TI Impact of vertebral deformities, osteoarthritis, and other chronic diseases on quality of life: a population-based study
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE chronic diseases; elderly; quality of life; spinal osteoarthritis; vertebral deformities
ID osteoporotic fractures; postmenopausal women; european foundation; older men; consequences; prevalent; risk; questionnaire; osteophytosis; mortality
AB Vertebral deformities and spinal osteoarthritis are common disorders in elderly persons and are associated with back pain, impaired physical functioning, and loss of quality of life. The objectives of this study were to assess the impact of vertebral deformities and osteoarthritis on quality of life in a population-based sample, and to compare this with the impact of six other important chronic diseases on quality of life. The study was performed as a substudy of the Longitudinal Aging Study Amsterdam. Vertebral deformities and osteoarthritis were assessed by spinal radiographs; chronic diseases were assessed by self-report; quality of life was estimated by the SF-12, EQ-5D (EuroQol) and Qualeffo-41 (n=336). In univariate analyses, severe osteoporosis of the vertebrae significantly worsened the physical component summary scale of the SF-12 and the total score of Qualeffo-41, while osteoarthritis of the spine did not significantly reduce quality of life. The other chronic diseases reduced quality of life, although not all changes reached statistical significance. In multivariate analyses, severe osteoporosis of the vertebrae, cardiac disease, peripheral arterial disease, and diabetes mellitus significantly reduced quality of life. In conclusion, most persons in an elderly population suffer from one or more chronic diseases, and therefore experience loss of quality of life. After adjustment for age, sex, and other chronic diseases, severe osteoporosis of the vertebrae, cardiac disease, peripheral arterial disease, and diabetes mellitus significantly reduced quality of life in the general population.

TI 3. Is exercise good for you?
SO MEDICAL JOURNAL OF AUSTRALIA
LA English
DT Article
ID osteoarthritis; death; guidelines; sports; knee
AB Physical activity can significantly reduce the risk of cardiovascular disease, diabetes, some forms of cancer, osteoporosis, obesity, falls and fractures, and some mental health problems. While the benefits of physical activity are clear, there is a slightly increased risk of sudden death while exercising (compared with while sedentary), especially in untrained people undertaking unaccustomed vigorous activity. Routine exercise testing yields a significant number of false-positive results, and has not been shown to prevent exercise-related acute cardiac events. There is no convincing evidence that exercise is itself associated with osteoarthritis, but significant joint injury which occurs during sport is associated with an increased risk of subsequent development of osteoarthritis.

TI Biglycan is a new extracellular component of the Chordin-BMP4 signaling pathway
SO EMBO JOURNAL
LA English
DT Article
DE Biglycan; BMP signaling; Chordin; embryonic patterning; extracellular matrix
ID heparan-sulfate proteoglycans; twisted gastrulation; xenopus-embryos; bmp-binding; deficient mice; organizer; inhibition; differentiation; osteoarthritis; osteoporosis
AB The BMP4 signaling pathway plays key roles during early embryonic development and for maintenance of adult homeostasis. In the extracellular space, BMP4 activity is regulated by a group of interacting molecules including the BMP antagonist Chordin, the metalloproteinase Tolloid and Twisted gastrulation (Tsg). In this study, we identified Biglycan (Bgn), a member of the small leucine-rich proteoglycan family, as a new extracellular modulator of BMP4 signaling. Xenopus Bgn (xBgn) is expressed uniformly in the ectoderm and mesoderm and their derivatives during development. Microinjection of Bgn mRNA induced secondary axes, dorsalized the mesoderm and inhibited BMP4 activity in Xenopus embryos. Biochemical experiments showed that Bgn binds BMP4 and Chordin, interaction that increased binding of BMP4 to Chordin. Bgn was also able to improve the efficiency of Chordin - Tsg complexes to block BMP4 activity. Using antisense morpholinos, we demonstrated that Bgn required Chordin to induce double axes in Xenopus. This work unveiled a new function for Bgn, its ability to regulate BMP4 signaling through modulation of Chordin anti-BMP4 activity.

TI Thermal stability and structure of cancellous bone mineral from the femoral head of patients with osteoarthritis or osteoporosis
SO ANNALS OF THE RHEUMATIC DISEASES
LA English
DT Article
ID cortical iliac crest; subchondral bone; osteo-arthritis; hydroxyapatite; density; apatites; phase; plate; neck

AB Background: Cancellous bone from patients with osteoarthritis (OA) has been reported to be undermineralised and that from patients with osteoporosis (OP) is more liable to fracture. Changes in the mineral component might be implicated in these processes. Objectives: To investigate the thermal stability and the mineral structure of cancellous bone from femoral heads of patients with either OA or OP. Methods: Powdered bone was prepared from femoral heads of patients with either OA or OP and a control group. Composition and thermal stability were determined using a thermogravimetric analyser coupled to a mass spectrometer. Unit cell dimensions and the crystallite size of the mineral were measured using x ray diffraction. Results: Thermal stability of the bone matrix, or of the mineral phase alone, was little altered by disease, though OA bone contained less mineral than OP or control bone. In all three groups, x ray diffraction showed that the mineral unit cell dimensions and crystallite sizes were the same. The mean carbonate content in the mineral from all three groups was between 7.2 and 7.6% and is suggested to be located in both the A site (that is, substituting for hydroxyl groups), and the B site (that is, substituting for phosphate groups). Conclusions: These results confirm that there is a lower mass fraction of mineral in OA bone, and indicate that the nature of the mineral is not a factor in either disease process.

TI Depression and concomitant diseases in a Turkish geriatric outpatient setting
SO ARCHIVES OF GERONTOLOGY AND GERIATRICS
LA English
DT Article
DE depression; elderly; concomitant diseases
ID bone-mineral density; primary-care patients; late-life depression; patients aged 65; blood-pressure; vascular depression; health-services; hypertension; symptoms; dementia
AB Depression is an important but inadequately diagnosed mood disorder ill elderly. Depressed elderly patients often have chronic concomitant diseases. This paper intended to determine the prevalence of depression and its relation with concomitant disorders and social status among the patients admitted to our geriatric unit. Seven hundred and eighty-nine females and 466 males admitted to our unit were examined for the presence of depression by using the geriatric depression scale (GDS) test. The presence of concomitant diseases was assessed. Depression was diagnosed in 273 patients (21.8%), 193 (70.7%) females and 80

(29.3%) males. Depressed patients suffered from a wide range of other diseases the number and prevalence of which were as follows: Alzheimer's disease (AD) (34; 12.5%), vascular dementia (27; 9.9%), hypertension (HT) (211; 77.3%), diabetes mellitus (DM) (64; 23.4%). osteoporosis (182; 66.7%), atherosclerotic coronary artery disease (CAD) (89; 32.6%), cardiac failure (23; 8.5%), bronchial asthma (8; 2.9%), chronic obstructive pulmonary disease (COPD) (25; 9.2%) and osteoarthritis (133; 48.8%). The correlation between depression and concomitant diseases was statistically significant in hypertensive, demented and osteoporotic patients, as determined in a large elderly population. Previous studies examined the correlation of depression with only one concomitant disease, while we performed the analysis on multiple correlations. (c) 2004 Elsevier Ireland Ltd. TI Circulating cortisone levels are associated with biochemical markers of bone formation and lumbar spine BMD: the Hertfordshire Cohort Study
SO CLINICAL ENDOCRINOLOGY
LA English
DT Article
ID 11-beta-hydroxysteroid dehydrogenase type-1; healthy elderly-men; mineral density; glucocorticoid action; women; corticosteroids; parameters
AB Objective Cortisone is an endogenous corticosteroid that has negligible intrinsic glucocorticoid activity but can be converted to the active corticosteroid cortisol by the enzyme 11 beta-hydroxysteroid dehydrogenase type 1 (11 beta-HSD1). 11 beta-HSD1 is expressed in osteoblasts and may play a role in determining susceptibility to glucocorticoid-induced osteoporosis. In intact osteoblasts enzyme activity, and thus cortisol generation, is dependent on substrate concentration with an almost linear increase in activity across the physiological range. We have therefore attempted to measure the impact of 11 beta-HSD1 activity on bone in vivo by examining the association of circulating cortisone with bone markers, bone mineral density (BMD) and bone loss in a cohort of women and men. Design and subjects Baseline cross-sectional association study involving 135 women and 171 men aged 61-73 years from the Hertfordshire Cohort Study and a 4 year follow-up study examining changes in BMD. Measurements Serum cortisone, cortisol and osteocalcin, and urinary type I collagen cross-linked N-telopeptide (NTX) were measured at baseline. BMD at spine and hip was measured at baseline and 4 years later. Results In men serum cortisone levels were negatively correlated with serum osteocalcin (r = -0.20, P = 0.01); a similar relationship was seen in women (r = -0.16, P = 0.06). No correlation was seen between serum cortisone and urinary NTX (r = 0.03, P = 0.74 for women; r = -0.03, P = 0.72 for men). A negative correlation was observed between serum cortisone and spine BMD in women (r = -0.18, P = 0.04); a similar relationship was also seen in men (r =-0.14, P = 0.07). However, cortisone did not correlate with BMD at the femoral neck or total hip or changes in BMD at any site over time. In analyses adjusted for adiposity, osteoarthritis grade and a range of life-style variables, these relationships did not change substantially. All these relationships were independent of cortisol concentrations. Conclusions The most plausible explanation for the association of circulating cortisone levels with osteocalcin is the presence of 11 beta-HSD1 activity within osteoblasts. The measurement of serum cortisone may independently give insights into the action of glucocorticoids on bone.

TI Aging bone and cartilage: cross-cutting issues
SO BIOCHEMICAL AND BIOPHYSICAL RESEARCH COMMUNICATIONS
LA English
DT Review
DE aging; cartilage; bone; osteoarthritis; osteoporosis; osteopenia; apoptosis; stem cells
ID glycation end-products; age-related-changes; human articular-cartilage; growth-factor-i; chondrocyte apoptosis; life-span; oxidative stress; extracellular-matrix; caloric restriction; cellular senescence
AB Aging is a major risk factor for osteoarthritis and osteoporosis. Yet, these are not necessary outcomes of aging, and the relationship between age-related changes in bone and cartilage and development of disease is not clear. There are some well-described cellular changes associated with aging in multiple tissues that appear to be fundamental to the decline in function of cartilage and bone. A better understanding of age-related changes in cells and tissues is necessary to mitigate or, hopefully, avoid loss of bone and cartilage with aging. In addition, a better understanding of the dynamics of tissue maintenance in vivo is critical to developing tissue replacement and repair therapies. The role of stem cells in this process, and why tissues are not well maintained with advancing age, are frontiers for future aging research. Published by Elsevier Inc.

TI MRI-controlled analysis of 104 patients with painful bone marrow edema in different joint localizations treated with the prostacyclin analogue iloprost
SO WIENER KLINISCHE WOCHENSCHRIFT
LA English
DT Article
DE bone marrow edema; avascular necrosis; osteoarthritis; bone bruise; vasoactive drug
ID femoral-head; transient osteoporosis; idiopathic osteonecrosis; avascular necrosis; follow-up; knee; hip; hypofibrinolysis; impairment; diagnosis
AB Background: Bone marrow edema (BME) is a common cause of pain of the musculoskeletal system. The aim of the study was to assess the efficacy of iloprost in the treatment of BME of different localizations and etiologies. Patients and methods: We reviewed 104 patients (54 male, 50 female) with BME, Their mean age was 52.8 +/- 14.7 years. BME was located 50 times in the knee, 19 times in the talus, 18 times in the femoral head and 17 times in other bones, Patients were allocated to three distinct etiological groups: 27 cases were estimated to have idiopathic BME, 16 post-traumatic BME and the other 61 BME secondary to activated osteoarthritis or mechanical stress. Therapy consisted of a series of five iloprost infusions with either 20, 25 or 50 mu g of iloprost given over 6 hours on 5 consecutive days each. Results: At the clinical follow-up four months after therapy, the pain level of the 104 patients at rest had diminished by a mean of 73% ($p < 0.0001$): 64% of patients reported a reduction, 34% no change and 2% an increase in pain at rest. Pain under stress decreased by a mean of 59%, ($p < 0.0001$): 76% of patients had less pain during activity, 22% no change from baseline and 2% an increased pain level. On MRI, 65% had significant reduction of BME size or complete normalization and 20% showed no change. Worsening of the MRI pattern was found in 2%. 13% were lost to MRI follow-up. Side effects were significantly reduced by lowering the daily dose from 50 to 20 mu g, without impairment of therapeutic effect. Conclusion: The authors conclude that the use of parenteral iloprost might be a viable method in the treatment of BME of different etiologies.

TI Interobserver reproducibility of criteria for vertebral body exclusion
SO JOURNAL OF BONE AND MINERAL RESEARCH
LA English
DT Article
DE aging; epidemiology; evidence/guidelines; osteoporosis; quantitation; bone densitometry
ID bone-mineral density; predict hip fracture; x-ray absorptiometry; quantitative ultrasound; elderly-women; population; risk; osteopenia; deformity
AB We studied reproducibility of the ISCD vertebral exclusion criteria among four interpreters. Surprisingly, agreement among interpreters was only moderate, because of differences in threshold for diagnosing focal structural defects and choice of which vertebra among a pair discordant for T-score, area, or BMC to exclude. Our results suggest that reproducibility may be improved by specifically addressing the sources of interobserver disagreement. Introduction: Although DXA is widely used to measure vertebral BNID, its interpretation is subject to multiple confounders including osteoarthritis, aortic calcification, and scoliosis. In an attempt to standardize interpretation and minimize the impact of artifacts, the International Society for Clinical Densitometry (ISCD) established criteria for vertebral exclusion, including the presence of a focal structural defect (FSD), discrepancy of >1 SD in T-score between adjacent vertebrae, and a lack of increase in BMC or area from L, to L, Whereas the efforts of the ISCD represent an important advance in BMD interpretation, the interobserver reproducibility with application of these criteria is unknown. We hypothesized that there would be substantial agreement among four interpreters regarding application of the exclusion criteria and the final lumbar spine T-score. Materials and Methods: Each interpreter read a set of 200 lumbar DXA scans obtained on male veterans, applying the ISCD vertebral body exclusion criteria. Results: Surprisingly, agreement among interpreters was only moderate. Differences in interpretation resulted from differing thresholds for recognition of FSD and the choice of excluding the upper or lower vertebral body for the criteria requiring comparison between adjacent

vertebrae. Conclusions: Despite their apparent simplicity, the ISCD vertebral exclusion criteria are difficult to apply consistently. In principle, appropriate refinement of the exclusion criteria may significantly improve interobserver agreement.

TI Association between physique characteristics and hand skeletal aging status
SO AMERICAN JOURNAL OF PHYSICAL ANTHROPOLOGY
LA English
DT Article
DE somatotype; osteoarthritis; osteoporosis; aging
ID bone-mineral density; body-mass index; population biology; osteoarthritis; age; somatotype; obesity; weight; knee; hip
AB The aim of the present study was to evaluate the association between skeletal aging traits (obtained from evaluation of hand radiographs) and physique characteristics, including indices of obesity, skeletal size, muscular development, and the somatotypes of Heath and Carter (1967) and of Deriabin (1985). To achieve our aims, we used multiple regression analysis, and Pearson's and canonical correlation analyses. The studied population comprised 629 males and 561 females aged 18-90 years, all members of the Chuvasha (Russian Federation). The present study provides evidence for a connection between hand bone aging traits and physique characteristics. The cortical index showed a small but significant correlation with adiposity and the index of overall physique, but bone mineral density (BMD) traits were not correlated with the index of overall physique. Deriabin's set of somatotypes was significantly correlated with BMD, but could explain only 2% of its variation. Significant correlations of the hand osteoarthritis trait were observed with indices of adiposity. Also observed were statistically significant canonical correlations with both sets of somatotypes, which enabled us to predict 2-3% of hand osteoarthritis variation by a combination of somatotype components. Osseometric score evinced statistically significant correlations with most indices of physique as well as with a combination of somatotype components. These findings may prove helpful in epidemiological studies, because they show that body composition is the factor that is statistically significantly associated with skeletal aging.

TI Association of radiological hand osteoarthritis with bone mineral mass: a population study
SO RHEUMATOLOGY
LA English
DT Article
DE epidemiology; bone mineral mass; calcaneal ultrasound; osteoarthritis; osteoporosis
ID finns aged 30; knee osteoarthritis; quantitative ultrasound; articular-cartilage; risk-factors; elderly-men; density; women; hip; osteoporosis
AB Objectives. A number of previous studies have reported an inverse relationship between osteoarthritis and osteoporosis. However, the association has remained controversial because osteoarthritis in hand joints seems to associate differently from osteoarthritis in weight-bearing joints with bone mineral mass. We studied osteoarthritis in distal interphalangeal (DIP) joints and osteoarthritis in the base of the thumb (CMC-1) for their cross-sectional associations with metacarpal cortical bone mineral mass, and for their prediction of calcaneal broadband ultrasound attenuation. Methods. A population sample of 8000 Finns aged 30 yr and over was invited to a comprehensive health examination in 1978-1980; 90% complied. Hand radiographs were taken from 3568 participants to diagnose osteoarthritis in various hand joints, and to determine two indicators of cortical bone mineral mass, the combined cortical thickness (CCT) and the metacarpal index (MCI). Calcaneal broadband ultrasound attenuation was measured 20 yr later in 340 of these participants with the Sahara sonometer. Results. In the cross-sectional setting, osteoarthritis in the DIP joints and osteoarthritis in the base of the thumb (CMC-1) were significantly associated with low CCT and low MCI. These associations were proportional to the radiological severity of osteoarthritis. In the follow-up setting, symmetrical DIP osteoarthritis adjusted for age, sex, body mass index, smoking, education, workload and MCI significantly predicted low values of broadband ultrasound attenuation. Conclusions. Our results indicate a direct relation of both radiological DIP osteoarthritis and CMC-1 osteoarthritis with low cortical bone mineral mass, in proportion to the severity of osteoarthritis. The presence of symmetrical DIP osteoarthritis, a possible indicator of generalized osteoarthritis, suggests an increased risk of osteoporosis over time.

TI Patients with knee osteoarthritis have lower total hip bone mineral density in the symptomatic leg than in the contralateral hip
SO JOURNAL OF CLINICAL DENSITOMETRY
LA English
DT Article
DE knee osteoarthritis; bone mineral density (BMD); asymmetry
ID chingford; incident; risk
AB Osteoarthritis (OA) of the knee is common in the aging population. In patients with OA, bone mineral density (BMD) is usually increased, but the fracture rate does not appear to be systematically lower than in age-matched healthy controls. The aim of our study was to describe hip BNID in patients presenting with unilateral symptomatic knee OA. Patients with painful knee OA were prospectively included in a single-center, randomized, double-blind, placebo-controlled clinical trial to evaluate the structure-modifying efficacy of an oral chondroitin sulfate treatment oil the knee joint. The majority of these patients underwent additional measurements of BMD of their lumbar spine and both hips using dual-energy X-ray absorptiometry (DXA). The hip BMD values of the leg with symptomatic knee OA were compared with the contralateral hip. One-hundred and sixty-one patients (81 men and 80 women; aged 62.6 +/- 9.2 yr, range 40-82 yr) underwent DXA. The median total hip BMD was higher than in age-matched controls, but patients had a relatively lower hip BMD in the knee OA-affected leg (p = 0.001). Our knee OA patients rarely presented with concomitant osteoporosis, but usually had a relatively lower hip BMD on the affected leg. Therefore, we suggest that the hip of the leg with symptomatic knee OA should be measured if DXA is acquired only at one hip. Future studies have to assess whether the relative decrease of BMD at the hip of the leg with knee OA might influence fracture incidence.

TI Reconstruction of the anterior cruciate ligament with a Patella-Tendon-Bone graft may lead to a permanent loss of bone mineral content due to decreased patellar tendon stiffness
SO MEDICAL HYPOTHESES
LA English
DT Article
ID skeletal structural adaptations; mechanical usage satmu; redefining wolff law; muscle strength; bed rest; density; knee; removal; osteoporosis; injury
AB Immobilisation induces bone loss. Evidence from studies in animals and healthy humans that were immobitised for a limited time indicates that, in general, bone mass may be restored even in adults. Following conservative management of partial tears of the anterior cruciate ligament (ACL), bone loss is often negligible (2-3%). After surgical reconstruction, however, there is greater bone loss (15-20%), with little or no recovery. Bones adapt to the stresses they experience. Also, the largest forces in the musculosketetal system arise from muscle pull. Tendons transmit these forces. Many surgical techniques for ACL reconstruction use autologous tendon grafts. We hypothesise that tissue harvesting causes weakening of the formerly intact tendon, which, in turn, leads to reduced muscle pull and subsequent bone loss in those parts of the bone that are loaded by the tendon. If our hypothesis holds true, it may change patients' and surgeons' choice of management. Clinical follow-up should assess the functional result with greater scrutiny, possibly including the assessment of bone mineral content. This may be particularly important since there is accumulating evidence that a decrease in bone mineral density (BMD) preceedes, and hence may be a cause of, osteoarthritis. (c) 2004 Elsevier Ltd. TI Stability of RNA isolated from human trabecular bone at post-mortem and surgery
SO BIOCHIMICA ET BIOPHYSICA ACTA-MOLECULAR BASIS OF DISEASE
LA English
DT Article
DE bone; mRNA; post-mortem; RNA stability; surgery
ID kappa-b ligand; messenger-rna; gene-expression; osteoclast differentiation; receptor activator; cancellous bone; cell biology; osteoblast; autopsy; osteoprotegerin
AB To determine the reliability of gene expression studies in human post-mortem bone, it is important to evaluate the stability of RNA isolated from such tissues as a

function of the post-mortem interval. The stability of total RNA and bone-specific mRNA species was examined in bone samples obtained from routine autopsies and at surgery. The optimal temperature for any storage and transport of the bone before RNA isolation was shown to be 4 degrees C, and RT-PCR analysis is the preferred technique for the analysis of gene expression in post-mortem bone as it tolerates partial RNA degradation. For gene expression studies in bone, post-mortem cases, with a post-mortem interval of less than 48 h, should be selected, and the time that bone is stored after retrieval at autopsy or surgery should be kept to a minimum. Overall, our findings indicate that with appropriate storage and handling, RNA can be reliably isolated from human bone obtained at post-mortem and surgery to study ex vivo the pattern of gene expression in healthy individuals and in patients with musculoskeletal diseases such as osteoporosis and osteoarthritis. TI The management of necrosis-associated and idiopathic bone-marrow oedema of the proximal femur by intravenous iloprost
SO JOURNAL OF BONE AND JOINT SURGERY-BRITISH VOLUME
LA English
DT Article
ID femoral-head; transient osteoporosis; core decompression; avascular necrosis; osteonecrosis; hip; mri; pain; pressure; osteoarthritis
AB Bone-marrow oedema can occur both in isolation and in association with necrosis of bone, but it has not been shown whether each respond to the same methods of treatment. We treated 16 patients with isolated oedema and 17, in which it was associated with necrosis of the proximal femur, with the prostacyclin derivative iloprost, which has been shown to be effective in the idiopathic form. The Harris hip score, the range of movement, the extent of the oedema as measured by MRI, pain on a visual analogue scale and patient satisfaction were recorded before and subsequent to treatment. In both groups, we were able to show a significant improvement ($p < 0.001$) in these observations during the period of follow-up indicating that iloprost will produce clinical improvement in both circumstances.

TI Musculoskeletal manifestations of mild osteogenesis imperfecta in the adult
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE fracture; impairment; musculoskeletal; osteogenesis imperfecta; tendon
ID sympathetic dystrophy syndrome; percutaneous vertebroplasty; transient osteoporosis; tendon-rupture; fractures; hip
AB The musculoskeletal manifestations of mild forms of osteogenesis imperfecta are not well defined in the adult. The aim of this study was to characterize the musculoskeletal manifestations and resulting impairments reported by adults with mild osteogenesis imperfecta. For this task a survey of musculoskeletal symptoms and impairments was hosted on the Osteogenesis Imperfecta Foundation web site for 6 weeks. Survey responses are reported herein. There were 111 unduplicated, adult respondents (78 female). Mean age was 40.8 years. More than one-quarter of 3,410 lifetime fractures occurred in adulthood. Nearly half of respondents reported an established diagnosis of "arthritis" (usually osteoarthritis), and the majority of these reported some degree of impairment attributable to arthritis. Articular pain, stiffness and instability were dominant in the large, weight-bearing joints of the lower extremities. Back pain and scoliosis were common. Of the respondents, 15% required assistance with light physical tasks and personal care. Two-thirds reported joint hyper-mobility, and one-third reported a previous tendon rupture. Complex regional pain syndrome was rare. Respondents reported frequent use of medications known to have potential adverse skeletal effects. In spite of these concerns the majority rated their overall physical health as good or excellent. Adults with mild osteogenesis imperfecta continue to sustain fractures into adulthood, and the majority reports some functional impairment due to musculoskeletal issues. Significant impairment is not rare.

TI How to assess the impact of arthritis on the individual patient: the WHOICF
SO ANNALS OF THE RHEUMATIC DISEASES
LA English
DT Article
ID international classification; outcome measures; health icf; disability; osteoarthritis
AB The ICF is not only a comprehensive and adequate framework for assessing the impact of arthritis on individual patients but also its impact on populations. The ICF framework and applications such as the ICF Core Sets for rheumatoid arthritis, osteoarthritis, osteoporosis, and low back pain are therefore likely to be used extensively not only in clinical practice but also in outcomes and rehabilitation research, education, health statistics, and regulation.

TI The influence of mechanical properties of subchondral plate, femoral head and neck on dynamic stress distribution of the articular cartilage
SO MEDICAL ENGINEERING & PHYSICS
LA English
DT Article
DE osteoarthritis; articular cartilage; subchondral plate; subchondral bone; femoral head; femoral neck; finite element analysis
ID coxarthrosis hip osteoarthritis; finite-element analysis; bone-mineral density; cancellous bone; shaft angle; osteoporosis; thickness; fracture; failure; joint
AB A few finite element models have addressed the dynamic juxtaarticular stress transmission but none focused the investigation on the combined influence of the individual moduli of the underlying bones, including the subchondral plate, the femoral head and the femoral neck of the proximal femur. A finite element model including the acetabulum and the proximal femur was analyzed with dynamic loadings to study the effects of mechanical property changes in the underlying bones of the proximal femur on the stress distribution in the cartilage at the hip joint. We found the stress distribution was most sensitive to the subchondral plate stiffening, while the overall stiffening of the underlying bones had mild effect on the shear stress on the cartilage surface (or at the subchondral bone/cartilage interface) and on the strain energy density in the cartilage. Our results indicate that the subchondral plate plays a predominant mechanical role in the initial degeneration of the cartilage. The results may offer a mechanical explanation as to why the cartilage failure is common in patients with osteoarthritis but rare in patients with osteoporosis. (c) 2004 IPEM. TI Clinical practice guidelines and quality of care for older patients with multiple comorbid diseases - Implications for pay for performance
SO JAMA-JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION
LA English
DT Article
ID adverse drug events; elderly-patients; atrial-fibrillation; medical-management; american-college; osteoarthritis; polypharmacy; preferences; adherence; pitfalls
AB Context Clinical practice guidelines (CPGs) have been developed to improve the quality of health care for many chronic conditions. Pay-for-performance initiatives assess physician adherence to interventions that may reflect CPG recommendations. Objective To evaluate the applicability of CPGs to the care of older individuals with several comorbid diseases. Data Sources The National Health Interview Survey and a nationally representative sample of Medicare beneficiaries (to identify the most prevalent chronic diseases in this population); the National

Guideline Clearinghouse (for locating evidence-based CPGs for each chronic disease). Study Selection Of the 15 most common chronic diseases, we selected hypertension, chronic heart failure, stable angina, atrial fibrillation, hypercholesterolemia, diabetes mellitus, osteoarthritis, chronic obstructive pulmonary disease, and osteoporosis, which are usually managed in primary care, choosing CPGs promulgated by national and international medical organizations for each. Data Extraction Two investigators independently assessed whether each CPG addressed older patients with multiple comorbid diseases, goals of treatment, interactions between recommendations, burden to patients and caregivers, patient preferences, life expectancy, and quality of life. Differences were resolved by consensus. For a hypothetical 79-year-old woman with chronic obstructive pulmonary disease, type 2 diabetes, osteoporosis, hypertension, and osteoarthritis, we aggregated the recommendations from the relevant CPGs. Data Synthesis Most CPGs did not modify or discuss the applicability of their recommendations for older patients with multiple comorbidities. Most also did not comment on burden, short- and long-term goals, and the quality of the underlying scientific evidence, nor give guidance for incorporating patient preferences into treatment plans. if the relevant CPGs were followed, the hypothetical patient would be prescribed 12 medications (costing her $406 per month) and a complicated nonpharmacological regimen. Adverse interactions between drugs and diseases could result. Conclusions This review suggests that adhering to current CPGs in caring for an older person with several comorbiclities may have undesirable effects. Basing standards for quality of care and pay for performance on existing CPGs could lead to inappropriate judgment of the care provided to older individuals with complex comorbiclities and could create perverse incentives that emphasize the wrong aspects of care for this population and diminish the quality of their care. Developing measures of the quality of the care needed by older patients with complex comorbidities is critical to improving their care.

TI Neridronate and human osteoblasts in normal, osteoporotic and osteoarthritic subjects
SO CLINICAL RHEUMATOLOGY
LA English
DT Article
DE neridronate; osteoarthritis; osteoblasts; osteocalcin; osteoporosis; vitamin D
ID rat bone-cells; in-vitro; bisphosphonates; alendronate; etidronate; calvaria; culture; osteoprotegerin; proliferation; osteogenesis
AB The objective of this study was to evaluate the metabolic in vitro effect of the bisphosphonate neridronate on normal and pathological human osteoblasts. Primary human osteoblast cultures were obtained from cancellous bone of osteoarthritic (OA) and osteoporotic (OP) patients and a corresponding healthy control group. Osteocalcin production was evaluated by cultured cells in neridronate 10(-4) M and 10(-6) M, both under basal conditions and after vitamin D-3 stimulation. In the absence of neridronate, vitamin D-3 increased osteocalcin production in all cell cultures; under the same conditions, and in the absence of vitamin D-3, OA osteoblasts showed a significantly higher osteocalcin production whereas OP osteoblasts showed a significantly lower osteocalcin production compared to the normal osteoblasts, respectively. In all cellular populations neridronate at a higher concentration (10(-4) M) induced a reduction in osteocalcin synthesis, but in normal and osteoarthritic osteoblasts did not reduce the stimulatory effect of vitamin D-3, whereas it inhibited the vitamin D-3-induced increase of osteocalcin synthesis in the osteoporotic cells. In normal and osteoporotic osteoblasts stimulation with the lower neridronate concentration (10(-6) M) significantly increased osteocalcin production, which was further enhanced by vitamin D-3 as an additional effect of the combined treatment. In OA osteoblasts, neridronate 10(-6) M did not induce an increase in osteocalcin synthesis and the additional effect of combined treatment with vitamin D-3 was not observed. Neridronate can modify the metabolic activity of human osteoblasts by enhancing or decreasing their biosynthetic activity, both in normal and in pathological conditions, depending on compound concentration and on different cell types. These results confirm the validity of using neridronate at doses usually administered in treating osteoporosis, and they suggest using it to treat other diseases which show an altered osteoblast metabolism, such as osteoarthritis.

DT Review
DE osteoporosis; systemic sclerosis; risk factors; bone mineral density
ID systemic-sclerosis; osteoarthritis
AB OBJECTIVE To review the literature describing the association of osteoporosis (OP) with scleroderma (SSc). METHODS A Medline (PubMed) search identified all studies from 1966 to 2004 that investigated the association between OP and SSc. Search terms included "scieroderma," "systemic sclerosis," "osteoporosis, " "bone mineral density," "bone densitometry," and "prevalence." RESULTS Eight case control studies and 1 retrospective study (comparing OP status to a reference standard) were identified. There is no clear association between bone mineral density (BMD) scores and scleroderma. Two of 4 studies have reported lower BMD scores in SSc, but appear not to have considered possible confounding risk factors. Earlier age of menopause has been reported in 2 of 3 studies, and thus, may be a confounder in some samples of women with SSc. Studies of bone metabolism markers have not provided any consistent explanatory mechanism for increased OP in SSc, and such markers may be unreliable in SSc as these are affected by the altered collagen turnover and fibrosis characteristic of SSc. CONCLUSIONS It is unknown whether OP is truly increased in SSc or whether this association has been observed in some studies as a result of other confounding risk factors for OP.

Clinical heterogeneity of SSc study samples and small sample sizes have contributed to the difficulty in obtaining valid estimates of the risk for the development of OP. There is no strong evidence in the literature for consistently lower BMD scores in SSc, or for altered biomarkers of bone resorption. Earlier menopause, corticosteroid use in some patients, and other factors secondary to SSc (such as malabsorption and inflammation), may be causal, factors or may be confounders in studies of OP in SSC. TI Hemochromatosis and femoral head aseptic osteonecrosis: A nonfortuitous association?
SO JOURNAL OF RHEUMATOLOGY
LA English

DT Article
DE hemochromatosis; femoral head; hip aseptic osteonecrosis
ID natural-history; hip arthropathy; arthritis; features
AB Chondrocalcinosis, chronic pseudo-osteoarthritis arthropathy, and osteoporosis are classic osteoarticular complications of hemochromatosis (HC). Within HC, femoral head aseptic osteonecrosis (FHAO) is not notified in textbooks. We describe 3 cases of FHAO occurring in this setting in 3 patients homozygous for the C282Y mutation on HFE gene who had no other risk factors for FHAO. FHAO was diagnosed 9 years before (Case 1), concomitantly with (Case 3), or 9 years after HC (Case 2). In one case, FHAO occurred although phlebotomies were regularly carried out. There are scarce data available in the literature on HC and FHAO. Our observations suggest FHAO may be an indicator for HC, and iron balance should be determined before considering FHAO as idiopathic. Thus phlebotomy may not be protective against the occurrence of FHAO. Studies are needed to determine the prevalence of HC in consecutive patients with FHAO.

TI Birthweight, vitamin D receptor gene polymorphism, and risk of lumbar spine osteoarthritis
SO JOURNAL OF RHEUMATOLOGY
LA English
DT Article
DE birthweight; lumbar spine; osteoarthritis; risk factors; vitamin D receptor gene
ID bone-mineral density; radiographic osteoarthritis; disc degeneration; early growth; back-pain; osteoporosis; association; environment; infancy; disease
AB Objective. To investigate risk factors for adult lumbar spine osteoarthritis (OA) including polymorphisms of the vitamin D receptor gene (VDR) and birthweight. Methods. Plain radiographs of the lumbar spine were taken in 392 healthy subjects and graded for osteophytes and disc space narrowing (DSN); demographic data were collected. Details of birthweight and weight at 1 year were retrieved from historical records. VDR gene allelic variation was analyzed in 291 subjects. Results.

The mean age of the cohort was 65.8 years; mean weight was 68.9 kg in women and 80.1 kg and men. Osteophytes of grade >= 2 were found in 63.5% of this cohort; DSN >= 2 was present in 14.3% of subjects. Increasing osteophyte severity was significantly associated with age, adult weight, and manual social class; DSN was not. Presence and severity of osteophytes were associated with low birthweight and lower weight at 1 year in men, but not in women. No associations were found for DSN. The B allele of the VDR gene was associated with increasing severity of osteophyte. There was a significant interaction between birthweight and VDR gene in determining risk of osteophytosis in men (p for interaction = 0.04). The VDR-birthweight interaction pattern was similar but not statistically significant in women. Conclusion. Lumbar spine OA was a prevalent finding in this cohort. Both birthweight and polymorphisms in the VDR gene were associated with the presence of lumbar spine osteophytes and a significant interaction was observed between these 2 factors in men.

TI Agastache rugosa leaf extract inhibits the iNOS expression in ROS 17/2.8 cells activated with TNF-α and IL-1β
SO ARCHIVES OF PHARMACAL RESEARCH
LA English
DT Article
DE nitric oxide; osteoarthritis; bone turn-over; osteoblast; Agastache rugosa
ID nitric-oxide synthase; inflammation-induced osteoporosis; osteoblast-like cells; experimental osteoarthritis; rheumatoid-arthritis; induced apoptosis; bone-resorption; kappa-b; rat; mouse
AB It has been suggested that nitric oxide (NO) derived from inducible nitric oxide synthase (NOS) may act as a mediator of cytokine-incluced effects on bone turn-over. NO is also recognized as an important factor in bone remodeling, i.e., participating in osteoblast apoptosis in an arthritic joint. The components of Agastache rugosa are known to have many pharmacological activities. In the present study, we investigated the effects of Agastache rugosa leaf extract (ELAR) on NO production and the iNOS expression in ROS 17/2.8 cells activated by a mixture of inflammatory cytokines including TNF-alpha and IL-1 beta. A

preincubation with ELAR significantly and concentration-dependently reduced the expression of iNOS protein in ROS 17/2.8 cells activated with the cytokine mixture. Consequently, the NO production was also significantly reduced by ELAR with an IC50 of 0.75 mg/mL. The inhibitory mechanism of iNOS induction by ELAR prevented the activation and translocation of NF-kappa B (p65) to the nucleus from the cytosol fraction. Furthermore, ELAR concentration-dependently reduced the cellular toxicity induced by sodium nitroprusside, an NO-donor. These results suggest that ELAR may be beneficial in NO-mediated inflammatory conditions such as osteoporosis.

TI Ovariectomy alters the structural and biomechanical properties of ovine femoro-tibial articular cartilage and increases cartilage NOS
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE ovariectomy; sheep; cartilage biomechanics; nitric oxide radical
ID estrogen replacement therapy; nitric-oxide synthase; sex-hormones; mechanical-property; lateral meniscectomy; in-vivo; osteoarthritis; 17-beta-estradiol; collagen; model
AB Objective: To examine the effect of oestrogen depletion produced by surgical ovariectomy on the structural and biomechanical properties of ovine femoro-tibial articular cartilage (AC), and the production of inducible nitric oxide synthase (iNOS) and nitrotyrosine by these tissues. Methods: Six aged ewes were surgically ovariectomised (OVX), while six were used as unoperated controls. Dynamic biomechanical indentation testing of tibial plateau AC was performed at 26 weeks post-op. Histological sections of medial tibial plateau and lateral tibial plateau (LTP), medial and lateral femoral condyles (MFC, LFC) and patellar AC were examined for histopathology, toluidine blue staining intensity, and patterns of collagen birefringence intensity. Immunoreactivity for iNOS and nitrotyrosine was assessed in full-thickness biopsy plugs of LFC and patellar AC, and patellar AC explants were cultured to determine in vitro NO release. Results: Phase lag was reduced overall in LTP-AC of OVX sheep (10.9 +/- 2.2 degrees vs 12.1 +/- 2.3 degrees; $P < 0.0001$). Cartilage thickness was reduced in the LTP of OVX sheep ($P = 0.0002$), in association with localised changes in dynamic shear modulus. Toluidine blue staining intensity was reduced in the patella, LFC, and MFC. Histological examination revealed greater histopathology scores in the MFC of OVX animals, and altered collagen birefringence intensity plots in the LTP. Immunostaining for iNOS was increased in patella AC ($P = 0.008$), whilst nitrotyrosine immunoreactivity was increased in patella ($P = 0.03$) and LFC ($P < 0.0001$) AC. NO release by patellar AC explants was also elevated. Conclusions: Oestrogen depletion induced by OVX caused regional thinning of femoro-tibial cartilage, with biomechanical and histological changes suggestive of a disturbance in the content and/or structural organisation of the proteoglycan and collagen macromolecular assembly. The observed up-regulation of cartilage iNOS suggests a possible mechanism for these matrix changes. (c) 2005 OsteoArthritis Research Society International. Published by Elsevier Ltd. TI Increased RANKL/OPG mRNA ratio in iliac bone biopsies from women with hip fractures
SO CALCIFIED TISSUE INTERNATIONAL
LA English
DT Article
DE osteoporosis; cytokines; bone biopsy; osteoprotegerin; PCR analysis
ID osteoclastogenesis-inhibitory factor; tumor-necrosis-factor; kappa-b ligand; receptor activator; osteoprotegerin ligand; differentiation factor; soluble interleukin-6; mineral density; resorption; osteoarthritis
AB RANKL (receptor activator of NF-kappaB) is a potent physiological inducer of osteoclastogenesis. Its actions are blocked by the decoy receptor osteoprotegerin (OPG), and treatment with OPG blocks bone resorption in postmenopausal women. Both positive and negative associations between serum OPG and bone mineral density (BMD) have been reported in the literature. We hypothesized that decreased OPG production relative to RANKL within bone itself could lead to increased risk of osteoporotic fracture. We included ten women with hip fracture (age 76.3 +/- 8.0 years, NS hip BMD 0.686 +/- 1.3 g/cm(2), p < 0.05) and 24 women with osteoarthrosis of the hip (age 72.8 +/- 7.2 years, hip BMD 0.832 +/- 1.1 g/cm(2)). Transiliac biopsies were obtained at the time of surgery. Total RNA was extracted from biopsies and reverse-transcribed. Real-time quantification of rnRNA was performed with a SYBR Green I real time PCR assay, calculating relative gene expession with normalization of results for 0 actin mRNA. Actin normalized mRNA levels for OPG and interleukin (IL)-6 were significantly lower in fracture patients, with a significantly higher RANKL/OPG ratio in patients with Fractures. There was no significant difference in tumor necrosis factor (TNF), IL-1, IL-1ra, or IL-7 expression. IL-6 mRNA levels were lower in fracture patients (P < 0.05). The effect of increased RANKL/OPG ratio (Z = 2.08, P < 0.05) on fracture risk was additive to that of hip BMD T score (Z = -1.95, P < 0.05) when assessed using logistic regression. Elderly women with hip fractures exhibit an increased RANKI_/0PG rnRNA content of iliac bone. This is associated with increased fracture susceptibility, which is not in itself explained by low BMD.

TI Evaluation of the spa therapy in Ataturk Balneotherapy and Rehabilitation center
SO PHYSIKALISCHE MEDIZIN REHABILITATIONSMEDIZIN KURORTMEDIZIN
LA English
DT Article
DE Balneotherapy; spa therapy; thermal water
ID controlled trial; rheumatoid-arthritis; exercise program; water exercise; fibromyalgia; bone
AB There are seven randomized, controlled studies made in Ataturk Balneotherapy and Rehabilitation Center (ABRC). In the present writing, we have the objective of making a review of these seven studies reported in international journals. Methods: Spa therapy in thermal water has been applied to patients with osteoarthritis, rheumatoid arthritis, fibromyalgia syndrome, low back pain and osteoporosis with different times of durations and water temperature for each disease. Results and conclusion: These studies show the superiority of the water or water-exercise combination in the improvement of pain and other clinical parameters, to exercise alone.

TI Perception, assessment, treatment, and management of pain in the elderly
SO CLINICS IN GERIATRIC MEDICINE
LA English
DT Article
ID analgesic efficacy; major depression; double-blind; tramadol; mirtazapine; osteoarthritis; pharmacology; surgery; placebo; safety
AB Twenty to 50% of community elderly suffer from pain. Up to 80% of the institutionalized elderly report at least one pain problem. Multiple pain etiologies that occur in elderly patients may be the occurrence of multiple chronic diseases: osteoarthritis, RA, cancer, DJD, bone/joint disorders, osteoporosis, surgical pain, trauma, neuropathic pain, and nociceptive pain. The incidence of unrelieved pain inhibits respiration, decreases mobility, and decreases their functional status, which may lead to iatrogenic events, which include pneumonia, constipation and deep vein thrombosis. Prolonged inpatient stays and extended care facilities or nursing homes may decrease the elderly patient's expectations of quality of life and initiate social isolation. There exists some roadblocks or barriers to the detection of pain in the elderly client. These include social, emotional, cognitive, and subjective issues with the patient.

TI Tibial plateau size is related to grade of joint space narrowing and osteophytes in healthy women and in women with osteoarthritis
SO ANNALS OF THE RHEUMATIC DISEASES

LA English
DT Article
ID cartilage volume; osteo-arthritis; knee cartilage; bone-density; iliac crest; hip; osteoporosis; therapy; neck
AB Objective: To determine the relation of bone size to radiographic severity in knee osteoarthritis. Methods: 149 women (81 healthy and 68 with knee osteoarthritis) underwent knee radiography and magnetic resonance imaging on their symptomatic or dominant knee. Tibial plateau bone area was measured at baseline and at follow up. Results: Women with osteoarthritis had larger medial and lateral tibial plateau bone area (mean (SD): 1850 (240) mm(2) and 1279 (220) mm(2), respectively) than healthy women (1670 (200) mm(2) and 1050 (130) mm(2)) (p< 0.001 for both differences). For each increase in grade of osteophyte, an increase in bone area was seen of 146 mm(2) in the medial compartment and 102 mm(2) in the lateral compartment. Similarly, for each increase in grade of joint space narrowing, tibial plateau bone area increased by 160 mm(2) in the medial compartment and 131 mm(2) in the lateral compartment (significance of regression coefficients all p< 0.001). These relations persisted after adjusting for potential confounders, with the exception of the association between grade of medial osteophytes and medial plateau area. Conclusions: With increasing severity of radiographic knee osteoarthritis, tibial plateau size increases. Whether this bone increase plays a role in the pathogenesis of osteoarthritis remains to be determined.

TI Cancellous bone changes in hip osteoarthritis: a short-term longitudinal study using fractal signature analysis
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE osteoarthritis; hip; femoral head; cancellous bone; fractal analysis
ID joint space width; subchondral bone; radiographic assessment; trabecular bone; proximal tibia; macroradiographs; knee; age; osteoporosis; organization
AB Objective: To quantify changes to the trabecular structure in the femoral heads of patients with hip osteoarthritis (OA). Methods: Patients with CA (n = 14; F = 7), mean (standard deviation age) 50.6 (10. 1) years, had macroradiographs at approximately X 4 magnification at baseline and 18 months later using a standardized protocol. Following digitization, computerized measurement was obtained of minimum hip joint space width and fractal signature analysis (FSA) measured longitudinal changes separately in the principal compressive (vertical) and horizontal trabeculae at the region of interest within the centre of the head. Results: The patient group had mean annual rate of joint space narrowing of 0. 14 +/- 0.36 mm/yr. FSA detected no significant changes in horizontal trabeculae, whereas the larger principal compressive (vertical) trabeculae (0.96 mm to 1.02 mm) increased significantly in thickness and the fine to medium trabeculae (0.18 mm to 0.54 mm) decreased significantly in number. Conclusion: The increased thickness of the larger trabeculae within the compressive structural element of the femoral head is a response to the increase in stress associated with an overall loss of trabeculae in this region, suggesting the presence of an osteoporosis within the femoral head in CA patients. TI Involvement of ICAM-1 in bone metabolism: a potential target in the treatment of bone diseases?
SO EXPERT OPINION ON BIOLOGICAL THERAPY
LA English
DT Review
DE adhesion blockade; bone diseases; ICAM-1; treatment
ID intercellular-adhesion molecule-1; tumor-necrosis-factor; rheumatoid-arthritis; e-selectin; synovial fibroblasts; monoclonal-antibody; leukocyte adhesion; cellular adhesion; human osteoblasts; soluble form
AB Bone diseases such as osteoporosis, osteoarthritis and rheumatoid arthritis (RA) affect a great proportion of individuals, with debilitating consequences in terms of pain and progressive limitation of function. Existing treatment of these pathologies has been unable to alter the natural evolution of the disease and, as such, a clearer understanding of the pathophysiology is necessary in order to generate new treatment alternatives. One therapeutic strategy could involve the targeting of intercellular adhesion molecule-1 (ICAM-1; CD54). In bone, ICAM-1 is expressed at the surface of osteoblasts (Obs) and its counter-receptor, leukocyte function-associated antigen-1 (LFA-1; CD11a), at the surface of osteoclast (Oc) precursors. ICAM-1 blockade between the Ob and the pre-Oc results in an inhibition of Oc recruitment and a modulation of inflammation, which could potentially help in controlling disease activity in bone pathologies. So far, clinical studies on ICAM-1 blockade in bone diseases have been limited to RA. A better understanding of the implication of this adhesion molecule in Ob/Oc interactions and inflammatory mediation in the bone pathological state, however, is needed. As new discoveries on the role of this adhesion molecule are being reported, ICAM-1 could become a potential target for other bone diseases as well.

TI The relationships between bone mineral density in the spine, hip, distal femur and proximal tibia and medial minimum joint space width in the knees of healthy females
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE minimum joint space width; knee; bone mineral density; osteoarthritis
ID x-ray absorptiometry; subchondral bone; articular-cartilage; cancellous bone; femoral-head; osteoarthritis; osteoporosis; turnover; incident; women
AB Objective: To investigate the relationships between bone mineral density (BMD) in the hip, spine, distal femur and proximal tibia and minimum joint space width (mJSW) in the knees of healthy women. Methods: Women 22-68 years old without a history of knee pain, bone or joint disease or injury underwent a single, fixed-flexion knee X-ray. Radiographs were graded according to the Kellgren-Lawrence scale and analyzed for mJSW using a computer algorithm. Dual X-ray absorptiometry scans of the spine, hip, distal femur and proximal tibia were also acquired for each participant. Femur and tibia scans were acquired and analyzed using a modified version of the lumbar spine software. Results: Forty-five females, mean [standard deviation (SD)] age and body mass index (BMI) of 40.1 (13.9) years and 24.6 (4.5) kg/m(2), respectively, participated. The mean (SD) mJSW was 4.64 (0.68) mm. Linear regression analyses controlling for age and BMI revealed that BMD in the femoral trochanter and the central two regions of the tibia (T2 and T3) was significantly related to mJSW in the knee. A backwards regression analysis performed to determine which region of interest is most significantly related to mJSW revealed that femoral trochanter BMD (beta-value = 0.416) is the most significant. Conclusions: In contrast to the suggestion that BMD is negatively correlated with mJSW in the knees of osteoarthritic individuals, these results suggest that increasing BMD in the femoral trochanter and tibia is significantly associated with increasing mJSW in healthy females. Further investigation of this relationship is warranted. (c) 2005 OsteoArthritis Research Society International. Published by Elsevier Ltd. All rights reserved.

TI Gene therapy for the treatment of musculoskeletal diseases
SO JOURNAL OF THE AMERICAN ACADEMY OF ORTHOPAEDIC SURGEONS
LA English
DT Article
ID bone-marrow-cells; in-vivo; adenoviral delivery; human joints; stem-cells; osteoarthritis; enhancement; ligament; repair; tissue
AB Research into the orthopaedic applications of gene therapy has resulted in progress toward managing chronic and acute genetic and nongenetic disorders. Gene therapy for arthritis, the original focus of research, has progressed to the initiation of several phase 1 clinical trials. Preliminary findings support the application of gene therapy in the treatment of additional chronic conditions, including osteoporosis and aseptic loosening, as well as musculoskeletal tumors. The most rapid progress is likely to be in tissue repair because it requires neither long-term transgene expression nor closely regulated levels of transgene expression. Moreover, healing probably can be achieved with existing technology. In preclinical studies, genetically modulated stimulation of bone healing has shown impressive results in repairing segmental defects in the long bones and cranium and in improving the success of spinal fusions. An increasing amount of evidence indicates that gene transfer can aid the repair of articular cartilage, menisci, intervertebral disks, ligaments, and tendons. These developments have the potential to transform many areas of musculoskeletal care, leading to treatments that are less invasive, more effective, and less expensive than existing modalities.

TI The application of topology optimization on the quantitative description of the external shape of bone structure
SO JOURNAL OF BIOMECHANICS
LA English
DT Article
DE external shape; internal structure; bone functional adaptation; topology optimization; bone
ID remodeling simulations; trabecular bone; stress; strain
AB The aim of this paper was to introduce the idea of topology optimization in engineering to the simulation of bone morphology. The external shape of bone structure was predicted with the quantitative bone functional adaptation theory. The high-order nonlinear equation of bone remodeling proposed by Zhu et al. (J. Biomech. 35(7)(2002)951) combining with the finite element method was adopted

to a rectangular design domain, which occupies a larger space than the external shape of bone structure. It was at this point we imported the idea of topology optimization in engineering. The proximal femur was used here as an example, whose external shape and internal density distribution were simultaneously simulated quantitatively to validate that the external shape of bone structure could be successfully predicted in this way. Then the growth of vertebral body from young to old was simulated numerically in its coronal section to discuss the significance of the prediction of external shape. The study in this paper provides computational basis for further studies on osteophyte formation, osteoporosis, osteoarthritis, bone growth and even bone evolution, etc. (c) 2004 Elsevier Ltd. TI Violation of the intent-to-treat principle and rate of missing data in superiority trials assessing structural outcomes in rheumatic diseases
SO ARTHRITIS AND RHEUMATISM
LA English
DT Article
ID randomized clinical-trials; incident vertebral fractures; methodological quality;

arthritis; osteoporosis; prevalent; articles
AB Objective. To evaluate the methodologic quality of and identify methodologic issues in superiority trials assessing structural outcomes in rheumatic diseases. Methods. We searched Medline and the Cochrane Central Register of Controlled Trials for reports of randomized controlled trials assessing structural outcomes in osteoarthritis (OA), rheumatoid arthritis (RA), and osteoporosis (OP) published between January 1994 and December 2003 in high-impact factor general medical and specialty journals. One reader extracted data (quality assessment, intent-to-treat analysis [ITT analysis], rate of missing data, and methods of handling missing data), using a standardized form. Results. A total of 81 reports were included in the analysis (37 on OP, 34 on RA, and 10 on OA). The mean +/- SD methodologic quality scores on the Jadad scale (possible range 0-5) and the Delphi list (possible range 0-9) were 2.9 +/- 1.2 and 6.4 +/- 1.3, respectively. Although it was reported in 54 articles (66.7%) that the analysis was done on an ITT basis, full ITT analysis was performed in only 6 of the studies (7.4%), modified ITT analysis in 11 (13.6%), and case-complete analysis in 48 (59.3%); the analysis was unclear in 16 articles (19.8%). The rate of missing data on structural outcomes could be determined in only 63 articles (77.8%) and was > 20% in approximately one-third of these reports. Methods for handling missing data on structural outcomes were described in 19 articles (23.5%) and were, in general, inappropriate. Conclusion. Lack of ITT analysis and a high rate of missing data in superiority trials assessing structural outcomes may bias results from such trials. Our recommendations for improving these shortcomings may help researchers plan, analyze, and report the results of such trials.

TI Clinical presentation of osteoarthritis in general practice: Determinants of pain in Italian patients in the AMICA study
SO SEMINARS IN ARTHRITIS AND RHEUMATISM
LA English
DT Review

DE osteoarthritis; pain; risk factors; general practice
ID of-rheumatology criteria; knee osteoarthritis; classification; hand; prevalence; overweight; women; risk
AB OBJECTIVE To assess the clinical characteristics and determinants of pain observed by general practitioners (GPs) in Italian patients with osteoarthritis (OA) of the hand, hip, and knee. METHODS The 2764 GPs participating in the study were asked to enroll 10 consecutive patients with OA diagnosed according to the American College of Rheumatology (ACR) clinical criteria. To standardize the diagnosis, the GPs received ad hoc training from musculoskeletal system specialists. A questionnaire evaluating demographic data, the clinical characteristics of OA, and previous diagnostic and therapeutic interventions was administered by the GPs. RESULTS 25,589 evaluable patients were enrolled during a mean period of 2.8 weeks by the GPs: 17,567 women (69%) and 7878 men (31 %). The most painful OA joints were the knee in 12,827 patients (54%), the hip in 5645 patients (24%), and the hand in 5467 patients (23%)percentages calculated on the 23,939 patients for whom this information was available. The weekly incidence of referrals to GPs for OA was higher for women and for knee OA. The median age of the patients was 70 years (range 50 to 104 years) and disease duration was 8.3 +/- 7.10 years. The most frequent comorbidities were hypertension (53%), obesity (22%), osteoporosis (21 %), type II diabetes mellitus (15%), and chronic obstructive pulmonary disease (13%). The median pain visual analog scale (VAS) score was higher for women than for men, for hip OA, and for generalized OA (GOA) than for knee and hand OA ($P < 0.0001$). Intense pain, defined as VAS readings of > 60 mm, was increased in women only in the knee (OR = 1.24; 95% CI 1.15 to 1.34) and in GOA (OR = 1.17; 95% CI 1.03 to 1.33). It was also significantly increased in patients older than 70 years (OR = 1.46; 95% CI 1.39 to 1.54), those with a low educational level (OR = 1.44; 95% CI 1.36 to 1.5), a BMI of 2:30 (OR = 1.52; 95% CI 1.42 to 1.61), a disease duration of more than 7 years (OR 1.60; 95% CI 1.52 to 1.68), comorbidities (OR = 1.61; 95% CI 1.5 to 1.73), and GOA (OR 2.05; 95% CI 1.91 to 2.19). Manual occupations were associated with highly intense pain only in men. CONCLUSIONS The results of this study underscore the major impact of OA on care in general practice, the high frequency of OA-associated comorbidities, and the role of different risk factors in OA pain.

TI Cancellous bone differences between knees with early, definite and advanced joint space loss; a comparative quantitative macroradiographic study
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE osteoarthritis; knee; subchondral bone; fractal analysis
ID fractal signature analysis; subchondral bone; trabecular bone; osteoarthritic knees; proximal tibia; medial condyle; cortical bone; iliac crest; osteoporosis; texture
AB Objective: To quantify differences in bone structure in the proximal tibia of patients with mild, definite and advanced osteoarthritis (OA) compared to healthy reference tibiae. Design: Patients with medial compartment CA (n = 110; F = 70), mean +/- SD age 61.0 +/- 10.2 years, and non-OA reference subjects (n 27; F= 10)

mean +/- SD age 36.3 +/- 11.4 years had 4 X macroradiographs cligitised by laser scanner. Computer measurement of minimum medial joint space width (JSW) subdivided available CA knees into those with early (JSW 3 mm, n = 70), definite (JSW less than or equal to 3 > 1.5 mm, n = 52) and advanced OA (JSW less than or equal to 1.5 mm, n = 60). Non-OA knees (n = 49) had JSW > 4.5 mm. Fractal Signature Analysis (FSA), a computerised image analysis technique, measured differences in cancellous bone structure between CA and non-OA tibiae at four regions of interest (ROIs). Results: Compared to non-OA, FSA of vertical trabeculae increased significantly (P < 0.05) at most sizes (0.12-1.14 mm) in all CA subgroups and ROIs, with greatest increase occurring in the medial diseased compartment. Compared to early OA, FSA of vertical trabeculae increased significantly (P < 0.05) at most sizes (0.36-1.14 mm) in subchondral and subarticular ROIs in definite and advanced OA. Compared to non-OA, FSA of horizontal trabeculae increased significantly (P < 0.05) at some small sizes in all ROIs and CA subgroups, and decreased significantly (P < 0.05) at large sized horizontal trabeculae (0.60-1.14 mm) in the medial subarticular region in advanced OA. Conclusion: The increase in FSA (consistent with increased trabecular number associated with thinning and fenestration in regions of dense cancellous bone) of most vertical and some horizontal trabeculae confirms that cancellous bone within the proximal tibia of CA patients is osteoporotic. TI Subtalar dislocation following ankle arthrodesis: A report of three cases
SO FOOT & ANKLE INTERNATIONAL
LA English
DT Article
AB Ankle arthrodesis is a procedure commonly done to alleviate pain and to correct deformity secondary to arthritis in an attempt to provide patients with a

functional lower extremity. The failures of immobilization and nonoperative management of painful ankle arthrosis have led to the development of operative techniques to decrease pain.(1) Successful arthrodesis has been achieved with a variety of techniques in 65% to 100% of patients.(4) Primary indications for ankle arthrodesis are posttraumatic and primary osteoarthritis, with functionally limiting pain that often is unresponsive to nonoperative management. Rheumatoid arthritis can affect the tibiotalar joint, but ankle pain in these patients more commonly results from subtalar arthritis. Relative contraindications to arthrodesis include peripheral neuropathy, severe osteoporosis, and previous infection. In the presence of peripheral neuropathy, arthrodesis may be required when the deformity is too severe to brace and ulceration has occurred or is imminent. Bracing or casting alone usually fails to relieve symptoms of disabling fixed deformities and instability, especially in patients with neuropathy.(2) Relative contraindications to internal screw fixation include septic arthritis and osteomyelitis. Complications of ankle arthrodesis include nonunion, delayed union, skin breakdown, and malalignment, with or without the development of subsequent subtalar arthrosis.(3) The frequency of failed reconstruction of neuropathic joints of the foot or ankle is approximately 60%: infection and failed arthrodesis are the most frequent contributing factors.(4,5) We are unaware of any description of subtalar dislocation after previous ankle arthrodesis. The purpose of this paper was to describe three patients who progressed to a chronic subtalar dislocation after an ankle arthrodesis. All patients were elderly. One patient had peripheral neuropathy, one had diabetic neuropathy, and one had posterior tibial tendon insufficiency as their presenting diagnoses. All patients required extension of the previous arthrodesis to manage progressive deformity despite attempted bracing with an ankle-foot orthosis. Both patients with neuropathy had recurrent ulceration and progressive deformity.

TI Effect of spinal degenerative changes on volumetric bone mineral density of the central skeleton as measured by quantitative computed tomography
SO ACTA RADIOLOGICA
LA English
DT Article
DE bone mineral density; dual X-ray absorptiometry; hip; osteoarthritis; spine;

volumetric QCT
ID x-ray absorptiometry; postmenopausal women; rheumatoid-arthritis; osteoporosis; osteoarthritis; fracture; osteophytes; diagnosis; men; ct
AB Purpose: To evaluate the impact of degenerative changes due to osteoarthritis (OA) at the spine on volumetric bone mineral density (BMD) as measured by volumetric quantitative computed tomography (vQCT). Material and Methods: Eighty- four elderly women (mean age 73 +/- 6 years), comprising 33 with vertebral fractures assessed by radiographs and 51 without vertebral fractures, were studied. Trabecular, cortical, and integral BMD were examined at the spine and hip using a helical CT scanner and were compared to dual X- ray absorptiometry (DXA) measurements at the same sites. OA changes visible on the radiographs were categorized into two grades according to severity. Differences in BMD measures obtained in the two groups of patients defined by OA grade using the described radiologic methods were compared using analysis of variance. Standardized difference (effect sizes) was also compared between radiologic methods. Results: Spinal trabecular BMD did not differ significantly between OA grade 0 and OA grade 1. Spinal cortical and integral BMD measures showed statistically significant differences, as did the lumbar spine DXA BMD measurement (13%, P = 0.02). The QCT measurements at the hip were also higher in OA 1 subjects. Femoral trabecular BMD was 13 - 15% higher in OA grade 1 subjects than in OA grade 0 subjects. The cortical BMD measures in the CT_ TOT_ FEM and CT_ TROCH ROI's were also higher in the OA 1 subjects. The integral QCT BMD measures in the hip showed difference between grades OA 1 and 0. The DXA measurements in the neck and trochanter ROI's showed smaller differences (9 and 11%, respectively). There were no statistically significant differences in bone size. Conclusion: There is no evidence supporting that trabecular BMD measurements by QCT are influenced by OA. Instead, degenerative changes have an effect on both cortical and integral QCT, and on DXA at the lumbar spine and the hip. For subjects with established OA, assessment of BMD by volumetric QCT may be suggested.

TI Increased bone mineral content but not bone mineral density in the hip in surgically treated knee and hip osteoarthritis
SO JOURNAL OF RHEUMATOLOGY
LA English
DT Article
DE bone mineral density; bone densitometry; hip; knee; dual energy x-ray absorptiometry; osteoarthritis
ID x-ray absorptiometry; femoral-neck; proximal femur; generalized osteoarthritis; fracture risk; women; osteoporosis; mass; population; rotation
AB Objective. The inverse relationship between the occurrence of osteoarthritis (OA) and osteoporosis is controversial. Some investigators have found higher bone mineral density (BMD) in the hips, lumbar spine, and other skeletal sites of patients with OA; others have not. We investigated the relationship between BMD and OA. Methods. We compared the BMD, bone mineral content (BMC), and projected area of the femoral neck (FN) and trochanter (TR) of 99 women with a validated diagnosis of primary OA from the Kuopio Osteoporosis Risk Factor and Prevention Study (OSTPRE) cohort, with 2012 controls. The measurements were made twice in women aged 47-59 years in 1989-91, and then repeated in 1994-98. Results. After correction for age, body mass index (BMI), menopausal status, and hormone replacement therapy use before inclusion, we found no significant difference in femoral BMD of the OA patients compared with controls at baseline and at 5-year followup (FN +2.7%, +4.6%, respectively; nonsignificant). However, the BMC was

significantly higher in all regions of interest in OA patients at baseline [FN +8.3% (p = 0.004); TR +13.3% (p = 0.017)]. The projected area of FN was also significantly higher at baseline and followup in OA patients (FN +3.7%, +3.9%, respectively; p < 0.001). The projected area of the bones increased in all subjects over the followup period. The BMD decrease rate was higher in OA patients for all regions of interest during followup. Conclusion. Hip BMD of women treated surgically for hip or knee OA was not different from that of healthy controls when measured twice with a 5-year interval. However, at 5-year followup, OA can be accompanied by an increase in bone size or changes in shape, and faster loss of BMD.

TI Basic fibroblast growth factor inhibits the anabolic activity of insulin-like growth factor 1 and osteogenic protein 1 in adult human articular chondrocytes
SO ARTHRITIS AND RHEUMATISM
LA English
DT Article
ID factor-i; proteoglycan synthesis; cartilage explants; factor stimulation; matrix synthesis; synovial-fluid; insulin; osteoarthritis; cultures; receptor
AB Objective. To determine the effects of basic fibroblast growth factor (bFGF) on the chondrocyte anabolic activity promoted by insulin-like growth factor 1 (IGF-1) and osteogenic protein 1 (OP-1). Methods. Human articular chondrocytes were cultured in alginate beads or as cartilage explants in serum-free medium with or without IGF-1 (100 ng/ml), OP-1 (100 ng/ml), or bFGF (0-100 ng/ml). Cell survival, proliferation, proteoglycan synthesis, and total proteoglycan accumulation were. measured after 21 days of culture in alginate beads, and proteoglycan synthesis was measured in explants. Results. Cell survival was not altered by bFGF at any dose, and chondrocyte proliferation was stimulated only at doses above 1 ng/ml. When combined with IGF-1, 1 ng/ml of bFGF stimulated proliferation to 170% of control, but when combined with IGF-1 and OP-1, proliferation increased to 373% of control. Doses of bFGF of 100 ng/ml decreased total proteoglycan levels accumulated per cell by 60% compared with control and also inhibited the ability

of IGF-1 or OP-1 to increase proteoglycan production. Likewise, sulfate incorporation in response to IGF-1 and OP-1 alone or together was completely inhibited by 50 ng/ml bFGF in both alginate and explant cultures. Conclusion. The anabolic activity of IGF-1 and OP-1, alone and in combination, is significantly inhibited by bFGF. The results suggest that excessive release of bFGF from the cartilage matrix during injury, with loading, or in arthritis could contribute to increased proliferation and reduced anabolic activity in articular cartilage.

