significantly higher for oral communications (75.6 %) than for poster presentations (27.4 %; $p<0.0001$). Publications derived from oral communications were published in journals with a higher impact factor (8.3 +/- 10.1) than those arising from poster presentations (4.0 +/- 2.3; $p<0.0001$), but there was no difference in the time to publication (OC 16.3 [IQR 8.4-23.3] months vs PP 11.3 [IQR 5.3-21.4]; $p=0.14$). Conclusion These results indicate a high research productivity and an appropriate selection of oral communication by the Scientific Advisory Committee of ESCEO-IOF.

TI Comparison between different bone treatments on areal bone mineral density (aBMD) and bone microarchitectural texture as assessed by the trabecular bone score (TBS)
SO BONE
LA English
DT Article
DE Osteoporosis treatments; Bone mineral density; Bone microarchitectural texture; TBS (trabecular bone score)
ID vertebral fracture risk; postmenopausal women; lumbar spine; prevent fractures; osteoporosis; men; osteoarthritis; teriparatide; risedronate; denosumab
AB Purpose: The objective of the study was to assess longitudinal effects of different osteoporosis treatments on TBS and aBMD at lumbar spine. Method: We analyzed 390 patients (men: 72; women: 318; age >40 years; mean follow-up of 20 months and BMI <37 kg/m(2)). We stratified the cohort by treatments: Naive of treatment (Naive, n = 67), Calcium and Vitamin D (CaVitD, n = 87), Testosterone (Te, n = 36), Alendronate (AL, n = 88), Risedronate (Ri, n = 39), Denosumab (Dmb, n = 43) and Teriparatide (PTH, n = 30). The follow-up changes from baseline were normalized at 24 months. Results: After 24 months, Naive group TBS decreased by 3.1% ($p < 0.05$) whereas a non-significant increase was observed for spine aBMD (Delta = + 0.5%). Compared to the Naive group, significant improvement ($p < 0.05$) was observed in both TBS and aBMD for Te, AL, Ri, Dmb and PTH groups and in the CaVitD group for TBS. At the end of the follow-up, significant improvement have been observed for aBMD in Te (+ 4.4%), AL (+4.1%), Ri (+4.8), D (+8.8%) and PTH (+8.8%) groups. Significant improvement was observed only in the AL (+1.4%), Dmb (+2.8%) and PTH (+3.6%) groups for TBS. Conclusion: As expected, TBS of

Naive subjects decreased with age. As expected a TBS preservation has been observed under AL and Ri.Te and CaVitD effects on TBS were evaluated for the first time: a similar preservation effect has been observed. A significant TBS increase was observed under Denosumab and PTH.TBS could be a useful tool to monitor treatment effects. (C) 2015 Elsevier Inc. All rights reserved.