TI General characteristics, clinical features and related factors of osteoporosis in a group of elderly Turkish men
SO AGING CLINICAL AND EXPERIMENTAL RESEARCH
LA English
DT Article
DE elderly; male; osteoporosis; risk factors; Turkey
ID bone-mineral density; quality-of-life; creatinine clearance; fractures; osteoarthritis; interventions; women; risk
AB Background and aims: Osteoporosis is an important problem for men as well as women, but data and trials for male osteoporosis, prevalence, evaluation and prognosis are limited. There are insufficient randomized placebo-con trolled, multicenter trial data. The aim of this study was to determine the frequency of osteoporosis in patients admitted to the Division of Geriatric Medicine of Hacettepe University, to compare osteoporosis in men and women, and to determine risk factors, relations with social and cultural differences, body weight and functional status. Methods: A retrospective study was conducted from February 2002 through July 2003, Participants were 783 female and 464 male patients aged 65 years and over. BMD measures were performed using dual-energy X-ray absorptiometry at femoral neck and lumbar spine. Data on calcium intake, history of fractures, smoking, alcohol habits, other possible risk factors, serum 25OH-Vitamin D and iPTH levels were obtained. Creatinine clearance was calculated with the Cockcroft-Gaut formula. Functional status was evaluated by geriatric evaluation scales. Results: 29.5% of cases of osteoporosis were found in males: 45.9% of male patients had osteoporosis, 36.6% had osteopenia. Risk factors for male osteoporosis were evaluated. Men with low body weight (< 57 kg), BMI <

19, physically inactive, and poorly educated men were significantly more osteoporotic. No relationships between 250H-Vitamin D, iPTH levels. creatinine clearance, quality of life scales or osteoporosis were found. Conclusions: Geriatrists and internists should focus on male as well as female osteoporosis. Nutritional support and physical activity should be encouraged. Age over 65 is identified as a major risk factor. Every man over 65 years of age should undergo BMD testing for osteoporosis screening. (c) 2005, Editrice Kurtis.

TI CT evaluation of the pattern of odontoid fractures in the elderly - relationship to upper cervical spine osteoarthritis
SO EUROPEAN SPINE JOURNAL
LA English
DT Article
DE fracture; odontoid; geriatrics; atlanto-odontoid joint; osteoarthritis
ID prevalence; joint
AB Odontoid fractures are common in the elderly following minor falls. Almost all of them have osteoarthritis of the cervical spine below the axis vertebra. As a result, there is increased stress on the spared upper cervical spine, resulting in a higher incidence of injuries. As movement in the upper cervical spine involves participation of five joints, degeneration in any one particular joint may affect the biomechanics of loading of the upper cervical spine. We aimed to analyse the relationship of odontoid fractures to the pattern of upper cervical spine osteoarthritis in the elderly. We studied the CT-scan images of the cervical spine in 23 patients who were over the age of 70 years and had odontoid fractures. In each patient, the type of odontoid fracture and the characteristics of the degenerative changes in each joint were analysed. Twenty-one of 23 patients had Type -II odontoid fractures. The incidence of significant atlanto-odontoid degeneration in these individuals was very high (90.48%), with relative sparing of the lateral atlantoaxial joints. Osteoporosis was found in 13 of 23 patients at the dens-body junction and in seven of 23 patients at the odontoid process and body of the axis. With ageing, progressively more severe degenerative changes develop in the atlanto-odontoid joint. These eventually obliterate the joint space and fix the odontoid to the anterior arch of the atlas. In contrast, the lateral atlantoaxial joints are hardly affected by osteoarthritis. Thus, ultimately, atlantoaxial movements including atlantoaxial rotation are markedly limited by osteoarthritis of the atlanto-odontoid joint. However, there is still potential for movement in the lateral atlantoaxial joints, as they remain relatively free of degenerative change. The vulnerability of the atlantoaxial segment is further increased by markedly limited rotation below the axis vertebra due to severe facet-joint degeneration. As a consequence, a relatively low-energy trauma to the lateral part of the face, for instance by a fall, will induce forced atlantoaxial rotation. This, with the marked limitation of movement at the atlanto-odontoid joint, will produce a torque force at the base of the odontoid process leading to a Type II fracture.

TI Older adults' knowledge and beliefs about osteoporosis: Results of semistructured interviews used for the development of educational materials
SO JOURNAL OF RHEUMATOLOGY
LA English
DT Article
DE osteoporosis; awareness; education; prevention
ID womens knowledge
AB Objective. Although osteoporosis and associated fractures have been recognized as a significant public health problem, underdiagnosis and undertreatment are common. We investigated older adults' knowledge and beliefs regarding osteoporosis and its prevention, in order to develop effective osteoporosis health education messages and materials. These messages will be used as part of a trial that will test the efficacy of both public and doctor education to improve osteoporosis management. Methods. We conducted semistructured one-on-one interviews with 15 older adult volunteers. A standard interview guide was developed and used for all interviews, which were audiotaped and transcribed. Key themes were extrapolated by 3 study staff using data abstraction forms. The data forms were then compared for consistency. Results. We found that the term "osteoporosis" was well recognized, but many participants had only a fragmented understanding of its meaning. All participants identified osteoporosis as a serious condition, but many did not perceive themselves to be at personal risk for developing the condition. Many participants were confused about the difference between osteoporosis and osteoarthritis. Participants expressed reservations about taking prescription medications because of concerns over cost, side effects, and

interactions with their current medications. Conclusion. Osteoporosis awareness is high, but the older adults interviewed had an incomplete understanding of the condition. This could hinder efforts to improve prevention and treatment of osteoporosis.

TI Long-term periarticular bone adaptation in a feline knee injury model for post-traumatic experimental osteoarthritis
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE osteoarthritis; post-traumatic injury; micro-computed tomography; feline; knee
ID anterior cruciate ligament; meniscectomized guinea-pig; subchondral bone; articular-cartilage; cancellous bone; trabecular bone; transection; kinematics; dogs; osteoporosis
AB Objectives: This study investigates the long-term changes of the periarticular bone, including cancellous bone and the subchondral plate, in an anterior cruciate ligament (ACL)-transected cat for post-traumatic osteoarthritis (OA). These periarticular bone changes are related to the health of all knee tissues including articular cartilage degeneration and may be a key component of osteoarthritic

development. Methods: Thirteen cats (mean mass 4.9 +/- 1.9 kg) were divided into three experimental groups: (1) normal controls, (2) 16 week, and (3) 5 year post unilateral ACL-transection (ACLT). Micro-computed tomography was used to scan the three-dimensional (3D) bone architecture of the proximal tibia, and analysis was performed on the subchondral plate and cancellous bone in the epiphyseal and metaphyseal regions of each bone. Results: A decrease in cancellous bone mass (BV/TV) and subchondral plate thickness (Ct.Th) was observed 16 week post-ACLT, and the trend was statistically significant for the long-term animals (> 5 year post-ACLT: BV/TV decreased 16.8%, $P < 0.003$; Ct.Th decreased 36.8%, $P < 0.03$). A decrease in bone mass was also observed as a function of animal age by comparing the young and aged normal control animals, however ACLT intensified those changes, particularly Ct.Th ($P < 0.009$) and anisotropy ($P < 0.045$). It was speculated that decreased internal joint loading despite normal kinematics may play an important role in the long-term reduction of cancellous bone volume and subchondral plate thinning. Conclusions: The periarticular bone changes measured in this study were concurrent with articular cartilage degeneration, and suggest that bone may be a contributing factor in the aetiology of post-traumatic OA development. TI Comorbid conditions in the AMICA study patients: Effects on the quality of life and drug prescriptions by general practitioners and specialists
SO SEMINARS IN ARTHRITIS AND RHEUMATISM
LA English
DT Review
DE osteoarthritis; comorbidity; quality of life; coprescriptions
ID nonsteroidal antiinflammatory drugs; rheumatology criteria; blood-pressure; risk-factors; osteoarthritis; health; knee; classification; disability; celecoxib
AB OBJECTIVE Osteoarthritis (OA) has been identified as the disease with the

highest rate of comorbidities, which may increase the likelihood of disability. The AMICA study evaluated how the presence of a coexistent disease and/or its chronic pharmacological treatment influenced the prescription of pharmacological and nonpharmacological therapy in patients with OA. PATIENTS AND METHODS The 2764 general practitioners (GPs) and 316 specialists (98 rheumatologists, 166 orthopedic surgeons, 52 physical medicine specialists) participating in the study were asked to enroll 10 consecutive patients with OA diagnosed according to the American College of Rheumatology clinical criteria. Information was collected regarding demographics, the clinical characteristics of OA, and previous diagnostic and therapeutic interventions. Pain intensity was assessed using a 100-mm visual analog scale WAS); the patients were also asked to report on their quality of life and joint function, as well as the presence of any concomitant disease and/or therapy. The influence of comorbidities on the quality of life, pain, and drug prescription was evaluated. RESULTS A total of 29,132 evaluable patients was observed (25,589 recruited by GPs and 3543 by specialists). The most frequent comorbidities were hypertension (52%), osteoporosis (21%), type II diabetes mellitus (15%), and chronic obstructive pulmonary disease (12%); myocardial infarction and/or angina pectoris were present in 6% and peptic ulcer was present in 5%. Comorbidities were more frequent in older patients and, except in the case of hypertension, were closely related to more intense pain and a decreased quality of life; they were also generally associated with worsened joint function. The presence of peptic ulcer was associated with a reduction in the prescription of nonsteroidal antiinflammatory drugs (NSAIDs) (odds ratio (OR) 0.61; confidence intervals (CD 0.53 to 0.69) and the more frequent use of Coxibs (OR 1.15; Cl 1.03 to 1.28) and simple analgesics (OR 1.42; Cl 1.26 to 1.61), as well as with greater use of physical therapy. Hypertension was associated with a reduction in the prescription of physical therapy. NSAIDs and Coxibs were less frequently prescribed if the patients were on anticoagulant therapy (NSAIDs: OR 0.86; Cl 0.70 to 1.06; Coxibs: OR 0.77; Cl 0.64 to 0.93). Gastroprotective therapy was more frequently used in patients treated with NSAIDs, Coxibs, and analgesics, with GPs giving greater preference to proton pump inhibitors than specialists. CONCLUSIONS Comorbidities decrease the quality of life and worsen the joint function in OA patients. Comorbidities and their treatment generally do not influence the physician's choice of OA treatment, with the exception of peptic ulcer and anticoagulant therapy, both of which were associated with a reduction in the prescription of antiinflammatory drugs. There was a preferential use of Coxibs in patients with peptic ulcer, and an underuse of gastroprotective measures in OA patients treated with NSAIDs.

TI Factors associated with the lumbar spine and proximal femur bone mineral density in older men
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE bone densitometry population studies; epidemiology; men; osteoporosis
ID hip fracture; risk-factors; elderly-men; osteoporotic fractures; rancho-bernardo; prostate-cancer; calcium intake; white women; health; depression
AB Bone mass is a major determinant of fracture, but there have been few comprehensive studies of the correlates of bone mineral density (BMD) in older men. The objective of the current cross-sectional analysis was to determine the factors associated with BMD of the lumbar spine and proximal femur in a large population-based sample of older men enrolled in The Osteoporotic Fractures in Men Study, "Mr.OS." We enrolled 5,995 men 65 years of age or older, 89% Caucasian, in Mr.OS at six US clinical centers. Demographic, medical and family history and lifestyle information was obtained by interview and physical function and anthropometric data by examination. Spine and hip BMD was measured using dual-energy X-ray absorptimetry. The multivariable linear regression models predicted 19 and 10% of the overall variance in BMD of the femoral neck and spine, respectively. African-American men had 6 to 11% higher BMD than Caucasian men independent of multiple factors. Hip BMD declined with advancing age, while spine BMD increased. Body weight (per 10 kg) and self report of diabetes were each associated with 2 to 4% higher BMD, while history of a

non-trauma fracture and current use of selective serotonin reuptake inhibitors, but not other antidepressants, were associated with at least 4% lower BMD. Both maternal and paternal histories of fracture were associated with 1.4-1.7% lower BMD. Osteoarthritis, physical activity, grip strength, alcohol intake, and dietary calcium were positively related to BMD, while a history of chronic lung disease, prostate cancer, and kidney stones was associated with lower BMD. Smoking, caffeine intake, and thiazide diuretics were not related to BMD in older men. A number of lifestyle and behavioral characteristics and medical conditions were associated with BMD in older men. Identification of these correlates could improve methods to identify men at risk for fracture and improve our understanding of fracture etiology.

TI Fractal analysis of trabecular bone in knee osteoarthritis (OA) is a more sensitive marker of disease status than bone mineral density (BMD)
SO CALCIFIED TISSUE INTERNATIONAL
LA English
DT Article
DE knee osteoarthritis; trabecular bone; fractal analysis; BMD
ID subchondral bone; proximal tibia; biomechanical property; articular-cartilage; radiographic assessment; signature analysis; texture analysis; osteoporosis; macroradiographs; organization
AB The purpose of this study was to determine whether fractal analysis (FSA) of macroradiographs or bone mineral density (BMD) is more sensitive in detecting disease-related cancellous bone alterations in knee osteoarthritis (OA). Differences in BNID between I I OA (6 females) and 11 non-OA reference (7 females) tibiae were compared with differences in trabecular organization measured by computerized method of fractal signature analysis (FSA) of digitized macroradiographs (x3.5 to x5). OA knees had anatomic and radiographic evidence of medial compartment disease. FSA measured cancellous bone organization at 4 regions of interest (ROI): medial and lateral subchondral (Sc) and subarticular (Sa) sites, dual X-ray absorptiometry (DXA) measured BMD at the same ROIs. Compared to non-OA, OA tibiae had significant increase ($P < 0.05$) in FSA of vertical trabeculae in the medial Sa region (trabecular size range: 0.42-0.54; 0.90-1.98 mm) and significant decrease ($P < 0.05$) in FSA for some horizontal trabeculae in the Sc region (trabecular size range: medial side 0.12-0.18 mm; lateral side 0.12-0.24 mm). Compared to non-OA, BMD of OA tibiae was not significantly different at any ROI. BMD was not sensitive to changes in trabecular organization detected by FSA. The increase in FSA of vertical trabeculae in the medial Sa region was consistent with trabecular fenestration and thinning, which may have been detected as decreased

BMD in a larger sample. For studies involving small sample sizes, quantifying changes in trabecular organization is more sensitive than BMD for detecting bone alterations in knee OA.

TI Spontaneous osteonecrosis of the knee: biochemical markers of bone turnover and pathohistology
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE biochemical marker; bone turnover; osteonecrosis; knee
ID collagen c-telopeptide; marrow edema syndrome; synovial-fluid; transient osteoporosis; metabolism; cartilage; disease; serum; osteoarthritis
AB Objective: The aim of this study was to evaluate bone metabolism in patients with spontaneous osteonecrosis (ON) of the medial femoral condyle. Method: In 22 consecutive patients, undergoing total knee arthroplasty, biochemical markers of bone metabolism were measured in aspirates from cancellous bone and in samples obtained simultaneously from peripheral blood. Specimens of the medial femoral condyle were available for histologic examination and the lesion size, assessed on radiographs, was compared with the results from bone turnover measurements. Twenty patients with osteoarthritis (OA) of the knee served as a control.

Bone-specific alkaline phosphatase (bone ALP), osteocalcin (OC), procollagen type I N-terminal propeptide (PINP), and C-terminal cross-linking telopeptide (ICTP) were studied. Results: Mean serum levels of analytes were not different in patients with ON and OA. The serum concentrations averaged 16.2 vs 13.3 ng/mL (OC), 10.2 vs 12.1 ng/mL (bone ALP), 4.6 vs; 4.1 ng/mL (ICTP), and 33.2 vs 40.4 ng/mL (PINP) in patients with ON and OA, respectively. In samples obtained from cancellous bone, mean concentrations of all markers were elevated significantly when compared to serum levels. The mean marker concentrations in samples obtained from cancellous bone were 33.8 vs 43.3 ng/mL (OC), 34.6 vs 37.3 ng/mL (bone ALP), 64.8 vs 36.1 ng/mL (ICTP, P=0.02), and 208.0 vs 176.2 ng/mL (PINP) in patients with ON and OA, respectively. The lesion size was at mean 440.5 +/- 275.8 mm(2) in knees with ON and did not correlate with either serum or bone concentrations of all markers tested (P>0.1). Conclusion: The marked elevation of markers in samples obtained from cancellous bone pointed at increased turnover in both diseases when compared to healthy individuals. In line with histologic findings of necrosis of subchondral bone, focal degradation of collagen type I was more pronounced in knees with ON. Mean serum concentrations of all markers, however, were not different from healthy individuals and thus did not provide any useful clue in the diagnosis spontaneous ON. TI Upper gastrointestinal tract safety of daily oral risedronate in patients taking NSAIDs: A randomized, double-blind, placebo-controlled trial
SO MAYO CLINIC PROCEEDINGS
LA English
DT Article
ID postmenopausal osteoporosis; alendronate; women; tolerability; fractures; efficacy
AB OBJECTIVE: To evaluate the frequency of upper gastrointestinal (GI) tract adverse events associated with risedronate during two (2-year) randomized, double-blind, parallel-group, placebo-controlled studies. PATIENTS AND METHODS: Male and female patients aged 40 to 80 years with mild to moderate medial-compartment knee osteoarthritis were enrolled. Data were pooled and analyzed for risedronate at 5 mg and at 15 mg once daily and compared with placebo. The results of the once-weekly dosages (35 or 50 mg) were assessed separately. RESULTS: A total of 2483 patients were randomized: 622 to placebo, 628 to risedronate at 5 mg/d, 609 to risedronate at 15 mg/d, 310 to risedronate at 35 mg once weekly, and 314 to risedronate at 50 mg once weekly. During the study, 77% of patients were regular nonsteroidal anti-inflammatory drug (NSAID) and/or analgesic users (defined as those who took medication >= 3 days per week), and 68% were regular NSAID users. The number of upper GI tract adverse events was similar between treatment groups, with no dose-related response: 161 for placebo, 176 for risedronate at 5 mg/d, and 150 for risedronate at 15 mg/d. The time to the

first upper GI tract adverse event was similar between treatment groups. There was no difference in the frequency of upper GI tract adverse events in risedronate-treated patients compared with patients who were regular users of NSAIDs or NSAIDs and/or analgesics. Findings were similar for those in the once-weekly risedronate groups. CONCLUSION: The results of this study show that risedronate regimens at 5 mg/d or 15 mg/d as well as once weekly at 35 mg or 50 mg are not associated with an increased frequency of upper GI tract adverse events, even in patients who have an increased risk for such events.

TI Estrogen receptor alpha regulates matrix metalloproteinase-13 promoter activity primarily through the AP-1 transcriptional regulatory site
SO BIOCHIMICA ET BIOPHYSICA ACTA-MOLECULAR BASIS OF DISEASE
LA English

DT Article
DE OA; MMP-13; ER-alpha; estrogenic ligand; AP-1 site; regulation
ID anterior cruciate ligament; rat collagenase-3 promoter; activator protein-1; osteoarthritis development; replacement therapy; articular-cartilage; endometrial cancer; connective tissue; lapine menisci; knee cartilage
AB Many females develop bone diseases such as osteoporosis, and joint diseases such as osteoarthritis after menopause when estrogen levels decline. As estrogen receptors (ER) are present in such tissues, it is possible that the loss of estrogen at menopause influences the expression of enzymes such as members of the MMP family of proteinases to affect bone and connective tissue metabolism. The present study was undertaken to assess a possible relationship between ER-alpha and MMP-13 expression at the promoter level, and to determine how such a relationship could be modulated by ligands such as estrogen. Using a rabbit synovial cell line lacking endogenous ER, a transient transfection system with an ER-a construct, and a series of MMP-13 promoter-luciferase constructs of varying lengths and with specific mutations in transcription factor binding sites, it was found that ER-alpha can significantly enhance MMP-13 promoter activity via the AP-1 site, with modulatory influences by the Runx and PEA-3 sites on this ER-alpha dependent enhancement of the promoter activity. This enhancement by ER-alpha was significantly depressed in the presence of 17-beta-estradiol in a dose dependent manner. The influence of tamoxifen and raloxifen on the activity of the ER-alpha was consistent with their known agonist/antagonist activity. These findings indicate that loss of estrogen in vivo could potentially lead to enhanced expression of MMP-13, a proteinase that has been implicated in both osteoporosis and osteoarthritis, and thus contribute to the development and progression of these conditions. TI The effect of cyclooxygenase-2 inhibitors on bone mineral density: results from the Canadian Multicentre Osteoporosis Study
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE bone mineral density; cyclooxygenase-2 inhibitors; inflammation; osteoporosis
ID nonsteroidal antiinflammatory drugs; prostaglandin g/h synthase-2; randomized controlled-trial; postmenopausal women; clinical-trial; fracture risk; older women; cells; osteoarthritis; aspirin
AB Introduction The use of cyclooxygenase-2 (COX-2) inhibitors has been demonstrated to not only impair load-induced bone formation but also prevent menopause-associated bone loss. We hypothesized that COX-2 inhibitor use would be associated with increased bone mineral density (BMD) in postmenopausal women not using estrogen therapy and, conversely, with decreased BMD in men. Methods The Canadian Multicentre Osteoporosis Study is a longitudinal, randomly selected, population-based community cohort. We present data from men (n=2,004) and postmenopausal women age 65 and older (n=2,776) who underwent a BMD measurement and structured interview in the 5th year of the study. The outcome measure was percent difference in BMD (g/cm(2)). Results Daily COX-2 inhibitor use was reported by 394 subjects. In men, daily use of COX-2 inhibitors was associated with a lower BMD at all hip sites, with a percent difference of -3.1% [95% confidence interval (CI), -6.0, -0.3] between users and nonusers at total hip. In postmenopausal women not using estrogen replacement therapy, daily COX-2 inhibitor use was associated with higher BMD at most sites [percent difference at total hip: +3.0% (95% CI, 0.3, 5.8)]. These effects appeared to be dose-dependent. Conclusion COX-2 inhibitor use was associated with a lower BMD in men and, on the other hand, with a higher BMD in postmenopausal women not using estrogen replacement therapy. Men who have used COX-2 inhibitors may wish to seek BMD measurement to assess their fracture risk. However, COX-2 inhibitors may have utility in postmenopausal women if bone-selective analogs can be developed.

TI Osmotic adjustment in leaves of Brassica oilseeds in response to water deficit
SO CANADIAN JOURNAL OF PLANT SCIENCE
LA English
DT Article
DE Brassica oilseeds; drought stress; osmotic adjustment; haploid lines
ID comparative adaptation; juncea; napus; tolerance; osmoregulation; accumulation; reagent; solute; sugar; yield
AB The influence of water deficit on water content (WC), total soluble solids (TSS), osmotic potential (OP), sugar content and osmotic adjustment (OA) of expanded and partly expanded leaves of Brassica oilseeds was examined. Nine canola (B. napus) cultivars (Karoo, Monty, Pinnacle, Hyden, Mystic, Rainbow, Surpass 300, Surpass 400, Surpass 501), two doubled haploids, one from Karoo (KDH) and the other from Monty (MDH) and one line of Indian mustard (B. juncea, PI-81792) were grown under glasshouse and net-house conditions. Expanded wilted leaves of Karoo and Monty absorbed excessive amounts of water per dry weight upon in vitro rehydration compared with control non-stressed leaves, resulting in underestimation of OA calculated on the basis of the relative water content (RWC). Hence, estimation of OA based on water weight per leaf dry weight (WC) was preferred. Young expanding leaves maintained visual turgor for 6-7 d after withholding irrigation, while expanded leaves on the same plants ceased to regain turgor overnight. The young expanding leaves exhibited greater accumulation of TSS and, consequently, more negative OPs compared with expanded leaves. Maintenance of OA after irrigation and turgor recovery was evident in both expanded and expanding leaves. Although OA under drought and upon turgor recovery varied within cultivars in different experiments, outstanding OA capacity, in terms of both magnitude and stability, was identified in the cultivar Hyden and in the doubled haploid of Monty, indicating the potential to select for this trait as

well as to exploit variability for OA through haploidization.

TI Prevalence of and factors associated with glucosamine use in Canada
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE glucosamine; complementary and alternative medicine; CAMs; prevalence
ID nutritional supplements; alternative medicine; knee osteoarthritis; complementary; arthritis; disease
AB Objective: Glucosamine is commonly used for the treatment of osteoarthritis,

and its use is increasing in the general population. The Canadian Multicentre Osteoporosis Study (CaMos) provided an opportunity to examine the prevalence of glucosamine use across age and gender groups, and to assess the factors associated with its use. Method, CaMos is a random, population-based sample of 9423 Canadians. Baseline assessments took place in 1996-1997 and the 5-year follow-up assessments in 2001-2002. The primary outcome of this analysis was glucosamine use at year 5. Prevalence estimates were age- and sex-standardized to the Canadian population. A number of factors potentially associated with glucosamine use were identified from the literature. Multivariable logistic regression was used to identify variables associated with glucosamine use. Results: At 5 years, complete data were available for 7652 of the original 9423 participants (81.2%). For men, glucosamine use increased from 0.9% to 4.7% (weighted values), and for women, it increased from 1.3% to 8.2%. Glucosamine use was higher among older participants, those living in western Canada, and those with arthritis, back pain, higher calcium intake from supplements, physical activity and prior glucosamine use. Conclusions: Glucosamine use increased substantially over 5 years, and its use is associated with a number of factors. Some may use glucosamine to manage pain and symptoms of arthritis and back pain, while others use it as a preventive measure to maintain health. TI No association between the aluminium content of trabecular bone and bone density, mass or size of the proximal femur in elderly men and women
SO BMC MUSCULOSKELETAL DISORDERS
LA English
DT Article
ID genetic-determinants; alzheimers-disease; dialysis encephalopathy; parenteral solutions; mineral density; hip-fractures; absorption; osteodystrophy; heritability; impact
AB Background: Aluminium is considered a bone toxic metal since poisoning can lead to aluminium-induced bone disease in patients with chronic renal failure. Healthy subjects with normal renal function retain 4% of the aluminium consumed. They might thus also accumulate aluminium and eventually be at risk of long-term low-grade aluminium intoxication that can affect bone health. Methods: We therefore examined 62 patients with femoral neck fractures or osteoarthritis of the hip (age range 38-93), with the aim of examining whether aluminium in bone is associated with bone-mineral density (BMD), content (BMC) or width of the femoral neck measured by dual-energy X-ray absorptiometry (DXA). During operations bone biopsies were taken from the trabecular bone of the proximal femur. The samples were measured for their content of aluminium using a mass spectrometer. Results: No significant association between the aluminium content in bone and femoral neck BMD, BMC or width could be found after multivariate adjustment. Conclusion: Our results indicate that the accumulated aluminium content in bone during life does not substantially influence the extent of osteoporosis.

TI Exercise self-efficacy, exercise benefits and barriers, and commitment to a plan for exercise among Korean women with osteoporosis and osteoarthritis
SO INTERNATIONAL JOURNAL OF NURSING STUDIES
LA English
DT Article
DE exercise; Korean; women osteoporosis; osteoarthritis
ID psychometric evaluation; physical-activity; health-promotion; risk-factors; adults; prevention; scale; falls; hip
AB This study compared perceived exercise self-efficacy, exercise benefits, exercise barriers, and commitment to a plan for exercise between Korean women with a diagnosis of either osteoporosis or osteoarthritis. The influence of exercise self-efficacy, exercise benefits and barriers on commitment to a plan for exercise was also assessed in each group. Participants in the study were 154 Korean women over 40 years of age who were recruited from hospitals, health centers or a nursing home. The two groups differed on commitment to a plan for exercise with commitment greater among women with osteoporosis. Exercise self-efficacy was the most influential variable on commitment to a plan for exercise accounting for 27% of the variance in commitment among osteoporosis patients and 53% of the variance among osteoarthritis patients. This study generated information relevant to tailoring exercise interventions to the differing needs and perceptions of Korean women with osteoporosis and osteoarthritis. (c) 2004 Elsevier Ltd. DT Review
ID bone-mineral density; systemic-lupus-erythematosus; low-dose prednisone; complicating ankylosing-spondylitis; population-based cohort; premenopausal women; follow-up; vertebral deformity; psoriatic-arthritis; elderly-men
AB Osteoporosis and related fragility fractures represent one of the most common complications that occurs in patients who have rheumatic diseases, and contributes to a dramatic decrease in quality of life. Bone is affected negatively by the disease process and often by the therapy itself in different rheumatic conditions, notably rheumatoid arthritis (RA), and the relationship between osteoporosis and osteoarthritis is a matter of concern. The clinical relevance of osteoporosis in rheumatic diseases is underestimated. Recent data demonstrated that patients who had RA and took oral corticosteroids did not undergo bone densitometry routinely. This article focuses on the burden of osteoporosis and fragility fractures in different rheumatic conditions, and emphasizes the importance of this complication for which effective preventive measures are available.

TI Exploring factors influencing osteoporosis prevention and control: A qualitative study of Iranian men and women in Australia
SO MATURITAS
LA English
DT Article
DE osteoporosis; qualitative study; prevention
ID bone-mineral density; immigrant women; american women; health; knowledge; fractures; community; beliefs; smoking; behaviors
AB Objective: To explore the understanding of osteoporosis risk factors and barriers that influence osteoporosis prevention and control in order to better inform the development of culturally appropriate osteoporosis preventive strategies. Methods: This qualitative study was based on data collected from 5 focus groups, 10 individual interviews and 3 opportunistic group discussions of Iranian men and women living in Australia. A thematic analysis approach was used and data were managed with a computer-assisted program. Data were collected over I year in community settings chosen by participants. Results: The participants had insufficient understanding of osteoporosis risk factors and its implications for their health as they age. There were minor misconceptions about the causes of the disease and how it could be prevented and controlled. Man), participants confused osteoporosis and osteoarthritis. Where they did indicate some knowledge of preventive actions, they perceived many obstacles to their undertaking preventive behaviours. Conclusions: These data suggest that factors adversely influencing osteoporosis prevention and control have their root in misconceptions about osteoporosis and its risk factors, and psychosocial and structural barriers to taking

preventive actions. These findings provide insights into barriers that need to be overcome if preventive strategies and intervention programs can be developed to reduce the overall burden of osteoporosis in the community. (c) 2005 Elsevier Ireland Ltd. All rights reserved.

TI Osteogenic protein 1 in synovial fluid from patients with rheumatoid arthritis or osteoarthritis: relationship with disease and levels of hyaluronan and antigenic keratan sulfate
SO ARTHRITIS RESEARCH & THERAPY
LA English
DT Article
ID growth-factor-beta; necrosis-factor-alpha; articular-cartilage; serum; expression; matrix; op-1; proteoglycan; interleukin-1; degeneration
AB The measurement of body fluid levels of biochemical markers in joint tissues has begun to provide clinically useful information. Synovial fluid (SF) plays an important role in articular joint lubrication, nutrition, and metabolism of cartilage and other connective tissues within the joint. The purpose of our study was to identify and characterize osteogenic protein 1 (OP-1) in SF from patients with rheumatoid arthritis (RA) or with osteoarthritis (OA) and to correlate levels of OP-1 with those of hyaluronan (HA) and antigenic keratan sulfate (AgKS). SF was aspirated from the knees of patients with either RA or OA and from the knees of asymptomatic organ donors with no documented history of joint disease. The presence of detectable OP-1 in SF was demonstrated by western blots with specific anti-pro-OP-1 and anti-mature OP-1 antibodies. Measurement of levels of OP-1, HA and AgKS was performed using ELISAs. OP-1 was identified in human SF in two forms, pro-OP-1 and active (mature) OP-1-mature OP-1 being detected only in SF from OA patients and RA patients. Levels of OP-1 and HA were higher in RA patients than in OA patients and asymptomatic donors, while the level of AgKS was highest in SF from asymptomatic donors. Statistically significant differences were

found between SF levels of OP-1 in RA and OA patients and between SF levels of AgKS among the three groups tested. The SF content of OP-1 tended to correlate positively with HA levels, but negatively with AgKS concentrations. In conclusion, the results of this study suggest that measurement of OP-1 in joint fluid may have value in the clinical evaluation of joint disease processes.

TI Risedronate decreases biochemical markers of cartilage degradation but does not decrease symptoms or slow radiographic progression in patients with medial compartment osteoarthritis of the knee - Results of the two-year multinational knee osteoarthritis structural arthritis study

SO ARTHRITIS AND RHEUMATISM
LA English
DT Article
ID joint space width; placebo-controlled trial; bone-mineral density; double-blind; pagets-disease; hip osteoarthritis; efficacy; bisphosphonates; acetaminophen; osteoporosis
AB Objective. Bisphosphonates have slowed the progression of osteoarthritis (OA) in animal models and have decreased pain in states of high bone turnover. The Knee OA Structural Arthritis (KOSTAR) study, which is the largest study to date investigating a potential structure-modifying OA drug, tested the efficacy of risedronate in providing symptom relief and slowing disease progression in patients with knee OA. Methods. The study group comprised 2,483 patients with medial compartment knee OA and 2-4 mm of joint space width (JSW), as determined using fluoroscopically positioned, semiflexed-view radiography. Patients were enrolled in 2 parallel 2-year studies in North America and the European Union. These studies evaluated the efficacy of risedronate at dosages of 5 mg/day, 15 mg/day, 35 mg/week (in Europe), and 50 mg/week (in North America) compared with placebo in reducing signs and symptoms, as measured by the Western Ontario and McMaster Universities Osteoarthritis (WOMAC) index and patient global assessment (PGA) scores, and in slowing radiographic progression. Results. A reduction of similar to 20% in signs and symptoms, as measured by WOMAC subscales and PGA scores, was observed in all groups, with no treatment effect of risedronate demonstrated. Risedronate did not significantly reduce radiographic progression as measured by decreased JSW or using a dichotomous definition of progression (joint space loss of >= 0.6 mm). Thirteen percent of patients receiving placebo demonstrated significant disease progression over 2 years. A dose-dependent reduction in the level of C-terminal crosslinking telopeptide of type H collagen, a cartilage degradation marker associated with progressive OA, was seen in patients who received risedronate. No increase in the number of adverse events was demonstrated for risedronate compared with placebo. Conclusion. Although risedronate (compared with placebo) did not improve signs or symptoms of OA, nor did it alter progression of OA, a reduction in the level of a marker of cartilage degradation was observed. A sustained clinically relevant improvement in signs and symptoms was observed in all treatment and placebo groups.

TI Effect of Buthus martensi Karsch on aromatase activity and cytokine-inducded NOS and NO production in osteoblasts and leukaemic cell line FLG 29.1
SO IMMUNOPHARMACOLOGY AND IMMUNOTOXICOLOGY
LA English
DT Article
DE aromatase; Buthus martensi Karsch (BMK); cytokine; IL1 beta; NO; NOS; osteoblast; TNF-alpha
ID nitric-oxide synthase; rheumatoid-arthritis; bone cell; estrogen biosynthesis; functional-role; expression; rat; cultures; growth; venom
AB Among the different scorpion species, Buthus martensi Karsch, a widely distributed scorpion species in Asia especially in Korea, has received a lot of attention. Indeed, over the past decade, more than 70 different peptides, toxins, or homologues have been isolated. It may prove a valuable resource for identifying potential anti-inflammatory and analgesic drugs. The recent observation has suggested that the aromatase is a possible local modulator of bone remodeling in osteoarthritis and osteoporosis. In the present study, therefore, the effect of Buthus martensi Karsch (BMK) extract, traditional immunosuppressive Korean aqua-acupuncture water, on the bone function of human osteoblastic cells was studied. To provide insights into the effect of BMK on aromatase activity in bone-derived cells, we examined the human leukaemic cell line FLG 29.1, which is induced to differentiate toward the osteoclastic phenotype by 12-O-tetradecanoylphorbol-13-acetate (TPA) and transforming growth factor (TGF)-beta 1, and the primary first-passage osteoblastic cells (hOB). Gene expression of the aromatase was not affected by Buthus martensi Karsch in FLG 29.1 and hOB cells. However, enzyme activity was stimulated in a time-dependent fashion by 10.0 mu g/ml BMK and by either 1 50 nM TPA or 0.01-0.5 ng/ml TGF-beta 1, with maximal responses after 2-3 hr exposure. On the other hand, BMK strongly inhibited interleukin-1 beta (IL-1 beta)- and tumor necrosis factor (TNF)alpha-induced Nitricoxide (NO) synthase expression with little effect on constitutive NO synthase expression. BMK extracts (10 mu g/ml) inhibited cytokine-induced iNOS and nNOS expression. BMK (10 mu g/ml) did not affect the ecNOS expression, indicating the extracts are not working on the constitutive NOS expression. BMK strongly inhibited the cytokine- induced NO production ($p < 0.01$). BMK also showed significant inhibition on NO production in both induced by

TNF-alpha+IL-1 beta. NO donors, sodium nitroprusside, and NONOate dose-dependently elevated alkaline phosphatase activity. These results suggest that NO directly facilitates osteoblastic differentiation. This result also suggests that BMK is effective for bone resorptive action in bone cells.

TI Clinical utility of spine bone density in elderly women
SO JOURNAL OF CLINICAL DENSITOMETRY
LA English
DT Article
DE bone mineral density; elderly; osteoporosis; spine osteoarthritis
ID international-society; official positions; osteoporotic fractures; mineral density; osteoarthritis; densitometry; classification; diagnosis; men
AB It is common clinical practice to obtain a bone density measurement at both the hip and spine to evaluate osteoporosis. With aging, degenerative changes in the lumbar spine may elevate the bone mineral density (BMD) results giving false assurances that the fracture risk at the spine is low. We examined the association of spine osteoarthritis and bone mineral density in 1082 community-dwelling ambulatory older women aged 50-96 years who participated in a 1992-1996 osteoporosis research clinic visit. The BMD was measured at the hip and posteroanterior (PA) and lateral lumbar spine using dual energy X-ray absorptiometry (DXA). Spine osteoarthritis was identified on the PA lumbar spine

DXA images by a musculoskeletal radiologist. Forty percent of women had evidence of spine osteoarthritis (OA). Women with spine OA had a mean age of 77.4 yr (95% confidence interval [CI]: 76.5-78.2), were significantly older than women without spine OA (mean age, 66.8 yr; 95% CI: 65.9-67.7), and were more likely to have prevalent radio,graphic fractures (14.2% vs. 9.5%; $p < 0.05$). Age-adjusted BMD at the femoral neck, total hip, PA spine, and lateral spine was significantly higher in women with spine CA. Women with spine OA were more likely to have osteoporosis by the World Health Organization classification at the femoral neck and total hip than those without spine OA, but less likely based on the PA spine (14.4% vs. 24.5%). Despite higher BMD levels, women with CA of the lumbar spine had higher prevalence of osteoporosis at the hip and more radiographic vertebral fractures. In elderly women 65 yr and older who are likely to have spine OA, the DXA measurement of the spine may not be useful in assessing fracture risk, and DXA of the hip is recommended for identification of osteoporosis.

TI Method guidelines for cochrane musculoskeletal group systematic reviews
SO JOURNAL OF RHEUMATOLOGY

LA English
DT Article
DE evidence-based medicine; review literature; metaanalysis; arthritis
ID randomized clinical-trials; short-term improvement; preliminary core set; ankylosing-spondylitis; preliminary definition; rheumatoid-arthritis; lupus-erythematosus; methodological quality; outcome measures; disease-activity
AB The Cochrane Musculoskeletal Group (CMSG), one of 50 groups of the not-for-profit international Cochrane Collaboration, prepares, maintains, and disseminates systematic reviews of treatments for musculoskeletal diseases. To enhance the quality and usability of systematic reviews, the CMSG has developed tailored methodological guidelines for authors of CMSG systematic reviews. Recommendations specific to musculoskeletal disorders are provided for various aspects of undertaking a systematic review, including literature searching, inclusion criteria, quality assessment, grading of evidence, data collection, and data analysis. These guidelines will help researchers design, conduct, and report results of systematic reviews of trials in the following fields of musculoskeletal health: gout, osteoarthritis, osteoporosis, pediatric rheumatology, rheumatoid arthritis, soft tissue rheumatism, spondyloarthropathy, systemic lupus erythematosus, systemic sclerosis, and vasculitis. Systematic reviews need to be conducted according to high methodological standards. These recommendations on developing and performing a systematic review will help improve consistency among CMSG reviews.

TI Lead accumulation in tidemark of articular cartilage
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE lead accumulation; tidemark; synchrotron micro XRF; calcified cartilage
ID x-ray-fluorescence; human bone; mobilization; zinc; rats; hydroxyapatite; osteoarthritis; mineralization; osteoporosis; osteocalcin
AB Objective: Determination of the spatial distribution of the toxic element lead (Pb) and other trace elements in normal articular cartilage and subchondral bone from adult humans with no history of work-related exposure to Pb. Methods: Four macroscopically normal femoral heads and three patellas were harvested from randomly selected forensic autopsies. All subjects died of acute illnesses, had no history of work-related exposure to Pb and had no metabolic bone disease. The elemental distribution of lead (Pb) together with zinc (Zn), strontium (Sr) and calcium (Ca) in the chondral and subchondral region was detected using high resolution synchrotron radiation induced micro X-ray fluorescence (SR mu-XRF) analysis. SR mu-XRF line scans in conventional and SR mu-XRF area scans in confocal geometry were correlated to backscattered electron (BE) images visualizing the mineralized tissue. Results: In all samples, we found a highly specific accumulation of Pb in the tidemark, the transition zone between calcified and non-calcified articular cartilage. Pb fluorescence intensities in the tidemark, which is thought to be a metabolically active mineralization front, were 13-fold higher when compared to subchondral bone. Pb intensities in the subchondral region were strongly correlated with Zn, but were distinctly different from Ca and Sr. Conclusions: The finding of the highly specific accumulation of lead in the tidemark of human articular cartilage is novel. However at this point, the exact mechanisms of the local Pb accumulation as well as its clinical implications are unknown. (C) 2006 OsteoArthritis Research Society International. TI Anthropometrics provide a better estimate of urinary organic acid anion excretion than a dietary mineral intake-based estimate in children, adolescents, and young adults
SO JOURNAL OF NUTRITION
LA English
DT Article
DE organic acid estimates; dietary potential renal acid load; 24-hour urine; healthy subjects; acid-base
ID glomerular-filtration-rate; postmenopausal women; citrate excretion; bone-resorption; german children; protein-intake; energy-intake; load; potassium; healthy
AB The role of elevated net endogenous acid production (NEAP) in the causation of osteoporosis, muscle wasting, and kidney stones is currently under discussion. The aim of this study was to examine whether urinary organic acid anion excretion, a major component of NEAP, is predicted primarily by anthropometric-(OA(anthro)) or diet-(OA(diet)) based estimates. Dietary intakes, anthropometric data, and 24-h urinary excretion rates of organic acids (24h-OA(urine)) were determined cross sectionally in healthy children (6-7 y; n = 217), adolescents (13-14 y; n = 91), and young adults (18-22 y; n = 82). OA(anthro) was computed from body surface area and OA(diet) calculated using a published algorithm based on dietary intakes of mineral anions and cations. There was a significant increase ($P < 0.0001$) in 24h-OA(urine) across the age groups that was no longer discernible after correction for body surface area. In almost all sex-stratified subsamples, OA(anthro) had a higher correlation with 24h-OA(urine) than OA(diet). Multiple regression analyses, using energy-corrected diet variables, revealed that OA(anthro) was

consistently the primary predictor of 24h-OA(urine) (R-2 varying from 0.15 to 0.39) and dietary fat and protein were sporadic predictors. In accordance with the observed age independency of 24h-OAurine after body surface area correction, our findings indicate that OAanthro is a better estimate of 24h-OA(urine) in healthy children, adolescents, and young adults than OA(diet). This further confirms that the (principally diet-dependent) NEAP comprises a component, i.e., organic acid anions, that is reasonably predictable by anthropometrics. Consequently, the other component, i.e., the potential renal acid load, appears to be the primary parameter that characterizes the diet-induced acid load.

TI On the realization of current transfer function using voltage amplifiers
SO INTERNATIONAL JOURNAL OF CIRCUIT THEORY AND APPLICATIONS
LA English
DT Article
DE current transfer function; current mode; VCVS; OP-AMP; nullator-norator
ID biquads
AB Current transfer function is a feature of current-mode filters. Current-mode filters have so far been realized principally using current amplifiers and current conveyors. Some current-mode filter architecture using operational amplifiers have also been reported. In this article it is shown that by using the principles of transposed network and nullor model for the active device, a current transfer function can be realized in a very simple way using a voltage amplifier, i.e. operational amplifier (OA). The key concept is the knowledge that each ideal (i.e. infinite gain) controlled source is exactly equivalent to a nullor. Thus, a voltage-mode filter implemented using an ideal three terminal (output, input and ground) OA can be very easily converted to a current-mode filter using the same OA. The principle has been illustrated by considering single-OA- and multi-OA-based second-order voltage-mode filters. SPICE simulation results are provided to validate the theoretical concept. TI Clinical factors as predictors of the risk of falls and subsequent bone fractures due to osteoporosis in postmenopausal women
SO JOURNAL OF BONE AND MINERAL METABOLISM
LA English
DT Article
DE osteoporosis; falls; single-leg stance with open eyes; predictive factors; logistic regression analysis
AB In Japan, the "bedridden state" is one of the most serious problems the aged face, and it is becoming a social problem. The main causes of the bedridden state are cerebrovascular disorders and bone fractures following falls. The purpose of this study was to predict risk factors for falls and resultant bone fracture due to osteoporosis. We explored mobility parameters for possible fall prevention. In order to examine the correlation between the risk of falling and resultant bone fracture due to osteoporosis, logistic regression analysis was performed between bone mass (independent variable) and various factors dependent variables: body mass index [BMI], body fat percentage, atherogenic index, presence of transformation-related osteoarthritis of knee, presence of transformation-related osteoarthritis of spine, maximum step length, single-leg stance with open eyes, and hip-joint flexion motion angle); predictive factors were then examined. Predictive factors were determined by the stepwise method. Subjects who could not perform the "single-leg stance with open eyes" test had a risk of falling and bone fracture 2.49 times as large as that of subjects who could. The "single-leg stance with open eyes" test may be considered a useful method for the early detection of the risk of falling and bone fracture associated with osteoporosis. As a first step to identify factors predicting the occurrence of falls and bone fractures due to osteoporosis, we intended to discover an indicator that would help to detect incipient osteoporosis.

TI Effects of alfacalcidol alone or in combination with elcatonin on incidence of osteoporotic vertebral fractures in postmenopausal women with spondylosis
SO JOURNAL OF BONE AND MINERAL METABOLISM
LA English
DT Article
DE osteoporosis; spondylosis; vertebral fracture; alfacalcidol; elcatonin
ID bone-mineral density; salmon-calcitonin; vitamin-d; 1-alpha-hydroxyvitamin d-3; osteophyte formation; biochemical markers; disc degeneration; elderly-women; iliac crest; osteoarthritis
AB Osteoporosis and spondylosis often occur simultaneously. However, there are no previous reports about the effects of osteoporosis medication on incidence of vertebral fractures in people with spondylosis. In this study, we conducted a retrospective investigation of the effects of alfacalcidol alone or in combination with elcatonin on incidence of osteoporotic vertebral fractures in women with spondylosis. The present subjects were 101 postmenopausal women with osteoporosis aged > 60 years, divided into three groups: D group (n = 45), treated for > 5 years with alfacalcidol; D+ECT group (n = 26), treated for > 5 years with alfacalcidol plus elcatonin; control group (n = 30), who received no medications for > 5 years. Over the 5-year treatment period, bone mineral density (BMD) of the lumbar spine and proximal femur did not significantly change in the D and D+ECT groups, but they significantly decreased in the control group ($P < 0.05$). The number of incident vertebral fractures per patient was significantly higher in the control group (2.9) than in the D group (1.2) and D+ECT group (1.5) ($P < 0.01$). There was no significant difference in BMD or incident vertebral fractures between

the D and D+ECT groups. In all three groups, the number of incident vertebral fractures positively correlated with the number of prevalent vertebral fractures (0.303 <= r <= 0.434), and negatively correlated with baseline BMD (-0.703 <= r <= - 0.326) and the osteophyte score representing the degree of spondylosis (-0.769 <= r <= -0.365). Further multiple regression analysis revealed that the medication (D or D+ECT, P < 0.001) and the osteophyte score (P < 0.001) were the most significant contributors for the number of incident vertebral fractures. In conclusion, elcatonin had no additive effects on BMD or prevention of vertebral fractures in postmenopausal women receiving alfacalcidol. Presence of spondylosis (indicated by a high osteophyte score) appears to have an effect on prevention of vertebral fractures.

TI Reliability and accuracy of vertebral fracture assessment with densitometry compared to radiography in clinical practice
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE absorptiometry; disc space osteoarthritis; spine radiography; vertebral deformity; vertebral fracture assessment
ID x-ray absorptiometry; morphometric radiography; identification; osteoporosis; deformity; hip; osteoarthritis; precision; spine; women
AB Absorptiometry of the thoraco-lumbar spine at the time of bone densitometry to detect vertebral deformities consistent with fracture is now available. The performance of absorptiometry in clinical practice compared to radiography has not been fully established, especially in the presence of osteoarthritis or scoliosis. Our first objective was to compare absorptiometry to radiography for detection of vertebral deformity in elderly women who were referred for bone densitometry with or without scoliosis or disc space osteoarthritis excluded. Our second objective was to assess the effect of osteoarthritis and scoliosis on the inter-rater reliability of both technologies. The study group comprised two hundred five women age 65 and older referred for bone densitometry in a large multispecialty group practice. Lateral and antero-posterior (AP) absorptiometry images and lateral spine radiographs were obtained on all participants. The vertebrae on all images were evaluated for vertebral deformity by two observers according to the Genant semiquantitative criteria who were blinded to each other's readings. Disc spaces were evaluated on radiographs for osteoarthritis. Absorptiometry AP images were evaluated for scoliosis. In the absence of scoliosis, the sensitivity and specificity of absorptiometry for persons with one or more radiographic grade 2-3 deformities (>= 25% reduction of vertebral height) for the two readers were 87-93% and 93-95%, respectively. The inter-rater reliability of absorptiometry improved in the absence of moderate or severe disc space osteoarthritis. A strategy of absorptiometry with follow-up radiography only in those with scoliosis or apparent grade 2 deformity accurately identifies those with prevalent grade 2 or 3 deformity on radiography (accuracy 0.98 and kappa 0.86 for reader 1; accuracy 0.99 and kappa 0.92 for reader 2). Lateral and AP absorptiometry imaging of the spine with

selective follow-up radiography accurately identifies elderly women with vertebral deformity consistent with moderate or severe fracture, but extra caution is necessary when evaluating vertebrae in the presence of adjacent disc space osteoarthritis.

TI Progressive junctional kyphosis at the caudal end of lumbar instrumented fusion: Etiology, predictors, and treatment
SO SPINE
LA English
DT Article
DE junctional kyphosis; sagittal balance; decompensation; pedicle subtraction osteotomy; flat back
ID spinal-fusion; harrington instrumentation; proximal kyphosis; motion segment; scoliosis; lordosis; thoracolumbar; flatback; management; deformity
AB Study Design. Clinical case series. Objective. To describe a series of patients with progressive sagittal decompensation caused by failure at the caudal end of an instrumented lumbar fusion. Summary of Background Data. Lumbar kyphosis in association with global sagittal decompensation can be a disabling problem,

particularly as a late complication of distraction instrumentation. Although kyphosis at the rostral end of instrumented fusions secondary to adjacent segment degeneration has been well described, substantially less has been documented about failure and kyphosis at the caudal end. Methods. Patients who have a progressive lumbar kyphosis and sagittal decompensation requiring operative revision were retrospectively reviewed, and radiographic measurements of lumbar lordosis and sagittal balance were performed to study this problem. Results. There were 13 patients identified. The most common mode of caudal junctional decompensation was related to failure of the most distal fixation. Sagittal decompensation occurred even in the presence of satisfactory lumbar lordosis. Revision surgery and improved sagittal balance were achieved typically using the technique of pedicle subtraction osteotomy and extension of the instrumentation to the sacrum. Osteoporosis, hip osteoarthritis, and substance abuse were commonly observed associations. Conclusions. Fixation failure at the caudal end of lumbar-instrumented fusion should be considered in patients with progressive sagittal decompensation. The high potential for failure of L5 pedicle screws after the index surgery warrants serious consideration of extending such fusions into the sacrum/ilium.

ID human articular chondrocytes; human osteogenic protein-1; matrix synthesis; cartilage; expression; promotes; repair; op-1
AB BMP-7 is a member of the TGF-beta superfamily which is supposed to be one of the most potent anabolic factors of chondrocytes. In this study we analysed the effect of BMP-7 on three dimensional cultured chondrocytes with and without serum. Cartilage samples from fourteen patients with osteoarthritis of the knee were harvested and chondrocytes were cultivated in alginate-beads with and without serum supplementation (10% FCS). BMP-7 was added in three different concentrations (200, 600 and 1000 ng/ml). After 4 and 21 days PG concentration was determined by a Blyscan-Assay. For gene expression analysis of aggrecan (AGG) quantitative Lightcycler-PCR was used to estimate the mRNA levels. Under serumfree culture conditions there was no stimulation after 4 days but there was a twofold increase of PG concentration after 21 days. Using BMP-7 together with serum supplemented medium we found comparable results, however not as pronounced. AGG expression was increased only after 4 days but not after 21 days. Beside a stimulatory effect under serumfree conditions we also found a stimulatory effect of BMP-7 in the presence of serum. This study pronounces that BMP-7 might be a suitable anabolic activator of osteoarthritic chondrocytes. (c) 2006 Elsevier Masson SAS. All rights reserved.

DT Review
ID teratocarcinoma stem-cells; embryonal carcinoma-cells; messenger-rna; retinoic acid; gene-expression; in-vitro; family-members; tnf-alpha; mouse; apoptosis
AB The bone morphogenetic protein (BMP)2 gene has been genetically linked to osteoporosis and osteoarthritis. We have shown that the 3'-untranslated regions (UTR) of BMP2 genes from mammals to fishes are extraordinarily conserved. This indicates that the BMP2 3'-UTR is under stringent selective pressure. We present evidence that the conserved region is a strong posttranscriptional regulator of BMP2 expression. Polymorphisms in cis-regulatory elements have been proven to influence susceptibility to a growing number of diseases. A common single nucleotide polymorphism (SNP) disrupts a putative posttranscriptional regulatory motif, an AU-rich element, within the BMP2 3'-UTR. The affinity of specific proteins for the rs15705 SNP sequence differs from their affinity for the normal human sequence. More importantly, the in vitro decay rate of RNAs with the SNP is higher than that of RNAs with the normal sequence. Such changes in mRNA: protein

interactions may influence the posttranscriptional mechanisms that control BMP2 gene expression. The consequent alterations in BMP2 protein levels may influence the development or physiology of bone or other BMP2-influenced tissues.

TI Can condition-specific health surveys be specific to spine disease? An analysis of the effect of comorbidities on baseline condition-specific and general health survey scores
SO SPINE
LA English
DT Article
DE Short-Form 36; Oswestry Disability Index; comorbidity
ID oswestry disability index; low-back-pain; multidisciplinary rehabilitation; stenosis; responsiveness; questionnaire; surgery; sf-36; reliability; assessments
AB Study Design. This is an observational cross-sectional study of 26,290 patients seen and evaluated in the 25 centers of the National Spine Network. Objective. To explore the correlation between medical and psychosocial comorbidities, and baseline Short-Form 36 Health Status questionnaire (SF-36) and Oswestry Disability Index (ODI) (Musculoskeletal Outcomes Data Evaluation and Management Systems version with scales reversed so that a score of 100 represents no disability, and a score of 0 represents severe disability) scores in spine patients. Summary of Background Data. It remains unclear whether general health questionnaires or condition-specific surveys are superior for evaluating spine patients (Spine 2000; 25: 3100-3). Most clinicians would suspect that comorbidities (medical and psychosocial) play a significant role in the presentation, treatment, and outcome of spine patients. Yet, it has been difficult to quantify specifically the association of comorbidities with traditional health status instrument scores for spine patients. Methods. Initial visit (baseline) health questionnaires were analyzed. Patients were stratified according to the number of self-reported comorbidities. Analysis of variance was performed to assess the difference in mean health status across comorbidity groups. Multiple linear regressions were used to identify the most influential individual comorbidities on baseline functional survey scores. Results. There is an associated decrease in baseline physical component summary (PCS) (from the SF-36) and ODI scores with the addition of each comorbidity. For the range of zero to >= 7 comorbidities, the PCS score decreases from 33.3 to 23.2 ($P < 0.001$). The average baseline ODI score for patients with zero comorbidities was 62.4, decreasing to 42.0 in the group with >= 7 comorbidities ($P < 0.001$). The strongest association was seen with the medical comorbidities of smoking, frequent headaches, osteoarthritis, and osteoporosis ($P < 0.001$). However, the association with psychosocial comorbidities (e.g., self-rated health, active

compensation case, depression) (P < 0.001) was higher for both health status measures. Health status measures in patients with lumbar problems show that these patients are more impacted by their disease than patients with cervical or thoracic spine problems (P < 0.001), although the correlation with comorbidities is smaller for the lumbar group (P < 0.001). Conclusion. Traditional medical comorbidities correlate with both SF-36 (e.g., PCS) general health survey scores as well as disease-specific ODI scores. However, psychosocial comorbidities such as poor self-rated health (SF-1), an active compensation case, and low education level have a higher association than traditional medical comorbidities on these health status measures. The results show that the type of survey (disease-specific e. g., ODI, vs. generic e. g., SF-36) used may be less important than the need to assess and control for psychosocial and medical comorbidities when any patient-reported health survey is used in the spine population.

TI An estimate of the worldwide prevalence and disability associated with osteoporotic fractures
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE disability-adjusted life-years; hip fracture; mortality; noncommunicable diseases
ID excess mortality; hip-fractures; burden; risk; epidemiology; projections
AB Objective The aim of this study was to quantify the global burden of osteoporotic fracture worldwide. Methods The incidence of hip fractures was identified by systematic review and the incidence of osteoporotic fractures was imputed from the incidence of hip fractures in different regions of the world. Excess mortality and disability weights used age- and sex-specific data from Sweden to calculate the Disability Adjusted Life Years (DALYs) lost due to osteoporotic fracture. Results In the year 2000 there were an estimated 9.0 million osteoporotic fractures of which 1.6 million were at the hip, 1.7 million at the forearm and 1.4 million were clinical vertebral fractures. The greatest number of osteoporotic fractures occurred in Europe (34.8%). The total DALYs lost was 5.8 million of which 51% were accounted for by fractures that occurred in Europe and the Americas. World-wide, osteoporotic fractures accounted for 0.83% of the global burden of non-communicable disease and was 1.75% of the global burden in Europe. In Europe, osteoporotic fractures accounted for more DALYs lost than common cancers with the exception of lung cancer. For chronic musculo-skeletal disorders the DALYs lost in Europe due to osteoporosis (2.0 million) were less than for osteoarthrosis (3.1 million) but greater than for rheumatoid arthritis (1.0 million). Conclusion We conclude that osteoporotic fractures are a significant cause of morbidity and mortality, particularly in the developed countries.

TI Relacatib -: Prevention and treatment of bone metastases treatment of osteoarthritis treatment of osteoporosis cathepsin K inhibitor
SO DRUGS OF THE FUTURE
LA English
DT Article
DE GSK-462795; SB-462795
AB Cathepsin K is a cysteine protease synthesized by osteoclasts and one of the major effectors of osteoclastic bone resorption. As such, it is an attractive target for therapeutic intervention in the treatment of osteoporosis and other bone disorders causing bone degradation. Relacatib (SB-462795) is a high-potency inhibitor of cathepsin K with demonstrated antiresorptive activity in normal and ovariectomized monkeys. Studies in ovariectomized monkeys also demonstrated a greater stimulatory effect on cortical bone compared to alendronate, with significant improvements in bone mineral density and bone mineral content compared with vehicle-treated controls. Studies in monkeys indicate site-specific differences between alendronate and relacatib which may translate into differential efficacy. Relacatib is scheduled to enter phase II development for the prevention and treatment of bone metastases in 2006.

TI High incidence of the os peroneum in a cadaver sample in Johannesburg, South Africa: Possible clinical implications?
SO CLINICAL ANATOMY
LA English
DT Article
DE sesamoid bone; prevalence; fractures; foot pain; epidemiology; ossification; dissection
ID fracture; stress
AB This study set out to investigate the incidence of the os peroneum in a cadaver sample from Johannesburg, South Africa and to note how bio-demographic parameters affect such incidence. The os peroneum (OP) is a sesamoid bone frequently found in the tendon of the fibularis longus muscle (FLM), as it passes on the plantar aspect of the cuboid bone. While this bone is often an incidental

dissection room or radiological finding, OP fractures, with or without associated rupture of the fibularis (peroneus) longus tendons have been reported. Some investigators have also suggested that the presence of the OP may render the tendon of the FLM susceptible to avulsion injuries. The reported incidences of the OP range between 8 and 26%. These data have emanated by and large from radiographic rather than dissection studies, and the influences of biological indices such as age, sex, population group of origin, and side of the body on these incidences remain largely unknown. Forty cadavers (average age = 75 years) were dissected. Os peronei were present in 36 of these cadavers (90.0%), with 96% of them occurring bilaterally. This bilateral incidence was statistically significant (P = 0.007), but there was no significant difference in age (P = 0.38), sex (P = 0.97), or population group (P = 0.17). We hope that the unusually high incidence of the OP reported here will stimulate further research into possible predisposing factors as well as into the speculated associations between sesamoid occurrence, osteoarthritis, and tendon injuries.

TI Micellar electrokinetic capillary chromatographic method for the quantitative analysis of uricosuric and antigout drugs in pharmaceutical preparations
SO ELECTROPHORESIS
LA English
DT Article
DE MEKC-UV; pharmaceutical analysis; uricosuric and antigout drugs
ID performance liquid-chromatography; active metabolite oxypurinol; electrophoresis; urine; allopurinol; colchicine; purines
AB A simple MEKC method is described for the separation and quantification of seven widely used uricosuric and antigout drugs, including allopurinol (AP), benzbromarone (BZB), colchicine (COL), orotic acid (OA), oxypurinol (OP), probenecid (PB), and sulfinpyrazone (SPZ). The drugs were separated in a BGE of borate buffer (45mM; pH 9.00) with SDS (20 mM) as the micellar source and the

separated drugs were directly monitored with a UV detector (214 nm). Several parameters affecting the separation and analysis of the drugs were studied. Based on the normalized peak-area ratios of the drugs to an internal standard versus the concentration of the drugs, the method is applicable to quantify BZB, COL, and SPZ (each 5-200 mu M), AP OA, OP and PB (each 10-200 mu M) with detection limits (S/N = 3, 0.5 psi, 5 s injection) in the range of 0.6-4.0 mu M. The precision (RSD; n = 5) and accuracy (relative error; n = 5) of the method for intraday and interday analyses of the analytes at three levels (30, 120, and 180 mu M) are below 4% (n = 3). The method was demonstrated to be suitable for the analysis of AP and COL in commercial tablets with speed and simplicity.

TI Subchondral bone micro-architectural alterations in osteoarthritis: a synchrotron micro-computed tomography study
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE subchondral bone; trabecular bone micro-architecture; micro-computed tomography; synchrotron radiation
ID anterior cruciate ligament; human cancellous bone; trabecular bone; radiation microtomography; articular-cartilage; microcomputed tomography; mechanical-property; knee osteoarthritis; finite-element; iliac crest
AB Objectives: We evaluated the three-dimensional (3D) micro-architecture of subchondral trabecular (Tb) bone in osteoarthritis (OA). Due to high signal-to-noise ratio and high resolution, micro-computed tomography (micro-CT) by synchrotron radiation is considered as the gold standard for bone micro-architecture imaging. Design: Subchondral bone were extracted from femoral heads in CA cases in areas without cartilage (OAc-; n = 6) and in adjacent areas with cartilage (OAc+; n = 6) and compared to eight subchondral bone cores from osteoporosis cases (OP). The voxel size of images was 10.13 mu m. We measured the bone volume fraction (BV/TV) and morphological parameters: Tb thickness (TbTh), Tb spacing (TbSp), Tb number (TbN), and bone surface/bone volume (BS/BV). The degree of anisotropy (DA), the connectivity by the Euler number and the degree of mineralization (DM) were equally assessed. Results: BV/TV and morphological parameters showed significant differences between OAc- and OP samples ($P < 0.01$ except TbTh: $P < 0.05$) and between OAc- and OAc+ ($0.05 < P < 0.01$) but no difference between OAc+ and OP except TbN ($P < 0.01$). The connectivity was higher in OAc- comparatively to OAc+ and OP. The DA were significantly different between OA and OP cases ($P < 0.01$) but not between OAc- and OAc+ specimens. The DMs (mean +/- SD) were 0.817 +/- 0.142 g/cm(3), 0.873 +/- 0.161 g/cm(3), 0.906 +/- 0.156 g/cm3 for OAc-, OAc+, OP ($P < 0.01$), respectively. Conclusion: Subchondral bone changes were mainly observed in advanced OA, when cartilage has been deleted and preserved in adjacent area. These data suggest that subchondral bone changes would be rather secondary to the cartilage deterioration than a primitive mechanism of CA. Nevertheless, longitudinal data could bring more accurate conclusions. (c) 2005 OsteoArthritis Research Society International. Published by Elsevier Ltd. All rights reserved.

TI Does back pain prevalence really decrease with increasing age? A systematic review
SO AGE AND AGEING
LA English
DT Review
DE back pain; age; epidemiology; systematic reviews
ID of-the-literature; general-population; neck pain; saskatchewan adults; disability; complaints; community; severity; project; health
AB Background: it is believed that the prevalence of back pain decreases around the middle of the sixth decade. However, back pain is still among the most commonly reported symptoms in the elderly and osteoarthritis, disc degeneration, osteoporosis and spinal stenosis all increase with age. In light of this, it is difficult to understand why the prevalence of back pain would decrease with increasing age. Objective: this study aimed at summarising the scientific evidence on the trends of back pain prevalence with age. Methods: population-based studies reporting the prevalence of back pain, including people aged 65 years and over, were systematically retrieved from several bibliographic databases. These were read and assessed by two reviewers, and papers retained ('good quality studies') were aggregated according to specific criteria. Results: good quality studies showed a large heterogeneity as to their methods and prevalence figures. No specific patterns were detected by country nor outcome measure. However, most studies that considered severe forms of back pain found an increase of prevalence with increasing age. The curvilinear association between age and back pain prevalence that is widely mentioned in the literature was found only for benign and mixed problems. Conclusions: the evidence concerning the association of back pain prevalence with age is more sparse than currently believed and this association seems to be modified by the severity of the problem. This knowledge could have important public health implications, as the proportion of older people will increase considerably in the coming years in most industrialised societies.

TI Discordantly high spinal bone mineral density values in patients with adult lumbar scoliosis
SO SPINE
LA English
DT Article
DE adult; osteoporosis; scoliosis; lumbar; degenerative; DEXA; bone mineral density
ID quantitative ultrasound; degenerative changes; screw fixation; osteoporosis; hip; osteoarthritis; impact; women
AB Study Design. Retrospective study. Objective. The purposes of this study were: 1) to investigate the validity of bone mineral density measurements with DEXA in patients with adult lumbar scoliosis and 2) to investigate the association between osteoporosis and adult lumbar scoliosis. Summary of Background Data. Osteoporosis and lumbar degenerative scoliosis are phenomena encountered with increased frequency in aging, often concurrently. It has been suggested that scoliosis predisposes to osteoporosis, but degenerative scoliosis could falsely elevate spinal bone mineral density measurements. Methods. The feasibility of measuring Cobb's angle in DEXA scans was established in 48 surgical candidates with standing anteroposterior lumbar radiographs and supine DEXA scans. Charts and radiographs of 454 consecutive adult patients evaluated at an osteoporosis center were reviewed thereafter. The association between age, lumbar curve, and various bone density measurements was investigated. Bone density measurements between nonscoliotic and scoliotic patients with and without a history of adolescent scoliosis were compared. Results. Cobb's angle on DEXA scan was measured with an error of 4 and correlated highly with the plain lumbar radiographs. The prevalence of scoliosis was 9.47% in this cohort of patients. Advancing age was associated with an increase in osteoporosis in both scoliotic and nonscoliotic patients. Scoliotic patients demonstrated increased spinal bone mineral density (BMD) measurements compared with nonscoliotic patients, resulting in discrepancies between hip and spine BMD values. This discrepancy correlated with aging and curve magnitude (up to 30% for curves of 43). Scoliotic patients demonstrated significantly lower hip BMD values than nonscoliotic. Curve magnitude did not correlate with severity of osteoporosis. Conclusions. Cobb's angle measurements on DEXA scans are reliable and comparable to conventional radiographs. Spinal BMD values are less valuable for monitoring osteoporosis than hip values in scoliotic patients; an increasing discrepancy with age was noted. Scoliotic patients exhibited discordantly high spinal BMD values, despite significant hip osteoporosis. The discrepancy correlated with aging and curve magnitude. Scoliosis was common among the osteoporotic population (9.47%). Lumbar scoliosis is a useful clinical marker for osteoporosis, irrespective of scoliosis history and magnitude. Viable alternatives for osteoporosis evaluation of adult patients with lumbar scoliosis are hip DEXA values, in conjunction with other BMD measurements.

TI Different responsiveness to mechanical stress of bone cells from osteoporotic versus osteoarthritic donors
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE bone cell culture; mechanosensitivity; osteoarthritis; osteoporosis; pulsating fluid flow
ID nitric-oxide; cancellous bone; fluid-flow; trabecular bone; shear-stress; strain; osteocytes; density; tissue; cox-2
AB Introduction: Osteoporosis (OP) and osteoarthritis (OA) are both common diseases in the elderly, but remarkably seldom coexist. The bone defects that are related to both diseases develop with increasing age, which suggests that they are related to some form of imperfect bone remodeling. Current opinion holds that the bone remodeling process is supervised by bone cells that respond to mechanical stimuli. An imperfect response of bone cells to mechanical stimuli might thus relate to imperfect bone remodeling, which could eventually lead to a lack bone mass and strength, such as in OP patients. Materials: To investigate whether the cellular response to mechanical stress differs between OP and OA patients, we compared the response of bone cells from both groups to fluid shear stress of increasing magnitude. Bone cells from 9 female OP donors (age 60-90 year) and 9 female age-matched OA donors were subjected to pulsating fluid flow (PFF) of low (0.4 +/- 0.1 Pa at 3 Hz), medium (0.6 +/- 0.3 Pa at 5 Hz), or high shear stress (1.2 +/- 0.4 at 9Hz), or were kept under static culture conditions. Results: We found subtle differences in the shear-stress response of the two groups, measured as nitric oxide (NO) and prostaglandin E-2 (PGE(2)) production. The NO-response to shear stress was higher in the OP than the OA cells, while the PGE(2)-response was higher in the OA cells. Conclusions: Assuming that NO and PGE(2) play a role in cell-cell communication during remodeling, these results suggest that slight differences in mechanotransduction might relate to the opposite bone defects in osteoporosis and osteoarthritis.

TI Osteogenic protein-1 promotes the formation of tissue-engineered cartilage using the alginate-recovered-chondrocyte method
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE cartilage; alginate; tissue culture; tissue engineering; bone morphogenetic protein-7; osteogenic protein-1
ID human articular chondrocytes; mature bovine chondrocytes; in-vitro; growth-factors; extracellular-matrix; repair; beads; redifferentiation; proteoglycans; metabolism
AB Objective: This study examined the effects of a growth factor, recombinant human osteogenic protein-1 (rhOP-1), on the formation of tissue-engineered cartilaginous tissue by adult bovine articular chondrocytes using the alginate-recovered-chondrocyte (ARC) method. Design: To ascertain if rhOP-1 enhances the formation of the cell-associated matrix (CM) and the characteristics of CM formation, bovine articular chondrocytes were first cultured for up to 14 days in alginate beads in medium supplemented with serum, with or without rhOP-1. Then, the recovered chondrocytes and their associated CM were resuspended in medium, with or without OP-1, seeded onto culture inserts, and incubated for an additional 14 days. The fabricated ARC tissues were subjected to biochemical and histological analyses. Results: The addition of rhOP-1 to the medium in the alginate bead culture step resulted in an increased accumulation of both proteoglycan (PG) and collagen, with a ratio of PG to collagen that was higher than that found in native adult cartilage. The addition of rhOP-1 in the second step had a similar stimulatory effect during 14 days of culture. Histological examination of the tissue formed under all conditions revealed a cartilage-like matrix, stained strongly by toluidine blue. The thickness of the tissues obtained from culture conditions that included the addition of rhOP-1 was four times greater than that of the tissues cultured without rhOP-1. Conclusions: Using the ARC method, rhOP-1 enhanced the formation of matrix and generated a voluminous tissue-engineered cartilaginous construct. These characteristics may be beneficial in generating constructs that can cover large defects. (c) 2005 OsteoArthritis Research Society International. Published by Elsevier Ltd. All rights reserved.

TI The ICF comprehensively covers the spectrum of health problems encountered by health professionals in patients with musculoskeletal conditions
SO RHEUMATOLOGY
LA English
DT Article
DE outcome assessment (health care); activities of daily living; rehabilitation; musculoskeletal diseases; ICF
ID international classification; rehabilitation-medicine; disability; osteoarthritis
AB Objectives. The objective of this study was to investigate, whether the International Classification of Functioning, Disablity and Health (ICF) comprehensively covers the spectrum of health problems encountered by medical doctors and physiotherapists in patients with musculoskeletal conditions. Methods. A worldwide e-mail survey with questionnaires that requested lists of relevant areas in the ICF components-body functions, body structures, activities and participation, and environmental factors-in patients with rheumatoid arthritis, osteoarthritis, low back pain and osteoporosis was conducted. The suitability of linking the named concepts to the ICF as well as the precision of the linking was characterized by assigning the concepts to six groups. Results. All concepts that were named by the experts could be linked to the ICF, with the exception of personal factors. Between 32% (environmental factors) and 51% (activities and participation) of the named concepts were linked to an ICF category with an identical meaning and the same grade of precision. All other named concepts were linked to ICF categories with a lower level of precision, or encompassed more than one ICF category, or were linked to an ICF category with a related, but not identical meaning. Conclusions. The ICF covers comprehensively the spectrum of problems encountered in patients with musculoskeletal conditions by clinical experts throughout the world. This strengthens the validity of the ICF in the view of the users and will encourage the use of ICF-based applications such as the ICF checklist and the now-developed ICF Core Sets.

TI Comparison of synchrotron radiation and conventional x-ray microcomputed tomography for assessing trabecular bone microarchitecture of human femoral heads
SO MEDICAL PHYSICS
LA English
DT Article
DE three-dimensional microtomography; synchrotron radiation; bone trabecular pattern
ID human cancellous bone; computed-tomography; micro-ct; 3-dimensional microarchitecture; mechanical-property; morphometric-analysis; elastic property; iliac crest; architecture; microtomography
AB Microcomputed tomography (mu CT) produces three-dimensional (3D) images of trabecular bone. We compared conventional mu CT (C mu CT) with a polychromatic x-ray cone beam to synchrotron radiation (SR) ACT with a monochromatic parallel beam for assessing trabecular bone microarchitecture of 14 subchondral femoral head specimens from patients with osteoarthritis (n = 10) or osteoporosis (n = 4). SR mu CT images with a voxel size of 10.13 Am were reconstructed from 900 2D radiographic projections (angular step, 0.2 degrees). C mu CT images with a voxel size of 10.77 Am were reconstructed from 205, 413, and 825 projections obtained using angular steps of 0.9 degrees, 0.45 degrees, and 0.23 degrees, respectively. A single threshold was used to binarize the images. We computed bone volume/tissue volume (BV/TV), bone surface/bone volume

(BS/BV), trabecular number (Tb.N), trabecular thickness (Tb.Th and Tb.Th*), trabecular spacing (Tb.Sp), degree of anisotropy (DA), and Euler density. With the 0.9 degrees angular step, all C mu CT values were significantly different from SR mu CT values. With the 0.23 degrees and 0.45 degrees rotation steps, BV/TV, Tb.Th, and BS/BV by C mu CT differed significantly from the values by SR mu CT. The error due to slice matching (visual site matching 10 slices) was within 1% for most parameters. Compared to SRACT, BV/TV, Tb.Sp, and Tb.Th by C mu CT were underestimated, whereas Tb.N and Tb.Th* were overestimated. A Bland and Altman plot showed no bias for Tb.N or DA. Bias was -0.8 +/- 1.0%, +5.0 +/- 1.1 mu m, -5.9 +/- 6.3 mu m, and -5.7 +/- 29.1 mu m for BV/TV, Th.Th*, Tb.Th, and Tb.Sp, respectively, and the differences did not vary over the range of values. Although systematic differences were noted between SR mu CT and CACT values, correlations between the techniques were high and the differences would probably not change the discrimination between study groups. CACT provides a reliable 3D assessment of human defatted bone when working at the 0.23 degrees or 0.45 degrees rotation step; the 0.9 degrees rotation step may be insufficiently accurate for morphological bone analysis. TI The effect of pulsed electromagnetic fields in the treatment of cervical osteoarthritis: a randomized, double-blind, sham-controlled trial
SO RHEUMATOLOGY INTERNATIONAL
LA English
DT Article
DE cervical osteoarthritis; pulsed electromagnetic fields
ID neck pain; low-frequency; collagen production; disability scale; magnetic-field; validity; therapy; knee; physiotherapy; osteoporosis
AB The purpose of this study was to evaluate the effect of electromagnetic field therapy (PEMF) on pain, range of motion (ROM) and functional status in patients with cervical osteoarthritis (COA). Thirty-four patients with COA were included in a randomized, double-blind study. PEMF was administrated to the whole body using a mat 1.8x0.6 m in size. During the treatment, the patients lay on the mat for 30

min per session, twice a day for 3 weeks. Pain levels in the PEMF group decreased significantly after therapy ($p < 0.001$), but no change was observed in the placebo group. The active ROM, paravertebral muscle spasm and neck pain and disability scale (NPDS) scores improved significantly after PEMF therapy ($p < 0.001$) but no change was observed in the sham group. The results of this study are promising, in that PEMF treatment may offer a potential therapeutic adjunct to current COA therapies in the future.

TI Radiographic features of lumbar disc degeneration and bone mineral density in men and women
SO ANNALS OF THE RHEUMATIC DISEASES
LA English
DT Article
ID vertebral osteoporosis; postmenopausal women; osteoarthritis; spine; fracture; hip; osteophytes; population; diagnosis; disease
AB Objectives: To determine the association between individual radiographic features of lumbar disc degeneration and bone mineral density (BMD) at the spine and hip. Methods: Subjects were recruited from a population register for a screening survey of vertebral osteoporosis. BMD was assessed at the spine and hip using dual energy x ray absorptiometry. Lateral spinal radiographs were evaluated for features of lumbar disc degeneration. Each vertebral level from L1/2 to L4/5 was assessed for the presence and severity of osteophytes, end plate sclerosis, and disc space narrowing. Linear regression was used to determine the association between each of these features and BMD at the spine and hip, with adjustments for age, body mass index, and levels of physical activity. Analyses were done separately in men and women. Results: 250 women and 256 men (mean age around 65 years) were studied. At the lumbar spine, after age adjustment there was an increase in BMD with increasing grade for all radiographic features of disc degeneration in both men and women. At the femoral neck, after age adjustment there was an increase in BMD with increasing osteophyte and end plate sclerosis grade though not disc space narrowing. Adjusting for body mass index and physical activity did not influence the strength of the associations. Conclusions: Radiographic features of lumbar disc degeneration are associated with an increase in BMD at the spine. Osteophytes and end plate sclerosis, but not disc space narrowing, are associated with an increase in BMD at the hip.

TI Patterns of dosage changes with transidermal buprenorphine and transdermal fentanyl for the treatment of noncancer and cancer pain: A retrospective data analysis in Germany
SO CLINICAL THERAPEUTICS
LA English
DT Article
DE cancer pain; noncancer pain; transdermal; buprenorphine; fentanyl; tolerance; dosage stability
ID long-term management; opioid tolerance; rotation; cohort
AB Background: Previous studies have suggested that buprenorphine may have a low association with tolerance development compared with other strong opioids. In a previous study by our group, mean cohort and intraindividual dosage increases over an entire course of treatment and on a per-day basis were significantly lower with transdermal (TD) buprenorphine than with TD fentanyl. However, no information concerning the relationship between qualitative and quantitative dose changes is available. Objective: The aim of this study was to compare TD buprenorphine and TD fentanyl with respect to dosage increases, dosage stability, and the nature of dosage changes. Methods: This retrospective analysis used data from the IMS Disease Analyzer-Mediplus database, which contains patient-related data documented by 400 medical practices in Germany. Data from patients with noncancer or cancer Pain treated with TD buprenorphine or TD fentanyl for at least 3 months between May 2002 and April 2005 were analyzed. Daily dosages were directly determined from the prescribed patch strength, taking into account the possibility of multiple patches applied simultaneously. To determine dosage stability, patients were classified based on the type of dosage change (stable,

increase, alternating, or decrease) of the prescribed dosages. From the prescribed daily dosages, mean percentage increases were calculated on a per-patient basis for the entire treatment period and per day, and these were assessed in relation to the type of dosage change. Results: In total, 631 patients with noncancer pain and 605 patients with cancer pain were included in the analysis (782 women, 454 men; mean age, 76.3 years [range, 29-100 years]). Treatment Indications included osteoarthritis, low back pain, osteoporosis (noncancer groups), and neoplasm (cancer groups). Patients had similar analgesic premedication requirements based on steps 1 to 3 of the World Health Organization analgesic ladder. Comedication requirements for breakthrough pain were also similar between the TD buprenorphine and TD fentanyl groups. The mean percentage increases per day were 0.10% (TD buprenorphine) and 0.25% (TD fentanyl) in the noncancer groups and 0.19% (TD buprenorphine) and 0.47% (TD fentanyl) in the cancer groups (both, $P < 0.05$). A significantly larger proportion of patients receiving TD buprenorphine had stable dosages over the entire treatment period compared with patients receiving TD fentanyl (noncancer groups: 56.9% vs 41.6%; cancer groups: 50.0% vs 26.2% [both, $P < 0.05$]). Compared with TD buprenorphine, the proportion of patients with alternating dosage changes was significantly greater in patients receiving TD fentanyl (noncancer groups: 22.7% vs 13.1%; cancer groups: 30.6% vs 11.8% [both, $P < 0.05$]). Conclusions: In this retrospective data analysis, compared with TD buprenorphine, the increase in mean daily dosage was significantly greater in patients treated with TD fentanyl. Also, compared with TD buprenorphine, alternating dosage changes were seen in a significantly greater proportion of patients receiving TD fentanyl. On the other hand, a significantly greater proportion of patients treated with TD buprenorphine had stable dosages over their entire treatment periods.

TI Evidence for prescribing exercise as therapy in chronic disease
SO SCANDINAVIAN JOURNAL OF MEDICINE & SCIENCE IN SPORTS
LA English
DT Review
ID quality-of-life; randomized controlled-trial; chronic heart-failure; bone-mineral density; cardiovascular risk-factors; resting blood-pressure; obstructive pulmonary-disease; dependent diabetes-mellitus; home-based exercise; high-intensity exercise
AB Considerable knowledge has accumulated in recent decades concerning the significance of physical activity in the treatment of a number of diseases, including diseases that do not primarily manifest as disorders of the locomotive apparatus. In this review we present the evidence for prescribing exercise therapy in the treatment of metabolic syndrome-related disorders (insulin resistance, type 2 diabetes, dyslipidemia, hypertension, obesity), heart and pulmonary diseases (chronic obstructive pulmonary disease, coronary heart disease, chronic heart failure, intermittent claudication), muscle, bone and joint diseases (osteoarthritis, rheumatoid arthritis, osteoporosis, fibromyalgia, chronic fatigue syndrome) and cancer, depression, asthma and type 1 diabetes. For each disease, we review the effect of exercise therapy on disease pathogenesis, on symptoms specific to the diagnosis, on physical fitness or strength and on quality of life. The possible mechanisms of action are briefly examined and the principles for prescribing exercise therapy are discussed, focusing on the type and amount of exercise and

possible contraindications.

TI A capsular incision leads to a fast osteoarthritic response, but also elevated levels of activated osteogenic protein-1 in rabbit knee joint cartilage
SO SCANDINAVIAN JOURNAL OF MEDICINE & SCIENCE IN SPORTS
LA English
DT Article
DE capsular incision; meniscectomy; osteogenic protein-1; articular cartilage; subchondral bone; osteoarthritis
ID human articular chondrocytes; meniscectomized guinea-pig; subchondral bone; inflammatory cytokines; matrix synthesis; in-vitro; damage; model; op-1; expression
AB We studied whether a small capsular incision alone, or combined with meniscectomy could induce early osteoarthritic changes in the rabbit knee. Thirty-one rabbits were operated on with a capsular incision in the left knee and

meniscectomy in the right knee. Another 12 rabbits were used as controls. The rabbits were killed 3, 6 and 12 weeks after surgery. Osteoarthritic changes in the articular cartilage were evaluated by the modified Mankin score. The subchondral bone was evaluated by scintimetry (Tc-99m-HDP) and semiquantitative grading of histological changes. Osteogenic protein (OP-1) in its mature and pro-form was examined by inummohistochemistry. Both a capsular incision and meniscectomy induced articular cartilage fibrillation and increased bone metabolic activity during the initial weeks after surgery. Capsular incision led to lesser changes than meniscectomy. Mature OP-1 was elevated, and its pro-form reduced, in meniscectomized knees. A similar pattern was observed in knees with capsular incision. Already 3 weeks after surgery, the articular cartilage and sulichondral bone showed typical signs of early osteoarthritis (OA), and a reparative response was suggested by increased intensity of OP-1 staining. As these signs were also found in knees with capsular incision only, it appears that trauma-related factors such as increased bleeding and inflammation are critical for the development of OA.

TI Efficacy of pulsed electromagnetic therapy for chronic lower back pain: a

randomized, double-blind, placebo-controlled study
SO JOURNAL OF INTERNATIONAL MEDICAL RESEARCH
LA English
DT Article
DE pulsed electromagnetic therapy; lower back pain; revised Oswestry disability score
ID controlled-trial; magnetic-fields; primary-care; osteoarthritis; osteoporosis; stimulation; pemfs; knee; rat
AB This randomized, double-blind, placebo-controlled clinical trial studied the effectiveness of pulsed electromagnetic therapy (PEMT) in patients with chronic lower back pain. Active PEMT (n = 17) or placebo treatment (n = 19) was performed three times a week for 3 weeks. Patients were assessed using a numerical rating scale (NRS) and revised Oswestry disability scores for 4 weeks after therapy. PEMT produced significant pain reduction throughout the observation period compared with baseline values. The percentage change in the NRS score from baseline was significantly greater in the PEMT group than the placebo group at all three time-points measured. The mean revised Oswestry disability percentage after 4 weeks was significantly improved from the baseline value in the PEMT group, whereas there were no significant differences in the placebo group. In conclusion, PEMT reduced pain and disability and appears to be a potentially useful therapeutic tool for the conservative management of chronic lower back pain.

TI Health promotion and health education with particular emphasis on bone diseases among rural population in Poland
SO ANNALS OF AGRICULTURAL AND ENVIRONMENTAL MEDICINE
LA English
DT Article
DE health promotion; health education; osteoporosis; osteoarthritis; rural population
ID lublin region; urban women; mineral density; risk-factors; osteoporosis; age; fractures
AB Osteoporosis and osteoarthrosis are the most common diseases of bone tissue affecting both rural and urban populations. The aim of the study was to investigate the level of education and requirement for health promotion within the scope of common diseases of the skeletal system among rural population in Poland. This was an exploratory study with a cross-sectional design performed between May 2004-September 2005 in rural areas of 16 Voivodeships (main provinces) of Poland. The study population comprised of 404 (62.9%) rural women and 238 (37.1%) rural men (total 642). All subjects were randomly sampled and recruited by personal contact in primary health care centres. Study data were obtained using a specially prepared questionnaire. The most commonly reported diseases were: arterial hypertension (26.1%), joint degenerative disease (24.6%) and osteoarthritis (14.7%). The occurrence of osteoarthritis and joint degenerative disease increased with age and was highest in the group aged over 50 (21% and 38.7% respectively). Osteoarthitis was more frequent in women compared to men (16% and 12.2% respectively). In most cases, the basic information about methods of prevention and treatment given by a General Practitioner or a specialist was characterized as "satisfactory" (73.6% and 62.9% respectively). The most popular prophylactic action performed in local communities was bone densitometry (14.1%), and the most important source of knowledge - TV and radio (65%). Populations living in rural areas have limited access to health education and health prophylaxis actions, irrespective of the geographical region of Poland. Inhabitants with secondary or higher education, as well as those with a higher household income, have better

knowledge about skeletal system diseases compared to those with a lower educational level. The practical implications of this study suggest the necessity for paying more attention to etiology, symptoms and methods of prevention and treatment of bone diseases when attending to patients in specialist practice.

TI Associated factors and outcomes of persistent occiput posterior position: A retrospective cohort study from 1976 to 2001
SO JOURNAL OF MATERNAL-FETAL & NEONATAL MEDICINE
LA English
DT Article
DE persistent OP position; maternal outcome
ID occipitoposterior position; intrapartum sonography; epidural analgesia; fetal head; delivery; labor
AB Objective. To identify maternal and fetal risk factors associated with persistent occiput posterior position at delivery, and to examine the association of occiput posterior position with subsequent obstetric outcomes. Methods. This is a retrospective cohort study of 30 839 term, cephalic, singleton births. Women with persistent occiput posterior (OP) position at delivery were compared to those with occiput anterior (OA) position. Demographics, obstetric history, and labor management were evaluated and subsequent obstetric outcomes examined. Potential confounding variables were controlled for using multivariate logistic regression analysis. Results. The overall frequency of OP position was 8.3% in the study population. When compared to Caucasians, a higher rate of OP was observed among African-Americans (OR 1.4, 95% CI 1.25-1.64) while no other racial/ethnic differences were noted. Other associated factors included nulliparity, maternal age >= 35, gestational age >= 41 weeks, and birth weight 44000 g, as well as artificial rupture of the membranes (AROM) and epidural anesthesia ($p < 0.001$ for all).

Persistent OP was associated with increased rates of operative vaginal (OR 4.14, 95% CI 3.57-4.81) and cesarean deliveries (OR = 13.45, 95% CI 11.94-15.15) and other peripartum complications including third or fourth degree perineal lacerations (OR = 2.38, 95% CI 2.03-2.79), and chorioamnionitis (OR = 2.10, 95% CI 1.81-2.44). Conclusion. Epidural use, AROM, African-American ethnicity, nulliparity, and birth weight 44000 g are associated with persistent OP position at delivery, with higher rates of operative deliveries and obstetric complications. This information can be useful in counseling patients regarding risks and associated outcomes of persistent OP position.

TI Osteoblast dysfunction in male idiopathic osteoporosis
SO CALCIFIED TISSUE INTERNATIONAL
LA English
DT Article
DE osteoblast; male osteoporosis; osteocalcin; macrophage colony; stimulating

factor; parathyroid hormone-related peptide
ID bone-mineral density; growth-factor-i; receptor expression; protein expression; estradiol levels; serum estradiol; binding-protein; messenger-rna; men; cells
AB The etiology of primary osteoporosis in young and middle-aged men is unknown. We have studied osteoblast function in cells derived from men with idiopathic osteoporosis and in control cells from age-matched men with osteoarthrosis. Osteoblasts were isolated from transiliac bone biopsies. Osteoblast function was measured as vitamin D-stimulated osteocalcin production and production of cytokines and factors involved in osteoclast activation and bone formation. Cell proliferation was measured as H-3-thymidine incorporation. Parathyroid hormone-related peptide (PTHrP) mRNA was measured using reverse-transcriptase polymerase chain reaction. In osteoporotic men, bone mineral density at the femoral neck was correlated to in vitro production of osteocalcin. Osteoblasts from osteoporotic men produced significantly less osteocalcin after vitamin D stimulation but had increased production of macrophage colony-stimulating factor (M-CSF) compared to controls. The osteocalcin response was negatively correlated to production of M-CSF, interleukin-6, and C-terminal propeptide of type I collagen. Basal H-3-thymidine incorporation was similar in cells from osteoporotic patients and controls. PTHrP (10(-9)M) significantly increased cell proliferation in control cells but not in osteoporotic cells. Basal PTHrP mRNA levels were significantly higher in osteoporotic cells than in cells from controls. The results are in agreement with previous histomorphologic studies indicating that men with idiopathic osteoporosis have an osteoblast dysfunction with decreased osteocalcin production and increased production of factors stimulating osteoclast activation. This indicates a catabolic cellular metabolic balance leading to negative bone turnover, resulting in osteoporosis. The cause of such cellular dysfunction needs further evaluation.

TI Bone mineral measurements of subchondral and trabecular bone in healthy and osteoporotic rabbits
SO SKELETAL RADIOLOGY
LA English

DT Article
DE osteoporosis; subchondral bone; trabecular bone; bone mineral density; rabbit
ID x-ray absorptiometry; dual-photon absorptiometry; dxa-systems qdr-1000; animal-models; ovariectomized rats; in-vivo; density; precision; accuracy; osteoarthritis
AB Introduction: Experimental models of osteoporosis in rabbits are useful to investigate anabolic agents because this animal has a fast bone turnover with predominant remodelling over the modelling processes. For that purpose, it is necessary to characterize the densitometric values of each type of bony tissue. Objective: To determine areal bone mass measurement in the spine and in trabecular, cortical and subchondral bone of the knee in healthy and osteoporotic rabbits. Design: Bone mineral content and bone mineral density were measured in lumbar spine, global knee, and subchondral and cortical bone of the knee with dual energy X-ray absorptiometry using a Hologic QDR-1000/W densitometer in 29 skeletally mature female healthy New Zealand rabbits. Ten rabbits underwent triplicate scans for evaluation of the effect of repositioning. Osteoporosis was experimentally induced in 15 rabbits by bilateral ovariectomy and postoperative corticosteroid treatment for 4 weeks. Identical dual energy X-ray absorptiometry (DXA) studies were performed thereafter. Results: Mean values of bone mineral content at the lumbar spine, global knee, subchondral bone and cortical tibial metaphysis were: 1934 +/- 217 mg, 878 +/- 83 mg, 149 +/- 14 mg and 29 +/- 7.0 mg, respectively. The mean values of bone mineral density at the same regions were: 298 +/- 24 mg/cm(2), 455 +/- 32 mg/cm(2), 617 +/- 60 mg/cm(2) and 678 +/- 163 mg/cm(2), respectively. Bone mineral content and bone density of healthy rabbits followed a normal distribution at the four skeletal regions studied. Precision after triplicate repositioning yielded a coefficient of variation ranging from 2.6% to 3.8%. The least significant change ranged between 7.3% and 10.7%. Bone mineral density measured at the four different skeletal regions correlated significantly. Bone mineral density in osteoporotic rabbits was significantly lower in the four regions studied than that in controls, rendering a T-score of, respectively, -2.0 +/- 1.1 in the lumbar spine, -2.2 +/- 2.1 in the global knee, -1.9 +/- 0.6 in the subchondral bone, and -5.7 +/- 3.1 in the cortical tibia ($P < 0.05$). Conclusions: DXA is a reliable and precise method to evaluate the bone mass in rabbits. Our results also suggest that subchondral bone is a bone of mixed densitometric characteristics with marked cortical bone predominance.

TI The ratio of medial to lateral tibial plateau bone mineral density and compartment-specific tibiofemoral osteoarthritis
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE bone mineral density; osteophytes; joint space narrowing; sclerosis
ID fractal signature analysis; knee osteoarthritis; cancellous bone; subchondral bone; postmenopausal osteoporosis; disease progression; cartilage damage;

marrow lesions; dynamic load; women
AB Introduction: Bone is thought to play an important role in osteoarthritis (OA) pathophysiology. Our aim was to look at specific features of CA and their relation to the ratio of medial:lateral tibial plateau bone mineral density (M:L BMD Ratio). Methods: We examined our research question in the Framingham OA Study Cohort. All participants had BMDs and weight-bearing plain radiographs of the knees (2002-2005). M:L BMD Ratios were calculated using BMD from medial and lateral regions in the tibial plateau. Knee x-rays were read for osteophytes (OSTs), joint space narrowing (JSN), and sclerosis (Osteoarthritis Research Society International (OARSI) scoring system). Knees were classified as having medial and/or lateral JSN if they had JSN >= 1 in the medial and/or lateral tibiofemoral compartments, respectively. Medial and/or lateral OSTs were defined as medial and/or lateral tibial and/or femoral OSTs >= 2, respectively. Medial sclerosis and lateral sclerosis were defined as medial and lateral tibial sclerosis >= 1, respectively. We performed a logistic regression with medial JSN as the outcome and with M:L BMD Ratio groups as predictor variables, using the median group as the referent. Analyses were adjusted for age, sex, and body mass index (BMI). Generalized estimating equations were used to adjust for correlation between knees. Identical analyses were performed with medial OSTs, medial sclerosis, lateral JSN, lateral OSTs, and lateral sclerosis as the outcomes. Results: Mean age of 1612 subjects (3048 knees) was 63.9 (Standard Deviation (SD) +/- 8.9), 56% were women, and mean BMI was 28.5 (SD +/- 5.5). M:L BMD Ratio was positively associated with medial JSN (P for linear trend <0.0001) and negatively associated with lateral JSN (P for linear trend <0.0001). The relations of the ratio with medial and lateral OSTs were j-shaped with P for quadratic trends <0.0001. There were also strong associations between M:L BMD Ratio and compartment-specific sclerosis (P for linear trends <0.0001) with most knees with medial and lateral sclerosis being in the highest and lowest M:L BMD Ratio groups, respectively. Conclusion: In summary, the extremes of the M:L BMD Ratio are strongly associated with individual radiographic features of OA. These findings add to existing evidence supporting the importance of understanding bone in OA pathophysiology. (C) 2006 OsteoArthritis Research Society International. Published by Elsevier Ltd. TI Rapid multifocal chondrolysis after liver transplantation in four patients
SO ANNALS OF THE RHEUMATIC DISEASES
LA English
DT Article
ID destructive osteoarthritis; idiopathic chondrolysis; hip-joint; disease
AB Background: Favourable clinical outcomes achieved with liver transplantation may be jeopardised by corticosteroid-induced osteoarticular complications, such as osteoporosis or aseptic osteonecrosis. Case report: A previously unreported joint complication in liver transplant recipients is described. Methods: Retrospective study of liver transplant recipients in whom destructive joint disease developed, identified among 330 symptomatic patients out of a total of 1260 managed over a 15 year period (November 1984-January 2000) in a university based liver transplantation centre. Results: In four patients (23-56 years), rapid chondrolysis developed 2-12 years after transplantation in more than three weightbearing or non-weightbearing joints free of radiological features of avascular osteonecrosis, evidence of infection, or defined inflammatory arthritis. Pathological examination of five hip joints and one knee joint found no evidence of infection or inflammation. Six joint replacement procedures were performed successfully in three patients. Conclusion: Clinicians managing liver transplant recipients, and perhaps recipients of other organs, should be aware that rapid chondrolysis may develop. The pathogenesis of this rare complication is unclear.

TI Differential diagnosis of a femoral neck/head stress fracture
SO JOURNAL OF ORTHOPAEDIC & SPORTS PHYSICAL THERAPY
LA English
DT Article
DE bone scan; imaging; MRI; physical therapy examination
ID of-the-literature; negative bone-scan; insufficiency fractures; hip pain; neck; runner; head; osteoporosis; injury
AB Study Design: Resident's case problem. Background: Identifying stress fractures of the hip can be a challenging differential diagnosis. Pain presentation is not always predictable and radiographs may not show the fracture, especially during its early stages. Hip stress fractures left untreated can displace and necessitate open reduction internal fixation or total hip arthroplasty. Diagnosis: A 70-year-old woman presented to the physical therapy clinic with complaints of right hip pain. She had been evaluated by a physician and radiographs of the hip, which revealed some arthritic changes, were otherwise normal. Upon examination, the physical therapist observed an antalgic gait, a noncapsular pattern of limitation of hip motion, an empty painful end feel at the end range of motion (ROM) for hip abduction, external rotation, and flexion, and extreme tenderness to palpation over the anterior hip region. The therapist suspected a more pernicious problem than osteoarthritis and discussed his suspicion with the physician. The physician subsequently requested an MRI that revealed a femoral neck and head stress fracture that was later confirmed with a bone scan. The patient was provided with a walker for ambulation with a non-weight-bearing status for 6 weeks, after which she returned to physical therapy for progressive weight bearing and strengthening. She was discharged with a relatively pain-free hip and was ambulating with a cane. A 2-month follow-up examination revealed a pain-free hip and a return to all premorbid activities, including ambulation without an assistive device. Discussion: The presence of a normal radiograph of the hip should not be considered conclusive in ruling out a stress fracture in the hip region. The current case demonstrates how careful evaluation can reveal occult pathologies and prevent potentially catastrophic morbidity.

TI Association between morbidity and skeletal biomarkers of biological aging
SO HUMAN BIOLOGY
LA English
DT Article
DE osseographic score; morbidity skeletal aging; Chuvashians
ID bone-mineral density; population biology; general-practice; osteoarthritis; disease; age; comorbidity; prevalence; determinants; osteoporosis
AB The Osseographie Scoring System (OSS) is a synthetic measure of skeletal aging that combines osteoporotic and osteoarthritic changes of the hand. The OSS is used to evaluate biological age in a population. The aim of the present study was to evaluate the association between certain chronic morbidities and the skeletal biomarker of biological aging. We performed a population-based study on a large sample of individuals who were receiving no medications to treat or prevent chronic morbidities [668 male (age 18-89 years) and 608 female (age 18-81 years) Chuvashians]. Morbidity data obtained from the individuals' medical records was sorted into 16 categories. A one-way ANOVA was used to elucidate the association between morbidity and age-adjusted OSS score. Statistically significant differences between means of OSS scores in affected vs. nonaffected individuals were found in the rheumatic diseases group. Ischemic heart disease, pulmonary diseases, traumatic brain injuries, and gynecological diseases also showed differences; however, after correction for multiple testing, the results were statistically nonsignificant. We conclude, that individuals who suffer from the mentioned chronic morbidities will show a higher degree of skeletal aging. Further research is needed to clarify the biological mechanisms of association between certain types of morbidities and changes in skeletal aging.

TI Osteoporosis and bone metabolism in postmenopausal women with osteoarthritis of the hand
SO MENOPAUSE-THE JOURNAL OF THE NORTH AMERICAN MENOPAUSE SOCIETY
LA English
DT Article
DE hand osteoarthritis; postmenopausal osteoporosis; bone metabolism; DEXA
ID mineral density; knee osteoarthritis; collagen metabolism; elderly-men; population; markers
AB Objective: Osteoarthritis and osteoporosis are two major health problems affecting postmenopausal women. Epidemiological observations seem to demonstrate a possible inverse relationship between osteoarthritis and osteoporosis. Erosive osteoarthritis (EOA) of the hand is a destructive form of primary osteoarthritis. This study evaluated bone mineral density and bone

metabolism changes in erosive and nonerosive hand osteoarthritis women. Design: Fifty-five women (mean age, 59 years; body mass index, 23 +/- 1.4 kg/m(2)) who had been postmenopausal for an average of 9 years and who presented with hand osteoarthritis according to American College of Rheumatology criteria were enrolled in the study; 15 women showed clinical and radiological evidence of hand EOA. Twenty women matched for age, age at menopause, and body mass index formed the control group. Bone mineral density (g/cm(2)) was measured at the hip and lumbar spine using dual-energy x-ray absorptiometry. Serum and urinary calcium and phosphate, serum 25-hydroxyvitamin D, parathyroid hormone, osteocalcin, and urinary breakdown products of bone matrix (CrossLaps) were analyzed. Results: Women with hand EOA had a statistically significant lower T- and Z-score L2-L4 value than non-hand EOA women and controls ($P<0.01$). Moreover, postmenopausal women with hand EOA had higher significant percentage of osteoporosis at lumbar spine when compared with non-hand EOA postmenopausal women and controls. Any statistically significant difference in osteocalcin and CrossLaps serum levels was noted among women with hand EOA, hand osteoarthritis, and controls. Conclusion: Our data suggest that postmenopausal women with clinical and radiological EOA are at risk for development of osteoporosis.

TI Predictors of dietary and health supplement use in older Australians
SO AUSTRALIAN JOURNAL OF ADVANCED NURSING
LA English
DT Article
DE aged; elderly; complementary medicines; dietary supplements; health surveys
ID vitamin-d deficiency; knee osteoarthritis; mineral supplements; fish-oil; glucosamine; progression; prevalence; people; trends; 3-year
AB Objective: This study aimed to identify the health conditions and symptoms that predicted dietary and health supplement use in older Australians. Design: Almost 2,500 Australians aged 65 years and over were randomly selected from the 2000 Australian Electoral Commission roll. All states and territories were proportionally represented in the sample. Data were obtained using a self-administered postal survey. Subjects: Approximately 1,200 individuals (51% males and 49% females) aged between 65-98 years completed the survey. Results: At the time of survey, 43% (n=548) reported using some form of supplement. Supplement use was significantly associated with gender (female) and chronic musculoskeletal ailments such as arthritis, osteoporosis and generalised back or neck problems. A diagnosis of hypertension or a heart condition were significant barriers to supplement use in this sample. The most common potential drug-supplement interaction was between calcium supplements and antihypertensives. Conclusion: Older supplement users may be of the opinion that supplements offer relief from the pain and suffering associated with their medical problems. If so, current supplement patterns would indicate that they are misguided. Nurses have an important role to play in encouraging older individuals to disclose their use of supplements to all health professionals involved in their continuing care.

TI Tibiotalar arthrodesis with the tibial compression nail
SO EUROPEAN JOURNAL OF TRAUMA AND EMERGENCY SURGERY
LA English
DT Article
DE tibiotalar arthrodesis; compression nail; intramedullary fixation; dowel technique
ID ankle arthrodesis; screw-fixation
AB Objective: Arthrodesis of the ankle joint in proper position (neutral position in respect to flexion/extension, 5 degrees external rotation, 0-5 degrees of valgus). Pain-free weight bearing of the affected limb. Indications: Painful osteoarthritis of the ankle joint resistant to conservative approaches even in the presence of poor bone quality of the distal tibia such as after pilon fractures and osteoporosis. Failure of other methods of internal fixation. Contra indications: Osteitis. Partial necrosis of the talar dome. Medullary canal of tibia not patent. Surgical Technique: Lateral approach and resection of lateral malleolus. If the joint position is normal, removal of articular cartilage of tibia and talus. If axial correction is necessary, wedge resection of articular surfaces with underlying bone. Opening of proximal tibial medullary canal, insertion of compression nail into tibia and talus. Compression osteosynthesis and cancellous bone grafting. Alternatively, the arthrodesis can be achieved with the dowel technique. Results: Between September 1993 and March 2001,137 patients (43 women, 94 men, average age 49 years [2179 years]) were operated. Follow-up of 110 patients after 42 months: successful bony fusion in 99 patients (90%). In six patients (5.5%) the goal of treatment was obtained after revision with recompression of the nail and bone grafting. Nonunion in five patients (4.5%). Complications: one tibial shaft fracture one hematoma needing evacuation, three superficial infections, and eight deep infections. Three patients developed an osteoarthritis of the subtalar joint. 70 patients (63.6%) reported an improvement, 37 (33.6%) no notable change of symptoms, and three (2.7%) a deterioration.

TI Modulation of Bone Morphogenetic Protein (BMP) 2 gene expression by Sp1 transcription factors
SO GENE
LA English
DT Article
DE transcription; retinoids; evolution; embryonal carcinoma cells
ID embryonal carcinoma-cells; beta family members; retinoic acid; candidate genes; osteoporotic fracture; knee osteoarthritis; mineral density; apoptosis; receptor; growth
AB Changes in Bone Morphogenetic Protein (BMP) 2 gene expression and activity have been linked to many pathological conditions including cancer, osteoarthritis, and birth defects. BMP2 gene polymorphisms have been linked to osteoporosis and osteoarthritis. Sp1 and related proteins are widely expressed regulators of gene expression whose transcription activating abilities vary in different cells and on different genes. We present data indicating that the ratio of Sp1 and Sp3 isoforms varies in cells that express or do not express BMP2. Furthermore, the orientation of Sp1 sites conserved between four orders of mammals influences BMP2 expression. Together our data indicate that the stoichiometry and orientation of Sp1 and Sp3 complexes on the BMP2 promoter influence BMP2 expression. (c) 2007 Elsevier B.V. All rights reserved.

TI The role of osteoactivin-derived peptides in osteoblast differentiation
SO MEDICAL SCIENCE MONITOR
LA English
DT Article
DE osteoactivin-derived peptides; osteoblast differentiation; RGD domain; casien kinase II
ID signal-transduction; extracellular-matrix; in-vitro; expression; integrins; kinase; phosphorylation; bioinformatics; proliferation; osteoporosis
AB Bacground In our previous studies, we found that osteoactivin (OA) plays an important role in the regulation of osteoblast differentiation in vitro. Our studies

also suggested that the region of OA protein that contains an RGD motif might play a vital role in the function of OA in osteoblast differentiation. In this study, we examined the functional role of OA-derived peptide containing the RGD motif (OA-D) in osteoblast differentiation. Material/Methods: For this purpose, we designed another peptide, termed OA-E, that has sequence similar to OA-D but with glutamic acid (E) instead of aspartic acid (D). The effect of OA-E peptide on osteoblast differentiation was exmined. Interestingly , OA-E peptide induced osteoblast differentiation in a manner similar to OA-D peptide. These data suggested that the effect of OA-derived peptides is RGD independent and it could be dependent on other features in the amino acid sequence of these peptides. Results OA-D peptide treatment markedly induced osteoblast differentiation markers in vitro compared to cultures treated with negative control peptide (NCP). Interestingly, OA-E peptide induced osteoblast differentiation in a manner similar to OA-D peptide. These data suggested that the effect of OA-derived peptides is RGD independent and it could be dependent on other features in the amino acid sequence of these peptides. Since phosphorylation of amino acid residues in proteins aiid peptides plays a major role in biological systems, the phosphorylation pattern of amino acid sequences of OA-derived peptides and OA protein family members were examined using bioinformatic analysis tools. We found that OA-derived peptides and OA protein family members have serine residue, close to c-terminus and might be phosphorylated with casein kinase II. Casein kinase II is known to phosphorylate many osteoblast-related proteins that regulate osteoblast development and differentiation such as osteopontin and vitronectin. Conclusions Collectively, these data showed both OA-D and OA-E peptides significantly induced osteoblast differentiation in vitro and that effect is RGD independent.

TI Prevalence and impact of osteoarthritis and osteoporosis on health-related quality of life among active subjects
SO AGING CLINICAL AND EXPERIMENTAL RESEARCH
LA English
DT Article
DE osteoarthritis; osteoporosis; prevalence; quality of life; workplace
ID survey sf-36; arthritis; questionnaire; reliability; validation; disability; fractures; diseases; burden

AB Background and aims: To assess the prevalence and impact of osteoarthritis (OA) and osteoporosis (OP) on health-related quality of life (HRQOL) among active subjects employed in the public workforce in Belgium. Methods: A cohort of 3440 subjects employed by the Liege City Council was prospectively followed for 6 months. The employees were asked to fill in a monthly log in a health record book, of data regarding their healthcare consumption due to OA and OP. HRQOL was assessed using the Medical Outcomes Study Short Form-36 (SF-36). Results: 1811 subjects (52.6%) filled in at least one questionnaire. The mean duration of follow-up was 3.46 months. The self-reported prevalence of OA and OP at entry to the study were respectively 34.1% and 5.3%. 3.6% of subjects reported suffering from both OA and OP. Subjects with OA and both OA and OP had significantly lower scores on all SF-36 dimensions compared with normal subjects, reflecting a worse HRQOL. The OP group had significantly lower mean scores for physical functioning and pain compared with controls. Subjects with both OA and OP had significantly lower values for physical functioning, physical role and pain when compared with the OA and OP groups. Conclusions: The results of this survey of a large sample of active subjects show that self-reported osteoarthritis and osteoporosis are common in the workplace. Both diseases have a major impact on health-related quality of life compared with that of people without self-reported musculoskeletal diseases.

TI OP-1/BMP-7 in cartilage repair
SO INTERNATIONAL ORTHOPAEDICS
LA English
DT Review
ID bone morphogenetic protein-7; human articular chondrocytes; human osteogenic protein-1; nucleus pulposus; disc height; defects; proteoglycan; op-1; insulin-like-growth-factor-1; interleukin-1
AB Three years ago we published a book chapter on the role of bone morphogenetic proteins (BMPs) in cartilage repair. Since that time our understanding of the function of osteogenic protein-1 (OP-1) or BMP-7 in cartilage homeostasis and repair has substantially improved and therefore we decided to devote a current review solely to this BMP. Here we summarise the information accumulated on OP-1 from in vitro and ex vivo studies with cartilage cells and tissues as well as from in vivo studies of cartilage repair in various animal models. The primary focus is on articular chondrocytes and cartilage, but data will also be presented on nonarticular cartilage, particularly from the intervertebral disc. The data show that OP-1 is a unique growth factor which, unlike other members of the same BMP family, exhibits in addition to its strong pro-anabolic activity very prominent anti-catabolic properties. Animal studies have demonstrated that OP-1 has the ability to repair cartilage in vivo in various models of articular cartilage degradation, including focal osteochondral and chondral defects and osteoarthritis, as well as models of degeneration in intervertebral disc cartilage. Together our findings indicate a significant promise for OP-1 as therapeutic in cartilage repair.

TI The Wnt signaling pathway and bone metabolism
SO CURRENT OPINION IN RHEUMATOLOGY
LA English
DT Review
DE beta-catenin; arthritis; low-density lipoprotein receptor related protein 5; sclerostin; Wnt
ID frizzled-related protein-1; parathyroid-hormone; controls osteoblast; stem-cells; receptor; lrp5; gene; expression; mass; inhibition
AB Understanding the role that the Writ signaling pathways play in the regulation of bone metabolism offers great promise for the developmental of new paradigms and pharmaceutical strategies for the treatment of various 1 diseases such as osteoporosis, rheumatoid arthritis and osteoarthritis. Progress in this regard has already been made.

DT Review
DE musculoskeletal; ageing; bone; cartilage; intervertebral disc; ligament; matrix; cell biology
ID age-related-changes; human articular-cartilage; growth-factor-i; primary immunolocalization; chondrocyte senescence; matrix biosynthesis; target-cells; bone-density; stem-cells; expression
AB In general terms, the recognized alterations in circulating Immoral factors (hormones, cytokines, growth factors) that occur in ageing, coupled with innate cellular senescence exaggerated by the slow turnover of many connective tissue cell populations and the age-associated alterations in matrix molecule cross-linking, predispose the elderly to altered connective tissue biology. These changes can be profound, leading to poor mobility, altered ability to withstand cold, weakness and an increased risk of falls, fractures and age-associated

'degenerative' diseases, such as osteoarthritis and osteoporosis. As understanding of the causes of altered connective tissue function with age increases, it is becoming clearer that many of the predisposing factors (growth hormone, cytokines, load/life style) are potential targets for improving quality of life in the elderly. TI Bone mineral density in patients with hand osteoarthritis compared to population controls and patients with rheumatoid arthritis
SO ANNALS OF THE RHEUMATIC DISEASES
LA English
DT Article
ID radiographic knee osteoarthritis; estrogen-receptor gene; elderly-men; vitamin-d; osteoporotic fractures; iliac crest; women; association; hip; classification
AB Objectives: Several studies have revealed increased bone mineral density (BMD)

in patients with knee or hip osteoarthritis, but few studies have addressed this issue in hand osteoarthritis (HOA). The aims of this study were to compare BMD levels and frequency of osteoporosis between female patients with HOA, rheumatoid arthritis (RA) and controls aged 50-70 years, and to explore possible relationships between BMD and disease characteristics in patients with HOA. Methods: 190 HOA and 194 RA patients were recruited from the respective disease registers in Oslo, and 122 controls were selected from the population register of Oslo. All participants underwent BMD measurements of femoral neck, total hip and lumbar spine (dual-energy x ray absorptiometry), interview, clinical joint examination and completed self-reported questionnaires. Results: Age- ,weight- and height-adjusted BMD values were significantly higher in HOA versus RA and controls, the latter only significant for femoral neck and lumbar spine. The frequency of osteoporosis was not significantly different between HOA and controls, but significantly lower in HOA versus RA. Adjusted BMD values did not differ between HOA patients with and without knee OA, and significant associations between BMD levels and symptom duration or disease measures were not observed. Conclusion: HOA patients have a higher BMD than population-based controls, and this seems not to be limited to patients with involvement of larger joints. The lack of correlation between BMD and disease duration or severity does not support the hypothesis that higher BMD is a consequence of the disease itself.

TI Correlation of plain radiographic indices of the hip with quantitative bone mineral density
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE bone density; cortical thickness; femoral geometry; osteoarthritis; osteoporosis; radiographs
ID vitamin-d deficiency; singh index; femoral-neck; trabecular pattern; osteoporosis; geometry; osteoarthritis; fractures; femur; women
AB Radiographic parameters of the hip can be useful as an indication of bone mineral density at the femoral neck. Measurements available from routine hip radiographs were correlated with DXA values. Although radiographs are not a test for osteoporosis, measurements of cortical thickness provide information useful for referral for osteoporosis assessment. Introduction Plain hip radiographs are widely used for evaluation of hip pathology in osteoarthritis. A purpose of this study was to determine whether there are relationships between radiographic parameters of bone structure and bone mineral density T-scores, as assessed by dual energy x-ray absorptiometry (DXA). Methods Pre-operative radiographs of 32 postmenopausal, osteoarthritic women undergoing hip arthroplasty were evaluated. Radiographic parameters including the Singh index, Dorr classification, canal-to-calcar ratio, and cortical thickness indices (CTI) were measured and compared with T-score, serum 25 hydroxyvitamin D levels, body mass index (BMI), and body weight. Results The T-score at the femoral neck for type C bone was significantly lower than that of type A (p= 0.041). The CTIs were correlated positively with T-scores for anteroposterior radiographs (r= 0.5814, p= 0.0005), and for lateral radiographs (r= 0.571, p= 0.0006). A threshold for lateral CTI set at a value of <== 0.40 results in sensitivity of 0.85 and specificity of 0.79 to segregate the osteoporotic and non-osteoporotic patients. Conclusion Femurs with small radiographic cortical thickness indices had lower T-scores. Finding a radiographic hip cortical thickness index (LAT) with a value of <= 0.40 should be an alert for referral for osteoporosis evaluation and bone mineral density testing.

TI Osteoarticular manifestations of Gaucher disease in adults:: pathophysiology and treatment
SO PRESSE MEDICALE
LA English
DT Article
ID enzyme replacement therapy; bone-marrow involvement; skeletal involvement; mineral density; type-1; scintigraphy; miglustat; crisis; complications; cytokines
AB Gaucher disease frequently has severe osteoarticular manifestations that may be disabling. Ischemic phenomena cause the most serious complications and lead to irreversible lesions. Aseptic osteonecrosis of the hip is the most disabling complication; it causes intense early bone pain and often joint collapse and secondary osteoarthritis in young adults. Localized or systemic bone fragility explains osteopenia, osteoporosis, and fractures (vertebral collapse with irreversible kyphosis causing chronic morbidity). Although no double-blind randomized studies hove assessed the bone effects of enzyme replacement therapy it has been shown effective in reducing bone pain in about half of all treatment-naive patients within 1 to 2 years and in improving bone mineral density after 3 years. In open-label trials, substrate reduction therapy (miglustat) reduced both bone pain and bone morrow infiltration. Specific treatment for bone fragility, with bisphosphonates for example, should be considered after rigorous individualized evaluation and assessment of other risk factors.

TI Methods to develop arthritis and osteoporosis measures: a view from the National Committee for Quality Assurance (NCQA)
SO CLINICAL AND EXPERIMENTAL RHEUMATOLOGY
LA English
DT Article
DE arthritis; osteoporosis; performance measurement; accountability; quality improvement
AB Objective. Performance measurement at various levels of the health care system promotes improved processes that can result in the provision of more consistent and effective care. This chapter articulates the methodology and criteria utilized in measures development to ensure accountability and serve the itformation needs of physicians, health care systems, health plans and consumers, using arthritis and osteoporosis as example conditions. Methods. Observational studies conducted to assess the validity and feasibility of performance measures focused oil arthritis and osteoporosis. Clinical expert panels were convened to develop measure specifications based on guidelines and evidence supporting critical aspects of care. The aspects of care that were assessed included: DMARD utilization for patients with rheumatoid arthritis; appropriate gastrointestinal prophylaxis for patients utilizing NSAIDS: comprehensive osteoarthritis care; comprehensive symptom assessment and medical management of Woman over 65 years who experienced a bone fracture. Results. The implementation of performance measures for key aspects of arthritis and osteoporosis care is challenged by the availability of administrative data. However, potential for improvement is evident in each of the areas studied. Conclusions. The key challenge to the feasibility of arthritis performance measures is the lack of administrative data to identify the eligible population. Administrative data capture suffers as a result of under-coding and under-recognition of arthritis. Consensus around a single set of measures creates a powerful tool for focusing on key components of care as a basis for quality improvement and allows,for a valid comparison of care within and across health care settings.

DT Article
ID rheumatoid-arthritis
AB More than 120 kinds of arthritis exist. This article focuses on the more common types of musculoskeletal disorders, which are osteoarthritis, rheumatoid arthritis,

and osteoporosis. Because of the pain, fatigue, and joint stiffness associated with arthritis, physical intimacy may be difficult. These symptoms can be ameliorated during sexual activity by good communication between the partners, timing medication, and experimenting with different positions. Clients may need to be taught to be creative and to be willing to experiment. Learning the relaxation response, in addition to fantasizing and guided imagery, can enhance the sexual experience for people who have arthritis.

TI Strontium ranelate reduces the urinary level of cartilage degradation biomarker CTX-II in postmenopausal women
SO BONE
LA English
DT Article
DE strontium ranelate; postmenopausal women; CTX-II; type II collagen degradation; RCT
ID estrogen replacement therapy; cynomolgus monkeys; subchondral bone; osteoarthritis; osteoporosis
AB Objective: Strontium ranelate significantly decreases the risk of osteoporotic fractures. The objective of the present study was to investigate whether strontium ranclate (2 g/day) also affects cartilage brakedown as measured by urinary marker

of cartilage degradation, designated CTX-II. Methods: A subgroup of 2617 postmenopausal osteoporotic women (aged 75.7 +/- 4.4 years) were selected from the TROPOS phase III study on the basis of a urinary sampling reported at each visit during the first three years of the study. When included in TROPOS, they were randomized to strontium ranelate or placebo in a double-blind fashion for 3 years. A calcium and vitamin D supplement was also provided to the subjects during the study. A marker of collagen type II degradation (CTX-II) corrected for urinary creatinine (CTX-II/cr.) was assessed at regular intervals throughout the study in 1310 patients in strontium ranelate group and 1307 patients in placebo group. Results: The response in CTX-II depended on time ($p < 0.0001$), and this time dependency differed statistically significantly between groups (time x treatment) ($p < 0.0003$). In addition, there was a statistically significant difference between treatments ($p < 0.0001$). The difference in the response of CTX-II/cr. appeared already after three months, with the strontium ranelate-treated subjects having approximately 15-20% lower values than the placebo-treated subjects for the remaining study period ($p < 0.0001$). Conclusion: Treatment with strontium ranelate significantly decreases urinary excretion of CTX-II, a marker of cartilage destruction. Further studies are warranted to investigate an effect on cartilage formation and symptoms of osteoarthritis. (c) 2006 Elsevier Inc. All rights reserved.

TI The crowned dens syndrome. Evaluation with CT imaging
SO RADIOLOGIA MEDICA

LA English
DT Article
DE crowned dens syndrome; CPPD crystal deposition disease; transverse ligament of the atlas; computed tomography
ID dihydrate deposition disease; crystal deposition; transverse ligament; pyrophosphate arthropathy; rheumatoid-arthritis; calcium; identification; calcification; myelopathy; flavum
AB Purpose. The purpose of this study was to verify the value of computed tomography (CT) in the diagnosis of the "crowned dens" syndrome, not only in crystal deposition diseases, but also in other rheumatic or nonrheumatic conditions. Materials and methods. Thirty-eight patients (15 men and 23 women; mean age 55 years; age range 35-79) with neck pain were examined and divided into two groups: (1) patients already identified as rheumatic and referred for further investigation of the atlantoaxial region; (2) patients with symptoms confined to the cervical spine, with inconclusive radiographic findings. Unenhanced CT of the cervical spine (Tomoscan SR 7000 Philips, Eindhoven, Netherlands) was performed in all patients. There were 11 cases of rheumatoid arthritis (ten women and one man), two calcium pyrophosphate dihydrate crystal deposition disease (both women), one of systemic sclerosis (a woman), one of osteoarthritis (a man), one of seronegative arthritis (a man), four of neoplasm (one woman and three men) with suspected cervical involvement, one (a man) of haematological disease (lymphoma), one (a woman) of menopausal osteoporosis, ten (five men and five women) of recent or previous trauma with suspected involvement of the skull base and first cervical vertebrae and six of unknown painful cervical dysfunction (three men and three women). Results. CT demonstrated calcific deposits around the dens in 12 patients (three men and nine women), in the transverse and alar ligaments, and in the anterior atlantooccipital membrane. CT revealed horseshoe- or crown-like calcification surrounding the odontoid process. In our series, other rheumatic diseases, especially rheumatoid arthritis, showed similar irregular calcifications of the atlantoaxial joint. Discussion. In calcium pyrophosphate dihydrate (CPPD) crystal deposition disease, the spine may be the only site of involvement, generally asymptomatic. Crystals located in the transverse ligament of the atlas give rise to the crowned dens syndrome, usually in patients affected by severe degenerative lesions of the atlantoaxial joint and peripheral chondrocalcinosis. Symptoms may be absent, or a neurological compressive syndrome may develop. Symptoms tend to worsen with age. The diagnosis is not always easy, as the symptoms are similar to those of other diseases, such as meningitis, cervicobrachial pain, occipitotemporal headache, calcific tendinitis of the longus colli muscle, spondylodiscitis and retropharyngeal abscess. Conclusion. CT is the gold standard in identifying crowned dens syndrome, as it is able to depict the shape and site of calcification and any bone erosions. Radiography of other joints (wrist, knee, pubic symphysis) may help to ascertain whether the disease is due to calcium pyrophosphate dehydrate or hydroxyapatite crystals, and is therefore recommended for routine patient management. Magnetic resonance

imaging (MRI) is indicated for the study of neurological complications.

TI Histomorphometric study of femoral heads in hip osteoarthritis and osteoporosis
SO HISTOLOGY AND HISTOPATHOLOGY
LA English
DT Article
DE bone histomorphometry; femoral heads; osteoarthritis; osteoporosis
ID trabecular bone; upper end; femur; fractures; density; age
AB During the period from 2000 to 2003, ninety eight samples of femoral heads were collected. In these pieces, two zones were analyzed: a high- load zone (the hard core of the head) and a low- load zone (the round ligamentum teres zone). As control group, 6 femoral heads (3 of women and 3 of men), proceeding from autopsy in peoples without pathological antecedents and youngs, were studied. After the samples had been embedded in methylmethacrylate and stained, they were subjected to an histomorphometric study. By means of histomorphometry, trabecular bone volume (TBV) and osteoid substance (OSV) was determined. Statistically significant differences were found as for peripheral osteoid volume (low- load zone) (p= 0.036) and trabecular bone volume, both peripheral and central. Both volumes decreased in osteoporotic samples and in those from women (p= 0.000), in comparison with control group. Regarding the relationship between the high- load and low- load zone, significant data were obtained. The high- load zone had a greater trabecular bone volume than the low- load zone, regardless of the pathology and sex, but this increase was more pronounced in the arthrosic samples and in those from men. Additionally, this trabecular bone volume in the high- load zone decreased with increasing age of the donor (p= 0.037), when the control group is compared. In sum, we observed a reduction in the formation of TBV and OSV in osteoporosis but also a decrease in the arthrosic, in samples from older subjects, in women, and in the low- load zone of the samples, when the control group is compared. These data suggest the coexistence of both

pathologies, which is more pronounced in older subjects and women.

TI Decreased handgrip strength and increased hip osteoporosis in patients with Alzheimer's disease
SO NEUROSCIENCES

LA English
DT Article
ID elderly-women; risk-factors; depression; fracture; muscle; mass; deficiency; exercise; dementia; people
AB Objectives: To evaluate the causes of disability in the musculoskeletal system, and depression in patients with Alzheimer's disease (AD) and healthy controls. Methods: A case-controlled study in which healthy elderly patients (n=56) and patients with AD (n=75) attending the Geriatric Rehabilitation Unit of Ankara Education and Research Hospital, Department of Physical Medicine and Rehabilitation were compared on several measures of disability including handgrip strength, knee x-rays graded for osteoarthritis, dual-energy x-ray absorptiometry results for osteoporosis, and depression scores in the training period of 2003-2004. Results: Handgrip strength values were significantly lower in patients with AD compared to the controls (19.4 versus 37 pounds force). Osteoporosis in the femoral neck was also more prominent in patients with AD compared to controls (T-scores: -2.1 versus -1.2). Handgrip strength was moderately correlated with femoral neck T-scores (r=0.6, p=0.001). Conclusion: Strategies should be developed to protect patients with AD from osteoporosis and reduced muscle strength.

TI Arthroscopic collagen meniscus implant results at 6 to 8 years follow up
SO KNEE SURGERY SPORTS TRAUMATOLOGY ARTHROSCOPY
LA English
DT Article
DE meniscus; collagen; arthroscopic; implant; DJD (degenerative joint disease)
ID partial meniscectomy; allograft transplantation; contact area; knee; regeneration; replacement; cartilage; ligament
AB Meniscal substitution is a fundamental procedure to prevent osteoarthritis of the knee after massive meniscectomy. Stone, Steadman and Rodkey have developed a bioreadsorbable collagen matrix (CMI) which acts as a scaffold to restore the original medial meniscal. The objective of this study was to prospectively evaluate the results of CMI implantation at a follow up from a minimum of 6 to a maximum of 8 years. Eight patients (mean age 25) were

evaluated at a final observation point from 6 to 8 years after CMI implantation. Inclusion criteria were an irreparable meniscal tear or a previous meniscectomy involving the medial meniscus. Follow up evaluation included Cincinnati Knee Rating Scale (CKRS), IKDC, subjective evaluation and X-ray and MRI control. There were no complications related to the device. All patients were able to return to day activities without limitations 3 months after surgery. Both subjective CKRS score and objective IKDC score showed improvement in all cases except one patient with an ACL re-injury. In two cases scores were slightly worse from 2 years after surgery to the final observation point. The other five cases obtained maximum score at final follow-up. In four cases the absence of pain remained until the final observation point, while in four cases a low entity of pain was described at long term follow-up. MRI showed in five cases mixoid degeneration signal, two had normal signal with reduced size, while one patient had no recognizable implant. Six patients had preserved cartilage and articular space, with no changes respect to pre-op control. Arthroscopic second look evaluation has been performed in three cases, revealing in two cases the presence of the implant, although with a reduced size respect to the original one, while in one case the CMI was almost disappeared. Our small series of eight patients prospectively followed from 6 to 8 years of follow-up has shown highly satisfactory results. Although the aspect of the implant was mostly abnormal, the implant may have helped reduce the deterioration of the knee joint at final observation time.

TI Validity and reliability of the Italian version of the ECOS-16 questionnaire in postmenopausal women with prevalent vertebral fractures due to osteoporosis
SO CLINICAL AND EXPERIMENTAL RHEUMATOLOGY

AB Objective To investigate the reliability and validity of the Italian version of ECOS-16 (Assessment of health related quality of life in osteoporosis) in comparison to other questionnaires in postmenopausal women with osteoporosis. Methods A cross-sectional multicentre study was carried out among postmenopausal women with osteoporosis who were attending primary care centres and hospital outpatient clinics. The patient group included 234 females (mean age 69 years, range 4889) who presented vertebral fractures due to osteoporosis. The control group consisted of 24 asymptomatic osteoporotic subjects matched for age with the patient group. The psychometric properties of the questionnaires were evaluated in terms of feasibility, validity (construct validity and discriminant validity) and internal consistency. Test-retest reliability was analysed for 196 outpatients who reported that their general health status due to osteoporosis had not changed after one week. In all patients the ECOS-16, the SF-36 (Medical Outcomes Study Short Form-36), EUROQoL (EQ-5D), mini-OQLQ (mini-Osteoporosis Quality of Life Questionnaire), and RMDQ (Roland-Morris Disability Questionnaire) were administered, and all clinical variables and sociodemographic variables were taken into account. Construct and discriminant

validity were assessed by Spearman's correlations, the Wilcoxon rank sum test, the Kruskal Wallis test and by receiver operating characteristic (ROC) curves. Internal consistency was evaluated using Cronbach's alpha and the test-retest reliability was evaluated by intra-class correlation coefficients (ICCs). Results 96.9% of the patients answered all items of the ECOS-16 questionnaires. The mean administration time was 10 minutes. Factor analysis yielded two factors that accounted for 88.4% of the explained variance in the ECOS-16 questionnaire. The first factor was the ECOS-16 Physical Component Score (PCS) (45.9% of the explained variance) and the second factor was the ECOS-16 Mental Component Score (MCS) (42.4% of the explained variance). The inter-item correlation between the two factors was 0.48. Significant correlations were found between the scores of similar domains or subscales of the ECOS-16 and SF-36, EQ-5D and mini-OQLQ, supporting the concept of convergent construct validity. The total ECOS-16 score progressively increased with the number of prevelant vertebral fractures ($p < 0.001$) and the effect of the first fracture was already statistically significant ($p < 0.01$). On ROC curve analysis the total ECOS- 16 score showed the highest performance among the different questionnaires in discriminating between patients with vertebral fractures and controls with no fractures. In the reliability study, internal consistency within the domain of ECOS-16 was generally good, with Chronbach's alpha values ranging from 0.81 to 0.89. Test-retest reliability was 0.87 for the total ECOS-16 score. Conclusions The Italian version of the ECOS-16 questionnaire was demonstrated to have good psychometric properties and could offer a useful tool in research and routine clinical practice to evaluate HRQoL in post-menopausal women with osteoporosis. A full validation of the psychometric properties will require data on its sensitivity to change.