TI Treatment with recombinant lubricin attenuates osteoarthritis by positive

feedback loop between articular cartilage and subchondral bone in ovariectomized rats
SO BONE
LA English
DT Article
DE Osteoarthritis; Osteoporosis; Lubricin; Subchondral bone; Cartilage; Ovariectomy
ID superficial zone protein; mesenchymal stem-cells; model; expression; immunolocalization; proteoglycan; degeneration; degradation; prevention; severity
AB Osteoarthritis (OA) is a most commonly multifactorial degenerative joint disease along with the aging population, particularly in postmenopausal women. During the onset of OA, articular cartilage and subchondral bone act in concert as a functional unit. This present study is to investigate the effects of early or late treatment with recombinant lubricin on the onset of osteoarthritis (OA) in ovariectomized (OVX) rats. We found that both early and late recombinant lubricin treatments attenuated the onset of OA by positive feedback loop between articular cartilage and subchondral bone, although late treatment contributed to a lesser effect compared with early treatment. Specifically, treatment with recombinant lubricin protected articular cartilage from degeneration, demonstrated by lower proteoglycan loss, lower OARSI scores, less calcification cartilage zone and reduced immunostaining for collagen X (Col X) and matrix metalloproteinase (MMP-13) but increased the expression of lubricin, in comparison with vehicle-treated OVX rat group. Further, chondroprotective effects of lubricin normalized bone remodeling in subchondral bone underneath. It's suggested that treatment with recombinant lubricin inhibited the elevation of TRAP and Osterix positive cells in OVX rats and led to the normalization of subchondral bone microarchitectures with the suppression of subsidence of bone volume ratio plum and trabecular thickness (Tb.Th) and the increase of trabecular separation (Tb.Sp) in vehicle-treated OVX rats. What's more, the normalization of subchondral bone in turn attenuated the articular cartilage erosion by inhibiting vascular invasion from subchondral bone to calcified cartilage zone, exemplified by inhibiting the elevation of CD31 positive cells in calcified cartilage and angiography in subchondral bone. Together, these results shed light that both early and late recombinant lubricin treatments attenuate the onset of OA by balancing the interplay between articular cartilage and subchondral bone in OVX rats, while also providing a further rationale for its therapeutic targeting to postmenopausal OA and suggesting that treatment timing is a pivotal factor for better effect acquisition. AB A variety of osteoarticular conditions possess an underlying genetic aetiology. Large-scale genome-wide association studies have identified several genetic loci associated with osteoarticular conditions, but were unable to fully account for their estimated heritability. Epigenetic modifications including DNA methylation, histone modification, nucleosome positioning, and microRNA expression may help account for this incomplete heritability. This articles reviews insights from epigenetic studies in osteoarticular diseases, focusing on osteoarthritis, but also examines recent advances in rheumatoid arthritis, osteoporosis, systemic lupus erythematosus (SLE), ankylosing spondylitis, and sarcoma. Genome-wide methylation studies are permitting identification of novel candidate genes and molecular pathways, and the pathogenic mechanisms with altered methylation status are beginning to be elucidated. These findings are gradually translating into improved understanding of disease pathogenesis and clinical applications. Functional studies in osteoarthritis, rheumatoid arthritis, and SLE are now identifying downstream molecular alterations that may confer disease susceptibility. Epigenetic markers are being validated as prognostic and therapeutic disease biomarkers in sarcoma, and clinical trials of hypomethylating agents as treatments for sarcoma are being conducted. In concert with advances in throughput and cost-efficiency of available technologies, future epigenetic research will enable greater characterisation and treatment for both common and rare osteoarticular diseases.

TI Evaluation of Bone Targeting Salmon Calcitonin Analogues in Rats Developing Osteoporosis and Adjuvant Arthritis
SO CURRENT DRUG DELIVERY
LA English
DT Article
DE Bisphosphonate; bone mineral density (BMD); bone targeting; bone volume; adjuvant arthritis; calcitonin; polyethylene glycol (PEG); micro-CT; osteoporosis
ID delivery-system; osteoclast; osteoarthritis; pathogenesis; pegylation; behavior