TI Recommendations from the Community Oriented Program for Control of Rheumatic Disease for data collection for the measurement and monitoring of health in developing countries
SO CLINICAL RHEUMATOLOGY
LA English
DT Review
DE COPCORD; education; epidemiology; risk factors; treatment
ID arthritis
AB The history of the World Health Organization-International League of Associations for Rheumatology Community Oriented Program for Control of Rheumatic Disease (COPCORD) for developing countries is described. Due to lack of funding and manpower, the COPCORD concept is designed in three stages for execution. Stage I is a community-based epidemiology of rheumatism in three phases by rheumatologist but non-epidemiologist to save time, money, and costs. Stage II is education of treatment of rheumatism. Stage III is the identification of environmental and genetic risk factors of musculoskeletal disorders to prevent or minimize rheumatism. Since 1980, COPCORD has collected valid community-based epidemiological data, which are published in 42 papers since 1985 in various international rheumatology journals. The publications were from 19 developing countries in the Asia Pacific region, South America, Europe, and Africa. Stage II education is deemed to be more appropriate handled by allied rheumatology health professionals. Low back pain, osteoarthritis, osteoporosis, and rheumatoid arthritis (RA) are the priority. The projected prevalence of RA in > 4 billion people in countries of the South are between 8 and 12 million patients and urgently require adequate control. After 5-15 years, the consequences of RA are disability, reduced productivity, loss of career and income, lowered quality of life, and early mortality notwithstanding existing therapy. The application of the Biologic DMARDs in RA in the Third World for reasons of treatment costs from $15,000 to $25,000 per patient per year is not feasible. The majority of the Third World population has an income of less than US$1.00 per day to less than US$2,000.00 per capita. The COPCORD has designed and applied successfully the step-down bridge guidelines of intravenous and oral combination of five generic immunosuppressants in prospective observational studies of rheumatoid factor positive RA in Indonesia, China, and Iran. Recommendations of the COPCORD stages are submitted.

TI Vitamin D and its implications for musculoskeletal health in women:: An update

SO MATURITAS
LA English
DT Review
DE vitamin D; vitamin D insufficiency; menopause; osteopenia; osteoporosis; osteoarthritis; neuromuscular function; fracture; secondary hyperparathyroidism; inadequate diet; aging; sun exposure; bisphosphonates; vitamin D and falls; postmenopausal women; musculoskeletal health
ID bone-mineral density; randomized controlled-trial; parathyroid-hormone levels; white premenopausal women; postmenopausal women; d deficiency; d supplementation; d inadequacy; secondary hyperparathyroidism; hypovitaminosis-d
AB Vitamin D is a hormone that controls phosphorus, calcium, and bone metabolism and neuromuscular function. Vitamin D synthesis is a process in which the skin, liver, and kidney are sequentially involved. The vitamin D pool is completed by the amount taken with food and supplements. Vitamin D deficiency causes osteopenia, precipitates and exacerbates osteoporosis, causes a painful disease, osteornalacia, and increases muscle weakness, which worsens the risk of falls and fractures. A high prevalence of vitamin D insufficiency exists in the apparently healthy population, osteoporotic patients, and patients with prior fractures. Factors contributing to low vitamin D levels include low sunlight exposure, decreased skin synthesis and intestinal absorption, and inadequate diet. The simplest way to correct hypovitaminosis is adequate nutrition and supplements. However, few patients with osteoporosis and/or fractures, receive adequate supplements. Vitamin D insufficiency may alter the regulatory mechanisms of parathyroid hormone and may induce a secondary hyperparathyroidism that increases the risk of osteoporosis and fractures, although the necessary degree of this is not established. Monitoring of serum 25-hydroxyvitamin D levels is the only way to assess vitamin D status. The ideal healthy blood levels of 25-hydroxyvitamin D are controversial, although a range from 30 to 60 ng/mL is widely accepted. The role of vitamin D supplementation is to provide humans with the nutrient in an amount closer to the biological norm for our species. This amount of vitamin D results in optimal function of many aspects of health, including balance and muscle strength, thus reducing the risk of fracture beyond what is possible via the quality and quantity of bone itself. TI Risk factors for pes anserinus tendinitis/bursitis syndrome - A case control study
SO JCR-JOURNAL OF CLINICAL RHEUMATOLOGY
LA English
DT Article
DE bursitis; knee; risk factors; tendinitis; pes anserinus
ID diabetes-mellitus; tendino-bursitis; knee; osteoarthritis
AB Background: Pes anserinus tendinitis/bursitis (PATB) is a frequent cause of knee pain. Its predisposing factors are still controversial. Objectives: Assess the effect of a set of demographic, clinical, somatometric, and biomechanical factors on the risk for PATB. Methods: A case control design was used to evaluate the association between clinically diagnosed PATB and the presence of diabetes; knee osteoarthritis (and its radiographic severity); obesity; knee collateral, and anteroposterior instability; and knee or hindfoot malalignment. Results: Twenty-two consecutive, incident PATB patients were included; all were females 62.1 +/- 11.5-year-old (limits 45-82). Thirty-eight sex- and age-matched (59.8 +/- 9.4-year-old; P = 0.41) subjects were used as controls-, these had asymptomatic osteoporosis (20) and a series of rheumatic syndromes (18). There was no difference in prevalence of diabetes, knee osteoarthritis, obesity, knee instability, varus knee deformity, and hindfoot malalignment between cases and controls. Furthennore, no difference in overall, lateral, medial, and patellofemoral knee osteoarthritis radiographic severity mean score was found between study groups. The presence of vaigus knee deformity alone (OR: 5.2; 95% CI: 1.1-25.5), or in combination with collateral instability (OR: 6.0; 95% CI: 1.4 26.0), was identified as associated with PATB. Conclusions: Valgus knee deformity, alone or in association with collateral instability, seems to be a risk factor for PATB. No association was found between PATB and some conditions previously reported as predisposing factors such as diabetes, knee osteoarthritis, and obesity. PATB should be kept in mind as a highly probable diagnosis in mature women with medial knee pain and valgus knee deformity.

TI Comorbidity of low back pain: Representative outcomes of a national health study in the Federal Republic of Germany
SO EUROPEAN JOURNAL OF PAIN
LA English
DT Article
DE back pain; etiology; morbidity; prevalence; theoretical models
ID musculoskeletal pain; working population; general-population; united-states; older-adults; prevalence; disability; morbidity; community; impact
AB Background: Unlike other biopsychosocial risk factors, the role of comorbidity in low back pain is largely unknown. Aims: The purpose is (1) to generate prevalence data on back pain in the total adult population and (2) to identify the most common physical comorbidities in subjects with back pain. This paper also (3) analyses the gender-specific and age-specific comorbidity structure. Methods: The National German Health Survey is the first study to provide the basis for a representative nationwide analysis of back pain prevalence and the associated comorbidities. The net sample comprises a total of 7124 Germans aged 18-79. Results: One in three Germans (34%) experienced back pain during the seven days prior to being interviewed. The one-year prevalence rate is 59%. All the morbidities investigated by us are more common in subjects with back pain than in individuals without back pain. The most common comorbidities associated with back pain are musculoskeletal disorders like rheumatoid arthritis, osteoarthritis and osteoporosis, followed by cardiovascular and cerebrovascular disease. Conclusions: The present study investigating 31 physical diseases is the most extensive analysis to date oil the topic of back pain and comorbidity. This is an attempt to cast light on the tangled relationships involved in developing and coping with back pain. In view of the large percentage of unspecific back pain, we believe it is important for physicians treating back pain to extend their history and diagnostic analysis skills to embrace comorbidities related to the back pain. TI Effects of boron poisoning on thymus development in Gushi chickens
SO INDIAN VETERINARY JOURNAL
LA English
DT Article
AB Boron is important for mineral metabolism, brain functioning and performance, and prevention of both osteoporosis and osteoarthritis. It is also anti-inflammation and antitumor and it lowers fat content (Lulin and Yuan Ying, et al., 2003). Boron poisoning can cause special pathological changes in the stomach, kidney, liver, brain, skin, lung, and other parts (Wang, 1996). Research has shown that high boron levels has detrimental effects on animal health and production performance. At present, there are no reports yet of the influence of boron poisoning on an animal's immune system. The effects of boron poisoning on thymus development in chickens were studied and reported in this paper.

TI Digital X-ray radiogrammetry better identifies osteoarthritis patients with a low bone mineral density than quantitative ultrasound
SO EUROPEAN RADIOLOGY
LA English
DT Article
DE bone mineral density; osteoarthritis; quantitative ultrasound; dual energy x-ray absorptiometry; digital x-ray radiogrammetry

ID age-related-changes; rheumatoid-arthritis; osteoporotic fractures; postmenopausal women; elderly-women; radiographic absorptiometry; knee osteoarthritis; population; risk; hand
AB This study assessed the ability of quantitative ultrasound (QUS) and digital X-ray radiogrammetry (DXR) to identify osteopenia and osteoporosis in patients with knee osteoarthritis (OA). One hundred and sixty-one patients with painful knee OA (81 men, 80 women; age 62.6 +/- 9.2 years, range 40-82 years) were included in this cross-sectional study and underwent dual-energy X-ray absorptiometry (DXA) of both hips and the lumbar spine, QUS of the phalanges and calcanei of both hands and heels, and DXR using radiographs of both hands. Unpaired t-test, Mann-Whitney U test, ROC analysis and Spearman's rank correlation were used for comparisons and correlation of methods. Using DXA as the reference standard, we defined a low bone mineral density (BMD) as a T-score <=-1.0 at the lumbar spine or proximal femur. In contrast to phalangeal or calcaneal QUS, DXR was able to discriminate patients with a low BMD at the lumbar spine ($p < 0.0001$) or hips ($p < 0.0001$). ROC analysis showed that DXR had an acceptable predictive power in identifying OA patients a low hip BMD (sensitivity 70%, specificity 71%). Therefore, DXR used as a screening tool could help in identifying patients with knee OA for DXA.

TI Synergistic effect of IGF-1 and OP-1 on matrix formation by normal and OA

chondrocytes cultured in alginate beads
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE human normal chondrocytes; human OA chondrocytes; growth factors; extracellular matrix
ID human articular chondrocytes; growth-factor-i; osteogenic protein-1 promotes; vi collagen; gene-expression; factor-beta; bovine cartilage; oncostatin-m; adult; insulin-like-growth-factor-1
AB Objective: Growth factor therapy may be useful for stimulation of cartilage matrix synthesis and repair. Thus, the purpose of our study was to further understand the effect of combined insulin-like growth factor-1 (IGF-1) and osteogenic protein-1 (OP-1) treatment on the matrix synthesized by human adult normal and osteoarthritic (OA) chondrocytes. Design: Chondrocytes were isolated post-mortem from articular cartilage from tali of normal human donors and femoral condyles of OA patients undergoing knee replacement surgery. Cells were cultured in alginate beads for 21 days in four experimental groups: (1) "mini-ITS" control; (2) 100 ng/ml IGF-1; (3) 100 ng/ml OP-1; (4) IGF-1 + OP-1, each at 100 ng/ml. Beads were processed for histological (Safranin O and fast green), morphometrical and immunohistochemical (aggrecan, decorin, type I, II, VI, and X collagens, and fibronectin accumulation) analyses. Results: Histology showed that IGF-1 alone did not induce substantial matrix production. OP-1 alone caused a considerable matrix formation, but the highest matrix accumulation by normal and OA chondrocytes was found when OP-1 and IGF-1 were added together. Morphometrical analysis indicated larger matrices produced by OA chondrocytes than by normal cells under the combined treatment. All tested matrix proteins were more abundant in the combination group. Type X collagen was detected only under the combined OP-1 and IGF-1 treatment and was present at very low levels. Type I collagen was found only in OA chondrocytes. Conclusions: The results obtained in the current study suggest that combined therapy with IGF-1 and OP-1 may have a greater potential in treating cartilage defects seen in OA than use of either growth factor alone. TI Bone marrow edema in sports: General concepts
SO EUROPEAN JOURNAL OF RADIOLOGY
LA English
DT Article
DE bone marrow edema; MRI; sport injury
ID transient osteoporosis; knee osteoarthritis; fracture; bruises; injury; ankle; mechanism; runners; pattern; lesions
AB This paper will discuss the value of medical imaging in the detection and follow-up of bone marrow edema (BME), resulting from acute and chronic trauma in sports. MR imaging is the only imaging technique that allows direct evaluation of bone marrow edema in sports medicine. The use of fat Suppressed T2-weighted or STIR images is particularly appropriate to detect bone marrow edema. The extent of bone marrow edema reflects the biomechanics of trauma. Compressive forces between two bony structures will result in extensive areas of bone marrow edema, whereas distraction forces provoke more subtle areas of bone marrow edema at the insertion of supporting structures of joints. In most clinical situations, a combination of compression and distraction forces is present, causing a complex pattern of bone marrow edema. A meticulous pattern approach of the distribution of these bone marrow changes around a joint can reveal in most instances the underlying mechanism of trauma. This may be helpful to analyze which joint supporting structures may be at risk. In the acute setting, plain radiography and CT scan may have an additional role in the detection of small avulsion fractures occurring at the site of minor areas of bone marrow edema. The clinical significance and natural history of bone marrow edema is still a matter of debate.

TI Groningen orthopaedic exit strategy: Validation of a support program after total hip or knee arthroplasty
SO PATIENT EDUCATION AND COUNSELING
LA English
DT Article
DE total hip arthroplasty; total knee arthroplasty; validation; support program; rehabilitation outcome
ID osteoporosis prevention; social support; self-efficacy; rehabilitation; community; discharge; impact; osteoarthritis; interventions; translation
AB Objective: Validation of the program theory of the Groningen orthopaedic exit strategy (GOES), a theory-driven program aiming to improve the rehabilitation of total hip and knee arthroplasty patients after shortened hospital stay. First part of the program theory is the action theory, hypothesising that the GOES treatment positively influences the mediating variables (self-efficacy, social support, pain-coping). The second part, the conceptual theory, hypothesis a positive relationship between these variables and the outcome variables (ADL functioning, physical activity behaviour, quality of life). Methods: Patients were randomly assigned to the GOES or control groups. Questionnaires were used to assess mediating and outcome variables in 103 patients (50 GOES, 53 controls) pre-operatively, and 6 and 26 weeks post-operatively. Results: No difference was seen between the two groups in terms of changes between pre-operative and post-operative mediating variables (action theory). Moderate-to-large correlations explaining reasonable amount of variance (22%, 25%, 56%) were found between the mediating and outcome variables (conceptual theory). Conclusion: The conceptual theory is supported; however, as the treatment did not influence the mediating variables (action theory), it has no added value in its current form. Practice implications: The treatment needs to be adjusted; it is discussed that individualised treatment could be more effective. (c) 2006 Elsevier Ireland Ltd. All rights reserved.

TI The cross-sectional relationship between fortnightly exercise and knee cartilage properties in healthy adult women in midlife
SO MENOPAUSE-THE JOURNAL OF THE NORTH AMERICAN MENOPAUSE SOCIETY
LA English
DT Article
DE osteoarthritis; cartilage; physical activity; knee exercise
ID early radiographic osteoarthritis; physical-activity; surface-area; volume; risk; association; defects; age; hip
AB Objective: Exercise has been strongly promoted for the prevention of the major diseases of aging in women, such as cardiovascular disease and osteoporosis. However, conflicting data exist as to whether exercise benefits joint health and thus helps protect against degenerative processes such as knee osteoarthritis. The aim of this study was to examine the cross-sectional relationship between exercise and knee joint cartilage in women at midlife. Design: A total of 176 women aged 40 to 67 years with no clinical knee osteoarthritis or history of significant knee injury were recruited from the community and had magnetic resonance imaging performed on their dominant knee to assess tibial cartilage volume and defects. The women completed a questionnaire to determine fortnightly exercise participation and frequency. Results: Fortnightly participation in exercise at an intensity that caused tachypnea and an increased pulse rate for at least 20 minutes was positively associated with the volume of the medial tibial cartilage (P = 0.02). There was a tendency for the frequency of exercise at this intensity to be positively associated with medial tibial cartilage volume (P = 0.07). Exercise participation was not significantly associated with the presence of knee cartilage defects. Conclusions: Participation in exercise that causes tachypnea and an increased pulse rate for at least 20 minutes was associated with greater medial tibial cartilage volume, but not knee cartilage defects in non-healthcareseeking women at midlife. More frequent exercise also tended to be associated with greater medial tibial cartilage volume. Although our findings need to be confirmed longitudinally, they provide further support for a beneficial effect of regular exercise on diseases related to aging.

TI Quantitative 3D MR evaluation of autologous chondrocyte implantation in the knee: feasibility and initial results

SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE autologous chondrocyte implantation; MRI; knee; cartilage volume; quantification
ID articular-cartilage volume; focal chondral defects; joint cartilage; rheumatoid-arthritis; gender-differences; image data; thickness; osteoarthritis; repair; reproducibility
AB Objective: To evaluate the feasibility of quantitative magnetic resonance imaging (MRI) based follow-up of cartilage volumetric data in patients after autologous chondrocyte implantation (ACI). To provide results from a 1-year follow-up study. Methods: From 21 ACI patients sagittal FS 3D FLASH (50/11/30; 0.6 x 0.6 x 1.5 mm(3)) MRI knee data sets were obtained pre and 1 -year post-ACI surgery in the femoral condyles. After semi-automated segmentation and 3D reconstruction of the cartilage plates, cartilage volume, mean thickness and size of the cartilage-bone interface were calculated. Susceptibility artifacts were evaluated in all, intra-observer reproducibility was evaluated in six of the patients. Volumetric parameters were compared during follow-up and sensitivity to change was assessed for the total femur vs the separately evaluated medial/lateral portions of the femur. Results: Reproducibility error (coefficient of variation %) was 3.9%/4.4% for the med./lat. tibial and 5.1 % for the femoral cartilage volume. Susceptibility artifacts led to the exclusion of three out of the 21 patients, but were moderate in the remaining 18 patients, not preventing reproducible segmentation. In contrast to lack of significant change in the (non-operated) tibiae, a mean 6% increase of volume and thickness in the treated femora ($P < 0.001$ Wilcoxon) relative to the pre-OP data was observed. Sensitivity to change for the femur ranged from 0.74 to 2.60 for cartilage volume and thickness and was improved when evaluating only the treated portion of the femur in contrast to the total femur. Conclusion: Our data indicate that despite postoperative susceptibility artifacts quantitative evaluation of cartilage volumetric parameters can be performed in ACI patients. The technique is able to describe changes of these parameters over 1 year. Volumetric follow-up may help to identify altered disease progression. TI Musculoskeletal conditions - What's new from Cochrane and how might this affect your practice?
SO AUSTRALIAN FAMILY PHYSICIAN
LA English
DT Article
ID children; density

AB Many general practitioners would suspect from their every day practice that musculoskeletal conditions such as osteoarthritis, rheumatoid arthritis and osteoporosis are common general practice clinical problems. This has been confirmed by research - an estimated 16.7/100 GP-patient encounters are for a musculoskeletal condition.(1) The costs to the community of these conditions are high, both economically and because they are a significant cause of morbidity and mortality.(2,3) Due to the high impact of musculoskeletal disorders, the World Health Organisation designated 2001-2010 as the 'bone and joint decade' and, since 2002, arthritis and related conditions have been an Australian National Health Priority Area.(4).

TI Multimorbidity is associated with better quality of care among vulnerable elders
SO MEDICAL CARE
LA English
DT Article
DE multimorbidity; comorbidity; vulnerable elders; quality of care; quality indicators
ID older patients; medical conditions; functional status; blood-pressure; womens health; mortality; community; people; comorbidity; population
AB Background: Older patients with multiple chronic conditions may be at higher

risk of receiving poorer overall quality of care compared with those with single or no chronic conditions. Possible reasons include competing guidelines for individual conditions, burden of numerous recommendations, and difficulty implementing treatments for multiple conditions. Objectives: We sought to determine whether coexisting combinations of 8 common chronic conditions (hypertension, coronary artery disease, chronic obstructive pulmonary disease, osteoarthritis, diabetes mellitus, depression, osteoporosis, and having atrial fibrillation or congestive heart failure) are associated with overall quality of care among vulnerable older patients. Materials and Methods: Using an observational cohort study, we enrolled 372 community-dwel ling persons 65 years of age or older who were at increased risk for death or functional decline within 2 years. We included (1) a comprehensive measure (% of quality indicators satisfied) of quality of medical and geriatric care that accounted for patient preference and appropriateness in light of limited life expectancy and advanced dementia, and (2) a measure of multimorbidity, either as a simple count of conditions or as a combination of specific conditions. Results: Multimorbidity was associated with greaer overall quality scores: mean proportion of quality indicators satisfied increased from 47% for elders with none of the prespecified conditions to 59% for those with 5 or 6 conditions ($P < 0.0001$), after controlling for number of office visits. Patients with greater multimorbidity also received care that was better than would be expected based on the specific set of quality indicators they triggered. Conclusions: Among older persons at increased risk of death or functional decline, multimorbidity results in better, rather than worse, quality of care.

TI The chemical biomarkers C2C, Coll2-1, and Coll2-1NO2 provide complementary information on type II collagen catabolism in healthy and osteoarthritic mice
SO ARTHRITIS AND RHEUMATISM
LA English
DT Article
ID articular-cartilage; biochemical markers; synovial-fluid; in-vivo; joint; degradation; urinary; denaturation; osteoporosis; chondrocytes
AB Objective. Compared with wild-type (WT) mice, biglycan/fibromodulin double-deficient mice develop severe knee osteoarthritis. We undertook this study to compare type 11 collagen catabolism in the 2 genotypes and to compare the usefulness of 3 biomarkers of collagen degradation (C2C [also known as Col23/4C(long mono)] as well as the peptide Coll2-1 and its nitrated form, Coll2-1NO(2)) for evaluating collagen catabolism in vivo. Methods. In 15 WT mice and 15 biglycan/ fibromodulin double-deficient mice, we determined serum levels

of C2C at ages 66 and 141 days, and we determined serum levels of Coll2-1 and Coll2-1NO(2) at ages 49, 81, 95, and 141 days. Expression of the biomarkers in knee sections was examined using immunohistochemistry. Results. The mean concentrations of C2C and Coll2-1 were higher in biglycan/fibromodulin double-deficient mice at all time points. For C2C and Coll2-1, the ratio of the serum concentration in biglycan/ fibromodulin double-deficient mice to that in WT mice (the double-deficient:WT ratio) was constant over time and was similar to 1.63 and similar to 1.15, respectively. In contrast, the double-deficient:WT ratio for Coll2-1NO(2) varied and, depending on age, was >1 or <1. No significant correlation was found between the expression of the different biomarkers, except for a weak, negative correlation between Coll2-1NO(2) and C2C. In both genotypes, antibodies to each biomarker labeled some fibroblasts in the tendons and menisci as well as chondrocytes above the tidemark in articular cartilage. Growth plates were unstained. For each biomarker, extracellular staining was limited to fibrocartilage areas in the tendons and menisci in all mice and was limited to some focal lesions of the cartilage in biglyean/fibromodulin double-deficient mice. Conclusion. The different double-deficient:WT ratios observed with C2C, Coll2-1, and Coll2-1NO(2) in the absence of any correlation between the expression of the 3 biomarkers indicate that these biomarkers give complementary, rather than redundant, information about in vivo type 11 collagen catabolism.

TI Trochanteric fractures in the elderly: the influence of primary hip arthroplasty on 1-year mortality
SO ARCHIVES OF ORTHOPAEDIC AND TRAUMA SURGERY
LA English
DT Article
DE mortality risk; trochanteric femoral fractures; total hip replacement
ID unstable intertrochanteric fractures; bipolar prosthetic replacement; failed internal-fixation; proximal femoral nail; pertrochanteric fractures; intramedullary fixation; screw; femur; complications; morbidity
AB Introduction The aim of the study was to compare the mortality risk and complication rate after operative treatment of pertrochanteric fractures with primary arthroplasty, dynamic hip screw (DHS) or proximal femoral nail (PFN). Patients and methods Clinical records including X-rays of all patients with trochanteric femoral fractures, except pathologic fractures and a minimum age of 60 years, which were treated between 1992 and 2005 were entered in this

retrospective study. Of these 283 patients, 132 were treated by primary arthroplasty, 109 with a DHS and 42 with a PFN. Survival after 1 year and complications, which had to be treated within this period were our main outcome measurement. Influencing cofactors such as age, gender and comorbidities were reduced by multivariate logistic regression analysis. Results Mortality was significantly influenced by age, gender and amount of comorbidities but not by fracture classification. Primary hip arthroplasty did not bear a higher 1-year mortality risk than osteosynthesis in a multiple regression analysis. The main complication with DHS and PFN were cutting out of the hip screw and non-union with a revision rate of 12.8%. With the introduction of hemiarthroplasty, the postoperative dislocation rate decreased from 12 to 0%. Conclusion For stable fractures a dynamic hip screw (DHS) and for unstable fractures a short proximal femoral nail (PFN) can be recommended. The mortality risk of primary cemented arthroplasty did not differ significantly from the other treatment groups and because of its low complication rate it is a viable treatment option for trochanteric fractures if osteoporosis prevents from full weight bearing or if osteoarthritis makes further operations likely. Primary total hip replacement should be handled with care due to its significantly higher dislocation rate compared with hemiarthroplasty especially in unstable fractures.

DT Article
AB To identify chronic musculoskeletal (CM) problems we used a chronic conditions list(1) classified according to ICPC-2.(2) Conditions included: congenital anomalies, musculoskeletal syndromes, osteoarthritis, osteoporosis, malignant neoplasms, and other less common conditions such as lupus erythematosus and scleroderma. Among the 101 993 encounters recorded in BEACH between April 2005 and March 2006, there were 7389 at which 7597 CM problems were managed. Encounters at which CM problems were managed made up 7.3% of all encounters. These problems accounted for 5.0% of all problems managed and 43.3% of all musculoskeletal problems managed.

TI Variation in the secreted frizzled-related protein-3 gene and risk of osteolysis and heterotopic ossification after total hip arthroplasty
SO JOURNAL OF ORTHOPAEDIC RESEARCH

LA English
DT Article
DE osteolysis; heterotopic ossification; total hip arthroplasty; genetic polymorphism; secreted frizzled-related protein-3
ID high-bone-mass; ectopic ossification; follow-up; in-vitro; osteoarthritis; osteoporosis; association; replacement; component; revision
AB Secreted frizzled-related protein-3 (sFRP3) antagonizes ligands that promote new bone formation in adult tissues. We examined whether variation in the FRZB gene that encodes sFRP3 is associated with development of osteolysis or heterotopic ossification (HO) after total hip arthroplasty (THA). Genomic DNA was extracted from 609 subjects (osteolysis group n = 268) at a mean of 11 years following cemented THA for idiopathic osteoarthritis and genotyped for the FRZB Arg200Trp and Arg324Gly polymorphisms. The Brooker classification was used to assess HO following primary THA in 563 of the subjects. The carriage rate of the FRZB 200Trp allele was 14.2% in subjects with osteolysis versus 21.0% in controls (p 0.041). The carriage rate of this allele was 21.7% in subjects with HO (n = 299) versus 12.0% in those without HO (p = 0.063). The odds ratio for osteolysis with carriage of FRZB 200Trp was 0.62 (95% CI 0.38 to 0.99; p = 0.049) and for HO was 1.64 (1.05 to 2.54;p 0.028), after adjustment for the effects of other risk factors associated with the development of osteolysis or HO. Variants in the FRZB 324 locus alone were not associated with osteolysis or HO. However, the most frequent haplotype (FRZB 200Arg:324Arg) was associated with osteolysis (OR 1.50,95% CI 1.09 to 2.07;p = 0.014). Our data suggest that the FRZB Arg200Trp locus may be a marker for pro-osteoblastic activity after THA. Carriage of the FRZB 200Trp allele is associated with a "positive" bone balance phenotype (osteolysis -: HO+). (C) 2007 Orthopaedic Research Society.

TI Structural parameters and mechanical strength of cancellous bone in the femoral head in osteoarthritis do not depend on age
SO BONE
LA English
DT Article
DE cancellous bone microarchitecture; osteoarthritis; strength; age variation; MicroCT scanning
ID coxarthrosis hip osteoarthritis; tibial trabecular bone; proximal femur; iliac crest; compressive property; morphometric-analysis; genetic-determinants; inverse relationship; computed-tomography; specimen geometry
AB For normal bone, aging has been associated with a decrease of both density and failure strength, and with the development of pathologies such as osteoporosis. Conversely, it has been reported that another common disease, osteoarthritis, may alter these age-related changes in cancellous bone, suggesting that it may have a protective role against osteoporosis and the correspondent fracture risk. It was reported that in the principal compressive region of the femoral head in osteoarthritis the bone density does not depend on age. However, it is not clear if this independence on age of the cancellous bone density corresponds also to a reduced dependence on age of the strength to failure. The present work examined cancellous bone from the principal compressive region of the femoral head of 37 patients having severe osteoarthritis. The aim was (1) to investigate the

dependence on age of both the structural parameters and the ultimate stress and (2) to investigate the relationships between the ultimate stress and the structural parameters. Using X-ray microcomputed tomography, three-dimensional structural parameters, such as bone volume fraction, direct trabecular thickness and structure model index were calculated. Then the specimens were compressed to failure to determine the ultimate stress. It was found that none of the investigated structural parameters did depend on age, and also the ultimate stress did not depend on age ($p > 0.05$ for all regressions on age). In addition, the ultimate stress was significantly correlated with the structural parameters, primary with the minimum bone volume fraction and the average bone volume fraction ($R-2 = 0.95$ and $R-2 = 0.84$, respectively). These findings show that severe osteoarthritis or a related factor may change the age dependences of both the structural parameters and the mechanical proper-ties usually reported for normal cancellous bone. These results suggest for this pathology to have a protective role against the age-related decrease in density, the age-related deterioration of the microarchitecture and the age-related decrease of the failure strength for the cancellous bone in the principal compressive region of the human femoral head. TI Risk factors affecting metaphyseal irregularities in the radius and ulna of growing Newfoundland dogs
SO JOURNAL OF ANIMAL SCIENCE
LA English
DT Article
DE alkaline phosphatase; body weight; canine; growth curve; metaphyseal irregularities
ID german-shepherd dogs; canine hip-dysplasia; heritability; growth; osteoarthritis; osteoporosis; disease; breeds
AB The main objective of this study was to study risk factors affecting metaphyseal irregularities (MI) in the distal radius and ulna of growing Newfoundland dogs.

Risk factors studied included the genetic effects, effects of litters, BW, circumferences of the distal radius and ulna (CDRU), and total serum alkaline phosphatase (ALP) concentrations. The study included 118 Newfoundland dogs (60 females, 58 males), derived from 32 litters. Body weight, separated on sex and MI, was fitted to the Gompertz function. Occurrence of MI differed significantly between sexes, with 55% of males and 35% of females affected (P = 0.03). Growth curves for the 2 groups of dogs, with and without MI, diverged after 60 to 70 d, and dogs with irregularities were heavier at maturity than dogs of the same sex without irregularities. In univariate analysis, the litter effect was a significant predictor of MI, explaining 32% of total variability of the MI incidence, but the genetic effects were not significant. However, the latter were significant in bivariate analysis of MI and BW. In the bivariate analysis, the effects of litter on MI and BW were significantly correlated at all observational points except at birth, 180 d, and 536 d. Total ALP concentrations decreased with increasing age, and differences between groups diminished with increasing age, indicating a negative effect of total ALP on MI. Correlation between MI and total ALP concentrations of litters was estimated in a bivariate analysis. This correlation was significant and ranged between - 0.34 and - 0.62. Similarly, the genetic relationship between total ALP and MI from 120 d of age onward varied between - 0.31 to - 0.60. However, correlations were only significant at 356 d of age (genetic correlation = 0.60; P = 0.01). The mean CDRU increased from 90 d of age toward a peak at 180 d. Thereafter, CDRU declined and stabilized at about 1 yr of age. The mean CDRU between the groups of dogs with and without MI diverged most at 90 d of age, then was nearly stable until 180 d and gradually declined until 356 d, when the CDRU began to equalize. Metaphyseal irregularities and CDRU levels of litter were significantly correlated. Litter effect was a significant predictor of MI. The effects of litters and the genetic effects on BW and MI were correlated at most phases of the growth of the dog. Similar, but lower, correlations were found for CDRU and MI, and total ALP and MI.

TI Statins and dietary fish offs improve lipid composition in bone marrow and joints
SO CLINICAL ORTHOPAEDICS AND RELATED RESEARCH
LA English
DT Article
ID clearing agents; fat-embolism; osteonecrosis; surfactant; risk
AB There have been numerous efforts to alter the lipid content of cardiovascular tissues. Although equally important, only limited information is available about musculoskeletal tissues. I characterized joint and bone marrow lipids in patients having joint replacement surgery and explored the effects of fish oils and statins on lipid composition in bone marrow and joint fluid. Joint drainage catheters were used to collect marrow lipids from 84 patients having 128 hip and knee replacements for osteoarthritis, osteonecrosis, and femoral neck fractures (osteoporosis). Statins reduced the amount of lipid by 22% in patients with osteoporosis, 26% in patients with osteoarthritis, and 41% in patients with osteonecrosis compared with pretreatment lipid levels in the same patients. Taking fish oils reduced the amount of lipid in bone marrow by 20%. Lipid profiles of disturbed marrow and joint fluid from patients who took statins or dietary fish oil showed an increase in the proportion of unsaturated fatty acids and longer-chain fatty acids relative to pretreatment profiles. The ability to change the amount and character of bone and joint lipids may have major importance for strengthening bone, reducing the severity or preventing osteonecrosis, and enhancing joint lubrication.

TI Genetic association analysis of LRCH1 as an osteoarthritis susceptibility locus
SO RHEUMATOLOGY
LA English
DT Article
DE osteoarthritis; LRCH1; genetic susceptibility; SNP
ID single-nucleotide polymorphism; hip osteoarthritis; knee osteoarthritis; asporin; risk; osteoporosis; variants; repeat
AB Objective. A genetic association with knee osteoarthritis (OA) of a single nucleotide polymorphism (SNP) in intron 1 of the LRCH1 gene was recently reported in a UK Caucasian case-control sample and confirmed in a Newfoundland Caucasian sample. Our objective was to assess whether the SNP was associated with OA in our large UK Caucasian sample. Methods. The SNP was genotyped in 1521 cases that had undergone elective joint replacement of the hip (1098 cases), of the knee (340 cases) or of the hip and knee (83 cases) due to end-stage primary OA. The SNP was also genotyped in 736 controls of similar ages in the cases. Results. There was no significant difference (all P-values > 0.05) in genotype or allele frequencies between our cases and our controls. There was also no significant difference when the cases were stratified by sex, by joint replaced or by sex combined with joint replaced. Conclusion. Our data on 2257 individuals implies that the LRCH1 intron 1 SNP is not a risk factor for OA aetiology of the knee or of the hip in our UK Caucasian sample.

TI Lumbar disc degeneration: association between osteophytes, end-plate sclerosis and disc space narrowing
SO ANNALS OF THE RHEUMATIC DISEASES
LA English
DT Article
ID bone-mineral density; vertebral osteoporosis; radiographic features; osteoarthritis; women; men
AB Background: Lumbar disc degeneration is characterised radiologically by the presence of osteophytes, end-plate sclerosis and disc space narrowing. Aim: To determine the strength of the association between increasing severity of combinations of these features in a population sample of men and women. Methods: Men and women aged >= 50 years were recruited from a primary care-based community health index in Aberdeen, UK. Participants had lateral spinal radiographs performed according to a standard protocol. The intervertebral disc spaces (L1/2-L4/5) were evaluated for the presence of anterior osteophytes, end-plate sclerosis and disc space narrowing using a graded semiquantitative score (grade 0-3). Log linear modelling was used to determine the associations (pairwise) between increasing severity of these features, with the results expressed as beta coefficients and 95% confidence intervals (CIs). Results: There were 286 men (mean age 65.3 years) and 299 women (mean age 65.2 years) with spinal radiographs, yielding a total of 2340 assessable lumbar vertebral levels. In all, 73% of vertebral levels had evidence of osteophytes, 26% of sclerosis and 37% of disc space narrowing. Increasing severity of osteophyte grade was associated with an increasing severity both of sclerosis and of disc space narrowing, whereas the severity of sclerosis was associated with the severity of narrowing. This was true at all vertebral levels. The strongest association, however, was between osteophytes and sclerosis (beta coefficient =2.7, 95% CI 2.4 to 3.1). For sclerosis and narrowing the beta coefficient was 1.9 (95% CI 1.7 to 2.1), whereas for osteophytes and narrowing the beta coefficient was much weaker at 1.2 (95% CI 1.1 to 1.3). There was no important influence of vertebral level on any of these associations. Conclusion: The association between increasing severity of osteophytes and

end-plate sclerosis is stronger than for other combinations of radiographic features of lumbar disc degeneration.

DT Review
ID dipeptidyl peptidase-i; ketoamide-based inhibitors; human procathepsin b; human coronavirus nl63; t-cell selection; bone-resorption; crystal-structure; proteinase-inhibitors; invariant chain; matrix-metalloproteinase
AB The general view on cysteine cathepsins, which were long believed to be primarily involved in intracellular protein turnover, has dramatically changed in last 10 to 15 years. The discovery of new cathepsins, such as cathepsins K, V, X, F and 0, and their tissue distribution suggested that at least some of them are involved in very specific cellular processes. Moreover, gene ablation experiments revealed that cathepsins play a vital role in numerous physiological processes, such as antigen processing and presentation, bone remodelling, prohorinone processing and wound healing. Their involvement in several pathologies, including osteoporosis, rheurnatoid arthritis, osteoarthritis, bronchial asthma and cancer have also been confirmed and today several of them have been validated as relevant targets for therapies. Compounds targeting cathepsins S and K are already in clinical evaluation, whereas others are in experimental phases. The cathepsin K inhibitor AAE-581 (balicatib) as the most advanced of them passed Phase 11 clinical trials in 2005. In this review, we discuss the current view on cathepsins as an emerging group of targets for several diseases and the development of cathepsin K and S

inhibitors for treatment ofosteoporosis and various immune disorders.

TI 5-((1H-pyrazol-4-yl)methylene)-2-thioxothiazolidin-4-one inhibitors of ADAMTS-5
SO BIOORGANIC & MEDICINAL CHEMISTRY LETTERS
LA English
DT Article
DE ADAMTS-5; aggrecanase-2; thioxothiazolidin-4-ones; osteoporosis
ID biological evaluation; aggrecanase; osteoarthritis; potent
AB A series of 5-((1H-pyrazol-4-yl)methylene)-2-thioxothiazolidin-4-one inhibitors of ADAMTS-5 (aggrecanase-2) is described. These compounds show mu M functional inhibition of ADAMTS-5, and represent a new class of agents with the potential of inhibiting degradation of aggrecan, a major component of cartilage which is lost in osteoporosis. Compound 12 is noteworthy in that it has an ADAMTS-5 IC50: 1.1 mu M and shows > 40-fold functional selectivity over ADAMTS-4 (aggrecanase-1). (c) 2006 Elsevier Ltd. All rights reserved.

TI Inflammatory cytokines in relation to adrenal response following total hip replacement
SO SCANDINAVIAN JOURNAL OF IMMUNOLOGY
LA English
DT Article
ID tumor-necrosis-factor; total joint replacement; c-reactive protein; rheumatoid-arthritis; knee arthroplasty; diseases; surgery; immune; interleukin-8; activation
AB Our objective was to investigate the initiation and course of pro- and anti-inflammatory cytokines in early inflammatory response and to elucidate the cytokine system in relation to the adrenal response caused by stress. Seven blood samples were collected, pre- and postoperatively (0-72 h) after total hip replacement (THR) due to osteoarthritis. The following cytokines were measured using Cytometric Bead Array: interleukin-1 beta (IL-1 beta), IL-6, tumour necrosis factor-alpha, IL-8, IL-12 and IL-10 (B&D). Thirteen patients took part in the study (67 +/- 9 years). C-reactive protein increased from < 6 to over 200 mg/l on the second post-op day. The concentration of IL-6 increased 10-fold just 3 h post-op (4-47 pg/ml) and reached its maximum value 6 h post-op (77 pg/ml; Wilcoxon test $P < 0.01$) Repeated measurements were also significant (Friedman $P < 0.05$). The concentration of IL-8 doubled the day of surgery but did not reach a significant level (Friedman test =0.069). None of the other cytokines showed any significant changes. The diurnal cortisol rhythm was interrupted after the surgery and there was a significant correlation between the cortisol secretion and IL-6 response. This study demonstrates an isolated elevation in IL-6 levels with only a minor elevation

in IL-8 following THR. This pro-inflammatory response seemed to decline without activation of anti-inflammatory cytokines (IL-10), but cortisol seemed to play a complicated role in halting the acute inflammatory response.

AB Extracellular matrix (ECM) remodeling is one of the underlying mechanisms in cardiovascular diseases. Cathepsin cysteine proteases have a central role in ECM remodeling and have been implicated in the development and progression of cardiovascular diseases. Cathepsins also show differential expression in various stages of atherosclerosis, and in vivo knockout studies revealed that deficiency of cathepsin K or S reduces atherosclerosis. Furthermore, cathepsins are involved in lipid metabolism. Cathepsins have the capability to degrade low-density lipoprotein and reduce cholesterol efflux from macrophages, aggravating foam cell formation. Although expression studies also demonstrated differential expression of cathepsins in cardiovascular diseases like aneurysm formation, neointima formation, and neovascularization, in vivo studies to define the exact role of cathepsins in these processes are lacking. Evaluation of the feasibility of cathepsins as a diagnostic tool revealed that serum levels of cathepsins L and S seem to be promising as biomarkers in the diagnosis of atherosclerosis, whereas cathepsin B shows potential as an imaging tool. Furthermore, cathepsin K and S inhibitors showed effectiveness in (pre) clinical evaluation for the treatment of osteoporosis and osteoarthritis, suggesting that cathepsin inhibitors may also have therapeutic effects for the treatment of atherosclerosis.

TI The burden of prevalent fractures on health-related quality of life in postmenopausal women with osteoporosis: The IMOF study
SO JOURNAL OF RHEUMATOLOGY
LA English
DT Article
DE vertebral fracture; postmenopausal osteoporosis; health-related quality of life; questionnaire
ID incident vertebral fractures; low-back-pain; rheumatoid-arthritis; italian version; validation; questionnaire; validity; impact; reliability; osteoarthritis
AB Objective. Vertebral fractures are a common complication of osteoporosis and may have a negative effect on health-related quality of life (HRQOL). We investigated the effect of prevalent vertebral fractures on HRQOL in patients with

osteoporosis. Methods. A cross-sectional multicenter study was carried out among postmenopausal women with primary osteoporosis attending primary care centers and hospital outpatient clinics: 234 women with vertebral fractures and 244 asymptomatic women. Women with secondary osteoporosis or taking medications that affect bone metabolism were excluded. All patients were questioned using the mini-Osteoporosis Quality of Life Questionnaire (mini-OQLQ), Medical Outcomes Study Short Form-36 (SF-36), and the EuroQuol-5D, after assessment of all clinical variables and anthropometric data. To assess comorbidity we used the Self-Administered Comorbidity Questionnaire (SCQ). Diagnosis of osteoporosis was confirmed in all patients by bone mineral density using dual energy x-ray absorptiometry. Radiographic evaluation was performed by a musculoskeletal radiologist. A total of 483 postmenopausal women, randomly matched for age out of 1579 healthy controls, were chosen to compare the SF-36 scores with respect to patients with and without vertebral fractures due to osteoporosis. A multivariable regression analysis was conducted to identify the strongest determinant for low HRQOL, adjusted for potential confounding variables such as comorbid conditions, education level, and psychosocial status. Results. The vertebral fracture group had significantly lower scores than patients without fractures and controls in all domains of the generic and specific questionnaires. Women with only 1 prevalent fracture had statistically significantly lower HRQOL scores than those without fractures on SF-36 measures of bodily pain, physical functioning, and role function physical (all $p < 0.01$). HRQOL scores were lower in women with lumbar fractures compared with women with thoracic fractures only when the physical functioning and bodily pain dimensions approached statistical significance. Based on the multivariate analysis, the strongest determinant for low HRQOL was physical functioning (explained by number of vertebral fractures) followed by comorbidity score and age. Adjusted R-2 in the final model was 35.9%. Using the SF-36 summary scales, comorbid conditions predominantly affected either mental or physical health ($p < 0.0001$). A significant correlation ($p < 0.0001$) was found between total score on the mini-OQLQ and the mean SCQ comorbidity score. Conclusion. Our results confirm previous findings that HRQOL, assessed by generic and osteoporosis-specific instruments, is decreased in patients with vertebral fractures due to osteoporosis as a function of the number of vertebral fractures, presence of comorbid conditions, and age.

TI Articular cartilage and biomechanical properties of the long bones in Frzb-knockout mice
SO ARTHRITIS AND RHEUMATISM
LA English
DT Article
ID frizzled-related protein-3; wnt signaling pathway; hip osteoarthritis; antagonist; growth; expression; association; modulation; variants; netrins
AB Objective. Ligands and antagonists of the WNT pathway are linked to osteoporosis and osteoarthritis. In particular, polymorphisms in the FRZB gene, a secreted WNT antagonist, have been associated with osteoarthritis. The aim of this study was to examine cartilage and bone in Frzb(-/-) mice. Methods. The Frzb gene in mice was inactivated using a Cre/loxP strategy. Three models of osteoarthritis were used: collagenase, papain, and methylated bovine serum albumin induced. Bone biology was studied using density measurements and microfocal computed tomography. Bone stiffness and mechanical loading-induced bone adaptation were studied by compression of the ulnae. Results. Targeted deletion of the Frzb gene in mice increased articular cartilage loss during arthritis triggered by instability, enzymatic injury, or inflammation. Cartilage damage in Frzb(-/-) mice was associated with increased WNT signaling and matrix metalloproteinase 3 (MMP-3) expression and activity. Frzb(-/-) mice had increased cortical bone thickness and density, resulting in stiffer bones, as demonstrated by stressstrain relationship analyses. Moreover, Frzb(-/-) mice had an increased periosteal anabolic response to mechanical loading as compared with wild-type mice. Conclusion. The genetic association between osteoarthritis and FRZB polymorphisms is corroborated by increased cartilage proteoglycan loss in 3 different models of arthritis in Frzb(-/-) mice. Loss of Frzb may contribute to cartilage damage by increasing the expression and activity of MMPs, in a WNT-dependent and WNT-independent manner. FRZB

deficiency also resulted in thicker cortical bone, with increased stiffness and higher cortical appositional bone formation after loading. This may contribute to the development of osteoarthritis by producing increased strain on the articular cartilage during normal locomotion but may protect against osteoporotic fractures.

TI Association of bone marrow lesions with knee structures and risk factors for bone marrow lesions in the knees of clinically healthy, community-based adults
SO SEMINARS IN ARTHRITIS AND RHEUMATISM
LA English
DT Review
DE bone marrow lesions; cartilage defects; bone size; osteoarthritis
ID tibial cartilage volume; early radiographic osteoarthritis; subchondral bone; surface-area; edema; joint; pain; osteoporosis; determinants; progression
AB Objectives: Subchondral bone marrow lesions (BML) are involved in pain and progression of knee osteoarthritis (OA). Little is known about their role in the knee in those without clinical OA. Our aim was to examine the prevalence and risk factors for BML, and their relationship with other knee structures in community-based adults without clinical OA. Methods: Two hundred ninety-seven healthy subjects without knee pain or injury were recruited from an existing community-based cohort recruited at baseline in 1990-1994. Subjects with a single magnetic resonance imaging (MRI) of their dominant knee at follow-up were studied in 2003-2004. BML, cartilage defects, cartilage volume, and bone area of the knee were assessed using MRI. Results: Thirty-nine subjects (13%) had evidence of BML. BML were associated with the presence of cartilage defects in the medial (odds ratio (OR) 1.80, P = 0.004) and lateral (OR 1.45, P = 0.04) tibiofemoral compartments, but not cartilage volume. BML were positively associated with total tibial bone area (OR 1.22, P = 0.02). Increasing age (OR 1.10, P < 0.001), male gender (OR 3.86, P = 0.01), and increasing body height (OR 1.07, P = 0.03) were independently associated with BML in the total tibiofemoral compartment. Conclusions: BML are present in the knees of community-based adults without clinical OA and are strongly associated with tibiofemoral cartilage defects. Risk

factors for BML were age, male gender, and body height. Longitudinal studies will be needed to clarify the role of BML in structural change of the knee and how this relates to the pathogenesis of symptomatic knee OA. (C) 2007 Elsevier Inc. All rights reserved.

TI Expression of bone resorption genes in osteoarthritis and in osteoporosis
SO JOURNAL OF BONE AND MINERAL METABOLISM
LA English
DT Article
DE cathepsin K; MMP-9; TRAP; RANKL; osteoprotegerin
ID kappa-b ligand; cathepsin-k; messenger-rna; receptor activator; trabecular bone; matrix metalloproteinases; osteoprotegerin ligand; cysteine-proteinases; protease expression; cancellous bone
AB Cathepsin K and MMP-9 are considered to be the most abundant proteases in osteoclasts. TRAP is a marker for osteoclasts, and there is increasing evidence of its proteolytic role in bone resorption. RANKL is a recently discovered regulator of osteoclast maturation and activity and induces expression of many genes. This study compared cathepsin K, MMP-9, TRAP, RANKL, OPG, and osteocalcin gene expression in the proximal femur of patients with osteoarthritis with that of patients with femoral neck fracture. Fifty-six patients undergoing arthroplasty because of osteoarthritis or femoral neck fracture were included in the study. Total mRNA was extracted from the bone samples obtained from the intertrochanteric region of the proximal femur. Real-time RT-PCR was used to quantify CTSK (cathepsin K), MMP-9 (matrix metalloproteinase 9), ACP5 (TRAP), TNFSF11 (RANKL), TNFRSF11B (OPG), and BGLAP (osteocalcin) mRNAs. The levels of mRNAs coding for MMP-9 and osteocalcin indicated higher expression in the osteoarthritic group ($P = 0.011$, $P = 0.001$, respectively), whereas RANKL expression and the ratio RANKL/OPG were both significantly lower in the osteoarthritic group than in the fracture group. Expression of cathepsin K, MMP-9, and TRAP relative to RANKL was significantly higher in the osteoarthritic group. Ratios of all three proteolytic enzymes relative to formation marker osteocalcin were higher in the fracture group. Gene expression of cathepsin K, MMP-9, TRAP, RANKL, OPG, and osteocalcin and the association between their mRNA levels pointed to higher bone resorption and bone formation in osteoarthritis, differences in balance between them, and differences in regulation of bone resorption in osteoarthritic and osteoporotic bone.

TI Relative bone mineral density measured by metacarpal index (MCI) and chronic spinal syndromes:: an epidemiological study
SO SCANDINAVIAN JOURNAL OF RHEUMATOLOGY
LA English
DT Article
ID low-back-pain; idiopathic skeletal hyperostosis; postmenopausal women; chronic neck; follow-up; determinants; osteoarthritis; osteoporosis; spondylosis; prevalence
AB Objectives: The results of previous studies on the association between bone mineral density (BMD) and chronic spinal syndromes have been contradictory. Therefore, we studied relative BMD measured by the metacarpal index (MCI) and its associations with chronic neck and low-back syndromes and diffuse idiopathic skeletal hyperostosis (DISH). Methods: A population sample of 8000 Finns aged 30 years and over was invited to a comprehensive health examination in 1978-1980; 90% complied. In the clinical phase, a trained physician diagnosed chronic neck and low-back syndromes. Hand and chest radiographs were taken from 3568 participants to determine the MCI and to diagnose DISH. Of these, 340 subjects were re-examined clinically in 2000. Results: After adjusting for potential confounding factors, a high MCI showed a significant cross-sectional association with chronic neck syndrome and DISH. The odds ratio (OR) per increment of one standard deviation (0.1) of MCI for chronic neck syndrome was 1.33 [95% confidence interval (CI) 1.21-1.47] and for DISH 1.29 (95% Cl 1.04-1.60). No association was found between MCI and chronic low-back syndrome. In the follow-up setting, however, baseline MCI did not predict the incidence of chronic neck or low-back syndromes. Conclusions: Relative BMD is directly proportional to the prevalence of chronic neck syndrome. Further studies are needed to clarify the mechanisms of the association. The close association found between high relative BMD and DISH suggests a joint metabolic factor, which needs to be studied further to determine its effects on bones and intervertebral discs.

TI Prevalence and cost of musculoskeletal disorders: A population-based, public hospital system healthcare consumption approach
SO JOURNAL OF RHEUMATOLOGY

LA English
DT Article
DE musculoskeletal diseases; healthcare costs; burden of illness; rheumatic diseases; orthopedics; cost of illness
ID quality-of-life; knee osteoarthritis; joint replacement; chronic diseases; risk-factors; vitamin-d; arthritis; hip; osteoporosis; disability
AB Objective. To use a population-level, public-hospital approach to compare the prevalence and cost of musculoskeletal diseases (MSD) with other clinical specialties. Methods. A healthcare utilization survey of 4 million individual records over 4 years, from all major public hospitals in the state of Victoria (estimated population 4.8 million residents in 2000/01) from 1997/98 to 2000/01. Main outcome measures were inpatient episodes of care, bed-days, and outpatient clinic encounters. MSD was defined as the combination of orthopedics and rheumatology. Results. After obstetrics, MSD was the most frequent outpatient service, with orthopedics accounting for 9.9% of all visits in 2000/01. The proportion of MSD outpatient encounters (on average 11.6% of the total) was constant over the study period. Among 26 medical specialties, MSD had the sixth highest number of inpatient episodes (6.2% in 2000/01), following renal dialysis (14.6%), general surgery (8.2%), obstetrics (7.6%), gastroenterology (7.1%), and general medicine (6.7%). MSD was the fifth highest consumer of bed-days, occupying on average 7.7% of all beds per annum in the period 1997/98 to 2000/01, behind psychiatry (10.1%), respiratory medicine (8.5%), rehabilitation (8.3%), and general medicine (7.8%). MSD was the third most-costly discipline in 2000/01, with total costs of over A$169 million (9.7% of total inpatient costs that year), behind respiratory medicine (11.6%) and general surgery (11.5%). Conclusion. Compared to other diseases, MSD consumes a substantial proportion of healthcare resources in Victorian public hospitals. These data have important implications for allocation of healthcare resources, clinical care pathways, and prevention strategies.

TI The incidence of osteopenia and osteoporosis in women with hip osteoarthritis scheduled for cementless total joint replacement
SO BONE
LA English
DT Article
DE hip arthroplasty; DXA; osteoarthritis; osteoporosis; metabolic bone markers
ID bone-mineral density; vitamin-d; femoral-neck; fracture; quality; risk; arthritis; strength; mass; age
AB Introduction: The co-existence of osteoporosis (OP) and osteoarthritis (OA) remains obscure. No systematic studies have been carried out to exclude the possibility that especially female osteoarthritic patients selected for cementless total hip arthroplasty (THA) suffer from primary or secondary OP. Methods: A subgroup of fifty-three female patients (average age, 64.7 years) with advanced primary hip OA scheduled for cementless THA were recruited for DXA and laboratory screening. Before surgery, bone mineral density (BMD) of the lumbar spine, the proximal femurs and the distal forearm were measured. The serum concentrations of calcium, 25-hydroxyvitamin D, parathyroid hormone and biochemical markers of bone resorption and formation were determined to exclude secondary OP. Results: The prevalence of OP (T score <-2.5) and osteopenia (- 1.0 > T score >-2.5) were 28% and 45%, respectively. Statistically, OP was related to patient's age, low BMI, postmenopausal status and not having estrogen replacement therapy. Five patients (9%) had laboratory findings of secondary OP. Two of them were found to have a parathyroid adenoma. The prevalence of vitamin D insufficiency [S-25(OH)D levels <= 50 nmol/l] was 36% (n - 19). As a sign of high bone turnover, the patients with reduced BMD values showed significantly increased serum levels of osteocalcin (p=0.049), intact procollagen type I N propeptide (p=0.040) and N-terminal crosslinking telopeptide of type I collagen (p=0.046). The BMC of the femoral necks of the osteoarthritic hips were significantly higher (p < 0.001) and the BMC of the trochanter regions significantly lower (p=0.005) compared to the contralateral hips. Conclusion: Against a general belief, OA does not seem to protect a patient from generalized primary OP. The

majority (74%) of the female hip OA patients were osteopenic or osteoporotic with signs of increased bone turnover. The observed prevalence of reduced BNID corresponds with the published data of age-matched population. An unexpectedly high number of patients required preoperative consultation with an endocrinologist. The altered distribution of BNID observed in the proximal femurs may explain the lower prevalence of fractures reported in the femoral necks of osteoarthritic hips. (c) 2006 Elsevier Inc. TI Association of the F352V variant of the Klotho gene with bone mineral density
SO BIOGERONTOLOGY
LA English
DT Article
DE Klotho; osteoporosis; fractures; estradiol; bone mineral density
ID functional variant; hip fracture; polymorphisms; osteoporosis; homocysteine; risk; identification
AB Klotho gene codes for a protein with glucuronidase activity and is thought to influence bone and vascular homeostasis. We studied the relationship of a common T/G polymorphism, resulting in a phenylalanine (F) to valine (V) substitution at aminoacid position 352, with bone mineral density (BMD) and osteoporotic fractures. The study group comprised 914 Spanish women, including 438 control subjects, 190 patients with osteoporosis, 198 with hip fractures, and 88 patients with severe osteoarthritis. BMD was measured by DEXA in 540 women from the control and osteoporosis groups. Allele frequencies were 86% and 14%, for the F and V alleles, respectively. In comparison with the most common FF genotype, postmenopausal women with FV/VV genotypes had higher hip BMD (femoral neck: 0.673 +/- 0.011 vs. 0.644 +/- 0.006 g/cm(2); P = 0.02; total hip: 0.807 +/- 0.014 vs. 0.774 +/- 0.008 g/cm(2); P = 0.03). Klotho alleles explained about 1.5% of BMD variance, but were not associated to the risk of osteoporotic spine or hip fractures. The Klotho genotype was not associated to BMD in premenopausal women. In conclusion, the F352V Klotho polymorphism is associated with BMD in postmenopausal women, suggesting that Klotho gene variants influence skeletal aging.

TI An atlas improves Interobserver agreement regarding application of the ISCD vertebral body exclusion criteria
SO JOURNAL OF CLINICAL DENSITOMETRY
LA English
DT Article
DE agreement; bone densitometry; diagnosis; exclusion; osteoporosis; T-score; vertebrae
AB Coexisting conditions such as osteoarthritis and compression fracture may spuriously elevate the dual-energy Xray absorptiometry (DXA)-measured lumbar spine bone mass. To improve the diagnostic utility of lumbar spine DXA to diagnose osteoporosis, the International Society for Clinical Densitometry (ISCD) suggests excluding vertebrae affected by focal structural anomalies or unusual T-score discrepancies. However, we previously demonstrated only moderate agreement between physicians regarding vertebral body exclusion. We hypothesized that an atlas containing examples of vertebrae to exclude would improve interobserver agreement. Subsequently, we developed an interactive web-based atlas of lumbar spine DXA images with options to exclude vertebrae and compare one's answers to those derived by group consensus. Before and after review of the atlas, 5 ISCD-certified physicians applied the exclusion criteria to 90 DXA scans, recording the indications for vertebral exclusion on a standardized worksheet. After development and review of the atlas, interobserver agreement regarding vertebral body exclusion improved significantly ($p < 0.0001$). We plotted the deviation of each physician's reported T-score vs the mean T-score for each of 90 scans, and demonstrated that the scatter from the mean is decreased after atlas review. Furthermore, correlations in T-score improved in 7 of 10 physician pairs after atlas review. We conclude that an interactive atlas promotes uniform lumbar spine DXA interpretation.

TI Osteoporosis increases the severity of cartilage damage in an experimental model of osteoarthritis in rabbits
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE osteoporosis; osteoarthritis; bone mineral density; cartilage
ID bone-mineral density; estrogen replacement therapy; radiographic osteoarthritis; knee osteoarthritis; articular-cartilage; risk; hip; receptors; incident; women
AB Objective: To evaluate the effect of osteoporosis (OP) in cartilage damage developed in an experimental model of osteoarthritis (OA) in mature female rabbits in order to investigate the relationship between OP and OA. Methods: OA was experimentally induced by anterior cruciate section and partial medial meniscectomy in the left knee of 12 rabbits. OP was experimentally induced prior to CA in six rabbits by bilateral ovariectomy (OVX) and systemic corticosteroid administration during 4 weeks. Knees were evaluated with high resolution magnetic resonance imaging (MRI) before knee surgery to rule out any detrimental effect of corticosteroids on cartilage. Gross and microscopic cartilage changes were assessed 16 weeks after surgery in bilateral knees. Left knees were considered osteoarthritic or osteoarthritic plus osteoporotic. Right knees were used as osteoporotic and healthy controls, respectively. Bone mineral density (BMD) was measured with dual energy X-ray absorptiometry (DXA) at the lumbar spine, global knee and subchondral knee bone, and its variations correlated with cartilage abnormalities. Results: MRI before knee surgery disclosed no cartilage or bone abnormalities in any of the studied groups. OP increased the severity of cartilage abnormalities in experimental knee OA significantly ($P < 0.05$). Cartilage damage was inversely correlated with BMD variations measured at the lumbar spine ($r= -0.74$; $P = 0.015$). BMD changes in global and subchondral knee bone also showed a trend to correlate inversely with cartilage damage. Conclusions: Prior induction of OP increases the severity of cartilage damage in experimental OA. Increase in cartilage damage correlates with bone loss. These findings suggest a direct relationship between OP and OA. (C) 2006 Osteoarthritis Research Society International. Published by Elsevier Ltd. All rights reserved.

DT Article
DE bone metabolism; cell adhesion; extracellular matrix; fatty acids; osteoblasts
ID messenger-rna expression; nitric-oxide; arachidonic-acid; bone-resorption; growth-factors; collagen; differentiation; osteoporosis; fibronectin; phenotype
AB To investigate the possible role for unsaturated free fatty acids in osteoblast adhesion, the effects of two polyunsaturated fatty acids (PUFAs), arachidonic (AA) and eicosapentaenoic (EPA) acids, and of one monounsaturated fatty acid, oleic acid (OA), on adhesion to the substrate and on gene expression of three extracellular matrix macromolecules were investigated in an in vitro model system-cultured osteoblast-like human cells. AA, but neither EPA nor OA, diminished bone cell adhesion, whereas both EPA and OA, but not AA, increased gene expression of type I collagen and fibronectin via a transforming growth factor-beta-independent mechanism. These results extend previous evidence for unsaturated fatty acids in bone cell metabolism.

TI Does bone quality predict loosening of cemented total hip replacements?
SO JOURNAL OF BONE AND JOINT SURGERY-BRITISH VOLUME
LA English
DT Article
ID osteoporotic fractures; polyethylene particles; femoral components; arthroplasty; osteoarthritis; osteolysis; resorption; pressure; model; inhibition
AB We matched 78 patients with a loose cemented Charnley Elite Plus total hip replacement (THR) by age, gender, race, prosthesis and time from surgery with 49 patients with a well-fixed stable hip replacement, to determine if poor bone quality predisposes to loosening. Clinical, radiological, biomechanical and bone mineral density indicators of bone quality were assessed. Patients with loose replacements had more pain, were more likely to have presented with atrophic arthritis and to have a history of fragility fracture, narrower femoral cortices and lower peri-prosthetic or lumbar spine bone mineral density (all t-test, $p < 0.01$). They also tended to be smokers (chi-squared test, $p = 0.08$). Vitamin-D deficiency was common, but not significantly different between the two groups (t-test, $p = 0.31$) In this series of cemented hip replacements performed between 1994 and 1998, aseptic loosening was associated with poor bone quality. Patients with a THR should be screened for osteoporosis and have regular radiological surveillance.

TI Microarray gene expression profiling of osteoarthritic bone suggests altered bone remodelling, WNT and transforming growth factor-β/bone morphogenic

protein signalling
SO ARTHRITIS RESEARCH & THERAPY
LA English
DT Review
ID mesenchymal stem-cells; cruciate ligament transection; frizzled-related protein-3; human trabecular bone; osteoblasts in-vitro; subchondral bone; factor-beta; tgf-beta; osteoclast differentiation; transcription factors
AB Osteoarthritis (OA) is characterized by alterations to subchondral bone as well as articular cartilage. Changes to bone in OA have also been identified at sites distal to the affected joint, which include increased bone volume fraction and reduced bone mineralization. Altered bone remodelling has been proposed to underlie these bone changes in OA. To investigate the molecular basis for these changes, we performed microarray gene expression profiling of bone obtained at autopsy from individuals with no evidence of joint disease (control) and from individuals undergoing joint replacement surgery for either degenerative hip OA, or fractured neck of femur (osteoporosis [OP]). The OP sample set was included because an inverse association, with respect to bone density, has been observed between OA and the low bone density disease OP. Compugen human 19K-oligo microarray slides were used to compare the gene expression profiles of OA, control and OP bone samples. Four sets of samples were analyzed, comprising 10 OA-control female, 10 OA-control male, 10 OA-OP female and 9 OP-control female sample pairs. Print tip Lowess normalization and Bayesian statistical analyses were carried out using linear models for microarray analysis, which identified 150 differentially expressed genes in OA bone with t scores above 4. Twenty-five of these genes were then confirmed to be differentially expressed ($P < 0.01$) by real-time PCR analysis. A substantial number of the top-ranking differentially expressed genes identified in OA bone are known to play roles in osteoblasts, osteocytes and osteoclasts. Many of these genes are targets of either the WNT (wingless MMTV integration) signalling pathway (TWIST1, IBSP, S100A4, MMP25, RUNX2 and CD14) or the transforming growth factor (TGF)-beta/bone morphogenic protein (BMP) signalling pathway (ADAMTS4, ADM, MEPE, GADD45B, COL4A1 and FST). Other differentially expressed genes included WNT (WNT5B, NHERF1, CTNNB1 and PTEN) and TGF-beta/BMP (TGFB1, SMAD3, BMP5 and INHBA) signalling pathway component or modulating genes. In addition a subset of genes involved in osteoclast function (GSN, PTK9, VCAM1, ITGB2, ANXA2, GRN, PDE4A and FOXP1) was identified as being differentially expressed in OA bone between females and males. Altered expression of these sets of genes suggests altered bone remodelling and may in part explain the sex disparity observed in OA.

TI Lateral unicompartimental knee arthroplasty: indications, technique and short-medium term results
SO KNEE SURGERY SPORTS TRAUMATOLOGY ARTHROSCOPY
LA English
DT Article
DE lateral knee arthritis; unicompartmental lateral arthroplasty; arthritic genu valgum; unicondylar arthroplasty; unicompartimental knee arthroplasty (UKA)
ID anterior cruciate ligament; 10-year follow-up; unicompartmental arthroplasty; clinical-experience; replacement; osteoarthritis; osteonecrosis; survivorship; deformity; osteotomy
AB Lateral unicompartmental knee arthroplasty (UKA) is a valid alternative treatment in the event of arthritis confined to the lateral compartment. This paper examines its indications, technique and short to medium-term results. A total of 159 Miller-Galante cemented UKA prostheses (Zimmer, Warsaw, Indiana) were implanted consecutively (131 medial and 28 lateral) by the same surgeon. This study investigates 28 lateral UKAs in 27 patients. Twenty-five implants in 24 patients (including a subject operated bilaterally) were followed up for 12-60 months. Three patients were discarded on account of to short a follow-up period. The Hospital for Special Surgery (HSS) knee score was used to compare the pre-and post-operative results of the lateral UKA patients. The HSS score improved from a pre-op mean of 59.92 (range 48-68) to 88.04 (range 71-95) at the last follow-up. There was a positive increase in the pain, function and ROM components of the score. The lateral UKA prosthesis can be regarded as a sound alternative to total knee replacement. Correct patient selection on the basis of optimum surgical indications, however, is essential.

TI Basic fibroblast growth factor stimulates matrix metalloproteinase-13 via the molecular cross-talk between the mitogen-activated protein kinases and protein kinase Cδ pathways in human adult articular chondrocytes
SO JOURNAL OF BIOLOGICAL CHEMISTRY
LA English
DT Article
ID bronchial epithelial-cells; receptor tyrosine kinases; factor-kappa-b; gene-expression; rheumatoid-arthritis; factor-i; osteoarthritic cartilage; interleukin-8 secretion; osteogenic protein-1; promoter activity
AB Excessive release of basic fibroblast growth factor (bFGF) during loading and/or injury of the cartilage matrix may contribute to the onset or progression of osteoarthritis. This pathological role may be related to the ability of bFGF to decrease proteoglycan synthesis and to antagonize the activity of anabolic growth factors in cartilage such as insulin-like growth factor-1 and bone morphogenetic protein 7 (BMP7 or OP-1). Matrix metalloproteinase-13 (MMP-13), a catabolic cartilage-degrading enzyme, is dramatically up-regulated by inflammatory cytokines or by fibronectin fragments in articular chondrocytes. In this study, we investigated MMP-13 production by bFGF using human articular chondrocytes. Endogenous concentration of bFGF in synovial fluids collected from arthritis patients and asymptomatic subjects showed a good linear correlation with the endogenous levels of MMP-13. bFGF stimulation of MMP-13 was mediated at the transcriptional level and, at least in part, by stimulation of interleukin-1 production. Also, our findings suggest that bFGF stimulation of MMP-13 required the activation of multiple MAPKs (ERK, p38, and JNK) by bFGF, and more importantly, bFGF activation of protein kinase C (PKC) delta played a key role in the MMP-13 stimulation. Indeed, PKC delta is the only isoform associated with MMP-13 stimulation among the PKC isoforms tested. PKC delta controls the bFGF response by regulating multiple MAPK pathways. Our results suggest that PKC delta activation is a principal rate-limiting event in the bFGF-dependent stimulation of MMP-13 in human adult articular chondrocytes. We propose that deregulation of cross-talk between MAPK and PKC delta signaling may contribute to the etiology of osteoarthritis in human patients.

TI Extra-skeletal effects of bisphosphonates
SO JOINT BONE SPINE
LA English
DT Review
DE bisphosponates; osteoclasts; inflammation; osteoarthritis; arthritis
ID acute-phase response; active rheumatoid-arthritis; bone-resorption; intravenous pamidronate; double-blind; etidronate therapy; induced apoptosis; zoledronic acid; single infusion; lining cells
AB Bisphosphonates are pharmacological agents which are currently used both in osteoporosis than in other pathological conditions characterised by an increased

bone resorption, such as Paget's disease of bone, malign hypocalcaemia during myeloma, osteolytic bone metastasis and fibrous dysplasia of bone. The most important biological effect of bisphosphonates is the reduction of bone remodelling through the inhibition of osteoclastic activity, but there are many clinical and experimental evidences of extra-skeletal biological effects of bisphosphonates. It has been shown that bisphosphonates exert their effects not only on bone tissue cells, but also on those of the immune system with an "immunomodulating" effect, influencing the production of pro- and anti-inflammatory cytokines and changing the molecular expression involved in the immune processes and anti-inflammatory response. Although the available data are conflicting, there are several reports concerning the beneficial effects of bisphosphonates in controlling the progression of chronic joint inflammatory diseases, suggesting a wider use for these therapeutic agents in clinical practice. TI Occurrence of organ-specific and systemic autoimmune diseases among the first- and second-degree relatives of Caucasian patients with connective tissue diseases: report of data obtained through direct patient interviews
SO CLINICAL RHEUMATOLOGY
LA English
DT Article
DE autoimmune thyroid disease; connective tissue diseases; familial aggregation; organ-specific autoimmune diseases
ID lupus-erythematosus; familial aggregation; increased prevalence; disorders
AB Studies have demonstrated a familial aggregation of systemic and organ-specific autoimmune diseases. The aim of the present survey was to obtain, by patient interviews, a preliminary estimate of the prevalence of systemic and organ-specific autoimmune diseases among the first- and second-degree relatives of Caucasian patients with connective tissue diseases (CTD) or inflammatory arthritis followed at our unit. Between June 2007 and January 2008, 626 patients and 85 controls (patients with osteoarthritis, osteoporosis, or fibromyalgia) were interviewed. Three hundred ten patients (50%) versus 21 controls (25%) were found to have at least one relative affected with an autoimmune condition ($p < 0.0001$). The most common conditions were organ-specific autoimmune diseases: 160 (34%) autoimmune thyroid (AT) disease, 112 (24%) psoriasis, 21 vitiligo, and 19 insulin-dependent diabetes mellitus. Systemic autoimmune diseases were reported in 126 relatives: rheumatoid arthritis (66 cases, 14%), 16 sacroileitis, and CTD (43 cases). A significant difference was observed in the prevalence of AT disease between the relatives of the patients and controls (3% versus 0.5%). In conclusion, these data confirm the high prevalence of autoimmune conditions, particularly of AT disease, among the relatives of patients.

TI Effect of fatty acids on bone marrow lesions and knee cartilage in healthy, middle-aged subjects without clinical knee osteoarthritis
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE fatty acids; bone marrow lesions; cartilage; cartilage defects
ID dietary habits; cohort; association; density; volume; determinants; osteoporosis; degradation; progression; thickness
AB Objective: There is evidence that omega-3 polyunsaturated fatty acids alleviate the progression of osteoarthritis (OA). However, little work has been done to investigate the effect of fatty acids on bone marrow lesions and knee cartilage in healthy subjects. We examined this in a cohort of healthy middle-aged subjects without clinical knee OA. Methods: Two hundred and ninety-three healthy adults without knee pain or injury were recruited from an existing community-based cohort. Intakes of fatty acids and food sources of these were estimated from a food frequency questionnaire at baseline. Tibial cartilage volume, tibial plateau bone area, tibiofemoral cartilage defects and bone marrow lesions were assessed

approximately 10 years later using magnetic resonance imaging. Results: In multivariate analyses, higher intakes of monounsaturated fatty acids (OR = 2.14, 95% CI 1.04-4.39, P = 0.04), total (OR = 1.77, 95% CI 1.13-2.77, P = 0.01) and n-6 polyunsaturated fatty acids (OR = 1.69, 95% CI 1.10-2.61, P = 0.02) were associated with an increased risk of bone marrow lesions. Intake of fatty acids was not significantly associated with cartilage volume or cartilage defects. Conclusion: These findings support the dietary recommendation towards a shift to foods rich in n-3 polyunsaturated fatty acids in order to maintain an optimal balance between dietary n-3 and n-6 polyunsaturated fatty acids, which is also important in the prevention of atherosclerosis. Although our findings will need to be confirmed in longitudinal studies, they suggest the potential of fatty acids to adversely effect the knee joint. turnover; index
AB A comparative study of bone metabolism between postmenopausal women with osteoarthritis and osteoporosis showed that differential levels of bone remodeling markers, leptin, free leptin index, and osteoprotegerin might partly contribute to the proposed inverse relationship in bone mass between postmenopausal women with osteoarthritis and osteoporosis. Introduction: Osteoarthritis (OA) and osteoporosis (OP) are two common disorders affecting the quality of life in the elderly. The association between OA and OP has always been debated. The objective of this study was to compare bone metabolism between postmenopausal women with OA and OP. Materials and Methods: A total of 120 postmenopausal women with OA and OP (n = 60, respectively) were included in this comparative study. Anthropometric parameters and BMD at the spine and the proximal femur were measured. Serum leptin, soluble leptin receptor (sLR), osteoprotegerin (OPG), and bone remodeling markers, including bone-specific alkaline phosphatase (BALP), osteocalcin (OC), deoxypyridinoline cross-links (DPD), and cross-linked N-telopeptides of type I collagen (NTX), were quantified with commercial ELISA or EIA kits. Free leptin index (FLI) was also calculated by the ratio between serum leptin and sLR levels. Results: Postmenopausal women with OA had higher body weight, body mass index, fat mass, and percentage of fat than those suffered from OP. Compared with the patients in OP group, the patients in OA group had significantly higher BMD values at all sites measured. Higher serum leptin and FLI and lower OPG levels were shown in the OA group (leptin: 31.22 +/- 6.4 versus 26.50 +/- 9.27 ng/ml, $p < 0.001$; FLL 3.20 +/- 1.02 versus 2.50 +/- 0.95, $p < 0.05$; OPG: 4.75 +/- 1.97 versus 6.96 +/- 2.75 pM, $p < 0.001$), whereas lower serum OC and higher urine DPD were noted in the OP group (OC: 16.45 +/- 8.45 versus 13.06 +/- 6.25 ng/ml, $p < 0.05$; DPD: 10.83 +/- 7.12 versus 15.29 +/- 6.65 nM BCE/mM Cr, $p < 0.001$). Serum OPG levels negatively correlated with BMD at all sites assessed. However, no correlation was found between leptin and BMD. Only in the OA group di positive correlations exist between FLI and Z-score at the femoral neck and Ward's triangle region. After stepwise regression analysis, it was found that differential factors were able to predict the variance of BMD at different sites to a certain extent. Conclusions: Our study suggests that there are significant differences in bone metabolism between postmenopausal women with OA and OP and provides evidence for the inverse relationship between OA and OP. Differential levels of bone remodeling markers, leptin, FLI, and OPG may partly contribute to the proposed inverse relationship. Roles of leptin and its soluble receptor in bone metabolism regulation should be explored further.

TI Inverse relationship between vertebral fractures and spine osteoarthritis in postmenopausal women with osteoporosis
SO ANNALS OF THE RHEUMATIC DISEASES
LA English
DT Article
ID bone-mineral density; intervertebral disc degeneration; radiographic osteoarthritis; hip; osteophytosis; association; population; chingford; risk; men
AB Background: Although the coexistence of osteoarthritis and osteoporosis is considered as uncommon, it has been suggested that, in postmenopausal women, disc space narrowing increases the risk of vertebral fracture. The aim of this study was to check this hypothesis in postmenopausal women with osteoporosis. Objective: We analysed the relationship between vertebral fractures and spine osteoarthritis in 410 postmenopausal women with osteoporosis: in this population both disc space narrowing and osteophytes are inversely related to vertebral fractures. Patients and methods: This study is based on baseline data collected in a multicentre, prospective and 6-month longitudinal observational study. 410

postmenopausal women (74 +/- 5 years) were enrolled who had consulted for back pain, and had osteoporosis (according to WHO definition). Spine x-rays were performed according to standardised procedures. Vertebral fractures were evaluated from T4 to L4 using the Genant's semiquantitative method; osteoarthritis was evaluated by scoring osteophytes and disc space narrowing at all levels of the thoracic and lumbar spine, and by a qualitative assessment of facet joint arthritis. Results: The prevalence of vertebral fractures was 52.4%. At least one osteophyte, one disc space narrowing and one facet arthritis were present in 90.2, 64.6 and 77.8% of patients respectively. There was an inverse association between vertebral fractures and osteoarthritis: odds ratios adjusted for age and weight (95% CI) were 0.38 (0.17 - 0.86), p = 0.02 and 0.27 (0.16 - 0.46), p, 1024 for the presence of at least one osteophyte, and of at least three disc space narrowings respectively. In a cluster analysis, it was possible to identify a subgroup of patients without any disc space narrowing, and another subgroup with all patients having at least one disc space narrowing; the proportion of patients having more than three vertebral fractures was 25.2 and 15.9% in these two clusters respectively. Conclusions: Disc space narrowing and osteophytes are associated with a decreased vertebral fracture prevalence in postmenopausal women with osteoporosis.

TI Salmon calcitonin: a review of current and future therapeutic indications
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Review
ID bone-mineral density; osteoporotic vertebral fractures; pagets-disease; postmenopausal women; nasal spray; double-blind; established osteoporosis; randomized-trial; antiresorptive treatment; nonvertebral fractures
AB Salmon calcitonin, available as a therapeutic agent for more than 30 years, demonstrates clinical utility in the treatment of such metabolic bone diseases as osteoporosis and Paget's disease, and potentially in the treatment of osteoarthritis. This review considers the physiology and pharmacology of salmon calcitonin, the evidence based research demonstrating efficacy and safety of this medication in postmenopausal osteoporosis with potentially an effect on bone quality to explain its abilities to reduce the risk of spine fracture, the development of an oral salmon calcitonin preparation, and the therapeutic rationale for this preparation's chondroprotective effect in osteoarthritis.

AB Objective: To evaluate trabecular bone structure in relationship with cartilage parameters in distal femur and proximal tibia of the human knee at 3 Tesla (3 T) using high-resolution magnetic resonance imaging (MRI) with parallel imaging. Method: Sixteen healthy controls and 16 patients with mild osteoarthritis (OA) were studied using a 3 T magnetic resonance (MR) scanner and an eight-channel phased-array knee coil. Axial 3D GeneRalized Autocalibrating Partially Parallel Acquisition (GRAPPA)-based phase cycled Fast Imaging Employing Steady State Acquisition (FIFSTA-c) images were acquired in order to quantify the trabecular bone structure. For assessing cartilage morphology (thickness, volume), sagittal high-resolution 3D spoiled gradient echo (SPGR) images were acquired. In a subset of the subjects. sagittal images were acquired for measuring T1 rho and T2 relaxation times, using 3D T1 rho and T2 mapping techniques. Results: Good measurement reproducibility was observed for bone parameters, the coefficients of variations (CVs) ranging from 1.8% for trabecular number (app. Tb-N) to 5.5% for trabecular separation (app. Tb.Sp). Significant differences between control and CA groups were found for bone volume fraction bone volume over total volume (app. BV/TV) and app. Tb.Sp in all compartments. Significantly increased values in T1 rho and T2 were demonstrated in CA patients compared with controls at the femur, but not at the tibia. Tip was negatively correlated with app. BV/TV, app. Tb.N and app. Tb.Sp both at the medial femoral condyle (MFC) and lateral tibia (LT), while T2 was only correlated at the LT. Also, medial tibia (MT) T1 rho was negatively correlated with app. BV/TV (R-2 - 0.49, $P < 0.05$) and app. Tb.N (R-2 = -0.42, $P < 0.05$) from the opposite side of lateral femoral condyle (LFC). Significant correlations were found between trabecular bone parameters and cartilage thickness and normalized volume, mainly at LT, tibia (T) and femur (F). Conclusion: At this early stage of CA, an overall decrease in bone structure parameters and an increase in cartilage

parameters (T1 rho, T2) were noticed in patients. Trabecular bone structure correlated with articular cartilage parameters suggesting that loss of mineralized bone is associated with cartilage degeneration. Published by Elsevier Ltd on behalf of Osteoarthritis Research Society International.

TI The health status burden of people with fibromyalgia: a review of studies that assessed health status with the SF-36 or the SF-12
SO INTERNATIONAL JOURNAL OF CLINICAL PRACTICE
LA English
DT Review
ID quality-of-life; systemic-lupus-erythematosus; double-blind; musculoskeletal diseases; rheumatoid-arthritis; widespread pain; classification; criteria; population; exercise
AB Objective: The current review describes how the health status profile of people with fibromyalgia (FM) compares to that of people in the general population and patients with other health conditions. Methods: A review of 37 studies of FM that measured health status with the 36-item Medical Outcomes Study Short-Form Health Survey (SF-36) or the 12-item Short-Form Health Survey (SF-12). Results: Studies performed worldwide showed that FM groups were significantly more impaired than people in the general population on all eight health status domains assessed. These domains include physical functioning, role functioning difficulties caused by physical problems, bodily pain, general health, vitality (energy vs. fatigue), social functioning, role functioning difficulties caused by emotional problems and mental health. FM groups had mental health summary scores that fell 1 standard deviation (SD) below the general population mean, and physical health summary scores that fell 2 SD below the general population mean. FM groups also had a poorer overall health status compared to those with other specific pain conditions. FM groups had similar or significantly lower (poorer) physical and mental health status scores compared to those with rheumatoid arthritis, osteoarthritis, osteoporosis, systemic lupus erythematosus, myofacial pain syndrome, primary Sjogren's syndrome and others. FM groups scored significantly lower than the pain condition groups mentioned above on domains of bodily pain and vitality. Health status impairments in pain and vitality are consistent with core features of FM. Conclusions: People with FM had an overall health status burden that was greater in magnitude compared to people with other specific pain conditions that are widely accepted as impairing.

TI Increased osteoblast density in the presence of novel calcium phosphate coated magnetic nanoparticles
SO NANOTECHNOLOGY
LA English
DT Article
ID bisphosphonates; bone; iron; expression; gene; size
AB Bone diseases (including osteoporosis, osteoarthritis and bone cancer) are of great concern to the medical world. Drugs are available to treat such diseases, but often these drugs are not specifically targeted to the site of the disease and, thus, lack an immediate directed therapeutic effect. The optimal drug delivery system should enhance healthy bone growth with high specificity to the site of bone disease. It has been previously shown that magnetic nanoparticles can be directed in the presence of a magnetic field to any part of the body, allowing for site-specific drug delivery and possibly an immediate increase in bone density. The objective of the present study was to build off of this evidence and determine the density of osteoblasts (bone forming cells) in the presence of various uncoated and coated magnetic nanoparticles that could eventually be used in drug delivery applications. Results showed that some magnetic nanoparticles (specifically, gamma Fe2O3) significantly promoted osteoblast density (that is, cells per well) after 5 and 8 days of culture compared to controls (no particles). These magnetic

nanoparticles were further coated with calcium phosphate (CaP; the main inorganic component of bone) to tailor them for treating various bone diseases. The coatings were conducted in the presence of either bovine serum albumin (BSA) or citric acid (CA) to reduce magnetic nanoparticle agglomeration, a common problem resulting from the use of nanoparticles which decreases their effectiveness. Results with these coatings showed that magnetic nanoparticles, specifically (gamma-Fe2O3), coated in the presence of BSA significantly increased osteoblast density compared to controls after 1 day. In this manner, this study provided unexpected evidence that CaP-coated gamma-Fe2O3 magnetic nanoparticles increased osteoblast density (compared to no particles) and, thus, should be further studied to treat numerous bone diseases.

TI Bone marrow edema pattern in advanced hip osteoarthritis: quantitative assessment with magnetic resonance imaging and correlation with clinical examination, radiographic findings, and histopathology
SO SKELETAL RADIOLOGY
LA English
DT Article
DE hip; osteoarthritis; bone marrow edema; MRI; histopathology
ID subchondral bone; knee osteoarthritis; destructive osteoarthritis; transient osteoporosis; core decompression; cartilage; lesions; joint; pain; microfractures
AB Objective To correlate the amount of bone marrow edema (BME) calculated by magnetic resonance imaging(MRI) with clinical findings, histopathology, and radiographic findings, in patients with advanced hip osteoarthritis(OA). Materials and methods The study was approved by The Institutional Human Subject Protection Committee. Coronal MRI of hips was acquired in 19 patients who underwent hip replacement. A spin echo (SE) sequence with four echoes and separate fast spin echo (FSE) proton density (PD)-weighted SE sequences of fat (F) and water (W) were acquired with water and fat suppression, respectively. T2 and water:fat ratio calculations were made for the outlined regions of interest. The calculated MRI values were correlated with the clinical, radiographic, and histopathologic findings. Results Analyses of variance were done on the MRI data for W/(W + F) and for T2 values (total and focal values) for the symptomatic and contralateral hips. The values were significantly higher in the study group. Statistically significant correlations were found between pain and total W/(W + F), pain and focal T2 values, and the number of microfractures and calculated BME for the focal W/(W + F) in the proximal femora. Statistically significant correlations were found between the radiographic findings and MRI values for total W/(W + F), focal W/(W + F) and focal T2 and among the radiographic findings, pain, and hip movement. On histopathology, only a small amount of BME was seen in eight proximal femora. Conclusion The amount of BME in the OA hip, as measured by MRI, correlates with the severity of pain, radiographic findings, and number of microfractures.

TI Bone marrow edema syndromes of the hip: MRI features in different hip disorders
SO CLINICAL RHEUMATOLOGY
LA English
DT Article
DE avascular necrosis of the hip; bone marrow edema syndromes; magnetic resonance imaging of hip disorders; transient bone marrow edema syndrome of the hip joint
ID femoral-head; transient osteoporosis; rheumatoid-arthritis; avascular necrosis; ankylosing-spondylitis; core decompression; osteonecrosis; spine
AB The objectives of this study were to describe the essential magnetic resonance imaging (MRI) features of bone marrow edema syndromes affecting the hip joint. In addition, to evaluate the role of MRI in the assessment of hip joint involvement in different clinical settings that may share similar clinical findings. Thirty-four patients who complained of hip pain were studied consecutively. Of these, 21 were men (61.8%) and 13 were women (38.2%). After clinical assessment of possible hip disease, plain radiograph and MRI study of both hips were performed. The literature was searched using keywords: bone marrow edema, hip, and MRI. All patients had antalgic gait and limping. Initial clinical examination revealed painful limited internal and external rotation of the affected hip/hips suspect for hip disease. Unilateral hip involvement was identified in 31 patients (91.2%), and bilateral hip involvement was found in three patients (8.8%), with a total of 37 hips evaluated by MRI. The final diagnoses in our patients were: reactive arthritis (1), transient osteoporosis (7), avascular necrosis (10), osteoarthritis (2), tuberculous arthritis (4), septic arthritis (2), osteomyelitis (2), sickle cell anemia (2), lymphocytic leukemia (1), and femoral stress fracture (3). Bone marrow edema affecting the hip is neither a specific MR imaging finding nor a specific diagnosis and may be encountered in a variety of hip disorders due to different etiologies. MR imaging is the modality of choice when clinical examination is suspect for hip disease and plain radiographs are normal or equivocal. Early diagnosis and treatment is important in many of the disorders. The literature is reviewed regarding bone marrow edema of the hip.

TI Association of bone morphogenetic protein-2 gene polymorphisms with susceptibility to ossification of the posterior longitudinal ligament of the spine and its severity in Chinese patients
SO EUROPEAN SPINE JOURNAL
LA English
DT Article
DE OPLL; BMP-2 gene; PCR; polymorphism; case-control study
ID knee osteoarthritis; candidate genes; cervical-spine; collagen; metabolism; receptors; haplotype; linkage; model; npps
AB A case-control study was conducted to examine the association between two single nucleotide polymorphisms (SNPs) in exon 2 of the bone morphogenetic protein-2 gene (BMP-2) and ossification of the posterior longitudinal ligament (OPLL), and to investigate whether SNPs of the Ser37Ala (T/G) and the Ser87Ser (A/G) in the BMP-2 gene are associated with genetic susceptibility to OPLL and its severity in Chinese subjects. The Ser87Ser (A/G) SNP has been implicated in bone mineral density (BMD) and increases the risk of OA in women. The Ser37Ala (T/G) SNP is associated with BMD and the rate of bone loss in osteoporosis and osteoporosis fractures. A total of 57 OPLL patients and 135 non-OPLL controls were studied. Radiographs of the cervical spine were analyzed to determine the presence and the severity of OPLL. The association of two SNPs with the occurrence and the extent of OPLL were statistically evaluated. There was a significant association between the Ser37Ala (T/G) polymorphism and the occurrence of OPLL in the cervical spine. However, no significant association was found between the Ser37Ala (T/G) polymorphism and the more number of ossified cervical vertebrae in OPLL patients. There was a significant association between the Ser87Ser (A/G) polymorphism and the more number of ossified cervical vertebrae in OPLL patients. However, there was no statistical difference between the Ser87Ser (A/G) SNP and the occurrence of OPLL in the cervical spine. In addition, the Ser87Ser (A/G) polymorphism in male patients and in female patients showed no statistical difference between cases and controls. The present results demonstrate that BMP-2 Gene is not only a factor associated with the occurrence of OPLL, but also a factor related to more extensive OPLL. The "G" allele in the Ser37Ala (T/G) polymorphism is associated with the occurrence of OPLL, but not more extensive OPLL in the cervical spine. The "G" allele in the Ser87Ser (A/G) polymorphism promotes the extent of OPLL, whereas the "A" allele in the Ser87Ser (A/G) polymorphism restricts ectopic ossification in the cervical spine at least in Chinese subjects.

TI Natural history and risk factors for bone loss in postmenopausal Caucasian women: a 15-year follow-up population-based study
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE age; bone loss; HRT; weight
ID mineral density; calcium supplementation; general-population; cigarette-smoking; proximal femur; weight change; osteoporosis; fat; osteoarthritis; premenopausal
AB In this 15-year follow-up study, we found that the estimated rate of bone loss at the femoral neck (FN) for women aged 45-68 was linear at a rate of 1.67% per year, but quadratic for lumbar spine (LS) at a rate of 3.12% initially, and slowing down with age. We also confirmed the protective role of HRT, increasing weight, and lean mass in long-term bone loss. Introduction The objective was to describe the natural history of bone loss and explore the role of environmental factors in postmenopausal women over a 15-year period. Methods Bone mineral density (BMD) at the FN and the LS were measured in postmenopausal women from the Chingford Study. Height, weight, HRT status, and calcium/vitamin D supplement were assessed at each visit. Osteoarthritis of hip and spine was assessed by X-ray at baseline and at year 8. Results A total of 955 postmenopausal women with an average age of 54.7 at baseline were included. Both FN and LS BMD decreased significantly with age ($p < 0.0001$). The decline was larger in the LS (-3.12% per year), which showed a quadratic relationship, than in the FN (-1.67% per year) with a linear relationship. The rate of bone loss was reduced by one third annually for the FN and LS respectively in current HRT users. Change in weight was positively associated with both Delta FN and Delta LS BMD (beta = 0.16% and 0.09% change in Delta FN and Delta LS BMD per kilogramme change in weight respectively, $p < 0.0001$ for both sites). Spine OA and progression were positively associated with Delta LS BMD (beta = 1.22% change in Delta LS BMD per grade in spine OA and 0.45% change in Delta LS BMD for patients who progressed, $p < 0.0001$ for spine OA and $p = 0.002$ for spine OA progression). Spine OA (beta = 0.54% change in

Delta FN BMD per grade, p < 0.0001), but not progression, and hip OA were positively associated with Delta FN BMD. Furthermore, both age and body weight at baseline were positively associated with both Delta FN and Delta LS BMD (beta = 0.02-0.04% change in Delta FN and Delta LS BMD per year increase in age at baseline and 0.004-0.007% change in Delta FN and Delta LS BMD per kilogramme increase in weight at baseline, all p < 0.0001). Conclusion This large population-based longitudinal study demonstrated that the decline of BMD over 15 years is linear with age for the FN, but quadratic for the LS. The study confirmed the protective role of HRT, increased weight and lean mass in long-term bone loss.

TI Quality of care in the rheumatic diseases: current status and future directions
SO CURRENT OPINION IN RHEUMATOLOGY
LA English
DT Review
DE gout; osteoarthritis; osteoporosis; quality of healthcare; rheumatic diseases; rheumatoid arthritis
ID fee-for-service; arthritis care; managed care; gout; osteoporosis; pay; performance; indicators; outcm; osteoarthritis
AB Purpose of review To review the recent literature examining quality of care for several prevalent rheumatic conditions, including rheumatoid arthritis, osteoarthritis, gout and osteoporosis, and to summarize quality measurement and improvement initiatives relevant to rheumatology in the USA. Recent findings In recent years, research has identified a significant gap between ideal and actual clinical practice in the USA. Consistent with trends seen in the US healthcare system as a whole, research suggests deficits in healthcare quality for populations with rheumatic conditions. We review the growing literature on quality of care for rheumatoid arthritis, osteoarthritis, gout and glucocorticoid-induced osteoporosis. Summary Existing evidence suggests suboptimal healthcare quality for four common rheumatic conditions, a finding that parallels trends in the healthcare system as a whole.

TI Beneficial effects of Ajuga decumbens on osteoporosis and arthritis
SO BIOLOGICAL & PHARMACEUTICAL BULLETIN
LA English
DT Article
DE osteoporosis; arthritis; Ajuga decumbens; inducible nitric oxide synthase; osteoclast; osteoblast
ID nitric-oxide synthase; neo-clerodane diterpenes; bone loss; ovariectomized mice; postmenopausal osteoporosis; estrogen deficiency; rats; osteoarthritis; isoflavone; activation
AB Extract of the whole plant, Ajuga decumbens (KE) has long been used in China as a medication for the relief of joint pain. Previously, we proved that KE up-regulated the synthesis of collagen in false aged model rats. In this paper we examined the effects of KE on nitric oxide (NO) production, expression of inducible nitric oxide synthase (iNOS), osteoblast and osteoclast activity. We also investigated whether KE had any anti-osteoporosis or anti-arthritic activity by using ovariectmized mice and adjuvant induced arthritic rats. KE exhibited down-regulation of differentiation into osteoclast and up-regulation of mineralization in osteoblast-like MC3T3-E1 cells in a concentration-dependent manner. NO synthesized by iNOS plays important roles in inflammatory disease and imbalance between bone resorption and bone formation caused by estrogen depletion. KE inhibited expression of iNOS which caused concentration dependent inhibition of NO production. Furthermore, KE prevented brittle bones in ovariectomized mice and swelling of the left hind ankle in adjuvant induced arthritic rats. Therefore, KE improved the balance of bone resorption and bone formation, showing anti-inflammatory effects. Consequently, KE is beneficial for sufferers of bone and joint disease.

TI Cysteine cathepsin S as an immunomodulatory target: present and future trends
SO EXPERT OPINION ON THERAPEUTIC TARGETS
LA English

DT Review
DE autoimmune disorders; cathepsin; cysteine protease; inhibitors
ID dipeptidyl-peptidase-i; t-cell selection; invariant chain; reduces atherosclerosis; antigen presentation; l deficiency; degradation; inhibitor; arthritis; proteases
AB Objective: Antigen presentation is the key to immune response. Cathepsin S plays a major role in the degradation of the invariant peptide chain associated with the major histocompatibility complex and thus affects antigen presentation. This review will focus on the recent developments made in field of cysteine cathepsins especially cathepsin S and their future prospects as a therapeutic target. Methods: Selective cathepsin inhibitors for targeting autoimmune disorders, atherosclerosis, osteoporosis, osteoarthritis and cancer are being pursued by many pharmaceutical companies. Recent publications in this field have been used as references to evaluate the current and future trends in cathepsin S inhibitors as an immunomodulatory target. Conclusions: The temporal and spatial position occupied by cathepsin S in immune presentation, gives rise to the hope that an inhibitor would impart selectivity with a lesser propensity for side effects than other immunosuppressive agents.

TI Prevalence and risk factors for knee osteoarthritis in elderly Japanese men and women
SO JOURNAL OF ORTHOPAEDIC SCIENCE
LA English
DT Article
ID bone-mineral density; osteoporosis; population; chingford; joint; association; weight; alpha; age
AB Background. The aims of the present study were to examine the prevalence and risk factors for knee osteoarthritis in elderly Japanese men and women. Methods. We examined 598 of the 1513 inhabitants of Miyagawa village aged >= 65 years (393 women, 205 men). Baseline data, obtained with standard questionnaires, included information on age, past history, sports activity, working, knee pain, smoking, and intakes of alcohol and milk. Bone mineral density of the forearm was measured using dual energy X-ray absorptiometry. Anteroposterior radiographs of both knees were graded for osteoarthritis using the Kellgren-Lawrence grading system. Definite osteoarthritis was defined as a grade of 2 or higher. We used logistic regression analysis by the stepwise method to determine the risk factors for radiographic knee osteoarthritis. Results. The prevalence of definite radiographic knee osteoarthritis was 30.0% overall: 17.7% in men and 36.5% in women. The prevalence of symptomatic knee osteoarthritis was 21.2% overall: 10.7% in men

and 26.7% in women. There were significant differences in the risk of radiographic knee osteoarthritis with body mass index (BMI), sex, age, and bone mineral density (BMD). Conclusions. The prevalence of definite radiographic knee osteoarthritis was 30.0% and that of symptomatic knee osteoarthritis was 21.2%. We found that higher BMI, female sex, older age, and higher BMD were significantly associated with an increased risk for radiographic knee osteoarthritis.

TI Determinants of disability chronic musculoskeletal health conditions: a literature review
SO EUROPEAN JOURNAL OF PHYSICAL AND REHABILITATION MEDICINE
LA English
DT Review
DE risk factors; low back pain; arthritis; disability evaluation
ID united-states adults; quality-of-life; low-back-pain; rheumatoid-arthritis; knee osteoarthritis; risk-factors; self-efficacy; functional disability; socioeconomic-status; psychosocial factors
AB Knowledge of the determinants of disability in musculoskeletal conditions (MSC) is critical for reducing their burden. No epidemiologic studies from a truly comprehensive perspective consider environmental factors (EF) and personal factors (PF) as determinants of disability. However, one can identify candidate EF from the International Classification of Functioning, Disability and Health (ICF) Core Sets for rheumatoid arthritis (RA), osteoporosis (OP), osteoarthritis (OA), low back pain (LBP) and chronic wide spread pain (CWP). The objective of this literature review was to contribute to the validation of the EF from the ICF Core Sets for MSC and the candidate PF from a (ICF) Delphi exercise, as well as from the report of the Bone and joint Decade (BJD) Health Strategy Project. The results of the literature search focus on reviews published between January 1991 and March 2006 that contained information on EF and PF that determine disability in LBP, RA and OA. Many PF and EF included in the ICF Core Sets were confirmed as potential determinants of disability. However, regarding some contextual factors, in particular EF referring to the physical environment, there is a lack of reviews and clinical studies that have investigated their relevance to disability. The predominant medical model in studies-on disability in MSC may explain this lack of evidence. However, the increasing attention given to the integrative model of functioning, disability and health of the World Health Organization (WHO) and the approval of the ICF by the World Health Assembly in 2001 may stimulate future research on the effect of EF and PF on disability.

TI Impact testing to determine the mechanical properties of articular cartilage in isolation and on bone
SO JOURNAL OF MATERIALS SCIENCE-MATERIALS IN MEDICINE
LA English
DT Article
ID unconfined compression; tissue inhibitor; joint fluid; modulus; load; osteoarthritis; osteoporosis; fragments; collagen; stress
AB The biomechanical response of cartilage to impact loads, both in isolation and in situ on its bone substrate, has been little studied despite the common occurrence of osteoarthritis subsequent to cartilage injury. An instrumented drop tower was used to apply controlled impact loads of different energies to explants of bovine articular cartilage. Results were compared with a conventional slow stress-strain test. The effects of the underlying bone were investigated by progressively shortening a core of bone removed with the cartilage, and by gluing cartilage samples to substrates of different moduli. The maximum dynamic modulus of isolated samples of bovine articular cartilage, at strain rates between 1100 and 1500 s(-1), was approximately two orders of magnitude larger than the quasistatic modulus and varied non-linearly with applied stress. When attached to a substrate of higher modulus, increasing the thickness of the substrate increased the effective modulus of the combination until a steady value was achieved. A lower modulus substrate reduced the effective modulus of the combination. Severe impacts resulted in damage to the bone rather than to the cartilage. The modulus of cartilage rises rapidly and non-linearly with strain rate, giving the tissue a remarkable ability to withstand impact loads. The presence of cartilage attenuated the peak force experienced by the bone and spread the impact loading period over a longer time.

TI Review of secondary physical conditions associated with lower-limb amputation and long-term prosthesis use
SO JOURNAL OF REHABILITATION RESEARCH AND DEVELOPMENT
LA English
DT Review
DE back pain; fracture; leg-length discrepancy; lower-limb amputation; osteoarthritis; osteopenia; osteoporosis; prosthetics; rehabilitation; secondary complications
ID below-knee-amputee; low-back-pain; trans-tibial amputation; leg-length discrepancy; bone-mineral density; lower-extremity amputations; weight-bearing; postural sway; residual limb; sach foot
AB Musculoskeletal imbalances or pathologies often develop into secondary physical conditions or complications that may affect the mobility and quality of life of people with lower-limb amputation. Using one or more prostheses causes people with amputation to alter the biomechanics of their movement. For example, people with lower-limb amputation often favor and stress their intact lower limb more during everyday activities. This can lead to degenerative changes such as osteoarthritis of the knee and/or hip joints of the intact limb. Since people with amputation spend less time on their residual limb, osteopenia and subsequent osteoporosis often occur secondary to insufficient loading through the long bones of the lower limb. A proper prosthetic fit increases the probability of equal force distribution across the intact and prosthetic limbs during ambulation, thus decreasing the risk of osteoarthritis. People with limb loss commonly complain of back pain, which is linked to poor prosthetic fit and alignment, postural changes, leg-length discrepancy, amputation level, and general deconditioning. We review the literature on secondary complications among people with lower-limb loss who are long-term prosthesis wearers.

TI Primary human osteoblasts and bone cancer cells as models to study glycodynamics in bone
SO INTERNATIONAL JOURNAL OF BIOCHEMISTRY & CELL BIOLOGY
LA English
DT Article
DE osteoblastic cells; osteoarthritis; cytokines; apoptosis; cell proliferation; glycoproteins; glycosyltransferases
ID growth-factor-beta; tnf-alpha; tgf-beta; endothelial-cells; human fas; glycosylation; expression; apoptosis; biosynthesis; sialoprotein
AB Bone cells produce many glycoproteins potentially involved in the maintenance of healthy bone tissues. Two cytokines produced in inflamed joints, tumor necrosis factor (TNF)alpha and transforming growth factor (TGF)beta, have previously been

shown to alter cellular glycosylation which may potentially affect the expression and function of glycoproteins. In order to evaluate models to study the glycodynamics of bone cells, we examined primary human osteoblastic cells from osteoarthritis patients, and compared these to human osteosarcoma cells MG63 and SJSA-1. We showed here for the first time that all of the human osteoblastic cells actively synthesize complex N- and O-glycan chains of bone cell glycoproteins, with quantitative differences between cell types. TNF alpha-induced apoptosis or TGF beta-induced cell differentiation and proliferation had significant effects on both cell surface carbohydrates and glycosyltransferase activities of osteoblasts and osteosarcoma cells. The results indicate that cultured human bone-derived osteoblastic cells are good models to examine the glycodynamics of osteoblasts under conditions of cell growth and cell death. The changes induced by cytokines can result in altered cell surface functions which may be of importance in osteoarthritis, osteoporosis and other bone diseases. (c) 2007 Elsevier Ltd. DE bone morphogenetic protein; bone; cartilage; frizzled related protein; osteoarthritis; synovium; wingless-type (WNT)
ID bone morphogenetic proteins; frizzled-related protein-3; tgf-beta-superfamily; articular-cartilage; osteophyte formation; proteoglycan synthesis; hip osteoarthritis; adenoviral overexpression; mechanical injury; wnt antagonist
AB Osteoarthritis is the major cause of joint failure. The outcome of the disease process is determined by complex interactions between cells and molecules steering homeostasis, destruction, restoration, and remodeling. The articular cartilage has a limited restoration and repair capacity. Genetic studies in humans and the development of mouse models have identified the role of signaling pathways that are important for skeletal development in the postnatal biology and pathology of articular cartilage. These include bone morphogenetic protein, transforming growth factor beta, fibroblast growth factor, wingless-type signaling, and their respective antagonists such as noggin and frizzled related protein. The synovium is prone to inflammation and emerging evidence suggests that innate and adaptive immune responses are important. Bone and cartilage form a biomechanical unit; stiffer bones might impair cartilage homeostasis. The biology of frizzled related protein provides a basis for the hypothesized inverse relationship between osteoarthritis and osteoporosis.

TI Prevalence & potential significance of vitamin D deficiency in Asian Indians
SO INDIAN JOURNAL OF MEDICAL RESEARCH
LA English
DT Review
DE osteomalacia; skeletal health; type 2 diabetes mellitus; vitamin D deficiency
ID bone-mineral density; inflammatory-bowel-disease; northern india; blood-pressure; parathyroid-hormone; multiple-sclerosis; d insufficiency; d-receptor; serum 25-hydroxyvitamin-d; 1,25-dihydroxyvitamin d-3
AB Studies from our center and other parts of India have drawn attention towards wide prevalence of vitamin D deficiency (VDD) in our country. VDD has been reported in all age groups including toddlers, school children, pregnant women and their neonates and adult males and females residing in rural and urban India. We reviewed implications of VDD in our population based on the preliminary data available from Indian studies on skeletal health. Besides, a brief review is made on the importance of VDD in various other disorders prevalent in equivalent proportions among Indians such as type 2 diabetes mellitus (DM), cardiovascular diseases (CVD), immune competence including relation to tuberculosis, malignancy and osteoarthritis. Data from the West have also associated VDD with increased prevalence of type 2DM, CVD, autoimmune disorders, tuberculosis, prostate, breast and colon malignancy and osteoarthritis. Such association has not been studied to date in our country. Overall results of various studies conducted to date in urban and rural Indians indicate that widely prevalent VDD is functionally relevant to skeletal health including osteomalacia and rickets. However, there is a need to

explore its association with osteoporosis related fractures and various other non skeletal disorders linked with VDD.

TI Weekly intra-articular injections of bone morphogenetic protein-7 inhibits osteoarthritis progression
SO ARTHRITIS RESEARCH & THERAPY
LA English
DT Article
ID human articular chondrocytes; anterior cruciate ligament; human osteogenic protein-1; proteoglycan synthesis; cartilage defects; rabbit knee; repair; model; op-1; rhbmp-2
AB Introduction We investigated the ability of a weekly intra-articular injection of bone morphogenetic protein (BMP)-7 to prevent osteoarthritis in rabbits with anterior cruciate ligament transections. Methods First, 36 knee joints were randomly divided into four groups: 50, 500, 5,000 ng BMP-7, and control. Knee cartilage was evaluated at 4, 8, and 12 weeks. Then, in order to control for individual differences, 500 ng BMP-7 was injected into one knee and phosphate-buffered saline (PBS) into the other, and the two knees were compared at 4, 8, and 12 weeks (n = 5). For pharmacokinetic analysis, cartilage was harvested at 1 hour and 1, 2, 4, and 7 days after knee injection of 500 ng BMP-7 or PBS (n = 3). Results Histological scores in the 500 and 5,000 ng BMP-7 groups were significantly better than those in the other groups at 12 weeks. Matched pair analysis demonstrated that both macroscopic and histological scores in the 500 ng BMP-7 group were better than those in the control group. Immunohistochemical analysis revealed higher BMP-7 expression by chondrocytes in the BMP-7 injected knees. Histology of whole knee and quantitative micro computed tomography analysis showed that weekly injections of 500 ng BMP-7 did not induce synovial fibrosis, ectopic bone, or osteophyte formation. As detected by enzyme-linked immunosorbent assay, BMP-7 concentration in the cartilage tissue was still higher in the BMP-7 treated group 7 days after the injection. Conclusions Weekly intra-articular injections of BMP-7 inhibited progression of osteoarthritis. Obvious adverse effects were not observed. BMP-7 concentration and expression in cartilage were still higher 7 days after injection.

TI Urban tropospheric ozone increases the prevalence of vitamin D deficiency among Belgian postmenopausal women with outdoor activities during summer
SO JOURNAL OF CLINICAL ENDOCRINOLOGY & METABOLISM
LA English
DT Article
ID parathyroid-hormone levels; d insufficiency; bone health; calcium; osteoporosis; 25-hydroxyvitamin-d; metabolism; prevention; exposure; sunlight

AB Context: By absorbing sunlight UVB and thereby reducing cutaneous vitamin D photosynthesis, ozone, a common urban pollutant, could cause hypovitaminosis D. Objectives: The objective of the study was to establish the characteristics and percentage of subjects with serum 25-hydroxyvitamin D [25(OH)D] less than 75 nmol/liter among postmenopausal women engaging in outdoor activities in either Brussels or the countryside. Design/Setting: This was a cross-sectional study conducted in a university research hospital. Patients/Methods: Among 249 women consulting for either shoulder tendonitis or lumbar spine osteoarthritis, 121 free of conditions and drugs affecting bone and calcium metabolism completed two food-frequency questionnaires within 15 d and we selected the 85 subjects with retest scores within the +/- 15% of test scores. Other parameters included sun exposure index (SEI), PTH levels, and femoral neck T-score. Results: Urban residents (n = 38) and rural residents (n = 47) did not differ in mean ages, body mass indices, and vitamin D intakes. When compared with rural inhabitants, urban inhabitants were exposed to ozone levels 3 times higher, and despite a higher mean SEI (113 vs. 87; P < 0.001), they had a higher prevalence of 25(OH)D less than 75 nmol/liter (84 vs. 38%). After adjusting for SEI, 25(OH)D was 2-fold higher in rural residents, and after adjusting for 25(OH)D, SEI was 3-fold higher in urban residents. Femoral neck T-scores correlated positively with 25(OH)D and negatively with PTH levels. Conclusions: Air pollution may be a neglected risk factor for hypovitaminosis D, which is known to compromise several health outcomes. As long as 25(OH)D is greater than 75 nmol/liter, calcium intakes greater than 17.5 mmol/d are unnecessary to prevent elevations in PTH levels.

TI Bone Metabolism in Postmenopausal Women With Lumbar Spinal Stenosis Analysis of Bone Mineral Density and Bone Turnover Markers
SO SPINE
LA English
DT Article
DE spinal stenosis; bone turnover rate; bone turnover marker; bone mineral density
ID peripheral arterial-disease; knee osteoarthritis; biochemical markers; hip osteoarthritis; hypovitaminosis-d; elderly-men; osteoporosis; resorption; chingford; common
AB Study Design. A cross-sectional study. Objective. To investigate bone mineral density (BMD) and the change of bone turnover rate in postmenopausal women

with lumbar spinal stenosis (LSS). Summary of Background Data. Symptomatic LSS prevents elderly patients from performing daily activities because of back pain and neurogenic claudication. Walking intolerance due to neurologic claudication might have a negative effect on bone metabolism and BMD. However, there has been no study on the relationship between LSS and bone metabolism, especially on bone turnover rate. Methods. Sixty-seven patients were in the LSS group. As a control group, 67 age- and weight-matched subjects were selected. In both groups, BMD, bone turnover markers, vitamin D, severity of knee osteoarthritis, and demographic data were obtained. In the LSS group, walking distance without rest was also recorded. BMD, bone turnover markers, vitamin D, and severity of knee osteoarthritis were compared between the two groups. In the LSS group, the correlation between walking intolerance and bone turnover markers was also analyzed. Results. In the LSS group, urinary N-terminal telopeptide of type I collagen (u-NTx) and alkaline phosphatase were significantly elevated when compared with those of the control group ($P < 0.05$). However, BMD was significantly low in the control group in all of the measured sites ($P < 0.05$). In the LSS group, neither bone markers nor BMD were correlated with the extent of walking difficulty. Conclusion. Our study highlights the fact that limited physical activity results in high bone turnover rate in patients with LSS.

TI Self reported receipt of care consistent with 32 quality indicators: national population survey of adults aged 50 or more in England
SO BMJ-BRITISH MEDICAL JOURNAL
LA English
DT Article
ID coronary-heart-disease; health-care; of-care; medical-care; management; uk; pay
AB Objective To assess the receipt of effective healthcare interventions in England by adults aged 50 or more with serious health conditions. Design National structured survey questionnaire with face to face interviews covering medical panel endorsed quality of care indicators for both publicly and privately provided care. Setting Private households across England. Participants 8688 participants in the English longitudinal study of ageing, of whorn 4417 reported diagnoses of one or more of 13 conditions. Main outcome measures Percentage of indicated interventions received by eligible participants for 32 clinical indicators and seven questions on patient centred care, and aggregate scores. Results Participants were eligible for 19082 items of indicated care. Receipt of indicated care varied substantially by condition. The percentage of indicated care received by eligible participants was highest for ischaemic heart disease (83%, 95% confidence interval 80% to 86%), followed by hearing problems (79%, 77% to 81%), pain management (78%, 73% to 83%), diabetes (74%, 72% to 76%), smoking cessation (74%, 71% to 76%), hypertension (72%, 69% to 76%), stroke (65%, 54% to 76%), depression (64%, 57% to 70%), patient centred care (58%, 57% to 60%), poor vision (58%, 54% to 63%), osteoporosis (53%, 49% to 57%), urinary incontinence (51%, 47% to 54%), fails management (44%, 37% to 51%), osteoarthritis (29%, 26% to 32%), and overall

(62%, 62% to 63%). Substantially more indicated care was received for general medical (74%, 73% to 76%) than for geriatric conditions (57%, 55% to 58%), and for conditions included in the general practice pay for performance contract (75%, 73% to 76%) than excluded from it (58%, 56% to 59%). Conclusions Shortfalls in receipt of basic recommended care by adults aged 50 or more with common health conditions in England were most noticeable in areas associated with disability and frailty, but few areas were exempt. Efforts to improve care have substantial scope to achieve better health outcomes and particularly need to include chronic conditions that affect quality of life of older people.

TI Managing comorbidity in patients with rheumatoid arthritis
SO INTERNATIONAL JOURNAL OF RHEUMATIC DISEASES
LA English
DT Article
DE clinical aspects (rheumatoid arthritis); comorbidity; rheumatoid arthritis
ID extraarticular disease manifestations; nonsteroidal antiinflammatory drugs; cardiovascular events; risk; predictors; mortality; osteoarthritis; osteoporosis; depression; celecoxib
AB Rheumatoid arthritis (RA) is a chronic inflammatory disease that decreases physical function and imposes substantial medical costs. Comorbid conditions are common in patients with RA and they adversely affect quality of life and RA-related outcomes such as work disability and mortality. Rheumatologists have the important responsibility to consider comorbidities and their risks when treating patients and to adapt therapies to the specific situation of individual patients. This paper discusses the common comorbidities in patients with RA and management approaches.

TI Fully automatic quantification of knee osteoarthritis severity on plain radiographs
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE Osteoarthritis; Knee; Diagnosis; Computer-aided diagnosis; Imaging; Plain radiograph
ID tibial cartilage volume; osteo-arthritis; bone-marrow; joint; progression; pain; impact; hip; association; symptoms
AB Objective: Although knee osteoarthritis (CA) is a major public health issue causing chronic disability, there is no objective or accurate method for measurement of the structural severity in general clinical practice. Here we have established a fully automatic program KOACAD (knee OA computer-aided diagnosis) to quantify the major OA parameters on plain knee radiographs, validated the reproducibility and reliability, and investigated the association of the parameters with knee pain. Methods: KOACAD was programmed to measure joint space narrowing at medial and lateral sides, osteophyte formation, and joint angulation. Anteroposterior radiographs of 1979 knees of a large-scale cohort population were analyzed by KOACAD and conventional categorical grading systems. Results: KOACAD automatically measured all parameters in less than 1 s without intra- or interobserver variability. All parameters, especially medial joint space narrowing, were significantly correlated with the conventional gradings. In the parameters, osteophyte formation was associated with none of the joint space parameters, suggesting different etiologic mechanisms between them. Multivariate logistic regression analysis after adjustment for age and confounding factors revealed that medial joint space narrowing and varus angulation of knee joints were risk factors for the presence of pain (594/1979 knees), while neither lateral joint space nor osteophyte area was. Conclusion: KOACAD was shown to be useful for objective, accurate, simple and easy evaluation of the radiographic knee OA severity in daily clinical practice. This system may also serve as a surrogate measure for the development of disease-modifying drugs for OA, just as bone mineral density does in osteoporosis. TI Palliative therapy of osteochondrosis dessicans in a Duroc boar
SO CANADIAN VETERINARY JOURNAL-REVUE VETERINAIRE CANADIENNE
LA English
DT Article
ID joint disease osteoarthrosis; dyschondroplasia osteochondrosis; pigs; osteoporosis; swine
AB A 2-year-old, 210-kg, Duroc boar manifested with a grade II-III left front lameness. The boar was treated systemically with isolfupredone acetate and a 5-week course of ketoprofen. The lameness resolved and the ketoprofen was discontinued; however, the lameness returned and the boar was euthanized humanely. Postmortem examination was consistent with osteochondrosis dessicans.

TI PREVALENCE OF VITAMIN D DEFICIENCY IN SOUTH ASIA
SO PAKISTAN JOURNAL OF MEDICAL SCIENCES
LA English
DT Review
DE Vitamin D deficiency; South Asia
ID bone-mineral density; breast-fed infants; secondary hyperparathyroidism; d insufficiency; northern india; pregnant-women; pakistani; norway; exposure; children
AB Vitamin D, also described as 'the Sun Vitamin' is a steroid with hormone-like activity. It regulates the functions of over 200 genes and is essential for growth and development of the body. Vitamin D deficiency is quite prevalent throughout the world, but it appears to be much worse in the countries of sunny South Asia, especially among children, women and elderly. Poor diet, cultural practices of the region and poverty are some of the important reasons for vitamin D deficiency. Hypovitaminosis D (vitamin D deficiency) is considered responsible for rickets, birth

defects, osteoporosis, osteoarthritis, osteomalacia, chronic pain and muscle pain. Recent research has associated vitamin D deficiency as a contributing factor in diseases, such as heart disease, hypertension, neurological disorders, autoimmune disease, depression and cancer. This paper reviews the problem of vitamin D deficiency with special reference to South Asia and recommends that education regarding adequate exposure to sunlight, proper diet and fortification of selected foodstuff with vitamin D may be helpful in reducing vitamin D deficiency in this part of the world.

TI The role of bone in osteoarthritis pathogenesis
SO RHEUMATIC DISEASE CLINICS OF NORTH AMERICA
LA English
DT Article
ID generalized nodal osteoarthritis; marrow edema pattern; articular-cartilage; osteophyte formation; knee osteoarthritis; subchondral bone; transient osteoporosis; radiographic features; calcified cartilage; trabecular bone
AB This article focuses on the specific skeletal features of osteoarthritis and the putative mechanisms involved in their pathogenesis. In addition, the relationship of these changes to the alterations in articular cartilage and the other tissues comprising the diarthrodial joint are reviewed.

TI Aromatase expression in osteoarthritic and osteoporotic bone
SO ARTHRITIS AND RHEUMATISM
LA English
DT Article
ID articular chondrocytes; estrogen; cartilage; therapy; replacement; estradiol; tissue
AB Objective. Estrogen deprivation is a central mechanism in the development of osteoporosis with aging. Results from recent studies also suggest the involvement of estrogens in the pathophysiology of osteoarthritis (OA). Aromatization of androgenic precursors in peripheral tissue is the main source of estrogens in postmenopausal women and in men. However, the importance of aromatase expression in bone is a subject of controversy. This study was undertaken to determine aromatase expression in bone samples from patients with hip fracture and patients with OA. Methods. We studied 104 patients with hip fracture (n = 60) or primary hip OA (n = 44). Aromatase expression was determined in trabecular bone samples from the femoral neck and in osteoblast cultures grown by the primary explant technique (n = 6.2), using real-time reverse transcriptase-polymerase chain reaction. Results. Aromatase RNA was detected in bone samples at levels similar to those found in adipose tissue. Transcript levels were significantly lower in bone tissue samples obtained from patients with OA than in those obtained from patients with fracture (P = 0.00001). Likewise, primary cultures of osteoblast cells from OA patients revealed lower aromatase expression than those of cells from fracture patients (P = 0.012). Results were independent of age or sex differences. Conclusion. Our findings indicate that. the aromatase gene is expressed in bone tissue in high amounts, similar to those found in adipose tissue, but transcript levels are lower in tissue samples and osteoblast cultures from patients with OA than in those from patients with hip fracture. Since estrogens may help to prevent local cartilage degradation, it can be speculated that such a reduced expression of aromatase could facilitate the development of OA.

TI Determination of the elemental distribution in human joint bones by SR micro XRF
SO X-RAY SPECTROMETRY
LA English
DT Article
ID x-ray-fluorescence; lead; mobilization; zinc; mineralization; osteoporosis; validation; particles; toxicity; emission
AB In humans the toxic trace element lead (Pb) mainly accumulates in the skeletal tissue where it resides for a long period. Although Pb is known to play a role in bone and cartilage diseases, the distribution Of Pb in these tissues is mostly unknown. Therefore synchrotron-radiation-induced micro x-ray fluorescence analysis (SR mu-XRF) in various geometries was used to determine the distributions of Pb, Ca, Zn and Sr at the cartilage-bone interface in human femoral heads and patellae. SR mu-XRF results were matched with backscattered electron (BE) images providing information on structural features of the tissue. Conventional SR mu-XRF at HASYLAB beamline L showed that Pb mostly accumulates in a zone of some micrometers around the transition between non-calcified and calcified cartilage. However, the relatively large sample thickness did not allow more precise conclusions. Exploiting the 3D capabilities of confocal SR mu-XRF and SR microfluorescence tomography at ANKA Fluo-Topo beamline and HASYLAB beamline L, the spatial resolution could be improved and a highly specific accumulation of Pb at the tidemark, the calcification front between non-calcified and calcified cartilage, was detected. It was found that Pb and Zn accumulation coincide at the tidemark. Since the tidemark plays an important role in

osteoarthritis, the results may strengthen other authors' conclusions that Pb is associated with this joint disease. Although offering less spatial resolution when compared to micro-tomography, confocal SR mu-XRF is best suited for such studies. It facilitates the comparison of element maps with other imaging techniques like BE imaging. Copyright (C) 2007 John Wiley & Sons, Ltd.

TI Prediction of labour and delivery by ascertaining the fetal head position with transabdominal ultrasound in pregnancies with prelabour rupture of membranes after 37 weeks
SO ULTRASCHALL IN DER MEDIZIN
LA English
DT Article
DE obstetrics; ultrasound; prelabour rupture of membranes (PROM); occiput posterior; outcome of labour
ID transvaginal digital examination; occiput posterior position; intrapartum sonography
AB Purpose: To evaluate the proportion of fetal head rotation from occiput posterior (OP) to occiput anterior (OA) during labour after term prelahour rupture of membranes (PROM), and to study if OP before labour are associated with a higher risk of operative deliveries and a longer duration of labour. Materials and Methods: A transabdominal ultrasound examination was performed in 152 women with PROM after 37 weeks with a single live fetus in cephalic position. The course of labour was compared in women with the fetal head in occiput posterior position or other positions before the start of labour. Results: Before the start of labour, 40 (26%) fetuses were in occiput posterior position (OP), but 34 (85%) of them rotated to occiput anterior (OA) during labour. Ten (6.6%) fetuses were delivered in OR and six of them were in OP before the start of labour. There were no statistically significant associations between the head position before the start of labour and the duration from PROM to delivery, induction of labour, use of epidural analgesia, augmentation with oxytocin, operative deliveries, perineal tears, Apgar scores, pH or base excess in the umbilical artery. Conclusions: Transabdominal ultrasound examination can determine the fetal head position before the start of labour, but the position of the head did not predict the course of labour, probably because the fetal head may rotate during labour even after PROM.

AB Practical procedures for treatment of fractures and dislocations have been used since the time of Hippocrates in fourth century BC. Orthopaeclic surgery became a recognized part of surgical treatment since the mid-nineteenth century, but saw major developments with the invention of x-rays and antibiotics in the early part of the twentieth century. Though orthopaeclic surgery had started with an interest in the correction of deformities in children, the major musculoskeletal problems facing orthopaedic surgery today relate to osteoarthritis, trauma (including sports injuries), and osteoporosis. The practice of orthopaeclic surgery has evolved with technology: advances in engineering and material science and increasing expectations towards faster rehabilitation have moved orthopaeclics into the era of joint replacements, arthroscopy, and less invasive surgical procedures. This chapter aims to provide an evidence-based condensed overview of the surgical management for a broad spectrum of musculoskeletal disorders encountered by primary-care clinicians and rheurnatologists.

TI Minimum joint space width and tibial cartilage morphology in the knees of healthy individuals: A cross-sectional study
SO BMC MUSCULOSKELETAL DISORDERS
LA English
DT Article
ID articular-cartilage; radiographic assessment; gender-differences; sex-differences; weight-bearing; united-states; 3 tesla; osteoarthritis; volume; adults
AB Background: The clinical use of minimum joint space width (mJSW) and cartilage volume and thickness has been limited to the longitudinal measurement of disease progression (i.e. change over time) rather than the diagnosis of OA in which values are compared to a standard. This is primarily due to lack of establishment of normative values of joint space width and cartilage morphometry as has been done with bone density values in diagnosing osteoporosis. Thus, the purpose of this pilot study is to estimate reference values of medial joint space width and cartilage morphometry in healthy individuals of all ages using standard radiography and peripheral magnetic resonance imaging. Design: For this cross-sectional study, healthy volunteers underwent a fixed-flexion knee X-ray and a peripheral MR (pMR) scan of the same knee using a IT machine (ONI OrthOne (TM), Wilmington, MA). Radiographs were digitized and analyzed for medial mJSW using an automated algorithm. Only knees scoring <= 1 on the Kellgren-Lawrence scale (no radiographic evidence of knee OA) were included in the analyses. All 3D SPGRE fat-sat sagittal pMR scans were analyzed for medial tibial cartilage morphometry using a proprietary software program (Chondrometrics GmbH). Results: Of 119 healthy participants, 73 were female and 47 were male; mean (SD) age 38.2 (13.2) years, mean BMI 25.0 (4.4) kg/m(2). Minimum JSW values were calculated for each sex and decade of life. Analyses revealed mJSW did not significantly decrease with increasing decade ($p > 0.05$) in either sex. Females had a mean (SD) medial mJSW of 4.8 (0.7) mm compared to males with corresponding larger value of 5.7 (0.8) mm. Cartilage morphometry results showed similar trends

with mean (SD) tibial cartilage volume and thickness in females of 1.50 (0.19) mu L/mm(2) and 1.45 (0.19) mm, respectively, and 1.77 (0.24) mu L/mm(2) and 1.71 (0.24) mm, respectively, in males. Conclusion: These data suggest that medial mJSW values do not decrease with aging in healthy individuals but remain fairly constant throughout the lifespan with "healthy" values of 4.8 mm for females and 5.7 mm for males. Similar trends were seen for cartilage morphology. Results suggest there may be no need to differentiate a t-score and a z-score in OA diagnosis because cartilage thickness and JSW remain constant throughout life in the absence of OA.

TI Predicting regional variations in trabecular bone mechanical properties within the human proximal tibia using MR imaging
SO BONE
LA English
DT Article
DE Trabecular bone; Proximal tibia; Bone volume fraction; MR; Mechanical properties
ID quantitative computed-tomography; high-resolution mri; in-vivo; mineral density; static alignment; femur; architecture; strength; quantification; osteoporosis
AB Trabecular bone density changes throughout the proximal tibia are indicative of several musculoskeletal disorders of the knee joint. Many of these disorders involve not only changes in the amount of bone, but also in the surrounding soft tissue. Osteoarthritis. for instance, involves bone density changes below the subchondral bone and throughout the proximal tibia, along with degradation evident in the articular cartilage. Osteoporosis, characterized by low bone density may also involve changes in bone size, structure or microarchitecture, each of which may Contribute to fracture risk. Recent studies have shown that magnetic resonance (MR) imaging, most frequently applied for soft tissue imaging, also allows non-invasive 3-dimensional characterization of bone microstructure. The purpose of the current study is to use whole joint MR images to acquire regional apparent bone volume fraction (appBVF) throughout the proximal tibia and correlate with mechanical properties measured on the corresponding ex vivo specimens. To compare our method to a high-resolution imaging modality, micro-CT analysis was performed in a subset of specimens. Using linear mixed-effects models, significant correlations ($p<0.05$) were determined between MR appBVF and Young's modulus ($r(2)=0.58$, MPSE=3633 MPa2), yield stress ($r(2)=0.73$, MPSE=1.53 MPa2) and ultimate stress ($r(2)=0.72$, MPSE=2.29 MPa2). Comparable significant correlations ($p<0.05$) were also determined between micro-CT BVF and Young's modulus ($r(2)=0.47$, MPSE=5179 MPa2), yield stress ($r(2)=0.80$, MPSE=1.23 Mpa(2)) and ultimate stress ($r(2)=0.83$, MPSE=1.76 MPa2). The current study demonstrates that MR imaging may be used as an in vivo imaging tool to determine differences in bone strength between subjects and regional variations within a single tibia. TI A Genome Wide Linkage Scan of Metacarpal Size and Geometry in the Framingham Study
SO AMERICAN JOURNAL OF HUMAN BIOLOGY
LA English
DT Article
ID quantitative trait loci; cortical bone loss; proximal hip geometry; 2nd metacarpal; body-size; gene; osteoporosis; maps; osteoarthritis; growth
AB Bone geometry is a significant component of bone strength, and has a clinical utility in predicting fractures and quantifying bone loss. Bone geometry is known to have a substantial genetic component. We performed linkage analysis to identify chromosomal regions governing metacarpal bone geometry. A genome-wide scan (with a set of 615 markers with spacing of similar to 5.7 cM) was performed on 1,702 individuals from 330 extended families of the Framingham Study. Midshaft width was measured and several indices calculated, namely Metacarpal Cortical Thickness (MCT), Cortical Index (MCI), and Section Modulus (MZ), using digitized X-rays of 1,380 participants (men, n = 666, mean age 55.2 yr, women, n = 714, 55.5 yr). Metacarpals 2, 3, and 4 were averaged. Heritability was significant for all indices, ranging from 0.51 to 0.72. Linkage analysis of indices adjusted for age, age 2, and estrogen status in women, identified chromosomal regions 6p21, 9p21, 11q21-q22, and Xq26-Xq27, with LOD scores >2.0. Additional adjustment for smoking, height, and BMI, generally reduced the LOD scores. Finally, bivariate linkage analysis confirmed that a QTL on chr. 6 (51 cM) was shared by midshaft width and MZ (LOD = 2.40, adjusted for all covariates). Neither MCT nor MCI shared linkage loci with width or MZ. In conclusion, we have identified chromosomal regions potentially linked to bone geometry. Genes in these regions may regulate bone geometry via effects on body size. Identification and subsequent characterization of loci for bone geometry can further elucidate the

genetic contributions to bone's resistance to stress. Am. J. Hum. Biol. 20:663-670, 2008. (C) 2008 Wiley-Liss, Inc.