AB Synthetic analogues of the peptide hormone calcitonin have been used in medicine as biologic drug therapies for decades, to treat pathological conditions of excessive bone turnover, such as osteoporosis, where more bones are removed than replaced during bone remodeling. Osteoporosis and other chronic skeletal diseases, including inflammatory arthritis, exact a substantial and growing toll on aging populations worldwide however they respond poor to synthetic biologic drug therapy, due in part to the rapid half-life of elimination, which for calcitonin is 43 minutes. To address those shortcomings, we have developed and synthesized bone-targeting variants of calcitonin as a targeted drug delivery strategy, by conjugation to bisphosphonate drug bone-seeking functional groups in highly specific reaction conditions. To evaluate their in vivo efficacy, bisphosphonate-mediated bone targeting with PEGylated (polyethylene glycol conjugated) and non-PEGylated salmon calcitonin analogues were synthesized and dose escalation was performed in female rats developing Osteoporosis. The bone-targeting calcitonin analogues were also tested in a separate cohort of male rats developing adjuvant-induced arthritis. Ovariectomized female rats developing Osteoporosis were administered daily sub-cutaneous injection of analogues equivalent to 5, 10 and 20 IU/kg of calcitonin for 3 months. Adjuvant arthritis was developed in male rats by administering Mycobacterium butyricum through tail base injection. Daily sub-cutaneous injection of analogues equivalent to 20 IU/kg of calcitonin was administered and the rats were measured for visible signs of inflammation to a 21 day endpoint. In both studies, the effect of drug intervention upon bone volume and bone mineral density (BMD) was assessed by measuring the trabecular bone volume percentage and BMD at the proximal tibial metaphysis using in vivo micro-computed tomography. With dose escalation studies, only bone targeting analogue dosed groups showed a trend towards increased BMD and bone volume at 4, 8 and 12 weeks. Significant preservation of bone volume and BMD as evidenced by nonsignificant ($P>0.05$) loss of bone volume and BMD at the end of 3 month study endpoint was seen in animals dosed with 20 IU/kg of calcitonin compounds. Similarly, in case of adjuvant-induced arthritis rats, there was a significant increase ($P<0.05$) in bone volume and BMD in calcitonin-bisphosphonate and calcitonin-PEG-bisphosphonate treated groups at 21 days compared to the baseline values. Improved efficacy in terms of preserving bone volume and BMD in Osteoporosis, and in rats developing adjuvant-induced arthritis, by these analogues suggests their potential as new drug candidates for further evaluation to determine their usefulness in bone diseases characterized by excessive bone resorption.

TI Incidence and predisposing factors of periprosthetic proximal femoral fractures: a literature review
SO INTERNATIONAL ORTHOPAEDICS
LA English
DT Review
DE Periprosthetic proximal femoral fracture; Hip arthroplasty; Risk factors; Incidence; Aetiology; Epidemiology
ID total hip-arthroplasty; revision total hip; risk-factors; femur fracture; replacement; management; epidemiology; knee; age; hemiarthroplasty
AB Purpose The purpose of this review article was to investigate the incidence and predisposing factors for periprosthetic proximal femoral fractures (PFF) following total hip arthroplasty. Methods We performed a comprehensive search of the medical literature in MEDLINE and EMBASE databases to review articles related to PFF, their incidence and risk factors. Results and Conclusions The incidence of PPF after primary THA was, in general, lower than after revision THA both for intra- and postoperative PFF. The rate of intraoperative PFF ranged from 0.1 % to 27.8 % and of postoperative PFF from 0.07 % to 18 %. Predisposing factors for intraoperative PFF are osteoporosis, rheumatoid arthritis, femoral preparation and surgical technique used to insert the rasp or femoral component, the use of press-fit cementless stems, and revision THA. In case of postoperative PFF, the following seem to be significant risk factors: advanced age, female gender, post-traumatic osteoarthritis, osteoporosis and rheumatoid arthritis, proximal femoral deformities, previous surgery of the affected hip, implant type (especially cementless stems and press-fit implantation), technical errors such as cortical perforation, cortical stress risers, low-energy trauma, osteolysis, loosening and revision THA.

TI Prevention of Acute Proximal Junctional Fractures After Long Thoracolumbar Posterior Fusions for Adult Spinal Deformity Using 2-level Cement Augmentation at the Upper Instrumented Vertebra and the Vertebra 1 Level Proximal to the Upper Instrumented Vertebra
SO SPINE
LA English
DT Article
DE adult spinal deformity; vertebroplasty; kyphoplasty; thoracolumbar fusion;