TI Difference in femoral head and neck material properties between osteoarthritis and osteoporosis
SO CLINICAL BIOMECHANICS

LA English
DT Article
DE Femoral head; Femoral neck; Osteoarthritis; Osteoporosis; Principal compressive region; Bone mineral density
ID bone mass; mechanical-property; articular-cartilage; cancellous bone; osteo-arthritis; hip-joint; coxarthrosis; coexistence; density; femur
AB Background Osteoarthritis and osteoporosis are the two most common musculoskeletal diseases found in the aged population. It is of interest to measure and study the material properties of the femoral head and neck of these two groups, and hopefully to offer explanation of the observed phenomenon that most patients suffer from one of the two disorders, not both. Methods. Seven osteoarthritic and seven osteoporotic femoral heads were used for this study. The principal compressive region of the femoral heads were cut to determine the Young's modulus and yielding stress by a material testing machine. Comparisons between these two groups were conducted by using material properties and the properties normalized by individual patient physical parameters, including body weight, body height and femoral head diameter, respectively. The finite element model of femoral neck cuboid in OA and OP were obtained based on the micro-CT-scan cross-section. The intrinsic material properties were calculated from the solid FE models. Findings. The results showed significant differences in density, modulus and strength between the osteoarthritic and osteoporotic femoral heads as measured, with the former having 2-3 times the values of the latter. Femoral head diameter has stronger influence in mechanical properties than patient's body weight and body height. Regarding to bone volume (BV), bone surface (BS), bone volume fraction (BV/TV), trabecular thickness (Tb.Th), trabecular number (Tb.N), and true trabecular elastic modulus, the intrinsic material properties of femoral neck with OA were higher than OP. Interpretation. It is still unknown why patients do not suffer from both osteoporosis and osteoarthritis at the same time. Many studies aimed to investigate the mechanical property of two groups. However, individual difference of the femoral head and neck is too difficult to obtain a reasonable comparison between these two groups. This study investigated the two groups more quantitatively and further estimated the factors which influence mechanical properties from a biomechanical point of view. TI Long term outcomes after arthroscopic management of tibial plateau fractures
SO EUROPEAN JOURNAL OF TRAUMA AND EMERGENCY SURGERY
LA English
DT Article
ID assisted operative management; internal-fixation; open reduction; osteosynthesis; system
AB Objectives: Tibial plateau fractures are efficiently treated using arthroscopy when limited to one condyle. Operative technique and early results are now well documented. However, long term results have not been widely reported. The goal of this study was to evaluate clinical and radiological outcomes of arthroscopically treated tibial plateau fractures in the long term. Methods: Fourteen out of thirty consecutive cases have been reviewed after more than 4 years post-op (4 to 8 years). The SF8 quality of life score and both IKS and Rasmussen knee function scores have been quoted. Radiological analysis looked at Resnick and Niwoyama

osteoarthritis score. Results: Functional knee scores at follow-up were 28.0 (Rasmussen) and 187.4 (IKS) in average. The average SF8 score was 4.64. The SF8 score did not correlated with Rasmussen and IKS scores, but with age. Radiological signs of osteoarthritis were noted in 50.0% of cases, with no relationships with the clinical status. Conclusions: Comparisons with historical long-term studies regarding open reduction and internal fixation show similar outcomes. No specific secondary degenerative problem would alleviate the advantages of the arthroscopic management of tibial plateau fractures in the early post-operative period.

TI Clinical and epidemiological features of rheumatic diseases in patients attending the university hospital in Kinshasa
SO CLINICAL RHEUMATOLOGY
LA English
DT Article
DE autoimmune diseases; Congo; Gout; osteoarthritis; osteoporosis; rheumatoid arthritis
ID arthritis; prevalence; hip; osteoarthrosis; nigeria; gout
AB The aim of the present retrospective and hospital-based study was to describe epidemiological and clinical features of rheumatic diseases in patients attending the University Hospital of Kinshasa (UHK). Rheumatic complaint was a reason for consultation in 12.1% of outpatients attending the Department of Internal Medicine of the UHK. Osteoarthritis was the most common rheumatic disease (59.2%), followed by soft tissue rheumatism (16.1%), gout (9.3%), and spondylarthropathies (7.5%). The cumulative frequency of autoimmune diseases (rheumatoid arthritis, systemic lupus erythematosus, systemic sclerosis, dermatomyositis, and mixed connective tissues disease) and the frequency of osteoporosis were 5.2 and 2.7%, respectively. Lumbar spine was the part of the skeleton mostly affected by osteoarthritis. Pathological fractures in osteoporosis, subcutaneous nodules, rheumatoid factor, and erosive bone lesions in rheumatoid arthritis were rarely found. Compared to the previous studies performed in the same hospital, our results disclose a threefold increase of rheumatic outpatients. The paucity of erosive arthritis and extra-articular manifestations suggest the less severity of rheumatoid arthritis in our patients. Likewise, the absence of femoral and wrist osteoporotic fractures and the scarcity of advanced vertebral crush fractures suggest the mildness of osteoporosis.

TI Towards an ICF Core Set for chronic musculoskeletal conditions:: commonalities across ICF Core Sets for osteoarthritis, rheumatoid arthritis, osteoporosis, low back pain and chronic widespread pain
SO CLINICAL RHEUMATOLOGY
LA English
DT Article
DE chronic widespread pain; ICF; ICF Core Sets; low back pain; musculoskeletal diseases; osteoarthritis; osteoporosis; rheumatoid arthritis
AB The objective of the study was to identify commonalities among the International Classification of Functioning, Disability and Health (ICF) Core Sets of osteoarthritis (OA), osteoporosis (OP), low back pain (LBP), rheumatoid arthritis (RA) and chronic widespread pain (CWP). The aim is to identify relevant categories for the development of a tentative ICF Core Set for musculoskeletal and pain conditions. The ICF categories common to the five musculoskeletal and pain conditions in the Brief and Comprehensive ICF Core Sets were identified in three steps. In a first step, the commonalities across the Brief and Comprehensive ICF Core Sets for these conditions were examined. In a second and third step, we analysed the increase in commonalities when iteratively excluding one or two of the five conditions. In the first step, 29 common categories out of the total number of 120 categories were identified across the Comprehensive ICF Core Sets of all musculoskeletal and pain conditions, primarily in the component activities and participation. In the second and third step, we found that the exclusion of CWP across the Comprehensive ICF Core Sets increased the commonalities of the remaining four musculoskeletal conditions in a maximum of ten additional categories. The Brief ICF Core Sets of all musculoskeletal and pain conditions contain four common categories out of a total number of 62 categories. The iterative exclusion of a singular condition did not significantly increase the commonalities in the remaining. Based on our analysis, it seems possible to develop a tentative Comprehensive ICF Core Set across a number of musculoskeletal conditions including LBP, OA, OP and RA. However, the profile of functioning in people with CWP differs considerably and should not be further considered for a common ICF Core Set.

TI Significance of sagittal reformations in routine thoracic and abdominal multislice CT studies for detecting osteoporotic fractures and other spine abnormalities
SO EUROPEAN RADIOLOGY
LA English
DT Article
DE routine MDCT; spine; osteoporosis; vertebral fractures; sagittal reformations
ID radiographic vertebral fracture; multidetector ct; postmenopausal women; chest radiography; older women; back-pain; prevalence; mortality; risk; recognition
AB The purpose was to assess osteoporotic vertebral fractures and other spinal lesions in sagittal reformations obtained from routine multidetector computed tomography (MDCT) studies of the thorax and abdomen, to compare sagittal reformations with axial images in detecting these lesions and to investigate how frequently they were missed in the official radiology report. Routine abdominal or thoracoabdominal MDCT using a standard protocol was performed in 112 postmenopausal women. Axial images and sagittal reformations were analyzed separately by two radiologists in consensus and were compared in order to evaluate how often spinal lesions could be detected. In addition the official radiology reports were assessed to determine how many of those abnormalities were identified. Spine abnormalities were visualized in 101/112 postmenopausal women. In 27 patients osteoporotic vertebral deformities were found; 6 of these were shown in the axial images, but none of these were diagnosed in the official radiology report. Additional abnormalities included degenerative disc disease, osteoarthritis of the facet joints, scoliosis, hemangiomas and bone metastases. In only 9/101 patients spine abnormalities were mentioned in the radiology report. Sagittal reformations of standard MDCT images provide important additional

information on spinal abnormalities; in particular, osteoporotic vertebral deformities are substantially better detected.

TI Prevalence of Osteoporosis in Osteoarthritic Patients Undergoing Total Hip or Total Knee Arthroplasty
SO ARCHIVES OF PHYSICAL MEDICINE AND REHABILITATION
LA English
DT Article
DE Osteoarthritis; Osteoporosis; Prevalence; Rehabilitation
ID density
AB Objective: To determine the prevalence of osteoporosis in osteoarthritic patients undergoing total hip or total knee arthroplasty. Design: Cross-sectional study. Setting: The Specialized Outpatient Rehabilitation Service's (SORS) Pre-surgical Arthroplasty Service located at the Chedoke Hospital, Hamilton Health Sciences, Hamilton, ON, Canada. Participants: SORS outpatients (N=364), from the period of March 2006 to March 2007. Interventions: Not applicable. Main Outcome Measures: Prevalence of osteoporosis was determined by review of a self-reported survey, and defined by (1) self-reported diagnosis of osteoporosis, (2) history of fragility fracture (defined by a bone fracture occuring as a result of a fall from standing height or less after the age of 50), or (3) current treatment for osteoporosis using bisphosphonates. Results: Of the study cohort, 26% were classified as having osteoporosis, according to our criteria. Of the patients with self-reported osteoporosis or a history of fragility fractures, only 37% and 17% reported current treatment with bisphosphonates, respectively. Conclusions: Osteoporosis is common in the osteoarthritic arthroplasty population, with a prevalence at least equal to that in the general population. Due to the self-reported nature of the study, the prevalence of osteoporosis in this population is likely significantly higher. Results from this study indicate need for further research, specifically in formal assessment for osteoporosis in patients undergoing a joint replacement.

TI The roles of prostanoids, leukotrienes, and platelet-activating factor in bone metabolism and disease
SO PROGRESS IN LIPID RESEARCH
LA English
DT Review
DE PGE(2); osteoblast; osteoclast; osteoporosis; PAF
ID tumor-necrosis-factor; nf-kappa-b; cytosolic phospholipase a(2); collagen-induced arthritis; prostaglandin-e receptor; osteoblast-like cells; nonsteroidal antiinflammatory drugs; osteoclast-like cells; protein-kinase-a; colony-stimulating factor
AB The production of a variety of lipid mediators is enhanced in bone-resorptive diseases such as osteoporosis, rheumatoid arthritis, osteoarthritis, and periodontitis. Prostaglandin E-2 (PGE(2)) is one of the most notable lipid mediators of bone remodeling, and has been linked clinically to many bone-resorptive diseases. In vitro studies with bone cell cultures have demonstrated that the bone-resorptive activity of PGE2, which is mediated by receptor activator of NF-kappa B ligand (RANKL), is key for the induction of osteoclast formation. Furthermore, interleukin (IL)-1- and IL-6-stimulated bone resorption involves PGE2 production. In addition to its bone-resorptive effects, PGE2 promotes bone formation in vitro by stimulating osteoblastic proliferation and differentiation. The multifaceted nature of PGE2 makes it difficult to discern its role during bone remodeling. Leukotrienes (LTs), and particularly LTB4, have also been implicated in bone remodeling and disease-specifically in rheumatoid arthritis. Moreover, recent studies from our laboratory have shown that platelet-activating factor (PAF) receptor-deficient mice develop only mild osteoporosis. Osteoclast survival in these mice is shortened and osteoclastic bone resorption is impaired. This review article focuses on these families of lipids and their function during bone metabolism and disease. (c) 2007 Elsevier Ltd. All rights reserved.

TI Bone mineral density and singh index predict bone mechanical properties of human femur
SO CONNECTIVE TISSUE RESEARCH
LA English
DT Article
DE bone density; Singh index; mechanical load; bone architecture
ID cancellous bone; femoral-head; in-vitro; osteoporosis; strength; osteoarthritis

AB The aim of our study was to assess the predictive value of the Singh index (SI), which estimates bone architecture, and bone density (BMD) when dealing with the mechanical competence of bone and to analze possible differences in bone properties between gender in humans. The relationship between SI, BMD, and mechanical competence was analyzed in 106 bone cylinders from 37 human femoral heads obtained during hip-joint replacement surgery for low energy fracture or for osteoarthritis. Bones from osteoporotic patients are less dense and more brittle compared with bones from osteoarthritic patients, as expected. Among osteoporotic patients female bones were more brittle than those from males, although BMD was similar. In osteoarthritic patients there were no significant differences among sexes. Bone mechanical competence varies according to BMD and to SI categories. Thus, our study suggests that bone strength is predicted by both BMD and bone architecture.

TI Hand osteoarthritis and bone mineral density in postmenopausal women; clinical relevance to hand function, pain and disability

SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE hand osteoarthritis; osteoporosis; AUSCAN
ID x-ray absorptiometry; rheumatoid-arthritis; knee osteoarthritis; elderly-men; osteoporosis; hip; population; scale; risk; epidemiology
AB Objective: The aim of the present study was to assess phalangeal bone mineral density (BMD) in postmenopausal females with hand osteoarthritis (OA) and to correlate the measured levels with the radiographic OA grade, pain, function and disability of the hand. Methods: The study group constituted 40 postmenopausal women with hand CA (range; 45-83 years). Socio-demographic data were collected. They underwent a comprehensive clinical examination of joint status and health outcome measure including Australian Canadian (AUSCAN) CA hand index. Hand radiographs were quantified and graded according to Kellgren and Lawrence (K-L) scoring system. Bone mineral content (BMC) and BMD of the third finger were measured using the accuDEXA (Schick, New York, NY). Twenty females matched for age and years of menopause were studied as a control group. Results: Phalangeal BMC and BMD were significantly reduced in women with hand CA compared to controls and related to radiological erosive OA. The AUSCAN pain and function subscales were worse in proportion to the severity of hand OA. CA X-ray score was significantly associated with reduced right grip strength, pain, and function scales while, decreased BMD was related to Ritchie index and pain scale. Conclusion: Postmenopausal women with clinical and radiological hand erosive OA are at risk of development of hand osteoporosis (OP). Phalangeal bone densitometry is an objective reproducible investigation. Poor physical function due to increased pain associated with increasing severity of radiographic hand CA leads to worse BMD results. (c) 2007 Osteoarthritis Research Society International. TI Biochemical markers of bone turnover and their association with bone marrow lesions
SO ARTHRITIS RESEARCH & THERAPY
LA English
DT Article
ID radiographic knee osteoarthritis; collagen metabolism; subchondral bone; mineral density; progression; cartilage; osteoporosis; degradation; osteocalcin; prediction
AB Introduction Our objective was to determine whether markers of bone resorption and formation could serve as markers for the presence of bone marrow lesions (BMLs). Methods We conducted an analysis of data from the Boston Osteoarthritis of the Knee Study (BOKS). Knee magnetic resonance images were scored for BMLs using a semiquantitative grading scheme. In addition, a subset of persons with BMLs underwent quantitative volume measurement of their BML, using a proprietary software method. Within the BOKS population, 80 people with BMLs and 80 without BMLs were selected for the purposes of this case-control study. Bone biomarkers assayed included type I collagen N-telopeptide (NTx) corrected for urinary creatinine, bone-specific alkaline phosphatase, and osteocalcin. The same methods were used and applied to a nested case-control sample from the Framingham study, in which BMD assessments allowed evaluation of this as a covariate. Logistic regression models were fit using BML as the outcome and biomarkers, age, sex, and body mass index as predictors. An receiver operating characteristic curve was generated for each model and the area under the curve assessed. Results A total of 151 subjects from BOKS with knee OA were assessed. The mean (standard deviation) age was 67 (9) years and 60% were male. Sixty-nine per cent had maximum BML score above 0, and 48% had maximum BML score above 1. The only model that reached statistical significance used maximum score of BML above 0 as the outcome. Ln-NTx (Ln is the natural log) exhibited a significant association with BMLs, with the odds of a BML being present increasing

by 1.4-fold (95% confidence interval = 1.0-fold to 2.0-fold) per 1 standard deviation increase in the LnNTx, and with a small partial R-2 of 3.05. We also evaluated 144 participants in the Framingham Osteoarthritis Study, whose mean age was 68 years and body mass index was 29 kg/m(2), and of whom 40% were male. Of these participants 55% had a maximum BML score above 0. The relationship between NTx and maximum score of BML above 0 revealed a significant association, with an odds ratio fo 1.7 (95% confidence interval = 1.1 to 2.7) after adjusting for age, sex, and body mass index. Conclusions Serum NTx was weakly associated with the presence of BMLs in both study samples. This relationship was not strong and we would not advocate the use of NTx as a marker of the presence of BMLs.

TI Quantitative assessment of bone marrow edema-like lesion and overlying cartilage in knees with osteoarthritis and anterior cruciate ligament tear using MR imaging and spectroscopic imaging at 3 tesla
SO JOURNAL OF MAGNETIC RESONANCE IMAGING
LA English
DT Article
DE bone marrow edema-like lesion; MR spectroscopic imaging; T-1p; knee; osteoarthritis; anterior cruciate ligament tear
ID acutely injured knee; articular-cartilage; lipid characterization; high prevalence; soccer players; fat-content; relaxation; bruises; pain; osteoporosis
AB Purpose: To quantitatively assess bone marrow edema-like lesion (BMEL) and the overlying cartilage in osteoarthritis (OA) or anterior cruciate ligament (ACL)-injured knees using magnetic resonance imaging (MRI) and spectroscopic imaging (MRSI). Materials and Methods: Eight healthy controls and 30 patients with OA and other injuries who showed BMEL were scanned at 3.0T. A regression model was constructed to automatically calculate the volume of BMEL. Normalized Tip z-scores were calculated within BMEL-overlying cartilage. Three-dimensional (3D) MRSI was acquired in the BMEL and surrounding bone marrow. Results: The mean Ti z-score was significantly higher in BMEL-overlying cartilage than that in surrounding cartilage in the lateral tibia of patients with ACL tears ($P < 0.001$). Significantly elevated' water and unsaturated lipids, and decreased saturated lipids were observed in BMEL. The volume of elevated water correlated with the volume of BMEL. Water content was significantly higher within BMEL than that outside BMEL. The unsaturation index outside BMEL was significantly higher in patients with ACL tears than that in OA. Conclusion: 3D MRSI and Tip mapping provide tools to quantitatively evaluate BMEL in OA and knee injury. This may allow us to better understand pathophysiology and evolution of injuries and degenerative conditions of the knee.

TI Effect of prayer on osteoarthritis and osteoporosis
SO RHEUMATOLOGY INTERNATIONAL
LA English
DT Article
DE prayer; osteoarthritis; osteoporosis
ID bone-mineral density; knee osteoarthritis; postmenopausal women; hip osteoarthritis; weight; risk; men
AB Prayer is one kind of worship that is composed of repetitive action during praying in Islam. The prayer is performed five times a day, every Friday, bairams and death ceremonies. The aim of this study is to search the role of this repetitive action on knee, hip osteoarthritis and osteoporosis. Forty-six patients who had been performing the prayer at least for 10 years, and 40 patients who had not performed the prayer, were included in this prospective study. Each patient was evaluated with standard questionnaire form, joint examination was done and various laboratory parameters were studied. Anterior-posterior radiography of the pelvis and weight-bearing knees of each patient were examined. Each film was evaluated by two investigators separately and first scored by using Kellgren and Lawrence (K&L) scale, then the width of the joint space of hips and knees were measured directly using a steel ruler and recorded to the nearest half millimeter. Bone mineral density (BMD) of lumbar spine and femur was measured. Patients having Heberden's nodes, Bouchard's nodes, and carpometacarpal disease were frequent in worshiper group. Joint space width measurements and assessment according to K&L scale did not differ between worshipers and non-worshipers. BMD of lumbar spine was decreased in worshipers and also decreased with patients having Heberden's nodes, Bouchard's nodes, female gender and age. Prayer has no effect on knee and hip osteoarthritis, and may be related with hand osteoarthritis. It seems to have negative effect on lumbar BMD, but further investigations are needed.

TI A review of the efficacy of tiludronate in the horse
SO JOURNAL OF EQUINE VETERINARY SCIENCE
LA English
DT Review
ID pagets-disease; double-blind; foot pain; bisphosphonates; bone; multicenter; prevention; mechanisms
AB Tiludronate is a compound in the bisphosphonate class of drugs. The main pharmacologic action of bisphosphapoptosis and disrupt intercellular trafficking of proinflammatory mediators. Bisphosphonates are used to treat humans with diseases such as osteoporosis and Paget's disease. Recently tiludronate has been studied as a treatment for bone resorptive diseases in horses. Tildren, an injectable form of tiludronate made for the horse, has been licensed to treat navicular disease and distal tarsal osteoarthritis in Europe. Some clinical studies have been completed to assess the efficacy of tiludronate in the horse. Many of the studies are reviewed here, and their standards of research are evaluated individually. Tiludronate may be beneficial in managing lameness isolated to the navicular bone and distal tarsal osteoarthritis by decreasing bone resorption and inflammation.

DT Article
DE anterior knee pain; bilateral; insufficiency fracture; patella
ID rates; risk
AB Bilateral patellae fractures represent a rare entity, accounting for approximately 2.9% of all lesions interesting in this anatomical district. In most cases found in the published work, they are described as stress fractures or as complications of chronic diseases such as osteoporosis, renal failure and secondary hyperparathyroidism. Although many pathogenetic mechanisms have been supposed, none have been proved for certain. Insufficiency fractures of the patellae are rare events and no data has been published on their incidence. We present a case of bilateral fracture of the patellae due to an indirect trauma occurring in an 85-year-old patient affected by Parkinson's disease, osteoporosis and diffuse degenerative osteoarthritis. X-ray of the knees (anteroposterior and lateral) and magnetic resonance imaging evaluation confirmed the fractures. The patient was treated conservatively. She had a good result, returning to her previous autonomous ambulation. This case is unusual because there was no direct trauma to the knees because of bilaterality, but confirmed previous observations about insufficiency fractures of patellae in the presence of comorbidity. Insufficiency fractures of patellae can be an insidious condition in elderly people. Prepatellar pain, a common symptom in the relapse phase of degenerative arthritis of the knee, should not be underestimated, particularly in patients with diseases influencing metabolism of bone and with an elevated risk of fall. A periodical clinical and instrumental follow up should be done in these patient. Moreover, we underline the necessity of a multidisciplinary approach.

TI Tai Chi Chuan exercises in enhancing bone mineral density in active seniors
SO CLINICS IN SPORTS MEDICINE
LA English
DT Article
ID quantitative computed-tomography; muscle strength; postmenopausal women; physical-activity; jogging exercise; balance; prevention; walking; falls; osteoarthritis
AB Osteoporosis is a silent, systemic, chronic disease characterized by low bone mass and structural deterioration of bone tissue. Its clinical and public health implications are substantial because of the mortality, morbidity, and medical care cost associated with osteoporotic fractures. Although estrogen-replacement therapy or anti-bone resorptive drugs can prevent postmenopausal bone loss, they also show side effects. Physical activity is an nonpharmacological approach for prevention of osteoporosis. Among different types of physical activities, Tai Chi Chuan (TCC) is a low- to moderate-intensity exercise particularly suitable for the elderly, and has been practiced by Chinese for centuries. This article reviews the benefits of TCC for the prevention of osteoporosis and falls by retarding bone loss, improving neuromuscular coordination, and promoting general health.

TI Polymorphisms in the promoter regions for human MMP-1 and MMP-13 lead to

differential responses to the alpha and beta isoforms of estrogen receptor and their ligand in vitro
SO BIOCHIMICA ET BIOPHYSICA ACTA-MOLECULAR BASIS OF DISEASE
LA English
DT Article
DE polymorphism; MMP-13; ER-alpha; ER-beta; 1G; 2G; gene regulation
ID matrix metalloproteinase-1 promoter; single nucleotide polymorphism; anterior cruciate ligament; breast-cancer cells; articular-cartilage; gene-expression; ovariectomized rats; transcription; osteoarthritis; collagenase-1
AB Estrogen receptors (ER) are present in connective tissues and therefore it is possible that the loss of estrogen after menopause influences the integrity of these tissues, contributing to development of degenerative conditions such as osteoporosis and osteoarthritis in a subset of women. Aberrant expression of matrix metalloproteinases (e.g. MMP-1 and MMP-13) has been implicated in the progression of these diseases. The present study investigated potential molecular mechanisms involved in the regulation of expression of MMP-1 and MMP-13 promoter variants by ER-alpha and ER-beta (+/-estrogen) in a transient transfection system. The results demonstrate that the activity of human MMP-1 and MMP-13 polymorphic variants is elevated in the presence of ER-alpha and ER-beta and the single nucleotide polymorphisms present in the promoters of MMP-1 and MMP-13 variants leads to differential activities in response to the ER isoforms. Furthermore, the influence of 17-beta estradiol also varies depending upon whether the alpha or the beta isoform of ER is the modulator of these polymorphic variants. These findings support the conclusion that ER isoforms may be contributing to disease development and/or progression in genetically distinct subsets of women following menopause, and provide mechanistic insights into how such contributions are manifested. TI Muscle Mass Is More Strongly Related to Hip Bone Mineral Density Than Is Quadriceps Strength or Lower Activity Level in Adults Over Age 50 Year
SO JOURNAL OF CLINICAL DENSITOMETRY
LA English
DT Article
DE Allometric scaling; bone mineral density; muscle mass; physical activity level; quadriceps strength; rehabilitation
ID postmenopausal women; body-size; physical-activity; proximal femur; older-adults; young-women; exercise; weight; osteoporosis; population
AB This cross-sectional study examined whether reduced hip bone mineral density (BMD) is better explained by isokinetic knee extensor strength (KES), lower limb

lean body mass (L-LBM). or Physical Activity Scale for the Elderly (PASE). Through population-based recruitment, 1543 adults without knee osteoarthritis were recruited. For men and women respectively, means +/- SD were age 60.8 +/- 8.0 and 61.1 +/- 7.9 yr: body mass index 29.6 +/- 4.6 and 29.1 +/- 5.4 kg/m(2): hip BMD 1.025 +/- 0.138 and 0.895 +/- 0.128 g/cm(2): KES 124.9 +/- 41 and 72.7 +/- 22.9 N . m: L-LBM 10.3 +/- 1.5 and 7.0 +/- 1.2 kg: and PASE 206.4 +/- 99.7 and 163.8 +/- 77.0. The relationship between BMD and KES in men (r(2) = 0.21, p >= 0.002) and women (r = 0.23, p < 0.001) was significant before adjustment. However, this association was no longer significant after controlling for L-LBM. Even after controlling for age, race, and sex, the association between BMD and KES was better explained by L-LBM (partial R-2 = 0.14, p < 0.001) than by PASE (partial R-2 = 0.00). Allometric scaling of KES to body size attenuated the association of BMD with KES (Std Beta = 0.03). The significant association between BMD and L-LBM (Std Beta = 0.36) remained stronger than that between BMD and weight (Std Beta = 0.21). Therefore, muscle mass accounted for a greater proportion of the variance in hip BNID than KES or activity level and explained a significant proportion of the association between weight and BMD.

TI Adaptations in trabecular bone microarchitecture in olympic athletes determined by 7T MRI
SO JOURNAL OF MAGNETIC RESONANCE IMAGING
LA English
DT Article
DE fuzzy distance transform; digital topology; trabecular bone; olympic fencers; fracture risk; osteoporosis; osteoarthritis
ID reveals structural implications; fuzzy distance transform; in-vivo; topological analysis; articular-cartilage; cortical bone; osteoporosis; architecture; calcaneus; radius
AB Purpose: To produce in vivo high-resolution images of the knee and to determine the feasibility of using 7T MR to detect changes in trabecular bone

microarchitecture in elite athletes (Olympic fencers) who undergo high impact activity. Materials and Methods: The dominant knees of four males from the U.S. Olympic Fencing Team and three matched healthy male controls were scanned in a 7T whole-body scanner using a quadrature knee coil with three-dimensional (3D) fast low angle shot (FLASH): 50 axial images at the distal femur (0.156 mm x 0.156 mm) and 80 axial images at the knee joint (0.195 mm x 0.195 mm). Bone volume fraction (BVF) and marrow volume fraction (MVF) images were computed and fuzzy distance transform (FDT) and digital topological analysis (DTA) were applied to determine: trabecular number (Tb.N), trabecular thickness (Tb.Th), and trabecular separation (Th.Sp); BVF (BV/TV); trabecular and marrow space surface-to-curve ratio (SC, marker of plate to rod ratio); and trabecular and marrow space erosion index (El, inverse marker for network connectivity). Quadriceps muscle volume (MV) was calculated as well. We calculated group means and performed two-tailed t-tests to determine statistical significance. Results: Compared to controls, fencers had: decreased Th.Sp ($P = 0.0082$ at femur, $P = 0.051$ at joint); increased Tb.N ($P < 0.05$ at both femur and joint) and BV/TV ($P < 0.001$ at both femur and joint): increased trabecular SC and decreased marrow space SC ($P < 0.01$ at both femur and joint); decreased trabecular El and increased marrow space El ($P < 0.01$ at both femur and joint); and increased MV ($P = 0.038$). There was no difference in Tb.Th at the distal femur ($P = 0.92$) or joint ($P = 0.71$) between groups. Conclusion: To our knowledge, this is the first study to perform 7T MRI of the knee in vivo. Elite athletes who undergo high impact activity have increased MV and improved trabecular bone structure compared to controls.

TI Nonunion of the femoral neck: Possibilities and limitations of the various treatment modalities
SO INDIAN JOURNAL OF ORTHOPAEDICS
LA English
DT Review
DE Fracture neck femur; nonunion; osteotomy; prosthetic replacement
ID failed internal-fixation; total hip-replacement; intertrochanteric osteotomy; non-union; fractures; adults; femur; head
AB Nowadays in cases of nonunions of the femoral neck, the surgeon is tempted to perform prosthetic replacement of the hip, more so if there is also evidence of avascular necrosis of the head of femur. This provides rapid pain relief and allows early mobilization. However, long-term results of hip arthroplasties, especially in younger people and in the presence of osteopenia, are not always as expected; and a less radical approach is worth considering. The intertrochanteric valgization osteotomy, described by Pauwels, is an excellent alternative for healthy patients up to 65 years of age with a nonunion of the femoral neck. A union rate of 80-90 of the nonunion is described by most authors. Leg length inequallity, rotational and angular deformities can be corrected at the same time. During the period

1973-1995, we performed valgization osteotomy according to Pauwels in 66 patients of, 18-72 years old (mean 49.5 years). 24 (37) of our patients died 4 months to 24 years (mean: 9.5 years) after the operation. Union of the femoral neck was achieved in 58 (88) of the 66 patients; union of the osteotomy in 65 patients (99). A good or excellent result was achieved in 62 (23 uneventful and 13 with healed, necrosis/arthrosis without need for further treatment) of our patients. However, the method has its limits. We feel if there is too little bone stock inside the femoral head, a valgization osteotomy does not give good result. The radiographic signs of avascular necrosis in patients over 30 years of age is considered a contraindication for an osteotomy. However our results show that it is worthwhile trying to save the joint of young patients even in case of a segmental collapse. In the race between revascularization and collapse, often revascularization is the winner. We deliberately give nature its chance and dont rely on the result of bleeding from drill holes in the head, nuclear scans and other methods to estimate vascularity. A secondary total hip replacement if necessary because of avascular necrosis or osteoarthritis is considerably postponed; and better milieu for hip replacement can be achieved by the development of sclerotic bone in the subchondral areas of the acetabulum and femoral head. Between 65 and 80 years of age, a total hip replacement is probably the best option for fit patients. We treat fresh femoral neck fractures with a hemiarthroplasty in patients over the biological age of 80 years. Logically the same choice will be made for patients with a nonunion. During the period 1973-1995 we performed hemiarthroplasty (n = 34) in patient with low general condition. Their mean age was 79 years. The average survival in these patients was less than three years and that explains probably the low late complication rate: in this group. Total hip replacement was performed in 37 younger patients with a mean age of 69 years. They were not considered for a valgization osteotomy because of age being over 70 years, severe osteoporosis or a total collapse of the femoral head. In this group, we observed one aseptic cup revision and two extractions of the prosthesis because of a deep infection.

TI The protective effect of OP-1 on articular cartilage in the development of osteoarthritis
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE OP-1; osteoarthritis; cartilage; chondrocytes
ID human osteogenic protein-1; bone morphogenetic protein-7; arthritic human hips; metabolic abnormality; gene-expression; rabbit knee; chondrocytes; repair; model; defects
AB Objective: The purpose of this study was to determine whether osteogenic protein 1 (OP-1) would protect articular cartilage from degeneration during the development of osteoarthritis (OA) in the rabbit anterior cruciate ligament transection (ACLT) model. Previous studies have shown that OP-1 is vital to cartilage matrix integrity and repair, stimulates synthesis of cartilage matrix components, proteoglycans, and collagen, and has a protective effect against catabolic mediators like matrix metalloproteinases and interleukin-1. Methods: The rabbit ACLT model was used in which the anterior cruciate ligament was transected leading to OA. OP-1 was delivered to the joint surgically for approximately 6 weeks by implantation of an Alzet osmotic pump into the medial thigh with a catheter threaded from the pump into the knee joint. Forty rabbits (20 control and 20 experimental) had the ACLT surgery and implantation of the pump performed simultaneously. They were sacrificed after 9 weeks for analysis. The OA was graded using the Outerbridge classification with India Ink staining. Histological staining

and histomorphometry with Hematoxylin & Eosin and Safranin 0 were performed to analyze OA progression and semi-quantitative polymerase chain reaction (PCR) was performed for anabolic and catabolic genes. Results: The experimental group had an average Outerbridge score of 1.8 vs 2.5 for the controls (P < 0.05). Histomorphometry showed 10.9% surface deterioration or an average depression of 0.05 mm vs 22.3% and 0.1 mm for the controls (P < 0.05). Semi-quantitative PCR showed a significantly greater expression of aggrecan and collagen type II in the OP-1 treated cartilage when compared to controls and less expression of aggrecanase, a catabolic mediator. Conclusions: OP-1 may have a potential benefit in protecting articular cartilage during the development of OA. (C) 2007 Osteoarthritis Research Society International. Published by Elsevier Ltd. TI Analysis of Cartilage Oligomeric Matrix Protein (COMP) in Synovial Fluid, Serum and Urine from 51 Racehorses with Carpal Bone Fracture
SO JOURNAL OF VETERINARY MEDICAL SCIENCE
LA English
DT Article
DE COMP; equine; fracture; osteoarthritis; urine
ID county osteoarthritis project; knee osteoarthritis; thoroughbreds; joint; degradation; fragments; collagen; horses
AB We investigated the relationship between cartilage oligomeric matrix protein (COMP) levels in synovial fluid (SF), serum and urine and the development of osteochondral damage and osteophyte (OP) formation following intraarticular fractures of the carpus in racehorses in order to assess the clinical usefulness of COMP as a diagnostic biomarker of developmental osteoarthritis (OA). Two monoclonal antibodies (mAb clones 2A 11 and 3C8) raised against equine COMP were shown to be capable of detecting the molecule in serum and urine as well as SF. Fifty-one samples were obtained from 26 OP-positive (OP(+)) and 25 OP-negative (OP(-)) racehorses with carpal bone fracture, in whom OP was ascertained arthroscopically and radiographically. The COMP measurements obtained using the two mAbs were highly correlated with each other in SF, serum, or urine. Horses with OP(+) showed a significantly higher [urinary COMP (mu

g)]/[urinary creatinine (mg)] ratio (4.94 +/- 5.10 and 1.46 +/- 1.19, using mAbs 2A 11 and 3C8, respectively) than OP(-) horses (2.80 +/- 1.72 and 0.93 +/- 0.49, respectively). The relationship between serum and urine COMP levels and the period from injury to surgery were extrapolated using a polynomial expression. Measurement of COMP, especially in urine, has potential as a predictive marker of advanced OA following carpal bone fractures in racehorses.

TI Bone mineral density is not related to severity of osteoarthritis in the knee in postmenopausal women
SO RHEUMATOLOGY INTERNATIONAL
LA English
DT Article
DE bone density; knee; osteoarthritis; osteoporosis; postmenopause
ID hip; osteoporosis; association; hand; end

AB Although some studies have suggested that osteoporosis and osteoarthritis are inversely related in epidemiologic terms, a spectrum of relations between the two diseases has been described in this study. In 95 postmenopausal women (mean age 64.4 +/- 8.49 years, range 49-83 years), we investigated the relation between bone mineral density (BMD) in the femoral neck and lumbar vertebrae (L2-L4) and osteoarthritis in the knee. BMD was measured with dual X-ray absorptiometry. Osteoarthritis was evaluated with anterior-posterior weight-bearing radiographs with the knee in extension, and these were graded for severity on a 5-point scale according to the Kellgren-Lawrence criteria. We found no clear statistical relation between BMD in the femoral neck or lumbar vertebrae and osteoarthritis in the knee. Given that some studies have found BMD to be significantly higher in patients with osteoarthritis, the lack of such relation in our patients may be due to environmental and/or genetic factors.

TI Rapid in vivo musculoskeletal MR with parallel imaging at 7T
SO MAGNETIC RESONANCE IN MEDICINE
LA English
DT Article
DE 7 Tesla; GRAPPA; trabecular bone micro-architecture; cartilage
ID to-noise ratio; trabecular bone; 3 tesla; grappa
AB The purpose of this work was to implement autocalibrating GRAPPA-based parallel imaging (PI) for in vivo high-resolution (HR) MRI of cartilage and trabecular bone micro-architecture at 7T and to evaluate its performance based on comparison of MR-derived morphology metrics between accelerated and conventional images and comparison of geometry factor measures between 3T and 7T. Using an eight channel coil array for trabecular MRI at the ankle, a higher maximum feasible acceleration (R) = 6 and lower geometry factor values than that at 3T were observed. The advantages of two-dimensional acceleration were also demonstrated. In knee cartilage and bone acquisitions, feasibility of PI with a dual-channel quadrature coil was investigated. Robust quantification of bone and cartilage metrics could be derived from accelerated ankle and knee acquisitions. PI can enhance the clinical feasibility of in vivo bone and cartilage HR-MRI for osteoporosis and osteoarthritis at 7T.

TI Cortical and trabecular bone distribution in the femoral neck in osteoporosis and osteoarthritis
SO BONE
LA English
DT Article
DE Femoral neck; Osteoporosis; Arthritis; fracture; Bone architecture
ID cancellous bone; hip fracture; computed-tomography; structural basis; proximal femur; connectivity; age; histomorphometry; architecture; mechanisms
AB The increased hip fragility in osteoporosis has been attributed mainly to a thinning of the cortex. In contrast, hip arthritis (OA) is not associated with increased risk of hip fracture. The purpose Of this Study was to assess cortical and trabecular

bone structures and their possible regional variability in the femoral neck taken from patients who Sustained an osteoporotic hip fracture (OP) compared with patients with OA. When compared the distribution of bone in the ultradistal femoral neck in 21 postmenopausal women with OA (mean age: 66 +/- 7.8 years) and 20 postmenopausal women with an osteoporotic hip fracture (011) (mean age: 79.5 +/- 1.9 years), Controlateral hip osteoporosis or osteopenia was confirmed in OP by DEXA (T-score: -2.5 +/- 0.8 in OP: -0.9 +/- 1.3 in OA). Histomorphometric parameters of bone Structure, architecture and connectivity were measured on sections from the ultradistal part of the femoral neck, divided in 4 quadrants. When compared to OA, cortical thickness was significantly decreased in OP ($p < 0.0005$) but was the highest in the inferior part in both groups. Cortical porosity was higher in CIA (13.48 +/- 1.02 and 8.4 +/- 1.07% in OA and OP respectively). Compared to CA, the trabecular bone volume was decreased by 50% in OP ($p < 0.0001$) with a diminution of the trabecular number ($p < 0.01$) and thickness ($p < 0.0001$). In parallel, OP group Was characterized by a poor connectivity evaluated by the decreased number of nodes ($p < 0.0001$). higher trabecular bone pattern factor ($p < 0.0001$) and greater marrow star volume ($p < 0.0001$).The connectivity was the lowest in the inferior quadrant in OP but not in CA. Our data suggest that in addition to the cortical thinning, the loss of the trabecular bone mass and connectivity plays a role in the skeletal fragility associated with hip fracture. Furthermore, the spatial distribution of the trabeculae differs between OP and OA whereas cortical thinning is homogenous. (c) 2008 Elsevier Inc. All rights reserved.

TI Calcitonin - A drug of the past or for the future? Physiologic inhibition of bone resorption while sustaining osteoclast numbers improves bone quality

SO BIODRUGS
LA English
DT Article
ID vertebral fracture risk; spray salmon-calcitonin; postmenopausal women; established osteoporosis; mineral density; alendronate treatment; oral delivery; antiresorptive therapy; antinociceptive activity; biochemical markers
AB Postmenopausal osteoporosis results from a continuous imbalance between bone resorption and bone formation, favoring bone resorption. An increasing, number of treatments for osteoporosis are in development and on the market. A range of differences and similarities are found between these treatment options, and these need to be carefully evaluated before the initiation of treatment. This article summarizes data from in vitro and animal studies, as well as clinical trials, on the effect of calcitonin on bone turnover. Calcitonin was found to exert its antiresorptive effects via directly reducing osteoclastic resorption, and thus leads to an increase in bone mineral density and bone strength. Furthermore, calcitonin appears to mainly target the most active osteoclasts, and in contrast to most other antiresorptive agents it does not reduce the number of osteoclasts. Finally, in humans, while attenuating resorption, calcitonin treatment does not interfere markedly with bone formation, in contrast to other currently available antiresorptive agents. Thus, we speculate that calcitonin treatment will lead to a continuously positive bone balance in contrast with other antiresorptive agents currently on the market and thereby, in a physiologic manner, result in improved bone quality. Calcitonin is currently only available in injectable and nasal formulations. An oral formulation may, however, improve patient acceptance and compliance. Currently, several different routes are being pursued to identify an optimal oral formulation, of which the technology based on 5-CNAC is the most advanced. There are promising clinical data available for this formulation from both osteoarthritis and osteoporosis clinical trials, although the antifracture efficacy is not yet known.

TI Predictors of podiatry utilisation in Australia: the North West Adelaide Health Study
SO JOURNAL OF FOOT AND ANKLE RESEARCH
LA English
DT Article
AB Background: Foot problems are highly prevalent in the community; however no large population-based studies have examined the characteristics of those who do and do not access podiatry services in Australia. The aim of this study was to explore patterns of podiatry utilisation in a population-based sample of people aged 18 years and over living in the northwest region of Adelaide, South Australia. Methods: The North West Adelaide Health Study is a representative longitudinal cohort study of 4,060 people randomly selected and recruited by telephone interview. The interview included questions regarding healthcare service utilisation in the past year. Data were also collected on education, income and major medical conditions. Results: Overall, 9.5% of the total sample and 17.7% of those who reported foot pain had attended a podiatrist in the past year. Participants who had

accessed podiatry treatment were more likely to be female, be aged over 45 years, be obese, and have major chronic medical conditions (osteoporosis, osteoarthritis, diabetes, cardiovascular disease and high blood pressure). Those who reported foot pain but had not accessed a podiatrist were more likely to be male and be aged 20 to 34 years. Conclusion: Only a small proportion of people who report foot pain have accessed podiatry services in the past year. There is a need to further promote podiatry services to the general community, particularly to men and younger people.

TI A type I collagen defect leads to rapidly progressive osteoarthritis in a mouse model
SO ARTHRITIS AND RHEUMATISM

DT Article
ID bone-mineral density; radiographic knee osteoarthritis; subchondral bone; articular-cartilage; osteogenesis imperfecta; hip osteoarthritis; murine model; risk-factors; osteoporosis; damage
AB Objective. This study was undertaken to test the hypothesis that abnormalities of the subchondral bone can result in osteoarthritis (OA). Methods. We used a knockin model of human osteogenesis imperfecta, the Brittle IV (Brtl) mouse, in which defective type I collagen is expressed in bone. OA in individual mice was documented by micro-magnetic resonance imaging (micro-MRI) and micro-computed tomography (micro-CT). Alterations in the knee joints were confirmed by histopathologic and immunohistochemical analysis. In addition, atomic force microscopy (AFM) was used to assess the ultrastructure of the articular cartilage and subchondral bone matrix. Results. Brtl mice had decreased integrity of bone but initially normal articular cartilage. However, by the second month of life, Brtl mice developed alterations of the cartilage that were characteristic of OA, as documented by micro-CT, micro-MRI, and histologic evaluation. In addition, chondrocyte loss and breakdown of the collagen matrix in

the residual cartilage were demonstrated using AFM. Conclusion. The Brtl mouse model demonstrates that progressive destruction of articular cartilage characteristic of OA may be secondary to altered architecture of the underlying subchondral bone.

ID bone-mineral density; vertebral fracture risk; double-blind; postmenopausal osteoporosis; nonvertebral fractures; knee osteoarthritis; glucosamine sulfate; hip fracture; women; progression
AB Strontium ranelate is a new agent developed for the management of post-menopausal osteoporosis. It has a unique mode of action, based on an uncoupling between bone formation (increased) and bone resorption (decreased). To review its effectiveness we searched the MEDLINE database from 1985 to 2008, as well as databases such as the Cochrane controlled register, for citations or relevant articles. After this extensive search of the literature, a critical appraisal of the data was obtained through a consensus meeting (AN, MH, SS, OB, and J-YR). We found that strontium ranelate reduces vertebral, nonvertebral, major nonvertebral, and hip fractures over 1, 3, 4, and 5 years. Its spectrum of activity covers women with osteopenia, osteoporosis, and severe osteoporosis. Elderly subjects also show a reduction in vertebral and nonvertebral fractures. Bone mineral density may be used as a monitoring tool for strontium ranelate, since early changes are predictive of long-term fracture reduction. Biochemical markers of bone turnover reflect the uncoupling between resorption and formation. The safety profile of strontium ranelate compares favorably with the other currently marketed antiosteoporosis medications. Preliminary results suggest that strontium ranelate is able to reduce the progression of spine osteoarthritis. In conclusion, strontium ranelate has the potential to be a candidate for first-line treatment of osteopenia and osteoporosis. However, further research is needed before suggesting its widespread use in osteoarthritis.

TI Synthesis and characterization of amorphous octakis-functionalized polyhedral oligomeric silsesquioxanes for polymer nanocomposites
SO POLYMER
LA English
DT Article
DE amorphous; nanoparticles; nanocomposites
ID hybrid nanocomposites; poss copolymers; oligosilsesquioxanes; octasilsesquioxanes; crystallization; nanoparticles; alcohol
AB We have synthesized the polyhedral oligomeric silsesquioxane (POSS) derivatives OS-POSS and OA-POSS through the hydrosilylation of styrene and 4-acetoxystyrene, respectively, with octakis(dimethylsiloxy)-silsesquioxane (Q(8)M(8)(H)). We then prepared OP-POSS through acetoxyl hydrazinolysis of OA-POSS with hydrazine monohydrate. The chemical structures of these POSS derivatives were characterized using FTIR and H-1 NMR spectroscopy and MALDI-TOF mass spectrometry. Unlike Q(8)M(8)(H), which is crystalline, these three hydrosilylated POSS derivatives are liquids at 25 degrees C. Through DSC and XRD analyses, we found that they exhibit polymer-like glass transitions and amorphous halos. These octakis-functionalized POSS derivatives can be regarded as amorphous glasses possessing low glass transition temperatures, the values of which depend on the intermolecular interactions of their outer organic groups. To investigate the dispersion of these POSS derivatives in polymer nanocomposites, we blended OS-POSS, OA-POSS, and OP-POSS with polystyrene, poly(4-acetoxystyrene), and poly(4-vinylpyridine), respectively, and investigated the effects of the resulting intermolecular aromatic hydrophobic, dipole-dipole, and hydrogen-bonding interactions, respectively. Dipole-dipole interactions provided the best dispersion of OA-POSS in poly(4-acetoxystyrene), in which the POSS-polymer intermolecular interactions were of similar strength to the POSS-POSS interactions. TI Type I Collagen α1 Sp1 Polymorphism and the Risk of Cruciate Ligament Ruptures or Shoulder Dislocations
SO AMERICAN JOURNAL OF SPORTS MEDICINE
LA English
DT Article
DE cruciate ligament rupture; shoulder dislocation; polymorphism; gene; collagen
ID bone-mineral density; single-nucleotide polymorphisms; binding-site polymorphism; d-receptor gene; osteogenesis imperfecta; osteoporotic fractures; postmenopausal women; association; col1a1; osteoarthritis
AB Background: Cruciate ligament ruptures and shoulder dislocations are often caused by trauma, but predisposing intrinsic factors might also influence the risk. These injuries are more common in those with a previously injured sibling, an observation that might indicate a genetic predisposition. It is well known that polymorphisms in the collagen I gene are associated not only with osteoporosis and osteoporotic fracture risk, but also with osteoarthritis. Hypothesis: Because collagen I is abundant in ligaments and tendons, the authors hypothesized that collagen I alpha 1 Sp1 polymorphism also was related to the occurrence of cruciate ligament ruptures and shoulder dislocations. Study Design: Case-control study; Level of evidence, 3. Methods: A total of 358 patients and 325 randomly selected population-based female controls were included in the study. Of the cases, 233 had a cruciate ligament rupture and 126 had had a shoulder dislocation. Age-adjusted odds ratios (ORs) with 95% confidence intervals (CIs) estimated by unconditional logistic regression were used as measures of association. Results: Compared with the homozygous SS category, the heterozygous participants displayed a similar risk (OR, 1.06; 95% CI, 0.76-1.49), whereas the ss genotype was underrepresented in the injured population compared with the controls (OR, 0.15; 95% CI, 0.03-0.68). This latter estimate was similar for both cruciate ligament ruptures and shoulder dislocations, and was furthermore not modified by general joint laxity. Conclusion: The authors found a substantially decreased risk of these injuries associated with collagen type I a1 Sp1 polymorphism. The study might encourage other investigators to consider further research in the area of genes and soft tissue injuries.

TI Total knee arthroplasty in osteogenesis imperfecta: Case report
SO KNEE
LA English
DT Article
DE Osteogenesis imperfecta; Total knee arthroplasty; Joint osteoarthritis; Dwarfism; Osteoporosis
ID replacement; bone
AB Osteogenesis imperfecta (OI) is a rare congenital disorder of type I Collagen production that results in brittle bones and affects body systems containing collagen. The increasing life span of patients with OI has recently revealed a high incidence of osteoarthritis of the knee. A 53 year-old man with OI presented with bilateral knee pain. He had severe deformities of the proximal part of the femur with subsegment post-traumatic osteoarthritis of both sides of the knees. However, the frequency of fracture gradually decreased and he had not experienced a fracture for 17 years. His bone mineral density was extremely low for his age. He underwent cemented total knee arthroplasty (TKA) on the left knee. One year later, the patient had relief of pain and lie Could walk Without assistance. To our knowledge, only three knee replacements in two patients with OI have been reported, so this case is extremely, rare. Although whether a patient with OI is a Suitable candidate for knee replacement, it was a useful treatment for osteoarthritis in this case. (C) 2008 Elsevier B.V. All rights reserved.

TI Quality of life assessments with SF 36 in different musculoskeletal diseases
SO CLINICAL RHEUMATOLOGY
LA English
DT Article
DE musculoskeletal disorders; quality of life; SF-36
ID health-status; rheumatoid-arthritis; knee osteoarthritis; classification; osteoporosis; fibromyalgia; population; criteria
AB The aim of this study is to evaluate comparatively the life quality of patients with knee osteoarthritis (KO), shoulder impingement syndrome(SIS), fibromialgia(FM), or osteoporosis(OP) using SF 36 and establish the impact of these diseases on quality of life (QoL). A total of 193 patients with one of the above-mentioned different diagnoses completed SF 36 scale. The diseases were compared to each other with SF 36 subgroups scores. There were significant differences among patients with KO and SIS,SIS and FM with respect to all SF 36 subgroups scores. According to these assessments, QoL of KO and FM patients was worst than that of SIS. The QoL scores of KO patients were worse than those of FM patients considering the physical function, while QoL scores of FM patients were lower than those of KO patients with respect to their general well-being. Scores of physical function and pain in KO patients were lower than those of OP patients. In domains of social functioning, emotional role, energy, pain, and general health condition QoL of FM patients was worse than that of OP patients. Quality of life of SIS patients was less affected than the patients of the other disease groups. In spite of their young age, FM patients appear to be the group with the worst quality of life scores.

TI Effects of strontium ranelate on spinal osteoarthritis progression

SO ANNALS OF THE RHEUMATIC DISEASES
LA English
DT Article
ID lumbar disc degeneration; knee osteoarthritis; postmenopausal women; double-blind; cartilage degradation; glucosamine sulfate; placebo; osteoporosis; trial; risk
AB Objective: The aim of this study was to determine whether a 3-year treatment with strontium ranelate could delay the progression of spinal osteoarthritis (OA). Methods: This study was a post-hoc analysis of pooled data from the Spinal Osteoporosis Therapeutic Intervention (SOTI) and TReatment Of Peripheral OSteoporosis (TROPOS) trials performed on 1105 women with osteoporosis and concomitant radiological spinal OA at baseline, and for whom lumbar x-rays were available at baseline and over the 3-year treatment period. The presence and severity of osteophytes, disc space narrowing and sclerosis in the lumbar intervertebral spaces was graded according to a validated method, and an overall OA score was calculated for each intervertebral space. Back pain (measured on a five-point Likert scale only in SOTI) and health-related quality of life (SF-36 questionnaire) were assessed at baseline and after 3 years. Patients who suffered an incident or progressive vertebral fracture during the study were excluded from the analysis. Results: The proportion of patients with worsening overall spinal OA score was reduced by 42% in the strontium ranelate group, compared with placebo (RR, 0.58; 95% CI, 0.42 to 0.79; p= 0.0005). Significantly more patients in the strontium ranelate group experienced an improvement in back pain after 3 years, compared with placebo (p= 0.03), while no significant difference was observed in terms of health-related quality of life between these patient groups. Conclusions: The results of this post-hoc analysis suggest that strontium ranelate could reduce the progression of the radiographic features of spinal OA and back pain in women with osteoporosis and prevalent spinal OA.

TI MRI-detected subchondral bone marrow signal alterations of the knee joint: terminology, imaging appearance, relevance and radiological differential diagnosis
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Review
DE Bone marrow lesion; Bone marrow edema; Magnetic resonance imaging; Knee;

Osteoarthritis; Cartilage; Trauma
ID regional migratory osteoporosis; of-the-literature; spontaneous osteonecrosis; articular-cartilage; osteochondritis-dissecans; cruciate ligament; injured knee; follow-up; arthroscopic meniscectomy; rheumatoid-arthritis
AB Objective: To discuss terminology, radiological differential diagnoses and significance of magnetic resonance imaging (MRI)-detected subchondral bone marrow lesions (BMLs) of the knee joint. Methods: An overview of the published literature is presented. In addition, the radiological appearance and differential diagnosis of subchondral signal alterations of the knee joint are discussed based on expert consensus. A recommendation for terminology is provided and the relevance of these imaging findings for osteoarthritis (OA) research is emphasized. Results: A multitude of differential diagnoses of subchondral BMLs may present with a similar aspect and signal characteristics. For this reason it is crucial to clearly and specifically define the type of BML that is being assessed and to use terminology that is appropriate to the condition and the pathology. In light of the currently used terminology, supported by histology, it seems appropriate to apply the widely used term "bone marrow lesion" to the different entities of subchondral signal alterations and in addition to specifically and precisely define the analyzed type of BML. Water sensitive sequences such as fat suppressed T2-weighted, proton density-weighted, intermediate-weighted fast spin echo or short tau inversion recovery (STIR) sequences should be applied to assess non-cystic BMLs as only these sequences depict the lesions to their maximum extent. Assessment of subchondral non-cystic ill-defined BMLs on gradient echo-type sequences should be avoided as they will underestimate the size of the lesion. Differential diagnoses of CA related BMLs include traumatic bone contusions and fractures with or without disruption of the articular surface. Osteonecrosis and bone infarcts, inflammation, tumor, transient idiopathic bone marrow edema, red marrow and post-surgical alterations should also be considered. Conclusion: Different entities of subchondral BMLs that are of relevance in the context of OA research may be distinguished by specific imaging findings, patient characteristics, symptoms, and history and are discussed in this review. TI EVALUATION OF BONE MECHANICAL STRENGHT AND FRACTURE RISK ASSESSMENT [FRAX®] IN PATIENTS WITH HIP JOINT REPLACEMENT SURGERY
SO ACTA REUMATOLOGICA PORTUGUESA
LA English
DT Article
DE Mechanical Tests; Osteoporosis; Hip Fracture; Fragility Fracture; FRAX (R)
ID femoral-head; osteoporosis; quality; matrix; women
AB Background: Fracture risk assessment tools are useful to calculate the long term probability of osteoporotic fracture. However, how it reflects bone quality is unknown. The aim of this study was to correlate the WHO clinical fracture risk assessment tool, FRAX (R), with bone mechanical properties. Methods: Six patients submitted to hip replacement surgery, either due to osteoporotic fractures or to osteoarthritis, were evaluated. Bone samples were collected and the mechanical properties assessed by compression tests. Patients' data regarding the presence of clinical risk factors for fracture were registered. Laboratorial assessment of bone metabolic parameters and a dual X-ray absorptiometry (DXA) were done. Results: Analysis of the load-displacement curves showed that patients with fragility fractures (n=4) had low values of elastic modulus, yield load and energy absorbed until yield point. Osteoarthritis patients tend to have a better biomechanical performance. Femoral neck DXA scan was also performed in 3 patients. Fragility fracture patients had a lower bone mineral density than the patients with osteoarthritis. FRAX (R) algorithm was applied and a positive relation was found between FRAX (R) results and biomechanical parameters. Blood bone metabolic Conclusions: The worse mechanical properties observed in the fragility fracture patients were related to high probability of fracture given by FRAX (R). These observations, in a very small sample, need further confirmation. However, they suggest that the fracture risk assessment tool, FRAX (R), may reflect the current mechanical bone behavior of the patient.

TI Scenes from the Past The Medici Project: Radiographic Survey
SO RADIOGRAPHICS
LA English
DT Article
ID idiopathic skeletal hyperostosis; hyper-ostosis; risk-factors; dish; florence; disease; gout
AB The remains of 12 members of the grand ducal (junior) branch of the Florentine Medici family were exhumed in 2003 as part of the Medici Project, a multidisciplinary study whose aim was to investigate the lifestyles, health status, and possible causes of death of members of one of the richest, most powerful families of the Italian Renaissance. Digital radiography and orthopantomography were performed on the skeletal remains of individuals who lived between 1562 and 1666. The observed bone malformations, deformities, and changes (degenerative, metabolic, and dental) challenge traditional views, based on portraits and historical accounts, about the appearance and lifestyle of some family members. Moreover, the occurrence of a constellation of bone changes related to diabetes (osteoporosis, osteoarthritis, diffuse idiopathic skeletal hyperostosis, cranial hyperostosis, and crystalline arthropathy) suggests that this metabolic disease was common in the grand ducal branch of the Medici family.

TI Predictive value of femoral head heterogeneity for fracture risk
SO BONE
LA English
DT Article
DE Human; Osteoporosis; Femoral head; Bone parameters; Micro-CT
ID cancellous bone; trabecular bone; mechanical-property; elastic property; proximal femur; hip-fractures; osteoporosis; osteoarthritis; architecture; morphology
AB Osteoporosis (OP) is characterized by low bone mass and weak bone structure, which results in increased fracture risk. It has been suggested that osteoporotic bone is strongly adapted to the main loading direction and less adapted to the other directions. In this Study, we hypothesized that osteoporotic femoral heads have 1) an increased anisotropy: 2) a more heterogenic distribution of bone volume fraction (BV/TV) throughout the femoral head; and, 3) a more heterogenic distribution of the trabecular thickness (Tb.Th.) throughout the femoral head, as compared to non-osteoporotic bone. To test these hypotheses, we used 7 osteoporotic femoral heads from patients who fractured their femoral neck and 7 non-fractured femoral heads from patients with osteoarthrosis (OA). Bone structural parameters from the entire trabecular region were analyzed using microCT. We found that the degree of anisotropy was higher in the fractured femoral heads, i.e. 1.72, compared to a value of 1.61 in the non-fractured femoral heads. The BV/TV and Tb.Th. and their variations throughout the femoral head, however, were all significantly lower in the fractured group. Hence, the first hypothesis was confirmed, whereas the other two were rejected. Interestingly, the variation of Tb.Th. throughout the femoral head provided a 100% discrimination between the OP and OA groups, i.e. for the same BV/TV, all fractured cases had a less heterogenic distribution. In conclusion, our results suggest that bone loss in OP takes place uniformly throughout the femoral head, leading to an overall decrease in bone mass and trabecular thickness. Furthermore, the variation of Tb.Th. in the femoral head could be an interesting parameter to improve the prediction of fracture risk in the proximal femur. (C) 2009 Elsevier Inc. TI Comparison of the analgesic effects of bisphosphonates: etidronate, alendronate and risedronate by electroalgometry utilizing the fall of skin impedance
SO JOURNAL OF BONE AND MINERAL METABOLISM
LA English
DT Article
DE Pain; Skin impedance; Etidronate; Alendronate; Risedronate
ID corticosteroid-induced osteoporosis; intravenous pamidronate; joint pain; bone;

disease; back
AB Analgesic effects of etidronate, alendronate and risedronate were compared in patients with osteoporosis and/or osteoarthritis by measuring the fall of skin impedance along with conventional subjective pain-estimation by visual rating scale (VRS). One hundred ninety-nine postmenopausal women consulting the Osteoporosis and Osteoarthritis Clinic of Katsuragi Hospital complaining of back and/or knee pain were randomly divided into four groups; Group A (49 subjects) given 5 mg/day alendronate, Group E (50 subjects) 200 mg/day etidronate, Group R (50 subjects) 2.5 mg/day risedronate and Group P no bisphosphonate. None of the four groups showed significant deviation from others as to age and parameters of bone metabolism. Proportions of subjects with osteoporosis was 18-40%. Those with osteoarthritis of the spine and knee, higher than Grade II according to the Nathan and Lawrence-Kellgren scale, respectively, was 45 and 61%, respectively, without a significant difference among the four groups. Significant positive correlation was found between the fall of skin impedance and pain expressed in VRS. Attenuation of exercise-induced fall of skin impedance and also subjective pain expressed in VRS was greatest in Group E with a highly significant difference from Groups A ($P = 0.0002$ and $P < 0.0001$), R ($P < 0.0001$ and $P = 0.0014$) and P ($P < 0.0001$ and $P < 0.0001$). Neither A nor R showed significant difference from P as to the fall of skin impedance. Among the three bisphosphonates tested, etidronate appeared to be outstanding in analgesic effects.

TI Data base to aid of diagnosis of osteoporotical changes in human pelvic bone
SO JOURNAL OF VIBROENGINEERING
LA English
DT Article
DE osteoporosis; osteoarthritis
AB The aim of the work is the facilitation of identification the osteoporotical changes which can contribute to earlier detection of osteoporosis. In the paper the

most important information and the main foundations of system to aid of diagnosis of osteoporosis in human pelvic bone are presented. The starting point in modeling of osteoporotical changes is the data from QCT (Quantitative Computed Tomography). The numerical model of analyzed structure is created by conversion of CT images. The next step of work is performing of the strength calculations. The obtained results (distributions of the stresses, strains and displacements) enables to notice the changes in physiological structure of pelvic bone and detecting dangerous states. The essence of aid of diagnosis the osteoporosis is on the base subordinating CT images suitable the effort of the pelvis bone.

TI Osteoarthitis of Leptin-Deficient ob/ob Mice in Response to Biomechanical Loading in Micro-CT
SO INTERNATIONAL JOURNAL OF BIOLOGICAL SCIENCES
LA English
DT Article
DE Bone mineral density; leptin; biomechanical loading; micro-CT; mice
ID cancellous bone; computed-tomography; microcomputed tomography; hypothalamic relay; trabecular bone; serum leptin; obese gene; rat model; mass; chondrocytes
AB Objective: Mechanotransduction is the mechanism that due to reacting chondrocytes on biomechanical loading of body mass. Higher biomechanical loading lead to increased degeneration of chondrocytes, whereas moderate loading is protecting. This suggests that body fat regulates bone metabolism first by means of hormonal factors and second that the effects of muscle and loading are signaling factors in mechanotransduction. Leptin, a peptide hormone produced predominantly by white fat cells, is one of these hormonal factors. The aim of this study was to investigate and measure the different effects of weight-bearing on trabecular bone formation in mice without the stimulation of leptin and with or without osteoarthritis. Materials and methods: 40 C57BL/ 6J ob/ob-mice in the age of 20 weeks have been devided into two groups with an ad-libitum-diet and with reduced diet. The hip- and knee-joints have been examinated in micro-CT-scan and histomorphologically. Results: Animals with an ad-libitum-diet were found to increase body weight significantly at the age of six weeks in comparison with lean mice. At the age of twenty weeks the obese mice were almost twice as heavy as the lean mice. Significant statistical differences are shown between the two groups for body weight and bone mineral density. Examination of trabecular bone in micro-CT revealed that the only statistically significant difference between the two groups

was the trabecular number for the proximal femur. High weight-bearing insignificantly improved all trabecular bone parameters in the obese mice. Correlation was found between trabecular number and bone mineral density on the one hand and body weight on the other hand. The correlation between body weight and osteoarthritis shows a significant increase in grade of osteoarthritis as body weight increases in hip- joint and knee-joint but not in osteoarthritis-positive (OP) versus osteoarthritis-negative (ON) mices. The correlation of the hip- joint between micro-CT data and body weight shows an increase in these data as body weight increases in OP mices. The correlation of the hip- joint between micro-CT data and osteoarthritis shows a decrease in these data as osteoarthritis increases in OP mices. The correlation of the knee-joint between micro-CT data and body weight shows differencies between ON and OP mices. The correlation of the knee-joint between micro-CT data and osteoarthritis shows an increase in these data as osteoarthritis increases in OP mices. Conclusion: biomechanical loading led to decreased bone mineral density by a decrease in the number of trabeculae. Trabecular thickness was not increased by biomechanical loading in growing mice. Decreased body weight in leptin-deficient mice protects against bone loss. This finding is consistent with the principle of light-weight construction of bone. Differences in osteoarthritis-positive and osteoarthritis-negative mices show the eventual importance of diet in leptin-deficience. It is not possible to conclude that these results also apply to human beings.

ID generalized nodal osteoarthritis; marrow edema pattern; articular-cartilage; osteophyte formation; knee osteoarthritis; subchondral bone; transient osteoporosis; radiographic features; calcified cartilage; trabecular bone
AB Much of the attention in developing diagnostic tools and therapeutic interventions for the management of osteoarthritis (OA) has focused on the preservation or repair of articular cartilage. It is clear that all of the joint components, including the ligaments, tendons, capsule, synovial lining, and periarticular bone, undergo structural and functional alterations during the course of OA progression. This article focuses on the specific skeletal features of OA and the putative mechanisms involved in their pathogenesis.

TI Long-term needs of adult patients with organic acidaemias: outcome and prognostic factors
SO JOURNAL OF INHERITED METABOLIC DISEASE
LA English
DT Article
ID propionic acidemia; successful pregnancy; methylmalonic acidemia; inborn-errors; management; acidurias; metabolism; genotype; disease; mut(-)
AB Background: With improvements in the treatment of children with organic acidaemias (OA), the number surviving to adulthood is increasing. To plan appropriate services for their care it is important to know what their needs are. Objective: To describe the clinical and social problems affecting adult patients with OA. Patients and methods: We reviewed the medical records of 15 adult patients diagnosed with OA. Social attainment (housing, schooling and occupation) was analysed. Nutritional status was evaluated by body mass index (BMI) and laboratory studies. Neurological and visceral complications were noted. Cognitive outcome was evaluated by psychometric testing and/or educational attainment. Results: Seven had methylmalonic acidaemia (MMA), 4 isovaleric acidaemia (IVA) and 4 propionic acidaemia (PA). Ten were female, and median age was 23.5 years (range 18-48). All but three had late-onset disease. Two patients became pregnant during follow up. Four patients had obtained university degrees and were working. Three-quarters of the patients required some kind of social support. All had a good nutritional status. Height was normal in IVA and 3 PA patients. Osteoporosis was present in 2 out of 8 patients assessed. A variety of neurocognitive or visceral complications were seen in two-thirds of the patients. Metabolic decompensations were unusual. Conclusions: The approach to adult patients with OA has to be

multidisciplinary, with the clinician and dietician as the core of the team, but with the collaboration of clinical nurses specialists, social workers and other specialist services and the support of a biochemical and molecular laboratory.

TI Novel insights into thyroid hormones from the study of common genetic variation
SO NATURE REVIEWS ENDOCRINOLOGY
LA English
DT Review
ID type-2 deiodinase; insulin-resistance; serum tsh; thr92ala polymorphism; levothyroxine therapy; targeted disruption; cerebral-cortex; free-thyroxine; dio2; association
AB Effects of thyroid hormones in individual tissues are determined by many factors beyond their serum levels, including local deiodination and expression and activity of thyroid hormone transporters. These effects are difficult to examine by traditional techniques, but a novel approach that exploits the existence of common genetic variants has yielded new and surprising insights. Convincing evidence indicates a role of type 1 iodothyronine deiodinase (D1) in determining the serum T(4):T(3) ratio and a role of phosphodiesterase 8B in determining TSH levels. in addition, studies of type 2 iodothyronine deiodinase (D2) variants have shown that thyroid hormones contribute to osteoarthritis and these variants influence intelligence quotient alterations associated with iodine deficiency. Preliminary evidence suggests associations between TSH-receptor variants and fasting glucose level, D1 variants and insulin-like growth factor I production, and D2 variants and hypertension, psychological well-being and response to T(3) or T(4) treatment.

intriguingly, most of these associations are independent of serum thyroid hormone levels, which highlights the importance of local regulation of thyroid hormones in tissues. Future research might reveal novel roles for thyroid hormones in obesity, cardiovascular disease, osteoporosis and depression and could have implications for interpretation of thyroid function tests and individualization of thyroid hormone replacement therapy.

TI The relationship between bone marrow edema size and knee pain
SO KNEE SURGERY SPORTS TRAUMATOLOGY ARTHROSCOPY
LA English
DT Article
DE Bone marrow edema; Knee; Activity pain; Rest pain; Size of edema
ID mr-imaging findings; spontaneous osteonecrosis; transient osteoporosis; osteoarthritis; lesions
AB The purpose of our study was to determine the changes in the size of the edema observed on MRI scans and its relation to the activity pain of the patient and the rest pain in bone marrow edema (BME). A total of 51 patients were followed up at 3-month intervals for a period of 1 year. During the follow-ups, MRI scans of the patients' knees were obtained; the scores obtained on the Stanmore functional rating scale and visual analog scale were determined. The changes in these parameters and the correlation between them were examined. The following are the observations recorded during the bone marrow edema follow-ups: the size of the edema as observed on MRI scans decreased, and the activity pain and the rest pain decreased. While there is a correlation between the decrease in the edema size observed on MRI scans and decrease in the activity pain, there is no correlation between the decrease in the edema size observed on MRI scans and the decrease in rest pain. No changes were observed after a particular period of time with regard to decrease in the edema size observed on MRI scans, decrease in activity pain, and decrease in rest pain in follow-ups of BME patients.

TI Prevalence of knee osteoarthritis, lumbar spondylosis, and osteoporosis in Japanese men and women: the research on osteoarthritis/osteoporosis against disability study
SO JOURNAL OF BONE AND MINERAL METABOLISM
LA English
DT Article
DE Epidemiology; Prevalence; Establishment of population-based cohort; Osteoarthritis; Osteoporosis
ID bone-mineral density; community; fracture; britain; spine
AB Musculoskeletal diseases, especially osteoarthritis (OA) and osteoporosis (OP), impair activities of daily life (ADL) and quality of life (QOL) in the elderly. Although preventive strategies for these diseases are urgently required in an aging society, epidemiological data on these diseases are scant. To clarify the prevalence of knee osteoarthritis (KOA), lumbar spondylosis (LS), and osteoporosis (OP) in Japan, and estimate the number of people with these diseases, we started a large-scale population-based cohort study entitled research on osteoarthritis/osteoporosis against disability (ROAD) in 2005. This study involved the collection of clinical information from three cohorts composed of participants located in urban,

mountainous, and coastal areas. KOA and LS were radiographically defined as a grade of a parts per thousand yen2 by the Kellgren-Lawrence scale; OP was defined by the criteria of the Japanese Society for Bone and Mineral Research. The 3,040 participants in total were divided into six groups based on their age: a parts per thousand currency sign39, 40-49, 50-59, 60-69, 70-79, and a parts per thousand yen80 years. The prevalence of KOA in the age groups a parts per thousand currency sign39, 40-49, 50-59, 60-69, 70-79, and a parts per thousand yen80 years 0, 9.1, 24.3, 35.2, 48.2, and 51.6%, respectively, in men, and the prevalence in women of the same age groups was 3.2, 11.4, 30.3, 57.1, 71.9, and 80.7%, respectively. With respect to the age groups, the prevalence of LS was 14.3, 45.5, 72.9, 74.6, 85.3, and 90.1% in men, and 9.7, 28.6, 41.7, 55.4, 75.1, and 78.2% in women, respectively. Data of the prevalence of OP at the lumbar spine and femoral neck were also obtained. The estimated number of patients with KOA, LS, and L2-L4 and femoral neck OP in Japan was approximately 25, 38, 6.4, and 11 million, respectively. In summary, we estimated the prevalence of OA and OP, and the number of people affected with these diseases in Japan. The ROAD study will elucidate epidemiological evidence concerning determinants of bone and joint disease.

TI Femoral Neck Stress Fractures
SO OPERATIVE TECHNIQUES IN SPORTS MEDICINE
LA English
DT Article
DE stress fractures; femoral neck; sports; minimally invasive
ID dynamic hip screw; military recruits; fatigue fractures; bone; management; injury; athlete; scintigraphy; fixation; adults
AB Stress fractures of the femoral neck account for roughly 5% of all stress fractures, affecting prevalently young, active, healthy, individuals Ge, recreational runners, endurance athletes, or military recruits), patients with metabolic bone disease, and older people with osteoporosis. In these stress fractures, the repetitive stress on the bone is greater than the ability of the bone to sustain the load and repair the microtrauma. Stress fractures of the femoral neck can be difficult to diagnose because of the diffuse and radiating pain and nonspecific findings on clinical examination. Early diagnosis has a pivotal role. MRI is useful to evaluate an early fatigue injury and to grade its recovery, with findings that can range from marrow edema to a frank fracture line. The most important risk in case of misdiagnosis is a progression to a displaced fracture: these require urgent surgery, and, if left untreated, may cause disastrous complications, including osteonecrosis of the femoral head, delayed-union, mal-union, non-union, varus deformity, and osteoarthritis. TI The effect of surface immobilized bisphosphonates on the fixation of hydroxyapatite-coated titanium implants in ovariectomized rats
SO BIOMATERIALS
LA English
DT Article
DE Bisphosphonate; Immobilize; Hydroxyapatite; Implant; Osteoporosis
ID total hip-arthroplasty; joint replacement; bone-resorption; in-vitro; osteoporosis; pamidronate; delivery; osteoarthritis; necrosis; cells
AB Immobilized bisphosphonates (BPs) have been introduced to improve implant fixation, however, no information could be found about the efficiency of this approach in osteoporotic bone. This study was designed to evaluate the bone response to surface immobilized BPs on implants inserted in tibiae of ovariectomized (OVX) rats. Three months after bilateral ovariectomy, 40 rats were randomly assigned into four groups for implantation of hydroxyapatite-coated titanium implants with or without immobilized BPs: (1) control group (without BP treatments); (2) pamidronate (PAM) group (1 mg/ml of PAM immersing); (3) ibandronate group (1 mg/ml of ibandronate immersing); and (4) zoledronic acid (ZOL) group (1 mg/ml of ZOL immersing). After implantation periods of 3 months, the peri-implant-bone density, trabecular microstructure, bone-implant interface and mechanical fixation of implants were evaluated by dual energy X-ray absorptiometry, micro-computed tomography, histology and push-out test. We

found that three BPs triggered pronounced bone-implant integration and early bone formation around implants in OVX rats, with a rank order of ZOL > ibandronate > PAM. These results provide new evidence that immobilized BPs have positive effects on implant fixation in osteoporotic bone, in addition to their well-documented potency to inhibit implant loosening in normal bone. DT Article
DE POSS; Nanoparticles; Miscibility
ID t-g increase; crystallization kinetics; miscibility enhancement; thermal-property; hybrid polymers; phase-behavior; blends; poss; methacrylate); resin
AB We synthesized the polyhedral oligomeric silsesquioxane (POSS) derivatives octakis[dimethyl(phenethyl)siloxy]silsesquioxane (OS-POSS), octakis[dimethyl(4-acetoxy phenethyl)siloxy]silsesquioxane (OA-POSS), and octakis[dimethyl(4-hydroxyphenethyl)siloxy] silsesquioxane (OP-POSS) through hydrosilylation with octakis(dimethylsiloxy)silsesquioxane (Q(8)M(8)(H)). To investigate the influence of these octuply functionalized POSS derivatives in polymer nanocomposites, we blended OP-POSS, OA-POSS, and OP-POSS with the homopolymer poly(ethylene oxide) (PEO) and characterized its resulting intermolecular interactions (e.g., hydroxyl-ether and carbonyl-ethylene oxide) using FTIR spectroscopy. The thermal properties of these blend systems were investigated using differential scanning calorimetry (DSC) and dynamic mechanical analysis (DIVA). The crystallization kinetics in the miscible binary blends of the crystalline polymer and these inorganic nanoparticles were also determined through DSC and optical microscopy (OM) analyses. Herein, we emphasize the effects of the functional groups on POSS nanocomposites on the crystallization kinetics of PEO. We found that OP-POSS/PEO blend had the highest thermal stability and lowest crystallization rate because its hydrogen bonding interactions (between its hydroxyl and ether units) were stronger than those (between carbonyl and methylene groups) in OA-POSS/PEO. ID degradation-products; postmenopausal women; ovariectomized rats; bone turnover; delivery; osteoarthritis; osteoclasts; osteoporosis; biomarkers; collagen
AB The aim of this study was to assess the bioavailability and pharmacodynamic

efficacy of synthetic salmon calcitonin (ssCT) and recombinant salmon calcitonin (rsCT) in healthy postmenopausal women. The study was a single-blind, randomized study. Participants were 36 postmenopausal women 62 to 74 years old, randomly assigned to a comparison of dosing with ssCT (n = 12) or rsCT (n = 24) given in the morning at 08:00. Study parameters were plasma CT levels measured up to 2 hours postdose and changes in the bone resorption marker serum CTX-I and the cartilage degradation marker urine CTX-II measured up to 4 hours postdose. For both formulations, peak plasma concentrations were obtained 15 minutes after dosage, and no statistically significant differences in the uptake of CT were observed. Measurement of bone resorption and cartilage degradation markers displayed comparable responses, with AUCs of relative change of serum CTX-I of -250% x hours and relative change of urine CTX-II of -180% x hours during the 4-hour observation period. In conclusion, oral synthetic and recombinant calcitonin displayed comparable pharmacodynamic and kinetic properties.

TI Wnt signaling as a therapeutic target for bone diseases
SO EXPERT OPINION ON THERAPEUTIC TARGETS
LA English
DT Review
DE Dkk1; GSK-3; Osteoporosis; Sclerostin; Sfrp1; SOST
ID frizzled-related protein-1; beta-catenin; negative regulator; dkk1-mediated inhibition; parathyroid-hormone; hip osteoarthritis; increases markers; distinct roles; osteoblast; lrp5
AB Background: There is a need to develop new bone anabolic agents because current bone regeneration regimens have limitations. The Wingless-type MMTV integration site (Wnt) pathway has emerged as a regulator of bone formation and regeneration. Objective: To review the molecular basis for Wnt pathway modulation and discuss strategies that target it and improve bone mass. Methods: Data in peer-reviewed reports and meeting abstracts are discussed. Results/conclusions: Neutralizing inhibitors of Wnt signaling have emerged as promising strategies. Small-molecule inhibitors of glycogen synthase kinase 3 beta increase bone mass, lower adiposity and reduce fracture risk. Neutralizing antibodies to Dickkopf 1, secreted Frizz led-related protein 1 and sclerostin produce similar outcomes in animal models. These drugs are exciting breakthroughs but are not without risks. The challenges include tissue-specific targeting and consequently, long-term safety.

TI Defining the load bearing axis of the lower extremity obtained from anterior-posterior digital radiographs of the whole limb in stance
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE Assessment; Mechanical axis deviation; Lower extremity; Digitally computed radiographs
ID knee alignment; functional axes; mechanical axis; osteoarthritis; angle; progression; anatomy; foot
AB Objective: The purpose of this study was to evaluate the reliability of inter-and intra-observer assessments of the mechanical alignment of the lower extremities with digitally computed radiographs of an anterior-posterior view of the whole leg using a new computer-assisted method. Method: Load bearing axis deviation of the lower extremities was quantitatively measured by three examiners in 105 knees of 73 subjects who had osteoarthritis of the knee with a Kellgren-Lawrence grade of 1 or more. A line representing the load bearing axis was drawn from the center of the femoral head to the center of the ankle and the alignment of the leg was assessed by measuring the width of the proximal tibia and the perpendicular distance from the middle of the proximal tibial condyle to the load bearing axis

(Fujifilm OP-A). A ratio of the values was calculated and expressed as a percentage. Results: The inter-observer mean difference was 2.9 % (SD, 2.7), and the intra-observer mean difference was 2.1% (SD, 2.2). The mean intraclass correlation coefficient (ICC) for inter-observer trials was 0.96; that for intra-observer trials was 0.99. Conclusion: Our computer-assisted method was reproducible, and should be considered an alternative method for the measurement of the alignment of the whole leg. TI A Label-Free Electronic Biosensor for Detection of Bone Turnover Markers
SO SENSORS
LA English
DT Article
DE immunosensor; label-free; electrochemical impedance; bone turnover marker
ID biochemical markers; serum crosslaps; fracture risk; elderly-women; dna detection; i collagen; resorption; immunosensor; telopeptide; predict
AB This paper describes the development of a biosensor based on label-free immunosensing for the detection of the C-terminal telopeptide bone turnover marker from type-1 collagen. A self-assembled monolayer (SAM) of dithiodipropionic acid was deposited on a gold electrode. Then streptavidin and biotinylated anti-human C-terminal telopeptide antibody were successively conjugated on the self-assembled monolayer. Electrochemical impedance measurements were made to characterize each step of the SAM/streptavidin/biotinylated antibody binding. Subsequently, electrochemical impedance was measured with different concentrations of C-teminal telopeptide. A detection limit of 50 ng/mL and a dynamic range up to 3 mu g/mL were achieved. To our knowledge, this is the first attempt to develop a label-free immunosensor based on electrochemical impedance with DC bias for detection of bone-related degradation and rebuilding products. The electronic biosensor might eventually be used for quantitative point-of-care screening of bone health. It is hoped that analysis of bone turnover markers can indicate the beginning of bone diseases such as osteoarthritis and osteoporosis so that treatment might start early when it is most effective.

AB Tremendous advances undergone in electrophoresis, chromatography, and MS have led proteomic research to unprecedented achievement over the last decade. Proteomics is presently employed for assessing protein expression levels, for monitoring cellular activities and for determination of biochemical pathways, revolutionizing the way we study disease by opening up the possibility to decipher the pathogenesis of clinical manifestations. Over 200 disorders including osteoarthritis (OA), rheumatoid arthritis (RA), and osteoporosis are considered rheumatic diseases (RDs), which affect the musculoskeletal system (joints and other supporting structures of the body such as muscles, tendons, ligaments, and bones) and are a leading cause of disability among older adults. Despite that an autoimmune origin has been proposed for some RDs like RA the pathogenesis of most of these diseases is still unclear. Therefore, proteomic research on RDs, notably OA and RA, can help clarify underlying disease mechanisms, develop biomarkers to improve early detection, measure response to treatment, and devise new therapies. Achievements in the field of proteomics research on RDs are summarized in this work.

ID bone-mineral density; facet joint osteoarthritis; quality-of-life; intervertebral disc; precision-measurement; postmenopausal women; degenerative changes; vertebral deformity; trabecular bone; chinese men
AB Study Design. Cross-sectional study. Objective. The purpose of this study was to examine disc morphology and spinal mobility in subjects with varying degrees of osteoporosis. Summary of Background Data. There was limited information on the effect of osteoporosis on lumbar morphology and spinal mobility. It was also unclear how osteoporosis affects the nonosseous tissues such as the intervertebral disc. Methods. Ninety elderly subjects with varying bone mineral densities (22 normal, 28 osteopenia, 40 osteoporosis) were recruited from an osteoporosis clinic. Lateral radiographs and magnetic resonance images of their lumbar spines were obtained. An electromagnetic tracking device was employed to measure the ranges of motion of the whole lumbar spine. Results. Although the thoracic spine had been shown to have decreased anterior vertebral body height in subjects with osteoporosis, this study revealed that the anterior height was increased in the lumbar region. Osteoporosis was associated with expansion of the middle of the disc with corresponding collapse of vertebral bodies, but osteoporosis was found not to be related to either disc preservation or degeneration. No significant change in spinal mobility was observed in patients with osteoporosis. Conclusion. Osteoporosis does not only affect the bone but also the nonosseous tissues. It was found to be associated with expansion of the intervertebral disc, which was likely to be secondary to changes in the vertebral endplate.

TI Differential articular calcified cartilage and subchondral bone in postmenopausal women with osteoarthritis and osteoporosis: Two-dimensional analysis
SO JOINT BONE SPINE
LA English
DT Article
DE Osteoarthritis; Osteoporosis; Articular cartilage; Bone morphometry
ID femoral-head; joint; zone; hip; histomorphometry; microcracks; metabolism; thickness; tissue; cells
AB Objectives: Osteoarthritis (OA) and osteoporosis (OP) are both common problems that affect life quality in aging society. It has been for decades of years to debate an inverse relationship between OA and OP. The objective of this paper was to compare structural properties of the articular calcified cartilage (ACC) and subchondral bone between postmenopausal women with OA and OP. Methods: Eight femoral heads were taken from postmenopausal women during total hip replacement surgery due to primary OA. They were compared with nine femoral

heads obtained from age-matched women with OP during hemi-hip arthroplasty surgery due to osteoporotic fracture of the proximal femur. Two-dimensional histomorphometric sections were prepared to measure the thickness of ACC and bone histomorphometric parameters. The ratio of ACC to the total articular cartilage (TAC) was also calculated in all bone specimens. Results: Osteoarthritic donors had higher ACC and the ratio of ACC to TAC (ACC: 117.69 +/- 28.16 mu m vs. 97.88 +/- 16.79 mu m, P=0.041; the ratio of ACC to TAC: 15.74% vs. 10.51%, P = 0.023). Lower bone Volume fraction (BV/TV), trabecular thickness (Tb.Th), trabecular number (Tb.N) and the ratio of nodes to termini (Nd/Tm) were demonstrated in donors with OP (BV/TV: 21.55 +/- 3.41% vs. 16.64 +/- 2.26%, P = 0.003; Tb.Th: 121.33 +/- 16.11 mu m vs. 98.59 +/- 18.56 mu m, P = 0.017; Tb.N: 2.41 +/- 0.73 m(-1) vs. 1.37 +/- 0.31 mm(-1), P = 0.001; Nd/Tm: 0.78 +/- 0.22 vs. 0.50 +/- 0.14, P = 0.007). However, trabecular space (Tb.Sp) increased in these osteoporotic patients (Tb.Sp: 345.49 +/- 106.18 mu m vs. 652.09 +/- 159.71 mu m, P=0.0004). Conclusions: The pathogenesis of OA and OP were influenced by differential properties of ACC and subchondral bone microstructure. Structural properties of the subchondral mineralized tissue supported that an inverse relationship existed between postmenopausal women with OA and OP. (C) 2009 Societe francaise de rhumatologie. TI Differences in zinc status between patients with osteoarthritis and osteoporosis
SO JOURNAL OF TRACE ELEMENTS IN MEDICINE AND BIOLOGY
LA English
DT Article
DE Zinc; Osteoarthritis; Osteoporosis; Bone strength; Bone density
ID bone-mineral density; growth-factor-i; growing rats; postmenopausal women; senile osteoporosis; cancellous bone; femoral-head; metabolism; hip; fracture
AB Zinc has been suggested to play an important role in the development of osteoporosis, whereas the influence of zinc on osteoarthritis has attracted much less attention. The aim of the study was to investigate and compare the zinc status and bone turnover, density, and biomechanical properties of osteoarthritic and osteoporotic patients. The study comprised 40 women who underwent hip

replacement due to osteoarthritis or osteoporosis. Serum and urine zinc content, and bone resorption markers and serum bone formation markers were determined. The unaffected hip and the exarticulated affected femoral head underwent DEXA scanning. Bone biopsies were obtained from the femoral heads and the biomechanical properties were determined. The biopsies were ashed and the bone zinc content was ascertained. Osteoarthritic patients had significantly higher serum zinc concentrations and lower urine zinc concentrations than osteoporotic patients, whereas the bone zinc content did not differ. The zinc status was not found to be a predictor for the bone strength. In conclusion, the finding that the zinc status of osteoporotic patients is significantly different from that of osteoartritic patients is new and supports the view that osteoporosis and osteoarthritis rarely occur in the same individual. DT Review
DE Gene microarray; Gene expression profiling; Fragility fracture; Osteoporosis; Osteoblastic osteoclastic adipocytic genes
ID human trabecular bone; a scavenger receptor; tissue growth-factor; microarray analysis; insulin-resistance; messenger-rna; negative regulator; annexin-ii; differentiation; protein
AB Osteoporosis (OP) is a common age-related systemic skeletal disease, with a strong genetic component, characterised by loss of bone mass and strength, which leads to increased bone fragility and susceptibility to fracture. Although some progress has been made in identifying genes that may contribute to OP disease,

much of the genetic component of OP has yet to be accounted for. Therefore, to investigate the molecular basis for the changes in bone Causally involved in OP and fragility fracture, we have used a microarray approach. We have analysed altered gene expression in human OP fracture bone by comparing mRNA in bone from individuals with fracture of the neck of the proximal femur (OP) with that from age-matched individuals with osteoarthritis (OA), and control (CTL) individuals with no known bone pathology. The OA sample set was included because all inverse association, with respect to bone density, has been reported between OA and the OP individuals. Compugen H19K oligo human microarray slides were used to compare the gene expression profiles of three sets of female samples comprising, 10 OP-CTL, 10 OP-OA, and 10 OA-CTL sample pairs. Using linear models for microarray analysis (Limma), 150 differentially expressed genes in OP bone with t scores >5 were identified. Differential expression of 32 genes in OP bone was confirmed by real time PCR analysis ($p<0.01$). Many of the genes identified have known or Suspected roles in bone metabolism and in some cases have been implicated previously in OP pathogenesis. Three major sets of differentially expressed genes in OP bone were identified with known or suspected roles in either osteoblast maturation (PRRX1, ANXA2, ST14, CTSB, SPARC, FST LGALS1, SPP1, ADM, and COL4A1), myelomonocytic differentiation and osteoclastogenesis (TREM2, ANXA2, IL10, CD14, CCR1, ADAM9, CCL2, CTGF, and KLF10), or adipogenesis, lipid and/or glucose metabolism (IL10, MARCO, CD14, AEBP1, FST, CCL2, CTGF, SLC14A1, ANGPTL4, ADM, TAZ, PEA15, and DOK4). Altered expression of these genes and others in these groups is consistent with previously Suggested underlying molecular mechanisms for OP that include altered osteoblast and osteoclast differentiation and function, and ail imbalance between osteoblastogenesis and adipogenesis. TI A weak link in metabolism: the metabolic capacity for glycine biosynthesis does not satisfy the need for collagen synthesis
SO JOURNAL OF BIOSCIENCES
LA English
DT Review
DE Collagen; collagen synthesis; collagen turnover; essential amino acid; glycine; glycine metabolism; osteoarthritis; osteoporosis
ID body protein-synthesis; 5-l-oxoproline pyroglutamic acid; essential amino-acid; human lung; urinary-excretion; rat-liver; intracellular degradation; compartmental analysis; carnitine metabolism; extracellular-matrix
AB In a previous paper, we pointed out that the capability to synthesize glycine from serine is constrained by the stoichiometry of the glycine hydroxymethyltransferase reaction, which limits the amount of glycine produced to be no more than equimolar with the amount of C 1 units produced. This constraint predicts a shortage of available glycine if there are no adequate compensating processes. Here, we test this prediction by comparing all reported fluxes for the production and consumption of glycine in a human adult. Detailed assessment of all possible sources of glycine shows that synthesis from serine accounts for more than 85% of the total, and that the amount of glycine available from synthesis, about 3 g/day, together with that available from the diet, in the range 1.5-3.0 g/day, may fall significantly short of the amount needed for all metabolic uses, including collagen synthesis by about 10 g per day for a 70 kg human. This result supports earlier suggestions in the literature that glycine is a semi-essential amino

acid and that it should be taken as a nutritional supplement to guarantee a healthy metabolism.

AB Joint inflammation in rheumatoid arthritis (RA) induces local periarticular osteoporosis. Generalised bone mineral density (BMD) decrease concerns approximately 50% of rheumatic patients. Both types of bone mass depletion can issue from cytokine-induced (TNF-alpha, IL-1, IL-6) osteoclasts' activation, osteoprotegerin and its ligand's (RANKL) function disorders, patients' immobilisation and glucocorticosteroid (GCS) intake, as well as from hormonal alterations in postmenopausal women, predominate among RA individuals. The aim of the study was to compare serum concentrations of marker of bone formation-serum aminoterminal propeptide of type I collagen (PINP), and bone resorption, carboxy (C) terminal telopeptide (Ctx), bone turnover markers in RA and osteoarthritis (OA) patients and in RA groups of different disease activity, different degree of joint damage and the history of GCS intake. A total of 50 RA female patients and 50 women with knee OA were included in the study. Blood for morphology and biochemistry laboratory tests was taken. Joint X-rays to establish OA and RA diagnosis and the degree of RA progression, as well as DEXA BMD measurements were performed. PINP and Ctx concentrations were assessed. In RA patients the number of swollen and painful joints, the duration of morning stiffness, visual analogue scale values and Waaler-Rose's test activity were recorded. The Disease Activity Index (DAS 28) was counted from the appropriate formula. No differences in bone turnover markers' concentrations were noted neither between RA and OA patients nor between the RA group when compared to the one without the history of GCS use. Bone turnover markers' concentrations in RA were proportional to the number of swollen and painful joints. However, no

correlation was found between the markers' concentrations and RA activity assessed by DAS 28 or by laboratory means. Ctx concentrations were higher in patients at II degree joint damage according to Larsen and Dale's than at more advanced stages. Ctx concentrations decreased with the disease duration. Serum morphogenesis and resorption markers' concentrations change in course of RA indicating the decrease in bone metabolic activity with the disease duration and progression. High RA activity and severity correlate with increased markers' levels-the resorption one. The influence of GCS on bone metabolism in RA requires further study.

TI Periodic Knee Injections of BMP-7 Delay Cartilage Degeneration Induced by Excessive Running in Rats
SO JOURNAL OF ORTHOPAEDIC RESEARCH
LA English
DT Article
DE BMP-7; articular cartilage; strenuous running; keratan sulfate; weekly injection
ID human articular chondrocytes; serum keratan sulfate; osteogenic protein-1; experimental osteoarthritis; repair; bone; op-1
AB Strenuous running of rats enhances mechanical stress on the knee, thereby inducing degeneration of articular cartilage. Bone morphogenetic protein-7 (BMP-7) has an inhibitory effect on cartilage degeneration, suggesting its usefulness for human osteoarthritis patients. However, its mode of administration should be investigated. We examined whether weekly knee injections of BMP-7 delayed the progression of cartilage degeneration. Wistar rats were forced to run 30 km in 6 weeks on a rodent treadmill, and BMP-7 was injected weekly into the knee. Macroscopically and histologically, this strenuous running regimen induced cartilage degeneration. Weekly injections of 250 ng BMP-7 delayed the progression of cartilage degeneration. Immunohistochemically, in the control knee, type II Collagen expression decreased, while BMP-7 expression in chondrocytes slightly increased. Interestingly, weekly injection of BMP-7 increased BMP-7 expression even 9 days after the final injection. Disulfate disaccharide keratan sulfate in serum transiently increased in the control group, while it remained at a low level in the BMP-7 group. Weekly BMP-7 injection increased BMP-7 expression in chondrocytes and its effect seemed to last more than 7 days. The effect of BMP-7 could be monitored by serum keratan sulfate concentration. Periodical injections of BMP-7 delayed progression of cartilage degeneration induced by excessive running in rats. (C) 2009 Orthopaedic Research Society. Published by Wiley Periodicals, Inc. TI GAIT analysis in patients operated with a novel total ankle prosthesis
SO GAIT & POSTURE
LA English
DT Article
DE Total ankle replacement; Human movement analysis; Total 3D gait protocol; Ankle motion
ID replacement; osteoarthritis; arthroplasty; design
AB A new three-part total ankle prosthesis was designed recently to restore natural joint motion while maintaining full congruity of the articulating surfaces. This was achieved by replicating natural function for the ligaments. Early functional recovery was assessed in the present study in patients who underwent replacement with this prosthesis. This was undertaken using the AOFAS clinical scoring system and gait analysis, performed preoperatively and at 6 and 12 months from surgery. The 10 patients had, at the time of operation, a mean age of 57.4 years (range 45-72), and BMI 25.8 (range 20.4-34.1). A recently proposed protocol for three-dimensional

and anatomically based analysis of joint kinematics and kinetics was used. The AOFAS score rose from 44.3 pre-op to 81.5 and 81.0 respectively at 6- and 12-month follow-up, with particular improvement in function. Spatio-temporal parameters improved considerably already at 6 months. More normal patterns and ranges of rotations and moments were observed in the three anatomical planes of the replaced ankle at 6 months and maintained at 12 months. In particular the improvement in dorsi-plantarflexion range in stance was significant, though a limited plantarflexion in swing occurred. EMG revealed a good recovery of physiological activity for the biceps femoris at 12-month follow-up. The new ankle prosthesis contributed to early functional recovery at 6 months, maintained at 1 year. (C) 2009 Elsevier B.V. All rights reserved.

DT Review
DE Osteoarthritis; Fracture; Hip; Knee; Analgesic
ID bone-mineral density; postmenopausal women; knee osteoarthritis; register; disease; hip; osteoporosis; metaanalysis; denmark
AB We conducted a case-control study on the effects of osteoarthritis (OA) on the risk of fractures. There were 124,655 fracture cases and 373,962 age- and gender-matched controls. The main exposure was OA, and the main confounders were use of diuretics, antihypertensive drugs, and pain medication. OA was associated with a decreased risk of any fracture and of hip, forearm, and spine fractures. In general a decreasing trend in the risk of fractures was present with increasing time sine diagnosis of OA. The effect on fractures in areas rich in cortical bone such as the hip in general was larger than effects on skeletal sites rich in trabecular bone such as the spine. OA in the hip and knee, in general, was associated with a decreasing risk of fractures with time since diagnosis of OA, while this was not the case for OA in other locations. OA seems to be associated with a decreased risk of fractures at multiple skeletal sites as well as sites far from the location of OA. This may indicate systemic effects on bone strength, especially in areas rich in cortical bone.

ID morbidly obese-patients; overweight; health; women; osteoarthritis; disability; increases; gender; state; life
AB BACKGROUND: The prevalence of obesity in developed countries has reached alarming levels, doubling in the United States since 1980. Although obese patients with chronic low back pain are frequently advised to lose weight, the association between these medical conditions remains unproven. PURPOSE: This study prospectively assessed clinically reported changes in chronic axial low back pain symptoms after weight reduction from bariatric surgery for morbid obesity. STUDY DESIGN: Prospective longitudinal study. PATIENT SAMPLE: Fifty-eight consecutive patients with morbid obesity and chronic axial low back pain undergoing bariatric surgery over a period of 6 months. Patients were considered morbidly obese if they were 50% to 100% above their ideal body weight or having a body mass index (BMI) greater than 40. OUTCOME MEASURES: Visual Analog Scale (VAS) for axial low back pain, Short Form-36 (SF-36) Health Survey, and Oswestry Disability Index (ODI). METHODS: Patients undergoing weight reduction surgery were assessed preoperatively and postoperatively at 12 months with validated clinical measures for axial back pain and disability (VAS, SF-36, and ODI). Bariatric surgery parameters included demographic data, weight, and BMI. Statistical analysis included paired t tests and multiple regression techniques. RESULTS: Of the initial 58 patients, 38

(65%) completed both preoperative (Pre-Op) and postoperative (Post-Op) questionnaires at 12 months. These 38 subjects included 30 women and 8 men, with an age range of 20 to 68 years (mean 48.4 +/- 10.1). Overall, these patients showed a decrease in mean weight from 144.52 +/- 41.21 kg Pre-Op to 105.59 +/- 29.24 Post-Op (p<.0001) and BMI from 52.25 +/- 12.61 kg/m(2) Pre-Op to 38.32 +/- 9.66 Post-Op (p<.0001). Patients demonstrated a statistically significant mean 44% decrease in axial back pain on the VAS scale (p=.006; 5.2 +/- 3.35 Pre-Op, to 2.9 +/- 3.1 Post-Op). Analysis of the SF-36 major components revealed that patients experienced significant increases in mean physical health by 58% (p<.0001; 44.5 +/- 20.09 to 70.24 +/- 26.84) and in median mental health by 6% (p=.03; 70 +/- 7.14 to 73.39 +/- 11.78). Patients also showed statistically significant 24% decrease in Post-Op ODI score for physical disability (p=.05) from 26.75 +/- 16.56 Pre-Op to 20.35 +/- 18.71 Post-Op (p=.05). CONCLUSION: This study suggests that the substantial weight reduction after bariatric surgery may be associated with moderate reductions in preexisting back pain at early-follow-up. This effect did not appear to be the result only of an overall improvement in well-being associated with weight loss. However, larger randomized controlled clinical studies with longer-term follow-up are needed to definitively determine a causal relationship. (C) 2009 Elsevier Inc. All rights reserved.

TI Experimental model to evaluate in vivo and in vitro cartilage MR imaging by

means of histological analyses
SO EUROPEAN JOURNAL OF RADIOLOGY
LA English
DT Article
DE Magnetic resonance imaging (MRI); Histology; Knee; Cartilage; Osteoarthritis
ID articular-cartilage; hyaline cartilage; osteoarthritis; knee; arthroscopy; defects; accuracy; lesions; morphology; sequences
AB Objectives: Implementation of an experimental model to compare cartilage MR imaging by means of histological analyses. Material and methods: MRI was obtained from 4 patients expecting total knee replacement at 1.5 and/or 3 T prior surgery. The time-frame between pre-op MRI and knee replacement was within two days. Resected cartilage-bone samples were tagged with Ethi (R)-pins to reproduce the histological cutting course. Pre-operative scanning at 1.5 T included following parameters for fast low angle shot (FLASH: TR/TE/FA = 33 ms/6 ms/30 degrees, BW = 110 kHz, 120 nun x 120 mm FOV, 256 x 256 matrix, 0.65 mm slice-thickness) and double echo steady state (DESS: TR/TE/FA = 23.7 ms/6.9 ms/40 degrees, BW = 130 kHz, 120 x 120 mm. FOV, 256 x 256 matrix, 0.65 mm, slice-thickness). At 3 T, scan parameters were: FLASH (TR/TE/FA = 12.2 ms/5.1 ms/10 degrees, BW = 130 kHz, 170 x 170 mm FOV, 320 x 320, 0.5 mm slice-thickness) and DESS (TR/TE/FA = 15.6 ms/4.5 ms/25 degrees, BW = 200 kHz, 135 mm x 150 mm FOV, 288 x 320 matrix, 0.5 mm slice-thickness). Imaging of the specimens was done the same day at 1.5 T MRI (Noyes) and histological (Mankin) score scales were correlated using the paired t-test. Sensitivity and specificity for the detection of different grades of cartilage degeneration were assessed. Inter-reader and intra-reader reliability was determined using Kappa analysis. Results: Low correlation (sensitivity, specificity) was found for both sequences in normal to mild Mankin grades. Only moderate to severe changes were diagnosed with higher significance and specificity. The use of higher field-strengths was advantageous for both protocols with sensitivity values ranging from 13.6% to 93.3% (FLASH) and 20.5% to 96.2% (DESS). Kappa values ranged from 0.488 to 0.944. Conclusions: Correlating MR images with continuous histological slices was feasible by using three-dimensional imaging, multi-planar-reformat and marker pins. The capability of diagnosing early cartilage changes with high accuracy could not be proven for both FLASH and DESS. (C) 2008 Elsevier Ireland Ltd. All rights reserved.

ID elastic-modulus; force spectroscopy; indentation; bone; plasticity; hardness
AB Tissue mechanical properties reflect extracellular matrix composition and organization, and as such, their changes can be a signature of disease. Examples of such diseases include intervertebral disk degeneration, cancer, atherosclerosis, osteoarthritis, osteoporosis, and tooth decay. Here we introduce the tissue diagnostic instrument (TDI), a device designed to probe the mechanical properties of normal and diseased soft and hard tissues not only in the laboratory but also in patients. The TDI can distinguish between the nucleus and the annulus of spinal disks, between young and degenerated cartilage, and between normal and cancerous mammary glands. It can quantify the elastic modulus and hardness of the wet dentin left in a cavity after excavation. It can perform an indentation test of bone tissue, quantifying the indentation depth increase and other mechanical parameters. With local anesthesia and disposable, sterile, probe assemblies, there

has been neither pain nor complications in tests on patients. We anticipate that this unique device will facilitate research on many tissue systems in living organisms, including plants, leading to new insights into disease mechanisms and methods for their early detection.

TI The association between socioeconomic status and osteoporotic fracture in population-based adults: a systematic review
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE Minimal trauma fracture; Osteoporosis; Social disadvantage; Socioeconomic status; Systematic review
ID public health-care; hip-fractures; risk-factors; marital-status; united-states; osteoarthritis; work; life; epidemiology; disparity
AB Although socioeconomic status (SES) is inversely related to most diseases, this systematic review showed a paucity of good quality data examining influences of SES on osteoporotic fracture to confirm this relationship. Further research is required to elucidate the issue and any underlying mechanisms as a necessary

precursor to considering intervention implications. The association between socioeconomic status (SES) and musculoskeletal disease is little understood, despite there being an inverse relationship between SES and most causes of morbidity. We evaluated evidence of SES as a risk factor for osteoporotic fracture in population-based adults. Computer-aided search of Medline, EMBASE, CINAHL, and PsychINFO from January 1966 until November 2007 was conducted. Identified studies investigated the relationship between SES parameters of income, education, occupation, type of residence and marital status, and occurrence of osteoporotic fracture. A best-evidence synthesis was used to summarize the results. Eleven studies were identified for inclusion, which suggested a lack of literature in the field. Best evidence analysis identified strong evidence for an association between being married/living with someone and reduced risk of osteoporotic fracture. Limited evidence exists of the relationship between occupation type or employment status and fracture, or for type of residence and fracture. Conflicting evidence exists for the relationship between osteoporotic fracture and level of income and education. Limited good quality evidence exists of the role SES might play in osteoporotic fracture. Further research is required to identify whether a relationship exists, and to elucidate underlying mechanisms, as a necessary precursor to considering intervention implications.

TI Primary Osteoarthritis No Longer Primary: Three Subsets with Distinct Etiological, Clinical, and Therapeutic Characteristics
SO SEMINARS IN ARTHRITIS AND RHEUMATISM
LA English
DT Review
DE primary osteoarthritis; subtypes; genetic alterations; menopause-related estrogen deficiency; aging

ID multiple epiphyseal dysplasia; estrogen replacement therapy; oligomeric matrix protein; ii procollagen gene; periarticular tibial osteophytes; knee osteoarthritis; skeletal-muscle; articular chondrocytes; postmenopausal women; symptomatic osteoarthritis
AB Background: Osteoarthritis (OA) has been historically divided into primary and secondary. Primary OA has been defined as an idiopathic condition developing in previously undamaged joints in the absence of an obvious causative mechanism. During the last few years a large amount of evidence has provided new insights into the biochemistry and molecular biology of cartilage, subchondral bone, and other articular tissues, which suggest distinct etiopathogenetic mechanisms in some forms of primary OA. Objective: To propose an etiopathogenic classification of primary OA in the light of the significant progress in the understanding of the disease. Methods: A review of the literature was performed by searching the Medline and PubMed databases From 1952 to November 2008 using the following keywords: genetic alteration, heritability, estrogen, menopause, and aging either alone or in various combinations with joint, cartilage, subchondral bone, synovium, ligaments, muscle, tendons, OA, and osteoporosis. Results: Numerous studies have shown that genetic alterations, menopause-related estrogen deficiency, and aging play crucial roles in the molecular pathophysiological events involved in the process of cartilage and joint damage and thus in development of OA. We propose classifying primary OA into 3 distinct although interrelated Subsets: type I OA, genetically determined; type II OA, estrogen hormone dependent; and type III OA, aging related. Conclusions: The 3 proposed subsets of OA display distinct etiological, clinical, and therapeutic characteristics and should therefore no longer be considered to be "Primary OA." TI Radiographic evaluation of foot osteoarthritis: sensitivity of radiographic variables and relationship to symptoms
SO OSTEOARTHRITIS AND CARTILAGE

LA English
DT Article
DE Osteoarthritis; X-ray; Prevalence; Foot; Pain
ID older-people; pain; association; prevalence; disability; community; joints; knee; population
AB Objectives: To evaluate a radiographic atlas for grading foot osteoarthritis (OA) in relation to the relative sensitivity of different radiographic and views and features, and to examine the relationship between radiographic OA and foot symptoms. Methods: Weightbearing clorso-plantar (DP) and lateral foot radiographs were obtained from 197 people (126 women and 71 men) aged 62-94 years (mean age 75.9, standard deviation [SD] 6.6). The prevalence of OA in five joints (the first metatarsophalangeal joint [1st MPJ], the first cuneo-metatarsal joint [1st CMJ], the second cuneo-metatarsal joint [2nd CMJ], the navicular-first cuneiform joint [N1st CJ] and the talo-navicular joint [TNJ]) was then determined using both views in combination (as recommended in the atlas), or by using either view in isolation. Associations between radiographic OA in individual foot joints and symptoms were then explored. Results: Joint-specific prevalence of OA using both DP and lateral views was 1st MPJ (42.4%), 1st CMJ (22.6%), 2nd CMJ (60.2%), N1st CJ (39.1%) and TNJ (32.7%). Using only the DP view detected almost all cases of 1 st MPJ OA (94.6%), however, the sensitivity was lower for the other joints (31.0-60.7%). Using only the lateral view detected almost all cases of OA (83.8 to 86.9%), with the exception of the 1 st MPJ and 1 st CMJ (50.9% and 60.7%, respectively). Using either osteophytes (OP) alone or joint space narrowing (JSN) alone showed low sensitivity for all joints (14.3-63.0%), with the exception of OP alone in the DID view for the 1 st MPJ and JSN in the lateral view for the 2nd CMJ (83.8% and 84.0%, respectively). Radiographic OA in individual foot joints and the total number of joints affected were both moderately associated with foot symptoms. Conclusion: Epidemiological and clinical studies should incorporate observation of both OP and JSN from both DP and lateral views to determine the presence of OA in the foot, as the number of cases detected is reduced if only one radiographic feature or view is used. Radiographic foot OA is common in older people and is moderately associated with foot symptoms. (c) 2008 Osteoarthritis Research Society International. Published by Elsevier Ltd. All rights reserved.

TI Geranylgeranylacetone, a non-toxic inducer of heat shock protein, induces cell death in fibroblast-like synoviocytes from patients with rheumatoid arthritis
SO MODERN RHEUMATOLOGY
LA English
DT Article
DE Apoptosis; Geranylgeranylation; Rheumatoid arthritis; Synovitis; Statin
ID gastric-mucosal cells; kinase-c; induced expression; synovial-cells; nitric-oxide; in-vitro; induction; apoptosis; statins; heat-shock-protein-72
AB Fluvastatin (Fluv) is reported to induce apoptosis in rheumatoid arthritis (RA) synoviocytes through the blocking of protein geranylgeranylation. We report here our investigation of whether geranylgeranylacetone (GGA) induces cell death in RA synoviocytes. Synovial tissues were obtained from patients with RA at the time of total knee arthroplasty. Fibroblast-like synoviocytes (FLS) cultured in three passages were used for the experiments. The FLS were then cultured for 48 h in 48-well

flat-bottomed plates containing various concentrations of GGA (0.1-4.0 mu g/ml) and either 0.1 or 0.5 mu M Fluv. We also examined the effect of GGA and Fluv in human fibroblasts from normal skin (CCD-25SK) and FLS from patients with osteoarthritis (OA). Cells demonstrating cell death were counted following trypan blue staining. In the absence of GGA, there was no apparent cell death, as evidence by trypan blue staining. Concentrations of GGA between 0.1 and 4.0 mu g/ml induced cell death in RA FLS, but not in skin fibroblasts (CCD-25SK) nor OA FLS. The number of synoviocytes demonstrating cell death induced by 0.1 or 0.5 mu M Fluv was significantly higher than that by the medium alone. In summary, we found that GGA induced cell death in RA FLS, suggesting that GGA may be a potential new therapeutic agent for RA as well as osteoporosis.

TI Bone loss in the lower leg during 35 days of bed rest is predominantly from the cortical compartment
SO BONE

AB Immobilization-induced bone loss is usually greater in the epiphyses than in the diaphyses. The larger fraction of trabecular bone in the epiphyses than in the diaphyses offers an intuitive explanation to account for this phenomenon. However, recent evidence contradicts this notion and suggests that immobilization-induced bone loss from the distal tibia epiphysis is mainly from the cortical compartment. The aim of this study was to establish whether this pattern of bone loss was a general rule during immobilization. We monitored various skeletal sites with different tissue composition during 5 weeks of immobilization. Ten healthy male volunteers with mean age of 24.3 years (SD 2.6 years) underwent strict horizontal bed rest. Bone scans were obtained during baseline data collection, at the end of bed rest and after 14 days of recovery by peripheral Quantitative Computed Tomography (pQCT). Sectional images were obtained from the distal tibia epiphysis (at 4% of the tibia's length), from the diaphysis (at 38%), from the proximal metaphysis (at 93%) and from the proximal epiphysis (at 98%), as well as from the distal femur epiphysis (at 4% of the femur's length) and from the patella. Relative bone losses were largest at the patella, where they amounted to -3.2% (SD 1.8%, $p<0.001$) of the baseline values, and smallest at the tibia diaphysis, where they amounted to -0.7% (SD 1.0%, $p=0.019$). The relative losses were generally larger from cortical than from trabecular compartments ($p=0.004$), and whilst all skeletal sites depicted such cortical losses, substantial trabecular losses were found only from the proximal tibia epiphysis. Results confirm that the differential losses from the various skeletal sites cannot be explained on the basis of trabecular vs. cortical tissue composition differences, but that endocortical circumference can account for the different amounts of bone loss in the tibia. The present study therefore supports the suggestion of the subendocortical layer as a transitional zone, which can readily be transformed into trabecular bone in response to immobilization. The latter will lead to cortical thinning, a factor that has been associated with the risk of fracture and with osteoarthritis. (C) 2009 Elsevier Inc. All rights reserved.

TI Relationship Between Low Bone Mineral Density and Varus Deformity in Postmenopausal Women with Knee Osteoarthritis
SO JOURNAL OF RHEUMATOLOGY
LA English

DT Article
DE OSTEOARTHRITIS; KNEE; BONE DENSITY; MENOPAUSE; OSTEOPOROSIS
ID high tibial osteotomy; hip osteoarthritis; static alignment; proximal tibia; osteoporosis; association; arthritis; severity; incident; men
AB Objective. To assess the relationship between bone mineral density (BMD) and varus deformity arising from bone structural changes caused by knee osteoarthritis (OA) in postmenopausal women. Methods. This cross-sectional study involved 135 consecutive postmenopausal female patients who had varus knee OA and a Kellgren-Lawrence grade >= 2. Knee radiographs were obtained with the patient standing on one lea, and subjects were classified into 3 tertile groups according to femorotibial angle, which was taken as a measure of varus knee OA severity. We also measured the 3 subangles that make up the femorotibial angle, and focused on the varus inclination of the tibial plateau. BMD was measured in the lumbar spine, femoral neck, and medial and lateral tibial condyles using dual-energy X-ray absorptiometry. Differences between femorotibial angle tertile groups were assessed. and associations between femorotibial sub-angles and BMD values at various points were evaluated. Results. After adjustment for age and body mass index, there was no significant association between the varus inclination of the tibial plateau and lumbar spine BMD. A weak but statistically significant negative correlation existed between varus inclination of the tibial plateau and BMD at the ipsilateral proximal femur and lateral tibial condyle. Conclusion. Varus inclination of the tibial plateau was significantly more severe in the femorotibial an-le tertile 3 group, and in patients with lower BMD in the ipsilateral lower limb. Varus knee OA may result not only from cartilage loss but also from structural changes of the bone. (First Release Feb 1 2009; J Rheumatol 2009;36:592-7: doi: 10.3899/jrheum.080699)

TI Chagas' disease and ageing: the coexistence of other chronic diseases with Chagas' disease in elderly patients
SO REVISTA DA SOCIEDADE BRASILEIRA DE MEDICINA TROPICAL
LA English
DT Article
DE Chagas' disease; Ageing; Elderly; Comorbidities
ID self-rated health; heart-failure; mortality; adults
AB This study aimed to identify the main comorbidities in elderly chagasic patients treated in a reference service and identify possible associations between the clinical form of Chagas' disease and chronic diseases. Ninety patients aged 60 years-old or over were interviewed and their clinical diagnoses recorded. The study population profile was: women (55.6%); median age (67 years); married (51.1%); retired (73.3%); up to four years' education (64.4%); and earning less than two minimum wages (67.8%). The predominant forms of Chagas' disease were the cardiac (46.7%) and mixed forms (30%). There was a greater proportion of mild cardiac dysfunction (84.1%), frequently in association with megaesophagus. The mean number of concurrent diseases was 2.856 +/- 1.845, and 33% of the patients M four or more comorbidities. The most frequent were systemic arterial hypertension (56.7%), osteoporosis (23.3%), osteoarthritis (21.2%) and dyslipidemia (20%). Positive correlations were verified between sex and comorbidities and between age group and comorbidities.

TI The Relationship Between Back Pain and Future Vertebral Fracture in

Postmenopausal Women
SO SPINE
LA English
DT Article
DE back pain; comorbidities; osteoporosis; osteoarthrosis; vertebral fracture risk
ID quality-of-life; diagnostic-criteria; risk-factors; association; health; prevalent; diseases; age
AB Study Design. Cross sectional and prospective observational study in Japanese postmenopausal women. Objective. The aim of the study was 2-fold. The first was to investigate what kind of comorbidities could be found in conjunction with back pain in Japanese postmenopausal women. The second was to investigate whether significant relationship between baseline back pain and future fracture exists or not. Summary of Background Data. Back pain has been reported to be associated with vertebral degeneration or vertebral fracture. However, there has been no available data that indicates the relationship between back pain and future fracture risks. Methods. The subjects who visited their practitioner were examined for their prevalent back pain or pains in other site. Bone mineral density, body height, body weight, and serum parameter were measured at baseline, and comorbidities were investigated by interview. Fragility fractures were also assessed at baseline and then followed up with 1- to 2-year intervals. The correlation between back pain and baseline characteristics was investigated by logistic regression analysis. The hazard ratio of back pain to future vertebral fracture was estimated by multivariate Cox regression analysis. Results. A total of 899 postmenopausal ambulatory women (62.5 +/- 10.3 years old) were enrolled and 81 subjects were dropped out from the study within 1 year. The remaining 818 postmenopausal women (62.1 +/- 10.3 years) were followed-up for 5.7 +/- 3.5 years. Compared to the group without pain, the group with back pain had significantly higher age, lower bone mineral densities at lumbar spine and hip, and higher number of prevalent vertebral fractures. The back pain was significantly associated with rheumatic arthritis (odds ratio [OR]: 2.01, $P < 0.05$), prevalent vertebral fracture (OR: 4.60, $P < 0.001$) and osteoporosis (OR: 2.14, $P < 0.001$). A total of 189 future fractures were observed, of which the most frequent was vertebral fractures (78.3%). The fact that baseline back pain was a significant risk factor for time-dependent vertebral fractures (hazard ratio: 1.62, 95% confidence interval: 1.16-2.27, $P = 0.005$) was demonstrated by the Cox hazards model after adjusting for traditional risk factors, such as age, bone mineral density, and prevalence of vertebral fractures. Conclusion. The data obtained in this study indicated that the back pain is significantly associated with osteoporosis and rheumatoid arthritis and that it can be useful predictor for future vertebral fracture risk in Japanese postmenopausal women in clinical settings.

TI Peroxisome proliferator-activated receptor-γ (PPAR-γ) ligands as potential therapeutic agents to treat arthritis
SO PHARMACOLOGICAL RESEARCH
LA English
DT Review
DE PPAR-gamma ligands; Arthritis; Osteoarthritis; Rheumatoid arthritis; Inflammation
ID human synovial fibroblasts; nonsteroidal antiinflammatory drugs; nonpsychoactive cannabinoid acid; prostaglandin e-2 synthase-1; retinoid-x-receptor; nf-kappa-b; rheumatoid-arthritis; differential expression;

psoriatic-arthritis; arachidonate cascade
AB Peroxisome proliferator-activated receptor-gamma (PPAR-gamma) has already been considered as an attractive molecular target for the treatment of human metabolic disorders. Pleiotropic functions beyond this limit, such as anti-inflammatory and anti-proliferative effects against several pathological states, including atherosclerosis, osteoporosis and cancer, are currently being explored. Several natural and synthetic PPAR-gamma ligands have been the focus of extensive research effort as potent anti-inflammatory agents in diverse disease states. In the last decade, accumulative experimental evidence has further suggested that PPAR-gamma is involved in several inflammatory signaling pathways associated with arthritis. PPAR-gamma appears to be expressed by major cell populations in joints, such as chondrocytes, synoviocytes, fibroblasts and endothelial cells. PPAR-gamma ligands have also been shown to inhibit major inflammatory signaling pathways, reducing the synthesis of cartilage catabolic factors responsible for articular cartilage degradation in arthritis. in the present review the crucial role of PPAR-gamma ligands in arthritis and the underlying mechanisms participating in essential inflammatory signaling pathways are summarized. Taking into consideration the data so far, PPAR-gamma ligands seem to represent potential therapeutic agents in the aim to reduce mainly the inflammation implicated in arthritis. However, the precise molecular mechanisms through which PPAR-gamma ligands exert their actions are strongly recommended to be clarified, as both receptor-dependent and -independent actions were shown to be elicited. TI The Combination of the Biomarkers Urinary C-Terminal Telopeptide of Type II Collagen, Serum Cartilage Oligomeric Matrix Protein, and Serum Chondroitin Sulfate 846 Reflects Cartilage Damage in Hemophilic Arthropathy
SO ARTHRITIS AND RHEUMATISM
LA English
DT Article
ID early rheumatoid-arthritis; induced joint damage; radiographic progression; degradation-products; knee osteoarthritis; articular-cartilage; diurnal-variation; markers; fragments; bone
AB Objective. Hemophilic arthropathy, with characteristics of inflammatory (rheumatoid arthritis) and degenerative (osteoarthritis) joint damage, occurs at an early age, is associated with minor comorbidity, and is restricted to 3 pairs of large joints. The aim of this study was to determine whether commonly used serum and/or urinary biomarkers of cartilage and bone turnover for which assay kits are commercially available are associated with the severity of joint damage in patients with various degrees of hemophilic arthropathy and, thus, whether this disease could be useful in the identification and evaluation of such biomarkers. Methods. Blood and urine samples were collected from 36 patients with various degrees of hemophilic arthropathy. Commercially available assays for the most frequently investigated serum and urine biomarkers were performed: urinary C-terminal telopeptide of type I collagen (CTX-I), urinary CTX-II, serum CTX-I, serum CTX-II, serum cartilage oligomeric matrix protein (COMP), serum cartilage cleavage products C1,2C and C2C, and serum chondroitin sulfate 846 (CS-846). Radiographs of the ankles, knees, and elbows in all patients were evaluated for the degree of joint damage according to the Pettersson score, which is based on cartilage and

periarticular bone changes and is specific for hemophilic arthropathy. Results. Urinary CTX-II, serum C1,2C, and serum CS-846 levels correlated with the overall Pettersson score and with the joint space narrowing component. Regression analysis showed that combined indexes of different markers increased the degree of correlation for the combination of urinary CTX-II, serum COMP, and serum CS-846. Bone-specific markers (urinary/serum CTX-I and serum C1,2C) did not correlate with specific bone-related items of the Pettersson score (osteoporosis and erosions). Conclusion. These results support the idea that a combination of biomarkers relates significantly better to the severity of joint damage than do individual biomarkers. The combination of urinary CTX-II, serum COMP, and serum CS-846 correlated best with the degree of arthropathy. Because of its specific characteristics and restricted involvement, hemophilic arthropathy may prove useful in the screening of newly developed biomarkers of joint damage.

TI Postmenopausal women with osteoarthritis and osteoporosis show different ultrastructural characteristics of trabecular bone of the femoral head
SO BMC MUSCULOSKELETAL DISORDERS
LA English
DT Article
ID scanning-electron-microscopy; human cortical bone; cancellous bone; resorption lacunae; hip-joint; fracture; men; consequences; cartilage; estrogen
AB Background: Osteoporosis (OP) and osteoarthritis (OA) are public health diseases affecting the quality of life of the elderly, and bring about a heavy burden to the society and family of patients. It has been debated whether or not there is an inverse relationship between these two disorders. Methods: To compare the exact

difference in bone tissue structure between osteoporosis and osteoarthritis, we observed the ultrastructure of trabecular bone from the femoral heads using scanning electron microscopy (SEM) and transmission electron microscopy (TEM). A total of 15 femoral head specimens from postmenopausal women were collected during the procedures of total or hemi hip replacement (OP, n = 8; OA, n = 7). The morphologic structure of the trabecular bone, collagen fibers, resorption lacuna and osteoblasts were observed. Results: Under SEM, osteoporotic trabeculae appeared to be thinning, tapering, breaking and perforating. A number of resorption lacunae of various shapes were seen on the surface of the trabeculum. The collagen fibers of lacuna were resorbed. On occasion, naked granular bone crystals could be found. In the OA group, the trabecular bone looked thick with integrated structure. Reticular and granular new bone could be found. The trabeculum was covered by well-arranged collagen fibers around the resorption lacuna. In the OP group, under TEM, marginal collagen fibers were observed to be aligned loosely with enlarged spaces. A few inactive osteoblasts and no inflammatory cells were seen. In the OA group, the collagen fibers inside the trabeculum were arranged in a dense manner with many active osteoblasts and inflammatory cells infiltrating the matrix. Conclusion: We found significant differences in the trabecular bone, collagen fibers, lacunae and osteoblasts between postmenopausal women with OP and OA. These findings support the hypothesis that there is an inverse relationship between OP and OA.

TI Dual energy x-ray absorptiometry analysis contributes to the prediction of hip osteoarthritis progression
SO ARTHRITIS RESEARCH & THERAPY
LA English
DT Article
ID bone-mineral density; subchondral bone; radiographic osteoarthritis; osteoporosis
AB Introduction To determine if structural bone parameters obtained from dual energy X-ray absorptiometry (DXA) contribute to the prediction of progression of hip osteoarthritis (OA) and to test if the difference between the most affected (OA) hip and the contralateral hip adds to this prediction. Methods The study group involves a prospective cohort of 189 patients that met the American College of Rheumatology (ARC) classification criteria for hip osteoarthritis. Progression was defined as 20% joint space narrowing or total hip replacement within a two years follow up. Software was developed to calculate geometrical aspects and bone mineral density (BMD) in different regions of interest of the proximal femur. Logistic regression was used to test if Kellgren and Lawrence (K-L) scores and DXA parameters can predict progression of OA. Models were compared using -2log likelihood tests, R-2 Nagelkerke and areas under the Receiver Operator

Characteristic curves, assessed using 10-fold cross validation. Results The model that included the DXA variables was significantly better in predicting hip OA progression than the model with K-L score of the affected side alone ($P < 0.01$). The addition of the differences in DXA parameters between the most affected and contralateral hip in the superior part of the femoral head, trochanteric and intertrochanteric area further improved the prediction of progression ($P < 0.05$). K-L score of the affected side was still the most significant single variable in the models. Conclusions DXA parameters can significantly contribute to the prediction of progression in patients with hip osteoarthritis. The analysis of the DXA differences between the hips of the patient represents a small but significant contribution to this prediction. These analyses show the importance of bone density changes in the etiology of OA.

DT Review
DE Bone healing; Osteoarthritis; Osteoporosis; Post-surgical pain; Fracture
ID nerve growth-factor; gene-related peptide; nonsteroidal antiinflammatory drugs; lumbar intervertebral disc; rat model; weight-bearing; immunoreactive nerves; skeletal pain; animal-model; secondary hyperalgesia
AB Non-malignant musculoskeletal pain is the most common clinical symptom that causes patients to seek medical attention and is a major cause of disability in the world. Musculoskeletal pain can arise from a variety of common conditions including osteoarthritis, rheumatoid arthritis, osteoporosis, surgery, low back pain and bone fracture. A major problem in designing new therapies to treat musculoskeletal pain is that the underlying mechanisms driving musculoskeletal pain are not well understood. This lack of knowledge is largely due to the scarcity of animal models that closely mirror the human condition which would allow the development of a mechanistic understanding and novel therapies to treat this pain. To begin to develop a mechanism-based understanding of the factors involved in generating musculoskeletal pain, in this review we present recent advances in preclinical models of osteoarthritis, post-surgical pain and bone fracture pain. The models discussed appear to offer an attractive platform for understanding the factors that drive this pain and the preclinical screening of novel therapies to treat musculoskeletal pain. Developing both an understanding of the mechanisms that drive persistent musculoskeletal pain and novel mechanism-based therapies to treat these unique pain states would address a major unmet clinical need and have significant clinical, economic and societal benefits. TI A traditional Chinese medicine formula extracts stimulate proliferation and inhibit mineralization of human mesenchymal stem cells in vitro
SO JOURNAL OF ETHNOPHARMACOLOGY
LA English
DT Article
DE TCM extracts; Human mesenchymal stem cell; Cell proliferation; Osteogenic differentiation; Osteoarthritis
ID marrow stromal cells; subchondral bone; osteoblastic differentiation; osteogenic differentiation; inverse relationship; growth-factors; osteoarthritis; osteoporosis; degradation; progression
AB Aim of the study: To investigate the effects of a traditional Chinese medicine (TCM) formula extract, named as ZD-I, on the proliferation and osteogenic differentiation of human mesenchymal stem cells (hMSCs) in vitro. Materials and methods: When hMSCs cultivated in the basal medium with ZD-I, cell viability was assessed by MTT assay and cellular proliferation was assessed by SYBR green I assay. The effects of ZD-I on osteogenic differentiation of hMSCs were assessed by alkaline phosphatase (ALP) activity, mineralization assay and real-time RT-PCR. Results: ZD-I (0.78-100 mu g/ml) was non-cytotoxic. The 50% inhibitory concentration (IC50) of hMSCs was 200 mu g/ml. ZD-I (0.78-50 mu g/ml) stimulated the proliferation of hMSCs. ZD-I did not change ALP activity of hMSCs cultivated in osteogenic medium in the early stage (4 and 7 days), but ZD-I inhibited the mineralization of hMSCs through down-regulation of several osteogenic markers (e.g. osteocalcin, bone morphogenetic protein 2 and

osteopontin) in the late stage. Conclusions: ZD-I stimulate cellular proliferation and decrease the bone mineral deposition of hMSCs. These results suggest ZD-I may play an important therapeutic role in osteoarthritic patients by improving proliferative capacity of hMSCs and inhibiting the mineralization of hMSCs. TI Osteoarthritis associated with estrogen deficiency
SO ARTHRITIS RESEARCH & THERAPY
LA English
DT Review
ID hormone-replacement-therapy; radiographic knee osteoarthritis; periarticular tibial osteophytes; human articular chondrocytes; alpha gene haplotype; bone-mineral density; receptor-alpha; skeletal-muscle; subchondral bone; postmenopausal women
AB Osteoarthritis (OA) affects all articular tissues and finally leads to joint failure. Although articular tissues have long been considered unresponsive to estrogens or their deficiency, there is now increasing evidence that estrogens influence the activity of joint tissues through complex molecular pathways that act at multiple levels. Indeed, we are only just beginning to understand the effects of estrogen deficiency on articular tissues during OA development and progression, as well as

on the association between OA and osteoporosis. Estrogen replacement therapy and current selective estrogen receptor modulators have mixed effectiveness in preserving and/or restoring joint tissue in OA. Thus, a better understanding of how estrogen acts on joints and other tissues in OA will aid the development of specific and safe estrogen ligands as novel therapeutic agents targeting the OA joint as a whole organ.

TI Equivalent osteoblastic differentiation function of human mesenchymal stem cells from rheumatoid arthritis in comparison with osteoarthritis
SO RHEUMATOLOGY
LA English
DT Article
DE Rheumatoid arthritis; Human meschenchymal stem cells; Osteoblast; Bone formation
ID bone-mineral density; necrosis-factor-alpha; disease; destruction; marrow; osteoporosis; methotrexate; pathogenesis; metabolism; expression
AB Objective. To evaluate the osteoblastic differentiation of human mesenchymal stem cells (hMSCs) in patients with RA. Methods. Heparinized bone marrow aspirate was obtained from patients with OA and RA. Mononuclear cells were cultured for 2 weeks and a colony-forming assay was performed. The phenotype of cells was analysed by flow cytometry. Passage 2 cells were cultured with -glycerophosphate (bGP) in the control group and bGP, ascorbic acid and dexamethasone in the differentiation group. After 2 weeks, ALP staining and activity were performed. After 3 weeks, Alizarin Red S assay was performed. Total RNA was extracted from cells cultured for 2 and 3 weeks. Gene expression of bone formation factor was examined by real-time PCR. Results. The phenotype of cells was identical in both OA and RA and the content was thought to be hMSCs. The results of ALP activity and Alizarin Red S assay showed higher levels in the differentiation group for both OA and RA samples compared with the control group. The results of a colony-forming assay were identical in both OA and RA samples. Gene expression in the differentiation group was higher than in the control group in both OA and RA samples. There was no significant difference

between OA and RA samples in all experiments. Conclusion. The function of osteoblastic differentiation of hMSCs is similar between OA and RA.