proximal junctional failure; fracture; revision surgery
ID body compression fractures; pedicle screw constructs; percutaneous vertebroplasty; risk-factors; lumbar fusion; adjacent; kyphoplasty; osteoporosis; segments; kyphosis
AB Study Design. Retrospective col tort analysis. Objective. To evaluate efficacy of proximal junction fracture (PIE) prevention in adult spinal deformity (ASD) using 2-level cement augmentation at the construct's proximal extent. Summary of Background Data. Prevention of PJF after thoracolumbar fusions is critical because they may result in neurological injury. Cement augmentation of constructs' proximal vertebrae is postulated to decrease PJF. Methods. Patients with ASD after PSI front pelvis to thoracolumbar bar junction with 6 months or more follow-up were retrospectively studied. Demographics, deformity radiographical parameters, and health-related quality of life outcomes (PIRQoL) scores were con pared with patients with no cement, 2-level cementaugmentation at upper instrumented vertebra (UIV) and vertebra 1 level proximal to UIV (UIV +1), and cement at another location ("Other"). Revision surgery for PJF was primary outcome. Univariable and multivariable logistic regression analyses were used for statistical analysis. Results. 51 patients [female-29; male-22; average age: 65 yr (33-82)] met inclusion criteria (2-level-19; no-cement-23; "Other" -9). Average follow-up (mo) was longer for no-cement (25 +/- 15) and "Other" (20 +/- 16) than 2-level (15 +/- 8) (P = 0.06). All perioperative radiographical parameters were similar, save first postoperative thoracic kyphosis and lumbopelvic mismatch. Compared with 2-level cement, non-2-level cement had significantly more revisions for PJF (0% vs. 19%; P = -0.02). After UIV adjustment, risks of PJF revision surgery were 13.1 times higher for "Other" (95% CI: 0.5-346.5, P -0.12) and 9.2 times higher (95% CI: OA 239.1, P = 0.18) for no-cement. All HRQoL. scores improved in 2-level cement; only back/leg pain significantly improved in non-2-level cement. Postoperative Oswestry Disability Index was significantly less in 2-level cement. Conclusion. The use of 2-level cement augmentation (UIV and UIV +1) in PSF from pelvis to thoracolumbar junction for ASD is associated with a decreased rate of acute proximal junctional fractures and associated revision surgeries. As only associations can be demonstrated from this study's design, prospective investigations with larger, consecutive cohorts should he performed to explore causal relationships.

TI Risk Factors for Osteoarthritis and Contributing Factors to Current Arthritic Pain in South Korean Older Adults
SO YONSEI MEDICAL JOURNAL
LA English
DT Article
DE Osteoarthritis; joint related pain; risk factors; older adults

ID body-mass index; radiographic knee osteoarthritis; c-reactive protein; physical-activity; hip osteoarthritis; hand osteoarthritis; prospective cohort; follow-up; progression; obesity
AB Purpose: Although previous studies have focused on risk factors for osteoarthritis, there is some debate on this issue. Furthermore, associated factors with arthritic symptom (arthralgia) have not been sufficiently investigated, despite its clinical importance in the management of osteoarthritis. This study was performed to examine the risk factors for osteoarthritis and the contributing factors to current arthritic pain in older adults. Materials and Methods: The Fourth Korean National Health and Nutrition Examination Surveys was conducted in 2009. Therein, 720 males and 1008 females aged 65 years and older were included. Comprehensive data on habitual, socioeconomic, medical, nutritional, and psychological factors were collected along with the presence of osteoarthritis and arthritic pain. After univariate analysis, binary logistic regression analysis was performed to identify risk factors for osteoarthritis and contributing factors to current arthritic pain. Results: Age ($p=0.005$), female gender ($p<0.001$), higher body mass index (BMI) ($p<0.001$), and osteoporosis ($p<0.001$) were significant risk factors for osteoarthritis, while higher education level ($p=0.025$) was a protective factor for osteoarthritis. Higher BMI ($p=0.047$), lack of weekly moderate intensity activity ($p<0.001$), and unfavorable subjective health status ($p<0.001$) were significant factors contributing to current arthritic pain among subjects with osteoarthritis. Both osteoarthritis and current arthritic pain adversely affected health related quality of life. Conclusion: Higher BMI, lack of weekly moderate intensity activity, and unfavorable subjective health status were significant factors contributing to current arthritic pain. More attention needs to be paid to psychiatric effects on osteoarthritis and joint related pain.

TI Analysis of conditions for the diagnosis of rheumatic diseases in primary health care in the city of Sorocaba-SP
SO REVISTA BRASILEIRA DE REUMATOLOGIA
LA English
DT Article
DE Rheumatic diseases; Primary health care; Continuing medical education
ID general-practice; competence
AB Objectives: The study had as main goal to define the profile of the attending professional working at the primary healthcare sector in the city of Sorocaba, and to analyze the environment in which this professional is inserted, trying to identify if there are conditions for the care of low-complexity rheumatic diseases and possible reasons that would lead to a high degree of referral to specialists. Methods: A quantitative study was performed in which physicians of primary health care were invited to answer a questionnaire that addressed personal aspects, besides the technical aspects of four rheumatic diseases: osteoarthritis, gout, fibromyalgia and osteoporosis, which served as the basis for evaluating the care for low-complexity diseases in UBSs. Results: It was observed that the professional is part integral of an organizational system that hinders his/her performance; moreover, certain personal difficulty techniques were realized. Together, these conditions turned out to be the factors that determine a quality of care that falls short of that expected. Conclusion: There must be a review of how medical education is offered, in order to seek a more qualified training, focused on the basic needs of the health system, as well as a restructuring of the entire health system in terms of its organization and management, in order to attain a suitable condition for the development of a good medical practice, and thus, for providing a good service to the community. TI Induction and antagonism of pica induced by teriparatide in rats
SO EUROPEAN JOURNAL OF PHARMACOLOGY
LA English
DT Article
DE Anti-emetic drugs; Nausea; Ovariectomized rats; Pica; Teriparatide
ID parathyroid-hormone 1-34; agents affecting emesis; bone turnover markers; postmenopausal women; mineral density; substance-p; osteoporosis; fracture; nausea; granisetron
AB Intermittent subcutaneous injection of teriparatide, an active fragment of human parathyroid hormone, is clinically used for the treatment of osteoporosis. Patients suffer from nausea, which is one of the side effects teriparatide induces; however, the etiology of teriparatide-induced nausea remains unknown. We have reported pica, kaolin ingestion behavior, can be used as an assessment of nausea-related response in rats. In this study, we investigated the characteristics of teriparatide-induced pica and the abilities of anti-emetic drugs to inhibit teriparatide-induced pica. Male and female adolescent (4-week-old), young (8-week-old), and adult (30-week-old) naive rats, and ovariectomized (OVX: 17-week-old) and sham-operated (17-week-old) rats subcutaneously received teriparatide (OA mg/kg, n=4), and their kaolin and food intakes were monitored for 24 h after the injection. Among the tested rats, we found that OVX rats, rather than male, female, and sham-operated rats, showed marked teriparatide-induced pica (0 mg/kg: 0.17 +/- 0.07 g, 0.4 mg/kg: 6.18 +/- 0.91 g). Teriparatide-induced pica in OVX rats was inhibited by intraperitoneal pretreatment with serotonin 5-HT3 (granisetron 0.5 mg/kg), dopamine D-2 (prochlorperazine 0.5 mg/kg), neurokinin NK1 (fosaprepitant 1 mg/kg), and histamine H-1 (diphenhydramine 10 mg/kg) receptor antagonists to 70%, 11%, 19%, and 59% of that in vehicle-treated control, respectively. These results suggest that teriparatide-induced pica in OVX rats has the potential to reflect teriparatide-induced nausea; 5-HT3, D-2, NK1, and H-1 receptor activation is involved in the development of this behavior; antagonists of

these receptors have the potential to be medical candidates used as treatments for teriparatide-induced nausea in human patients. (C) 2015 Published by Elsevier B.V.

TI A Growing Problem Acetabular Fractures in the Elderly and the Combined Hip Procedure
SO ORTHOPEDIC CLINICS OF NORTH AMERICA
LA English
DT Article
DE Acetabular fracture; Elderly; Combined hip procedure; Total hip arthroplasty
ID reduction internal-fixation; operative treatment; pelvic fractures; arthroplasty; trauma; older; outcm; epidemiology; management; age
AB Acetabular fractures in the elderly are most frequently the result of low-energy trauma and present unique management challenges to orthopedic surgeons. Evaluation and treatment should be performed in a multidisciplinary fashion with early involvement of internal medicine subspecialists and geriatricians. Distinct fracture patterns and pre-existing osteoarthritis and osteoporosis necessitate careful preoperative planning. The role of total hip arthroplasty should also be considered when surgical treatment is indicated. The outcomes of acetabular fractures in the elderly have improved, but complications remain higher and results less satisfactory than in younger individuals. The lack of randomized controlled trials has limited the ability to establish an evidence-based treatment algorithm.

TI Functional Outcomes After Total Hip Arthroplasty for the Acute Management of Acetabular Fractures: 1-to 14-Year Follow-up
SO JOURNAL OF ORTHOPAEDIC TRAUMA
LA English
DT Article
DE acetabular fracture; osteoporosis; total hip arthroplasty; geriatric trauma; trauma
ID reduction internal-fixation; elderly-patients; singh index; replacement; classification; osteoporosis; failure; radiography; migration; component
AB Objective: This study reports the complications and functional outcomes in patients treated acutely with combined open reduction internal fixation (ORIF) and immediate total hip arthroplasty (THA) for displaced comminuted acetabular fractures. Design: Single surgeon retrospective case series. Setting: Level 1 trauma center. Patients: Thirty-three consecutive patients (18 women; mean age, 66 years) from 1996 to 2011 with an average follow-up of 5.6 years (range, 1-14.3 years) were included in this study. Intervention: ORIF and immediate THA. Main Outcome Measurements: Oxford Hip Score and reoperation. Methods: All patients had at least 1 year of telephone or clinical follow-up. Postoperative complications, reoperations, and available radiographs were reviewed. Results: Six patients died of causes unrelated to their injuries or surgery; before death, these patients had

well-functioning hips. There was a 15% complication rate. At last follow-up, 94% of hips remained in situ and were functioning well. The average Oxford Hip Score at final follow-up was 17 (range, 12-32), with 93% of patients reporting good to excellent function. There was no statistical association between fracture type, age, or fixation type and outcome. Conclusions: Acute ORIF and immediate THA for selected acetabular fractures is a safe viable treatment option with good to excellent functional outcomes and may reduce the need for 2 separate operations in many patients. Functional outcomes are equivalent to those after primary THA for osteoarthritis. This study does not address at which age acute THA is a cost-effective treatment option.

TI AN UNEXPECTED CASE OF ATYPICAL FEMUR FRACTURE MISDIAGNOSED AS RADICULOPATHY AND HIP OSTEOARTHRITIS: A PATIENT TREATED WITH BISPHOSPHONATE
SO TURKISH JOURNAL OF GERIATRICS-TURK GERIATRI DERGISI
LA English
DT Article
DE Alendronate; Bisphosphonates; Femoral Fractures
AB Bisphosphonates are the most commonly used drugs in the treatment of osteoporosis. Several randomized controlled studies have proved their effectiveness in the treatment of postmenopausal osteoporosis and today BPs are considered a first-line therapy for osteoporosis. Bisphosphonates inhibit osteoclastic activity, decrease bone turnover and increase bone mineral density. Although there is strong evidence that bisphosphonates prevent osteoporotic fractures, in recent years, there have been several reports that show the increasing risk of atypical femoral fractures that is related to prolonged usage (5 years or longer) of bisphosphonates. This may be related to prolonged suppression of bone turnover. By suppressing the bone turnover they impair the ability of bone to repair the microdamages and leads the accumulation of microcracs. In this case, we report 67-year-old female who presented with atypical femoral fracture.