TI RESTORATION OF THE ROTATION CENTER IN MINIMALLY-INVASIVE TOTAL HIP REPLACEMENT
SO ACTA ORTOPEDICA BRASILEIRA
LA English
DT Article
DE Arthroplasty; replacement; hip; Minimally-invasive surgical procedures; Human
ID mini-incision; arthroplasty; complications; surgery
AB Objective: Our aim was to evaluate the challenges in obtaining a successful restoration of the rotation center as well as a good positioning of the acetabular component when using the minimally-invasive posterior approach for uncemented total hip replacement. Methods: In a comparative non-random prospective study, 64 adult patients underwent elective total hip arthroplasty using the minimally-invasive posterior approach performed by one single surgeon, All patients included in this study had a superior and lateral migration of the rotation center of the hip in comparison to the normal contralateral hip. Patients were excluded from the study if they presented the following: diagnosis of femoral neck fracture, displasic hip types 2, 3 and 4 (Crowe's classification), osteoarthritis of the contralateral hip. Of the 64 patients in the study, 39 had a radiographic pre-op acetabular size planning equal or less than 50 mm and 25 patients had a radiographic pre-op acetabular size planning equal or more than 52 mm. We considered a good result the following goals: acetabular bend between 35 and 50 degrees, acetabular size according to the pre-op estimative with full contact in the three zones of DeLee-Charnley, a lower medial and vertical positioning of the rotation center in comparison with the pre-op values and a final limb discrepancy lower than 10 mm. Results: A better restoration of the rotation center, as well as, excellent acetabular positioning was found in patients with smaller acetabular size (equal or less than 50), p=0, 04. We must draw attention to two risks when using the minimally-invasive posterior approach: a vertical acetabular position and a lateral position of the acetabular component increasing the risk of a poor contact in the zone 1 due to an insufficient reaming of the medial acetabular host bone. Conclusion: We propose standard surgical approaches in patients with larger anatomical measurements (acetabular planning size more than 50).

TI Cemented bipolar hemiarthroplasty in osteoporosis for failed femoral neck fixation
SO CANADIAN JOURNAL OF SURGERY
LA English
DT Article
ID total hip-arthroplasty; osteopetrosis; patient
AB Osteopetrosis refers to a group of disorders characterized by severe impairment of osteoclast-mediated bone resorption. Other terms that are often used for this disease are marble bone disease, which describes the solid radiographic appearance of the involved skeleton, and Albers-Schonberg disease, which refers to the milder, adult form of osteopetrosis of or autosomal dominant osteopetrosis type 2. The major types of osteopetrosis, include malignant (severe, infiantile, autosorrial recessive) osteopetrosis and benign (adult, autosomal dominant) osteopetrosis types I and II. A third form is a rare autosomal recessive type characterized by a carbonic anhydrase II deficiency; it is associated with renal tubular acidosis and cerebral calcification.(1) Radiographically, there is a generalized, symmetric Increase in bone mass with thickening of both cortical and trabecular bone. Despite the excess boric formation, osteopetrosis bone tends to be brittle in nature.(2) There is presently no cure for the disease, but bone marrow transplant is ail option for sonic children.(1) Osteoarthritis and periarticular nonunions are indications for joint replacement surgery in these patients. Most reports of hip-replacement surgery performed in this population focus on total hip arthroplasty (THA) for osteoarthritis.(3-4) One previous report discusses THA for femoral neck nonunion with retained hardware.(9) Most authors recommend the use of cemented femoral fixation and uncemented acetabular fixation. There are no reports of bipolar hemiarthroplasty in osteopetrosis patients. We describe a case of cemented bipolar hemiarthroplasty as a salvage option for failed femoral neck fixation with retained hardware, despite end-stage acetabular cartilage degeneration.

TI Mechanical and structural anisotropy of human cancellous femur bone
SO JOURNAL OF VIBROENGINEERING
LA English
DT Article
DE osteoporosis; osteoarthritis
AB The function of bone tissue, which is a very complex material, is due to the structure and mechanical properties. According to Wolff's law, the permanent loaded hip is well-motivated and adapts his inner and outer architecture to the environment. The body mass is transferred through the femur bone, where the trabeculae aligns along stress trajectories. This theorem has the important corollary that affects architecture of cancellous bone and determines its mechanical properties. The main goal of this paper was to find correlation between mechanical and structural properties of healthy and pathological trabecular femur bone (osteoporosis and osteoarthritis).

TI Incorporation of excess gadolinium into human bone from medical contrast agents
SO METALLOMICS
LA English

DT Article
ID nephrogenic systemic fibrosis; blood lead levels; gd-eob-dtpa; safety; gadodiamide; tissue; retention; transmetalation; mineralization; resorption
AB We find anomalously high gadolinium (Gd) concentrations in the femoral head bones of patients exposed to chelated Gd, commonly used as a contrast agent for medical imaging. Gd is introduced in chelated form to protect patients from exposure to toxic free Gd3+, a calcium antagonist which disrupts cellular processes. Recent studies suggest Gd chelates break down in vivo, and Gd accumulation in tissue is linked to medical conditions such as nephrogenic systemic fibrosis (NSF), acute kidney failure, and in some cases death. We measure Gd and other rare earth element (REE) concentrations in 35 femoral heads by solution based ICP-MS. Gd concentrations in patients with documented exposure to Gd-based contrast agents (n = 13: Gd DTPA-BMA (Omniscan) n = 6; Gd HP-DO3A (Prohance) n = 5; unknown type n = 4) are significantly higher ($p < 0.001$) than the control group (n = 17). We use our control group to establish the 'natural' background level of Gd in human bone (cortical 95% CI: 0.023, 0.041 nmol/g; trabecular 95% CI: 0.054, 0.107 nmol/g). A control group outlier reveals the occurrence of individuals with high concentrations of all REEs, including Gd. Because of this, we calculate Gd anomalies from the concentrations of adjacent REEs and normalize to the control group mean to isolate Gd input from contrast agents. Normalized Gd anomalies, (Gd/Gd*)(N), for exposed patients range up to 4800 times the 'natural' level (95% CI: 124, 460). Our data confirm that Gd, introduced in chelated form, incorporates into bone and is retained for more than 8 years. No difference was observed in bone Gd concentrations and anomalies between patients dosed with Gd DTPA-BMA (Omniscan; n = 6) and Gd HP-DO3A (Prohance; n = 5). Osteoporotic fracture patients exposed to Gd have significantly lower Gd concentrations than osteoarthritis patients ($p < 0.001$). This indicates different mechanisms of metal incorporation and/or retention in osteoporotic bone tissues, and may signal an increased risk of endogenous Gd release for patients with increased rates of bone resorption (e. g. osteoporosis patients and menopausal, pregnant, and lactating women) who are exposed to Gd-based contrast agents.

DT Article
ID human osteogenic protein-1; human articular chondrocytes; rabbit knee; cartilage; repair; model; expression; defects; op-1; proteoglycan
AB Osteoarthritis is a degenerative disorder resulting from breakdown of articular cartilage. Previous work has shown bone morphogenic protein-7 has a potential protective effect on cartilage during the development of osteoarthritis. The purpose of this study was to determine whether bone morphogenic protein-7 could decrease the amount of cartilage degradation in preexisting osteoarthritis. The rabbit ACLT model was used as a model of osteoarthritis. Bone morphogenic protein-7 was delivered via Alzet osmotic pump to the joint 4 weeks after anterior cruciate ligament transection; thus cartilage injury was preexisting. The experimental group showed less cartilage degradation than the controls, with an average Outerbridge score of 1.9 versus 2.6 for the controls. Histomorphometry showed a trend toward less cartilage degradation in the bone morphogenic protein-7 group when compared with controls. Semiquantitative real-time polymerase chain reaction showed a considerably greater expression of aggrecan in the bone morphogenic protein-7-treated cartilage when compared with controls and less expression of matrix metalloproteinase-3 and matrix metalloproteinase-13, important catabolic mediators. The synovial tissue of the experimental group also showed considerably less expression of matrix metalloproteinase-3, matrix metalloproteinase-13, and aggrecanase. These results indicate bone morphogenic protein-7 may reduce degradation of articular cartilage in osteoarthritis.

TI Epidemiology of lumbar osteoporosis and osteoarthritis and their causal relationship-is osteoarthritis a predictor for osteoporosis or vice versa?: The Miyama study
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE Causal relationship; Disc space narrowing; Incidence; Population-based cohort; Prevalence; Risk factors
ID rural japanese community; bone-mineral density; disc degeneration; inverse relationship; radiographic osteoarthritis; postmenopausal women; knee osteoarthritis; vertebral fracture; risk; spine
AB In a 10-year follow-up of a population-based cohort of Japanese subjects, incidences of and causal relationships between osteoporosis (OP) and osteoarthritis

(OA) at the lumbar spine were clarified. OP might reduce the risk of subsequent OA at the spine in women, but not in men. The aim of this study is to clarify the contribution of osteoarthritis (OA) to osteoporosis (OP) and vice versa. A population-based, epidemiological study was conducted in a Japanese rural community. From 1,543 participants aged 40-79 years, 200 men and 200 women were selected and followed up for 10 years. Bone mineral density measurements were repeated after 3, 7, and 10 years, and X-rays were repeated after 10 years. The incidence of lumbar OP per 10,000 person-years for persons in their 40s, 50s, 60s, and 70s was 0, 0, 109.5, and 151.1 for men and 124.2, 384.0, 227.3, and 239.5 for women, respectively. The cumulative incidence of lumbar OA over 10 years aged 40-79 years was 25.8% in men and 45.2% in women. Cox's proportional hazards model showed no significant relationship between the presence of lumbar OA at the baseline and incidence of lumbar and femoral neck OP in both genders. A significant relationship was demonstrated between the presence of lumbar OP, not femoral neck OP, at the baseline and cumulative incidence of lumbar OA in women (odds ratio, 0.20; 95% confidence interval, 0.05-0.80; P = 0.02). OP in women appears to reduce the future incidence of OA at the lumbar spine.

TI ACTIVE CIRCULATOR CIRCUITS USING OA, CCII, CFOA AND DVCC
SO JOURNAL OF CIRCUITS SYSTEMS AND COMPUTERS
LA English
DT Article
DE Active circuits; op amps; CCII; CFOA; DVCC; active circulators
ID current conveyor; op-amp; realization; amplifiers
AB A review of the two types of circulators using Operational Amplifiers (OA) with detailed comparison is given. Novel active circulator circuits using Current Conveyors (CCII) and Current Feedback Operational Amplifiers (CFOA) and Differential Voltage Current Conveyor (DVCC) are introduced. The proposed CCII circulator circuit uses six CCIIs and three floating resistors. Two different circulator types using the CFOA are given. A circulator circuit which uses three DVCCs and has the advantage of using three grounded resistors is also introduced. Spice simulation results using 0.5 mu m CMOS transistors are included to support the theoretical analysis and demonstrate comparisons among the different types of circulators.

TI A comparison of four different HRQoL generic questionnaire in five different patient groups
SO RHEUMATOLOGY INTERNATIONAL
LA English
DT Article
DE Health-related quality of life; Generic; QoL-5; NHP; SF-6D; VAS
ID quality-of-life; nottingham health profile; rheumatoid-arthritis; ankylosing-spondylitis; osteoarthritis; validation; knee
AB Most of musculoskeletal diseases involve pain and reduced physical functioning. Recognition of the coexistence of more than one musculoskeletal disease is important because they are relatively common and has a substantial impact on health-related quality of life (HRQoL). Our aim was to compare the results of four generic QoL questionnaires-QoL-5, Nottingham Health Profile (NHP), Short Form (SF)-6D, and Visual Analogue Scale (VAS)-in five different patient groups. Two hundred and one patients representing five different disease groups (knee osteoarthritis, osteoporosis, back pain, rheumatoid arthritis and ankylosing spondylitis), randomly selected through the Ankara Numune Education and Research Hospital Physical Medicine and Rehabilitation Outpatient Clinic, were included in the study. Scores indicating low QoL for each of the five diseases compared are reported. Patients in each disease group stated high disability. No strong correlation between any of the scales could be determined, and NHP was identified as the only scale able to differentiate between the diseases. Many

instruments are available for measuring HRQoL. The QoL-5, NHP, SF-6D, and VAS are four commonly used generic (i.e., not disease-specific) measures for quantifying HRQoL in patients with musculoskeletal disorders. Most studies have focused on only one musculoskeletal disease, but comorbidity of musculoskeletal disorders is common. We emphasize in this study the effect of multiple musculoskeletal diseases on HRQoL.

TI Bone Mineral Density and Vitamin D Status in Female and Male Patients with Osteoarthritis of the Knee or Hip
SO EUROPEAN SURGICAL RESEARCH
LA English
DT Article
DE Osteoporosis; Vitamin D; Osteoarthritis; Bone mineral density
ID randomized controlled-trial; osteoporotic fractures; d inadequacy; postmenopausal women; elderly-women; calcium supplementation; secondary hyperparathyroidism; radiographic osteoarthritis; vertebral deformity; d deficiency
AB Objective: Osteoporosis (OP), osteoarthritis (OA) and vitamin D deficiency are

age-related disorders. We investigated the association between bone mineral density (BMD), vitamin D and OA in patients undergoing total hip or knee replacements. Method: In total, 82 women and 35 men with mean ages of 70 and 68 years, respectively, were recruited for the study. The BMD of the lumbar spine and the proximal femur were measured by dual-energy X-ray absorptiometry. The vitamin D status was assessed by 25(OH) D levels, with a cut-off of <= 30 ng.ml(-1). Results: In total, 84.7% of the patients had a vitamin D deficiency; 20% of the men had a T-score below -2.5; 23.2% of the women were affected by OP. Furthermore, 37.1 and 42.7% of the male and female patients, respectively, had osteopenia. We concluded that OP and osteopenia were not due to immobility. Conclusion: The average age, rather than the frequency of OP, in cases with OA of the hip or knee differed from the general population. The incidence of low BMD in the male cohort was notably higher than expected. We detected a high prevalence of vitamin D deficiency, independent of the BMD. Copyright (c) 2008 S. Karger AG, Basel

TI Quantitative analysis of subchondral sclerosis of the tibia by bone texture parameters in knee radiographs: site-specific relationships with joint space width
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE Severe osteoarthritis; Bone texture parameters; Radiograph; Subchondral bone; Location-specific joint space width
ID trabecular bone; articular-cartilage; axial alignment; osteoarthritis; density; histomorphometry; osteoporosis; progression; thickness; disease
AB Objectives: To determine the ability of radiographic bone texture (BTX) parameters to quantify subchondral tibia sclerosis and to examine clinical relevance for assessing osteoarthritis (OA) progression. We examined the relationship between BTX parameters and each of (1) location-specific joint space width (JSW)

[JSW(x)] and minimum JSW (mJSW) of the affected compartment, and (2) knee alignment (KA) angle in knee radiographs of participants undergoing total knee arthroplasty (TKA). Design: Digitized fixed-flexion knee radiographs were analyzed for run-length and topological BTX parameters in a subchondral region using an algorithm. Medial JSW(x) was computed at x = 0.200, 0.225, 0.250 and 0.275 according to a coordinate system defined by anatomic landmarks. mJSW was determined for medial and lateral compartment lesions. KA angles were determined from radiographs using an anatomic landmark-guided algorithm. JSW measures and the magnitude of knee malalignment were each correlated with BTX parameters. Reproducibility of BTX parameters was measured by root-mean square coefficients of variation (RMSCV%). Results: Run-length BTX parameters were highly reproducible (RMSCV% < 1%) while topological parameters showed poorer reproducibility (>5%). In TKA participants (17 women, 13 men; age: 66 +/- 9 years; body mass index (BMI): 31 +/- 6 kg m(-2); WOMAC: 41.5 +/- 16.1; Kellgren-Lawrence score mode: 4), reduced trabecular spacing (Tb.Sp) and increased free ends (FE) were correlated with decreased JSW after accounting for BMI, gender and knee malalignment. These relationships were dependent on site of JSW measurement. Conclusion: High reproducibility in quantifying bone sclerosis using Tb.Sp and its significant relationship with JSW demonstrated potential for assessing OA progression. Increased trabecular FE and reduced porosity observed with smaller JSW suggest collapsing subchondral bone or trabecular plate perforation in advanced knee OA. TI The Minimally Invasive Anterolateral Approach Combined with Hip Onlay Resurfacing
SO OPERATIVE ORTHOPADIE UND TRAUMATOLOGIE
LA English
DT Article
DE Minimally invasive; Hip; Approach; Onlay; Prosthesis; Osteoarthritis; Resurfacing
ID arthroplasty
AB Minimally invasive anterolateral approach in hip resurfacing with complete preservation of muscular integrity. Primary or secondary osteoarthritis of the hip. Approach: - None. Onlay implant: - Females > 55 years with osteoporosis. - Males > 60 years with osteoporosis. - Severe varus deformity (CCD [collodiaphyseal] angle < 100A degrees). - History of metal allergy. - Clinically relevant renal insufficiency. - Radiologic appearance of avascular necrosis stage 3 and 4 according to Ficat. - Femoral head cysts > 1 cm in diameter. Supine position with possible overextension of the hip, longitudinal incision along the intermuscular septum and blunt intermuscular dissection between gluteus medius and tensor fasciae latae, partial resection of the anterior capsule and anterior dislocation of the hip with complete proximal release of the capsule. Dislocation of the femoral head and dorsal positioning, reaming of the acetabulum to implant the cementless acetabular component, exposition and reaming of the femoral head in extension/adduction and external rotation, implantation of the cemented onlay endoprosthesis. Prophylaxis of thromboembolism and periarticular ossification. Rehabilitation with weight bearing as tolerated starting on the day of surgery,

ergometer training from day 4 after surgery. 31 patients with osteoarthritis underwent onlay resurfacing via a minimally invasive approach. The Harris Hip Score improved from 43.9 to 97.1 at 12 months after surgery. Adverse events such as fracture, dislocation, nerve or muscle lesions did not occur, and clinically significant thromboembolism or infection was not observed.

TI RANKL/OPG in primary cultures of osteoblasts from post-menopausal women. Differences between osteoporotic hip fractures and osteoarthritis
SO JOURNAL OF STEROID BIOCHEMISTRY AND MOLECULAR BIOLOGY
LA English
DT Article
DE Human osteoblast culture; Osteoporosis; OPG/RANKL; 17-Beta-estradiol; 1,25-Dihydroxyvitamin D
ID kappa-b ligand; osteoclastogenesis inhibitory factor; messenger-rna levels; estrogen-receptor; vitamin-d; regulates osteoclast; cancellous bone; femoral-neck; osteoprotegerin production; differentiation factor
AB The OPG/RANKL/RANK system is important in the balance between bone formation and resorption. We used primary human osteoblasts (hOBs) cells to examine the impact of 17-beta-estradiol (E2) or/and 1,25-dihydroxyvitamin D (1,25D) in OPG/RANKL system in 28 post-menopausal (PM) women; (a) with hip fracture (OP) or (b) with osteoarthritis (OA). The hOB from OP patients proliferated slower during the first stage, than the OA women (31.5 +/- 2.6 and 21.4 +/- 1.3 days, respectively, $p < 0.05$). The OP group secreted significantly higher OPG protein levels than the OA women (10.1 +/- 2.6 and 4.4 +/- 0.8 pmol/L,

respectively, p < 0.05). The 1,25D and 1,25D+E2 induce an increase in RANKL and RANKL/OPG mRNA expression in OP patients above 200% (p < 0.05). HOBS from the osteoporotic hip initially proliferate slower but after reaching the first cellular confluence, the proliferation rate is equal in both groups. Furthermore, hOBs from hips with OP present a higher protein secretion of OPG, and higher RANKL and RANKL/OPG expression ratio in response to 1,25D and 1,25D+E2, than hOBs from OA women. All this could suggest that the greater bone loss that characterizes OP patients can be mediated due to differences in the secretion and expression of the RANKL/OPG system in response to different stimuli. TI Lumbar lordosis in osteoporosis and in osteoarthritis
SO EUROPEAN SPINE JOURNAL
LA English
DT Article
DE Lumbar lordosis; Osteoarthritis; Osteoporosis
ID low-back-pain; spinal curvatures; physical-activity; inverse relationship; pelvic inclination; women; adults; population; posture; epidemiology
AB The curvature of the lumbar spine and the risk of developing either osteoporosis (OP) or osteoarthritis (OA) are influenced by many common factors. The aim of this study is to determine whether lumbar lordosis is different between patients with either disease and healthy persons. A cross-sectional, blinded, controlled design was implemented. One hundred and twelve postmenopausal women were evaluated for bone mineral density as well as undergoing spinal radiography. Lordosis measurement was performed with Cobb's method. The sample was divided in four groups: patients with OP (n = 34, L1-L5 = 40.7A degrees, L1-S1 = 54.1A degrees), patients with OA (n = 29, L1-L5 = 38A degrees, L1-S1 = 52.3A degrees), patients with both diseases (n = 20, L1-L5 = 41.8A degrees, L1-S1 = 52.3A degrees) and controls (n = 29, L1-L5 = 38.6A degrees, L1-S1 = 51.8A degrees). For all participants age, height, weight, body mass index, physical activity level and basal metabolic rate were measured and recorded. The results revealed that although the four groups have significant constitutional differences, lumbar lordosis was comparable between them. The reasons for the lack of association are discussed.

TI Predicting osteoporosis in patients with a low-energy fracture
SO ARCHIVES OF GERONTOLOGY AND GERIATRICS
LA English
DT Article
DE Osteoporosis; Falls; Risk factors; Prediction rule; Low-energy fracture
ID risk-factors; tai-chi; falls; metaanalysis; impairment; balance; women; men
AB The multicenter cross-sectional study was designed to develop a simple rule to predict the risk of osteoporosis in the patients with a low-energy fracture (LEF). Furthermore, we aimed to investigate the incidence of fall-related risk factors. We included 206 patients with age over 50 and an LEF at the emergency room. All patients underwent osteoporosis and fall risk assessment and dual-energy X-ray absorptiometry (DEXA) of both hips and the lumbar spine. The incidence of osteoporosis in our study population was 41% (84 cases of 206). Fifty-four percent of the patients reported at least one fall-related risk factor. Mobility problems occurred in 31% and osteoarthritis in 19%. The final osteoporosis prediction rule included age, positive family history, immobility, and low-body weight. The discrimination of the rule after correction for over-optimism was good (receiver operating curve (ROC) = ROC area = 0.79). This simple rule may be helpful to select patients who need further osteoporosis assessment. (C) 2008 Elsevier Ireland Ltd. All rights reserved.

TI Methylation of the OP-1 promoter: potential role in the age-related decline in OP-1 expression in cartilage
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE Chondrocyte; Aging; Growth factors; Osteoarthritis
ID growth-factor-i; osteogenic protein-1; dna methylation; osteoarthritic

chondrocytes
AB Objective: An age-related decline in chondrocyte production of osteogenic protein-1 (OP-1) (Bone Morphogenetic Protein-7) may contribute to cartilage loss in osteoarthritis, This study was designed to determine it increased methylation of the OP-1 promoter might serve as a mechanism for the age-related decline in OP-1 expression. Methods: Human articular chondrocytes were isolated from cartilage obtained after death from tissue donors (ages 19-86 years) without a known history of arthritis. DNA was obtained from isolated chondrocytes in primary culture and analyzed for OP-1 promoter methylation by polymerase chain reaction (PCR) after bisulfite treatment. Cultured cells were treated with the DNA methyltransferase inhibitor 5-azacytidine and OP-1 production was measured in the media by enzyme-linked immunosorbent assay (ELISA). RNA was isolated to measure expression of insulin-like growth factor-1 (IGF-1), the IGF-1 receptor (IGF-1 R), aggrecan, and OP-1 by real-time PCR. Results: Methylation of the OP-1 promoter was detected in chondrocytes isolated from tissue obtained from older adults and there was a positive correlation between age and OP-1 methylation status (n = 22, R(2) = 0.277, P = 0.014). Inhibition of methylation in cultured cells with 5-azacytidine increased chondrocyte production of OP-1 protein and increased the expression of the IGF-1, the IGF-1R, aggrecan, and OP-1 genes but not GAPDH. Conclusion: Age-related methylation of the OP-1 promoter may contribute to a decrease in OP-1 production in cartilage and a decrease in expression of OP-1 responsive genes such as IGF-1, the IGF-1 R, and aggrecan. TI Nuclear Quadrupole Resonance Frequency in Multilayered Cuprates
SO JOURNAL OF THE PHYSICAL SOCIETY OF JAPAN
LA English
DT Article
DE nuclear quadrupole resonance; multilayered cuprates; exact diagonalization; apical site; Madelung potential
ID induced structural-changes; electric-field gradients; local hole distribution; crystal-structure; single-crystals; charge-transfer; superconductor; temperature; oxygen; diffraction
AB The Cu-63 nuclear quadrupole resonance (NQR) frequency nu(Q) in the multilayered cuprates is calculated in the cluster model by the exact diagonalization method. The charge imbalance between the outer CuO2 plane (OP) with apical oxygen O-A and the inner plane (IP) without OA in three-layered Tl2Ba2Ca2Cu3O10 is estimated by comparing Our results with the experimental nu(Q). In Tl-based cuprates with more than three layers, we predict a large enhancement of the splitting of nu(Q) between OP and IP by taking into account the reduction in bond length between Cu and O-A and the resulting increase in charge transfer energy. Our results show that the NQR frequency is a useful quantity for estimating the charge imbalance in the multilayered cuprates.

TI Bone marrow lesions from osteoarthritis knees are characterized by sclerotic bone that is less well mineralized
SO ARTHRITIS RESEARCH & THERAPY
LA English
DT Article

ID subchondral bone; cancellous bone; trabecular bone; mechanical-property; biochemical markers; femoral-head; osteoporosis; association; cartilage; turnover
AB Introduction Although the presence of bone marrow lesions (BMLs) on magnetic resonance images is strongly associated with osteoarthritis progression and pain, the underlying pathology is not well established. The aim of the present study was to evaluate the architecture of subchondral bone in regions with and without BMLs from the same individual using bone histomorphometry. Methods Postmenopausal female subjects (n = 6, age 48 to 90 years) with predominantly medial compartment osteoarthritis and on a waiting list for total knee replacement were recruited. To identify the location of the BMLs, subjects had a magnetic resonance imaging scan performed on their study knee prior to total knee replacement using a GE 1.5 T scanner with a dedicated extremity coil. An axial map of the tibial plateau was made, delineating the precise location of the BML. After surgical removal of the tibial plateau, the BML was localized using the axial map from the magnetic resonance image and the lesion excised along with a comparably sized bone specimen adjacent to the BML and from the contralateral compartment without a BML. Cores were imaged via microcomputed tomography, and the bone volume fraction and tissue mineral density were calculated for each core. In addition, the thickness of the subchondral plate was measured, and the following quantitative metrics of trabecular structure were calculated for the subchondral trabecular bone in each core: trabecular number, thickness, and spacing, structure model index, connectivity density, and degree of anisotropy. We computed the mean and standard deviation for Teach parameter, and the unaffected bone from the medial tibial plateau and the bone from the lateral tibial plateau were compared with the affected BML region in the medial tibial plateau. Results Cores from the lesion area displayed increased bone volume fraction but reduced tissue mineral density. The samples from the subchondral trabecular lesion area exhibited increased trabecular thickness and were also markedly more plate-like than the bone in the other three locations, as evidenced by the lower value of the structural model index. Other differences in structure that were noted were increased trabecular spacing and a trend towards decreased trabecular number in the cores from the medial location as compared with the contralateral location. Conclusions Our preliminary data localize specific changes in bone mineralization, remodeling and defects within BMLs features that are adjacent to the subchondral plate. These BMLs appear to be sclerotic compared with unaffected regions from the same individual based on the increased bone volume fraction and increased trabecular thickness. The mineral density in these lesions, however, is reduced and may render this area to be mechanically compromised, and thus susceptible to attrition.

AB Bone mineral density and perceived menopausal symptoms: factors influencing low back pain in postmenopausal women. This paper is a report of a study of the relationships between the factors influencing low back pain in postmenopausal women (i.e. menopausal symptoms, bone mineral density, duration of menopause, hormonal therapy, obesity, inactivity during leisure time, parity, osteoarthritis and drinking coffee). Previous studies have shown that low back pain in postmenopausal women is associated with bone mineral density, menopausal symptoms and lifestyle factors, yet the factors influencing low back pain are not clear and vary with ethnicity. A survey was conducted with postmenopausal women (n = 134) in Korea in 2006. Bone mineral density in the lumbar spine, back pain status, menopausal symptoms and health habits were assessed. Participants' mean age was 59 years. About 70% experienced back pain on more than 1 day during the week prior to the survey and 35% suffered back pain daily. Women with back pain reported more severe menopausal symptoms than those without back pain. Based on bone mineral density scores, 26.9% of the women were considered to be at risk of osteoporosis. However, there was no association between back pain status and fracture risk status. Based on a multiple logistic regression model, menopausal symptoms, drinking coffee and inactivity during leisure time were statistically significant influencing factors for low back pain in this sample. The prevalence of low back pain in postmenopausal women should be recognized in association with menopausal symptoms and health habits. Further research is needed to develop interventions for the management of low back pain in postmenopausal women.

TI Prevalence and correlates of musculoskeletal pain in Chinese elderly and the impact on 4-year physical function and quality of life
SO PUBLIC HEALTH
LA English
DT Article
DE Musculoskeletal pain; Elderly; Physical function; Quality of life
ID older disabled women; hong-kong-chinese; dwelling senior-citizens; knee osteoarthritis; frailty index; social-status; population; disability; community; health
AB Objective: To examine the prevalence, correlates and prospective impact of musculoskeletal pain on physical and psychological function in a population health survey of elderly Chinese men and women. Study design: Cohort study. Methods: Four thousand men and women, aged 65 years and over, living in the community

in Hong Kong took part in this study. A questionnaire to determine demographics, socio-economic status, medical history. smoking, alcohol intake and level of physical activity was administered by an interviewer. Participants were asked about the presence of pain in the back, neck, hip and knee in the past 12 months. They were re-interviewed after 4 years of follow-up to document physical performance measures, psychological function and occurrence of falls, fractures and mortality. Results: Overall, back pain was most prevalent (48%), followed by knee (31%), neck (22.5%) and hip (8.9%) pain; the values was nearly twice as high in women compared with men for all sites. The presence of pain was not correlated with age, but was associated with various measures of socio-economic status as well as comorbidities. Baseline prevalence of pain was related to physical performance and quality-of-life measures, and fracture incidence after 4 years of follow-up. Conclusion: Musculoskeletal pain is prevalent among elderly men and women, being much higher in the latter, giving rise to considerable functional and psychological impairments. Osteoporosis and osteoarthritis are likely to be the main underlying causes. The condition may be considered part of the frailty syndrome, and in this context, prevention and management represent major public health challenges. (C) 2009 The Royal Society for Public Health. TI A Radiologic and Histologic Study of the Os Peroneum: Prevalence, Morphology, and Relationship to Degenerative Joint Disease of the Foot and Ankle in a Cadaveric Sample
SO CLINICAL ANATOMY
LA English
DT Article
DE sesamoid; osteoarthritis; cuboid tuberosity; 1st metatarsophalangeal joint; fibularis longus
ID fibrocartilage; osteoarthritis; cartilage; ligaments; tendons; bones
AB The present study investigated the prevalence of an os peroneum (OP, a sesamoid bone) in a cadaveric sample and its relationship to the shape of the cuboid tuberosity, and cartilage degeneration at the cuboid tuberosity and in regional joints within the foot (first metatarsophalangeal and calcaneocuboid) and ankle. The fibularis longus tendon of 33 embalmed human cadavers (mean age 81 years) were obtained from the anatomy laboratory. Nineteen of 64 tendons (30%) displayed an OP both radiographically and histologically. The os peronei ranged in size from small spicules to prominent masses: mean area 2.48 mm(2) (left) and 2.70

mm(2) (right). Histologically, the os peronei were cancellous bone, the largest occupying most of the tendon at the point of contact with the cuboid tuberosity. Fibrocartilage was present at their borders, merging with dense regular fibrous tissue and peritenon. The talocrural, calcaneocuboid, and first metatarsophalangeal joints were examined for cartilage integrity and osteophytes based on an earlier suggestion that there may be an association between degenerative joint disease and endochondral bone formation. There was no statistical correlation between presence of an OP with any of the following parameters: age, gender, body size, cartilage degeneration, or osteophytes within any of the joints examined. Therefore, the presence of an OP does not appear to be associated with increased endochondral ossification or degenerative joint disease. This study does not preclude the possibility that sesamoid bone formation may be associated with biomechanical functions within the foot; thus, future studies may be warranted. Clin. Anat. 22:747754, 2009. (C) 2009 Wiley-Liss, Inc.

TI Population attributable risk (PAR) of overweight and obesity on chronic diseases: South Australian representative, cross-sectional data, 2004-2006
SO OBESITY RESEARCH & CLINICAL PRACTICE
LA English
DT Article
DE Population attributable risk; Overweight; Obesity; Chronic conditions
ID coronary-heart-disease; life-style; body-mass; bone loss; prevalence; osteoarthritis; epidemiology; determinants; asthma; trends
AB Background: To determine the contribution of overweight and obesity to five chronic conditions using the population attributable risk (PAR) statistic. Method: Self-reported data were collected in Australia using a representative, ongoing monthly risk factor surveillance system using computer assisted telephone interviewing (CATI) for the period 2004-2006 (n = 15,261). The PAR, adjusted for various demographic and health-retated risk factors, was used to determine the contribution of overweight and obesity to diabetes, asthma, cardiovascular disease (CVD), arthritis and osteoporosis for people aged 18 years and over. Results: In total, 19.0% of South Australians aged 18 years and over were obese, and 36.0% were overweight. The PAR of overweight and obesity was highest among those with diabetes (17.3% and 28.4%). After adjusting for demographic and risk factors, overweight and obesity had a significantly high PAR for diabetes (11.3% and 23.1%), asthma (4.0% and 10.3%) and arthritis (6.7% and 8.1%). The unadjusted PAR of overweight and obesity for CVD was significant (10.8% and 11.7%) but was reduced when controlled for other factors. The PAR of overweight and obesity was significant for osteoporosis but the association was protective. Conclusions: The use of PAR contributes to the understanding of how overweight and obesity are related to various chronic conditions however the size of this association depends on the chronic disease and other socio-demographic and health-related risk factors that may or may not be modifiable. The information provides evidence of the

association of overweight and obesity with chronic disease and the potential for reducing the burden of chronic disease by addressing the obesity epidemic. Crown Copyright (C) 2009 Published by Elsevier Ltd on behalf of Asian Oceanian Association for the Study of Obesity. All rights reserved.

DT Review
DE connective tissue disease; diabetes; diffuse idiopathic skeletal hyperostosis; osteoarthritis; tendinopathy
ID idiopathic skeletal hyperostosis; human parathyroid-hormone; charcot arthropathy; oral glucosamine; nigella-sativa; bone mass; insulin; osteoarthritis; tendinitis; combination
AB Purpose of review This review summarizes recent advances in the field of diabetes and rheumatic disease. These conditions exert a significant healthcare burden on our society and much remains to be learned regarding their pathophysiology and treatment. Recent findings We summarize new insights into diabetes and its association with osteoarthritis, rheumatoid arthritis, carpal tunnel syndrome, osteoporosis, diffuse idiopathic skeletal hyperostosis, crystalline arthropathy, neuropathic arthropathy, and tendinopathy. Diabetes has major effects on connective tissues, which have significant impact on both the development and outcome of these diseases of cartilage, bone, ligament, and tendon. An improved understanding of the mechanisms through which diabetes alters connective tissue metabolism should lead to better preventive and therapeutic interventions. Summary Incremental progress has been made in understanding the interactions between diabetes and common musculoskeletal syndromes. Although this review highlights exciting areas of future interest, more work in this field is certainly warranted.

DT Article
ID x-ray absorptiometry; mineral density; femoral stem; osteoporosis; osteoarthritis; replacement; implant; prevention; osteopenia; prostheses
AB Background and purpose Factors that lead to periprosthetic bone loss following total hip arthroplasty (THA) may not only depend on biomechanical implant-related factors, but also on various patient-related factors. We investigated the association between early changes in periprosthetic bone mineral density (BMD) and patient-related factors. Patients and methods 39 female patients underwent cementless THA (ABG II) with ceramic-ceramic bearing surfaces. Peri-prosthetic BMD in the proximal femur was determined with DXA after surgery and at 3, 6, 12, and 24 months. 27 patient-related factors were analyzed for their value in prediction of periprosthetic bone loss. Results Total periprosthetic BMD was temporarily reduced by 3.7% at 3 months ($p < 0.001$), by 3.8% at 6 months ($p < 0.01$), and by 2.6% at 12 months ($p < 0.01$), but recovered thereafter up to 24 months. Preoperative systemic osteopenia and osteoporosis, but not the local BMD of the operated hip, was predictive of bone loss in Gruen zone 7 ($p = 0.04$), which was the only region with a statistically significant decrease in BMD (23%, $p < 0.001$) at 24 months. Preoperative serum markers of bone turnover predicted the early temporary changes of periprosthetic BMD. The other patient-related factors failed to show any association with the periprosthetic BMD changes. Interpretation Female patients with low systemic BMD show greater bone loss in Gruen zone 7 after cementless THA than patients with normal BMD. Systemic DXA screening for osteoporosis in postmenopausal patients before THA could be used to identify patients in need of prophylactic anti-resorptive therapy.

TI Osteogenic Potential and Responsiveness to Leptin of Mesenchymal Stem Cells between Postmenopausal Women with Osteoarthritis and Osteoporosis
SO JOURNAL OF ORTHOPAEDIC RESEARCH
LA English
DT Article
DE mesenchymal stem cells; bone formation; osteoarthritis; osteoporosis; leptin
ID bone-mineral density; articular-cartilage; subchondral bone; progenitor cells; trabecular bone; marrow; hip; osteoprotegerin; osteoblasts; metabolism
AB The aim of this study was to compare the osteogenic potential and responsiveness to leptin of mesenchymal stem cells (MSCs) from bone marrow between postmenopausal women with osteoarthritis (OA) and osteoporosis(OP). MSCs of the proximal femur from OA and OP donors were cultured tinder control and different experimental mediums. After verifying the availability of primary cells, their osteogenic potential and responsiveness to leptin were compared between two groups. Similar patterns of cell growth were shown in both OA and OP groups.

However, after the sixth passage, the viability of undifferentiated cells decreased more in OP than in OA donors. Under the same osteogenic supplements condition, the mRNA expression of osteogenesis-specific genes, osteocalcin (OC) and alkaline phosphatase (ALP) were higher in OA group. Comparison of bone matrix mineralization was parallel to that of mRNA expression. The level of bone-specific ALP (BAP) was higher in cells from donors with OA, whereas osteoprotegerin (OPG) was higher in OP group. This difference in BAP expression proved to be insignificant after the administration of leptin. Although leptin upregulated the expression of OPG, a significant difference still existed between OA and OP. In conclusion, differential osteogenic potential and responsiveness to leptin of MSCs were noted between postmenopausal women with OA and OP. Differential biological behavior of MSCs seems to be partly related to the different distribution of bone mass between OA and OP populations. (C) 2009 Orthopaedic Research Society. TI Bone density in patients with chondromalacia patella
SO RHEUMATOLOGY INTERNATIONAL
LA English
DT Article
DE Bone density; Chondromalacia patella; Dual energy X-ray absorptiometry; DXA
ID osteoarthritis
AB Chondromalacia of the patella is the most common cause of anterior knee pain in young women. The etiology of the disease is not well-understood but the initial lesion is a disorganization of collagenous structures. Since the disease is proposed to be due to generalized constitutional disturbance, we postulated that bony structures could also be involved. To investigate this hypothesis we measured the bone density of 286 patients with the diagnosis of chondromalacia of the patella during a 4-year period using dual energy X-ray absorptiometry (DXA) method. We found a significant number of patients having low bone densities. This problem was more pronounced in men and in younger age groups. We suggest base-line bone density evaluation in all patients, treatment of osteopenia or osteoporosis in select patients and regular follow-ups using DXA.

TI Ochratoxin A in Roasted Coffee from French Supermarkets and Transfer in Coffee Beverages: Comparison of Analysis Methods
SO TOXINS
LA English
DT Article
DE ochratoxin; coffee; beverage; immunoaffinity column; CEN 14132; CEN 15141
ID immunoaffinity column cleanup; green coffee; liquid-chromatography; bladder-cancer; beans; toxicity; risk; polymorphisms; performance; consumption
AB The OTA content of 30 roasted coffees purchased in French supermarkets was evaluated by two validated different methods: one using immunoaffinity column (IAC) clean-up after alkaline extraction; the second using toluene extraction under acidic conditions. OTA recoveries (0.5 to 5 mu g/kg) ranged from 16-49% with the alkaline extraction method and 55-60% with the acidic method. OTA recoveries from prepared beverages were similar with all methods (75-80%). All samples containing OTA ranged from trace (<LOQ) to 11.9 mu g/kg. About 20 to 140% of OTA passed through the beverages. Recoveries of over 100% of OTA in beverages were due to three types of interferences: (i) formation of open-ring OTA (OP-OA) during alkaline extraction, (ii) isomerization of OTA during roasting, and (iii) presence of the nonchlorinated analogue OTB. The first two types of interference generate OTA derivatives that are not recognized by OTA antibodies, while OTB cross-reacts with OTA-antibodies. These analytical problems will seriously impact the amount of OTA detected, especially at the levels close to the limits from the EU legislation. Underestimation of OTA could be highly dangerous for health.

TI Regional variations of gender-specific and age-related differences in trabecular bone structure of the distal radius and tibia
SO BONE
LA English
DT Article
DE Regional variations; Trabecular structure; HR-pQCT; Age; Tibia; Radius
ID quantitative computed-tomography; finite-element-analysis; postmenopausal women; estrogen deficiency; ultradistal radius; mineral density; stance phase; femoral-neck; hr-pqct; microarchitecture
AB Regional variation in trabecular structure across axial sections is often obscured by the conventional global analysis, which takes an average value for the entire trabecular compartment. The objective of this study is to characterize spatial variability in trabecular structure within a cross-section at the distal radius and tibia, and gender and age effects using in vivo high-resolution peripheral quantitative computed tomography (HR-pQCT). HR-pQCT images of the distal radius and tibia were acquired from 146 healthy individuals aged 20-78 years. Trabecular bone volume fraction (BV/TV), number (Tb.N), thickness (Tb.Th), separation (Tb.Sp), and heterogeneity (Tb.1/N.SD) were obtained in a total of 11 regions-the entire trabecular compartment (the global means), inner, outer, and eight defined subregions. Regional variations were examined with respect to the global means, and compared between women and men, and between young (20-29 years old) and elderly (65-79 years old) adults. Substantial regional variations in trabecular bone structure at the distal radius and tibia were revealed (e.g. BV/TV varied -40% to + 57% and -59% to + 100% of the global means, respectively, for elderly women). The inner-lateral (IL) subregion had low BV/TV, Tb.N, and Tb.Th, and low Tb.Sp and Tb.1/N.SD at both sites; the opposite was true in the outer-anterior (OA) subregion at the distal radius and the outer-medial (OM) and -posterior (OP) subregions at the distal tibia. Gender differences were most pronounced in the inner-anterior (IA) subregion compared to the other regions or the global mean differences at both sites. Trabecular structure associated with age and differed

between young and elderly adults predominantly in the inner-posterior (IP) subregion at the distal radius and in the IL and IA subregions at the distal tibia: on the other hand, it remained unchanged in the OA subregion at the distal radius and in the OM subregion at the distal tibia for both women and men. This study demonstrated that not only the conventional global analysis can obscure regional differences, but also assuming bone status from that of smaller subregion may introduce a confounding sampling error. Therefore, a combined approach of investigating the entire region, each subregion, and the cortical compartment may offer more complete information. (C) 2010 Elsevier Inc. All rights reserved.

TI The influence of nanoscale grooved substrates on osteoblast behavior and extracellular matrix deposition
SO BIOMATERIALS
LA English
DT Article
DE Nanotopography; Osteoblast; Interface; Calcification; Cell morphology; Gene expression
ID osteoprogenitor response; contact guidance; in-vitro; cells; adhesion; alignment; titanium; topography; bone; nanotopography
AB To fight bone diseases characterized by poor bone quality like osteoporosis and osteoarthritis, as well as in reconstructive surgery, there is a need for a new generation of implantable biomaterials. It is envisioned that implant surfaces can be improved by mimicking the natural extracellular matrix of bone tissue, which is highly a organized nano-composite. In this study we aimed to get a better understanding of osteoblast response to nanometric grooved substrates varying in height, width and spacing. A throughput screening biochip was created using electron beam lithography. Subsequently, uniform large-scale nanogrooved substrates were created using laser interference lithography and reactive ion etching. Results showed that osteoblasts were responsive to nanopatterns down to 75 nm in width and 33 nm in depth. SEM and TEM studies showed that an osteoblast-driven calcium phosphate (CaP) mineralization was observed to follow the surface pattern dimensions. Strikingly, aligned mineralization was found on even smaller nanopatterns of 50 nm in width and 17 nm in depth. A single cell based approach for real time PCR demonstrated that osteoblast-specific gene expression was increased on nanopatterns relative to a smooth control. The results indicate that nanogrooves can be a very promising tool to direct the bone response at the interface between an implant and the bone tissue. (C) 2010 Elsevier Ltd. All rights reserved.

TI The epidemiology of osteonecrosis: findings from the GPRD and THIN databases in the UK
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE Avascular necrosis; Epidemiology; Osteonecrosis; Risk factors
ID systemic-lupus-erythematosus; avascular necrosis; symptomatic osteonecrosis; oral corticosteroids; risk; bisphosphonates; validation; jaws; fractures
AB We conducted a case-control study to examine osteonecrosis (ON) incidence, patient characteristics, and selected potential risk factors using two health record databases in the UK. Statistically significant risk factors for ON included systemic corticosteroid use, hospitalization, referral or specialist visit, bone fracture, any cancer, osteoporosis, connective tissue disease, and osteoarthritis. The purpose of this case-control study was to examine the incidence of osteonecrosis (ON), patient characteristics, and selected potential risk factors for ON using two health record databases in the UK: the General Practice Research Database and The Health Improvement Network. ON cases (n = 792) were identified from 1989 to 2003 and

individually matched (age, sex, and medical practice) up to six controls (n = 4,660) with no record of ON. Possible risk factors were considered for inclusion based on a review of published literature. Annual incidence rates were computed, and a multivariable logistic regression model was derived to evaluate selected risk factors. ON of the hip represented the majority of cases (75.9%). Statistically significant risk factors for ON were systemic corticosteroid use in the previous 2 years, hospitalization, referral or specialist visit, bone fracture, any cancer, osteoporosis, connective tissue disease, and osteoarthritis within the past 5 years. Only 4.4% of ON cases were exposed to bisphosphonates within the previous 2 years. This study provides further perspective on the descriptive epidemiology of ON. Studies utilizing more recent data may further elucidate the understanding of ON key predictors.

TI The Founder's Lecture 2009: advances in imaging of osteoporosis and osteoarthritis
SO SKELETAL RADIOLOGY
LA English
DT Review
DE Osteoporosis; Osteoarthritis; Quantitative imaging; MRI; CT
ID trabecular bone-structure; in-vivo assessment; subchondral insufficiency fracture; quantitative computed-tomography; reveals structural implications; t2 relaxation-times; high-resolution mri; vertebral fractures; articular-cartilage; knee cartilage
AB The objective of this review article is to provide an update on new developments in imaging of osteoporosis and osteoarthritis over the past three decades. A literature review is presented that summarizes the highlights in the development of bone mineral density measurements, bone structure imaging, and vertebral fracture assessment in osteoporosis as well as MR-based semiquantitative assessment of osteoarthritis and quantitative cartilage matrix imaging. This review focuses on techniques that have impacted patient management and therapeutic decision making or that potentially will affect patient care in the near future. Results of pertinent studies are presented and used for illustration. In summary, novel developments have significantly impacted imaging of osteoporosis and osteoarthritis over the past three decades.

TI Herniation pits and cystic-appearing lesions at the anterior femoral neck: an anatomical study by MSCT and AμCT
SO SKELETAL RADIOLOGY
LA English
DT Article
DE Spiral computed tomography; Bone cysts; Ganglion cyst; Femur neck; Hip joint
ID mr arthrographic findings; femoroacetabular impingement; degenerative arthritis; intraosseous ganglion; bone; osteoarthritis; prevalence; appearance; cam; hip
AB To determine distinguishing features between herniation pits (HPs) and other cystic-appearing lesions at the anterior femoral neck in multi-slice computed tomography (MSCT) and micro-computed tomography (microCT) examinations. Institutional review board approval was obtained to examine 37 proximal femora of 23 cadaveric specimens (mean age available in 19 cadavers, 83 years; range 68-100 years; 9 female, 8 male, 6 unknown). All 37 femora were investigated by MSCT. 23 femora, which revealed cystic-appearing lesions at the anterior femoral neck in MSCT examinations, were additionally examined by microCT. Cystic-appearing lesions were categorized by their location, sclerotic margin, demarcation and shape in MSCT with assessment of inter-observer agreement. Detailed cortical and trabecular properties were evaluated in microCT examinations. There were seven

HPs in three femora. There were a number of abnormalities potentially imitating HPs, including focal osteoporosis (13 in 13 femora), degenerative changes (5 in 4 femora) and trabecular restructuring (5 in 4 femora) at the anterior femoral neck. HPs were differentiated on the basis of their subchondral/subcortical location, completely surrounding sclerosis, clear demarcation and round-to-oval shape in MSCT. Because of their location and their microscopic appearance, HPs seem to resemble intra-osseous ganglia at the anterior femoral neck. HPs have to be differentiated from other cystic appearing lesions at the anterior femoral neck to avoid overestimation of their incidence in the context of diagnosis of femoroacetabular impingement.

TI Wnt Pathway and IL-17: Novel Regulators of Joint Remodeling in Rheumatic Diseases. Looking Beyond the RANK-RANKL-OPG Axis
SO SEMINARS IN ARTHRITIS AND RHEUMATISM
LA English
DT Review
DE Wnt; joint remodeling; bone; rheumatic diseases; rheumatoid arthritis; IL-17; Th17; osteoblastogenesis; osteoclastogenesis
ID collagen-induced arthritis; frizzled-related protein-1; ldl-receptor-related-protein-5 lrp5 gene; high bone mass; articular-cartilage; interleukin 17; t-cells; hip osteoarthritis; missense mutations; receptor activator
AB Objectives: During the last decade research has focused on the RANK-RANKL-OPG (Receptor Activator of Nuclear factor KappaB-Receptor Activator of Nuclear factor KappaB Ligand-Osteoprotegerin) pathway that is currently considered the final common route to bone and joint remodeling. The potential role of novel additional mediators has been highlighted by several reports. This review focuses on the recent information about the pathophysiology of the Wingless (Wnt) pathway and interleukin-17 (IL-17) in relation of their role in bone and joint remodeling. Methods: An extensive internet search was performed (PubMed) from 1998 and onward using the following keywords: Wnt, bone remodeling, bone, rheumatic diseases, rheumatoid arthritis, IL-17, Th17, osteoblastogenesis, and osteoclastogenesis. Results: Several members of the Wnt pathway play an important role in bone remodeling. Recent experimental data indicate a key role for Dickkopf-1, a soluble inhibitor of the Wnt pathway, in bone remodeling. Increased Dickkopf-1 levels are linked to bone resorption and decreased levels to new bone formation. Low-density lipoprotein receptor-related protein-5, the main receptor that mediates Wnt signaling, plays a critical role in bone mass regulation. Gain-of-function mutations of lipoprotein receptor-related protein-5 cause high bone mass phenotypes, whereas loss-of-function mutations are linked to severe osteoporosis. IL-17 is a proinflammatory, cytokine that is produced by a recently described T-cell subset, known as Th17 cells. Evidence suggests that IL-17 is a critical mediator of joint destruction in animal models of arthritis. IL-17 blockade has beneficial effects on murine arthritis, a fact that points to the direction of this cytokine as a potential therapeutic target in human inflammatory arthritides as well. Conclusions: The available data suggest that mediators in these 2 biologic systems are critical in joint remodeling and may be appropriate targets in the treatment of bone and joint abnormalities that characterize a variety of inflammatory arthritides and bone diseases. TI COMPREHENSIVE REHABILITATION OF PATIENTS WITH RHEUMATIC DISEASES

IN A WARM CLIMATE: A LITERATURE REVIEW
SO JOURNAL OF REHABILITATION MEDICINE
LA English
DT Review
DE arthritis; climate; exercise therapy; physical therapy; rehabilitation; rheumatic disease; tropical climate
ID health-assessment questionnaire; ankylosing-spondylitis; preliminary definition; team care; arthritis; bath; improvement; efficacy; weather; index
AB Objective: To present the evidence for the efficacy of comprehensive rehabilitation in a warm climate of patients with a wide variety of rheumatic diseases. Methods: A systematic review of the literature was undertaken, searching in PubMed, Cinahl, Pedro, SweMed and Embase from 1970 to 2010, and using the GRADE (Grading of Recommendations, Assessment, Development and Evaluation system) criteria. Results: Six studies met the inclusion criteria. For patients with rheumatoid arthritis, moderate evidence was found for reduction of disease activity, pain, fatigue, and global disease impact. The evidence was also moderate that comprehensive rehabilitation in a warm climate did not improve fitness or reduce activity limitation beyond levels reached by rehabilitation in Scandinavia. Among patients with ankylosing spondylitis, low evidence was found for reduction of disease activity, pain, joint range of motion, activity limitation, and global disease impact. In groups with mixed rheumatic diagnoses, low evidence was found for reduction of pain, activity limitation, global disease impact and improved health-related quality of life. No studies on psoriatic arthritis, osteoarthritis, fibromyalgia or osteoporosis were found. Conclusion: Well-designed studies to validate and improve the low-to-moderate evidence found for the efficacy of comprehensive rehabilitation in a warm climate among patients with inflammatory rheumatic disease are greatly needed.

TI Hyperhomocysteinemia is not associated with reduced bone quality in humans with hip osteoarthritis
SO CLINICAL CHEMISTRY AND LABORATORY MEDICINE
LA English
DT Article
DE biomechanics; bone mineral density; B vitamins; histomorphometry; hyperhomocysteinemia
ID collagen cross-linking; high-aged subjects; mineral density; homocysteine concentrations; folic-acid; osteoporotic fractures; mechanical-property; plasma homocysteine; cancellous bone; clinical-use
AB Background: Recent clinical and animal studies suggest that increased serum homocysteine (HCY) concentrations may be a risk factor for osteoporosis. In vitro studies showed that increasing HCY concentrations stimulate the activity of human osteoclasts. However, there is no data demonstrating that circulating HCY is related to structural and biomechanical properties of human bones. This study investigated the relationship between morphological as well as biomechanical bone properties and HCY serum concentrations in humans suffering from hip osteoarthritis (OA). Methods: Fasting blood samples and femoral heads were obtained from 94 males and females who underwent hip arthroplasty due to OA. Bones were assessed by dual energy X-ray absorptiometry (DXA), biomechanical testing (indentation method), and histomorphometry. Blood was collected for measurement of HCY, folate, vitamin B6, and vitamin B12. Subjects were classified as hyperhomocysteinemic (>12 mu mol/L, n = 47) and normohomocysteinemic (<12 mu mol/L, n = 47) according to their serum HCY concentrations. Results: Folate and vitamin B6, but not vitamin B12, were significantly lower in hyperhomocysteinemic subjects compared with controls. However, DXA, biomechanical testing, and histomorphometry did not reveal significant differences in bone quality between hyperhomocysteinemic subjects and controls. Conclusions: The results of the present study do not indicate a significant relationship between circulating HCY concentrations and morphological or biomechanical bone properties in humans with OA of the hip. Clin Chem Lab Med 2010;48:821-7.

TI Osteoporosis research thrives: IOF WCO-ECCEO10
SO EXPERT REVIEW OF PHARMACOECONOMICS & OUTCOMES RESEARCH
LA English
DT Article
DE fragility fractures; osteoporosis; prevention and treatment; world congress
AB The recent World Congress on Osteoporosis (IOF WCO-ECCEO10), held in Florence on 5-8 May 2010, not only drew a record number of researchers and clinicians, it also attracted a far greater number of scientific abstracts than ever before (850). Needless to say, the organizing societies, the International Osteoporosis Foundation (IOF) and the European Society for Clinical and Economic Aspects of Osteoporosis and Osteoarthritis (ESCEO), were delighted to welcome a record number of attendees (5500). The record numbers suggest that research in the field is thriving and that there is strong interest in the epidemiology, diagnosis and management of osteoporosis and fragility fractures around the world. This is reflected in the attendance statistics, which showed that, as expected, the largest delegation of participants (73.89%) was from Europe, with comparatively large delegations from Asia (8.20%) and North America (6.35%). Researchers and clinicians from South America and the Middle East (similar to 3% each) were also in attendance. Participants experienced an enriching scientific program featuring a broad range of topics covered in 12 plenary sessions, 19 primarily clinically oriented meet-the-expert topics in multiple sessions, and eight special sessions and symposia. A total of 12 satellite symposia enhanced the program by offering a wealth of information and practical new knowledge for clinicians.

TI Osteoarthritis and osteoporosis: coexistence of osteoporosis in patients with

osteoarthritis
SO MINERVA ORTOPEDICA E TRAUMATOLOGICA
LA English
DT Review
DE Osteoarthritis; Osteoporosis; Bone density; Absorptiometry, photon
ID bone-mineral density; total hip-arthroplasty; human articular-cartilage; vitamin-d deficiency; age-related-changes; knee osteoarthritis; subchondral bone; postmenopausal women; proximal femur; risk-factors
AB Osteoarthritis (OA) and osteoporosis (OP) are two age-related degenerative diseases previously believed to be mutually exclusive. OA is a painful, debilitating disease, while OP may be silent until the subject has a fragility fracture. Several studies of bone mineral density (BMD) with dual-energy X-ray absorptiometry report that between 20% to 29% of women and men with OA have occult OP, which increases their risk of fracture. Furthermore, BMD measurements of the femoral neck of a hip with OA may be elevated due to subchondral osteosclerosis and may not reflect the status of the contralateral hip or the general skeleton. Vitamin D-deficiency is common in patients with OA, with OP, or with both, and should be corrected in order to reduce progression of OA and risk of fracture. Patients with hip OA who appear to be at risk for occult OP are those with advanced age and lower body mass index and with radiographic evidence of thin cortices and osteopenia. Awareness of fracture risk in patients with OA may require paradigm shifts in multidisciplinary care of those patients.

TI Whole-mount specimens in the analysis of en bloc samples obtained from revisions of resurfacing hip implants A report of 4 early failures
SO ACTA ORTHOPAEDICA
LA English
DT Article
ID surface replacement; femoral-head; arthroplasty; vascularity; density; femur
AB Background Modern metal-on-metal hip resurfacing implants are being increasingly used for young and active patients, although the long-term outcome and failure mechanisms of these implants are still unknown. In this consecutive revision case series, early failures of femoral implants (at < 4 years) were studied. Methods 3 revisions were done due to a fracture of the femoral neck and 1 due to loosening and varus position of the femoral component. Femoral heads were removed en bloc 2-46 months after the primary operation, embedded in methylmethacrylate, sectioned, stained, and analyzed as whole-mount specimens in 4 55-62-year-old patients with osteoarthritis. Results Histopathology was characterized by new but also partly healed trabecular microfractures, bone demineralization, cysts, metallosis, and abnormal formation of new woven bone. All samples displayed signs of notching, osteoporosis, and aseptic necrosis, which seemed to have been the main reason for the subsequent development and symptoms of the patients and revision operations of the hips. Interpretation Based on these early revision cases, it appears that aseptic necrosis is a common cause of early loosening of resurfacing hip implants.

TI Knee and Hip Radiographic Osteoarthritis Predict Total Hip Bone Loss in Older Adults: A Prospective Study
SO JOURNAL OF BONE AND MINERAL RESEARCH
LA English

DT Article
DE OSTEOARTHRITIS; BONE LOSS; KNEE; HIP; OLDER ADULTS
ID mineral density; postmenopausal women; hand osteoarthritis; osteoporotic fractures; degenerative disease; vertebral fracture; cartilage volume; lumbar spine; elderly men; risk
AB The relationship between osteoarthritis (OA) and osteoporosis remains controversial This study was designed to determine the association between hip and knee radiographic OA and change in total hip bone mineral density (BMD) over 2 6 years A total of 867 population-based randomly selected subjects (mean age 62 years, range 51 to 80 years, and 49% female) were included Hip and knee joint space narrowing (JSN, 0 to 3) and osteophytes (0 to 3) in both lower limbs was assessed using Altman's atlas Total hip BMD was measured by dual-energy X-ray absorptiometry (DXA). We found that radiographic OA (score of JSN or osteophytes > 0) was common in this sample (hip 45%, knee 68%). In multivanable analyses, percentage change in total hip BMD per year was predicted by right and left hip axial (beta - -0.25% and -0.29% per grade, respectively, both p < .05), right hip superior femoral osteophytes (grades 2 and 3 versus 0 beta - -1 60, p < 05), combined right and left knee tibiofemoral JSN (beta = -006 per grade from grades 0 to 12, p < 05), and osteophytes (beta = -0 06 per grade from grades 0 to 14, p < 05) independent of each other and joint pain In conclusion, older subjects with radiographic hip and knee OA have higher total hip bone loss over 2.6 years regardless of symptoms, suggesting that consideration should be given to the monitoring of bone mass in these subjects. (C) 2010 American Society for Bone and Mineral Research.

TI Dietary Vitamin D Intake Among Elderly Residents in a Veterans' Centre
SO CANADIAN JOURNAL OF DIETETIC PRACTICE AND RESEARCH

LA English
DT Article
ID supplementation; canadians; calcium
AB Purpose: Dietary vitamin D intake was assessed among residents in a long-term care (LTC) facility, so that recommendations could be made about vitamin D supplementation. Methods: Three-day tray audits were completed for all meals and snacks, including nutritional supplements (Boost (TM) and/or high-protein pudding). Total daily and three-day vitamin D intake was calculated for each resident, and the total sample was compared with the recommended Adequate Intake (AI) of 600 IU. Vitamin D content was calculated Using the Canadian Nutrient. File and product labels. Resident charts were reviewed for micronutrient supplements and diagnoses. Results: The daily average vitamin D available to and consumed by 30 residents was 414 IU and 295 IU, respectively. Those provided with nutritional supplements received an average of 480 IU and consumed 357 IU, while those without received an average of 245 IU and consumed 207 IU. Thirty-three percent of residents were diagnosed with osteoporosis, osteoarthritis, and falls and/or fractures. Vitamin D micronutrient supplementation varied from above 600 IU (43%) to below 600 IU (30%) to no supplementation (27%). Conclusions: None of the study participants met the recommended AI of 600 IU through dietary sources alone. Study results suggest that all LTC residents require vitamin D micronutrient supplementation of at least 400 IU to achieve the recommended AI of 600 IU. TI Synthesis, characterization and in vitro evaluation of a bone targeting delivery system for salmon Calcitonin

SO INTERNATIONAL JOURNAL OF PHARMACEUTICS
LA English
DT Article
DE Calcitonin; Bisphosphonate; Bone targeting; Drug delivery system; Osteoporosis; Paget's disease; Bone cancer; Rheumatoid arthritis; Osteoarthritis
ID bisphosphonate conjugation; receptors; peptide; identification; disposition; affinity; behavior; sites
AB Synthetic salmon Calcitonin (sCT) is currently used to treat and manage conditions associated with low bone mass, and elicits its antiresorptive effect by acting upon Calcitonin receptors (CTRs) located on bone-resorbing osteoclast cells. However, CTRs are also widely distributed in many non-skeletal tissues (such as kidney, brain, and lung), and the competitive uptake of available sCT amongst such CTRs likely reduces sCT availability for bone resident osteoclast cells, particularly if the drug is administered systemically and not specifically targeted to bone. Hence, the objective of this study was to synthesize and characterize a bisphosphonate (BP)-mediated bone targeting delivery system for sCT and to determine whether the bioactivity of sCT was retained after BP conjugation. BP-sCT conjugates were synthesized by initially reacting sCT with sulfosuccinimidyl-4-[N-maleimidomethylicyclohexane-1-carboxylate (sulfo-SMCC) in dimethyl formamide in the presence of triethylamine (TEA) at room temperature. Thiolated (Thiol)-BP was then reacted with the sCT-sulfo-SMCC conjugates to generate sCT-BP conjugates, which were purified by dialysis and assayed using the micro-BCA protein assay. Non-BP containing control sCT-Cysteine conjugates were also synthesized using the same procedure. Reactions were monitored and characterized using matrix-assisted laser desorption ionization time-of-flight mass spectrometer (MALDI-TOF) analysis and Tris-Tricine SDS-PAGE. Conjugates were evaluated for in vitro bone mineral affinity using a hydroxyapatite binding test, for bone mineral specificity using different calcium salt binding affinity assays, and for continued sCT bioactivity after conjugation using an intracellular cAMP stimulation in human T47D breast cancer cells. Our results confirmed that BP-conjugated sCT exhibited significantly greater affinity and specificity for bone mineral over unmodified sCT, and that sCT-BP conjugates retained strong CT bioactivity after conjugation. Our conjugation strategy holds the promise of facilitating the delivery of sCT preferentially to skeletal bony tissues, thereby increasing its local concentration to bone surfaces. This peptide hormone-bisphosphonate drug system represents a new class of antiresorptive drug that has not previously been attempted, nor has a bone targeting formulation of sCT been reported. AB In this article, a low-voltage complementary metal-oxide semiconductor (CMOS) input signal adapter (ISA) suitable for input rail-to-rail operation of various types of analogue basic building blocks is presented. The adapter acts as a pre-stage with infinite input resistance and linear transfer characteristics. Its input signal is translated into the region fitting the operating range of the following stage. The generality of the proposed method is proven through the application of the ISA in different types of analogue basic building blocks designed in 0.5m CMOS technology. They are the following:
below-negative-rail-to-above-positive-rail voltage-controlled transconductor, quasi rail-to-rail voltage-controlled resistor (VCR), rail-to-rail operational amplifier (OA) and quasi rail-to-rail second generation current conveyor. The proposed negative resistance quasi rail-to-rail VCR and rail-to-rail OA have been used in a Sallen and Key band-pass filter. All of these analogue basic building blocks and their applications in the form of the Sallen and Key band-pass filter operate from a single supply of 1.5V. Simulation results confirm the predictions of the analysis performed.

TI Progressive load training for the quadriceps muscle associated with proprioception exercises for the prevention of falls in postmenopausal women with osteoporosis: a randomized controlled trial
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE Exercises; Falls; Muscular strength; Osteoporosis; Prevention; Proprioception
ID bone-mineral density; hip fracture; older-people; go test; risk; balance; strength; osteoarthritis; probability; prediction

AB This study aims to evaluate the effect of 18-week progressive muscular strength and proprioception training program on the muscle strength of the quadriceps, in prevention of falls in postmenopausal women with osteoporosis. The incidence of falls in the intervention group was significantly lower than in the control group (incidence rate ratio (IRR) = 0.263, 95% CI 0.10-0.68). This study aims to evaluate the effect of a progressive muscular strength and proprioception training program on the muscle strength of the quadriceps, balance, quality of life, and reduction in the risk of falls in postmenopausal women with osteoporosis. One hundred sedentary postmenopausal women with osteoporosis, ages ranging from 55 to 75, were selected and randomized into two groups: the intervention group comprised of 50 patients who underwent a 18-week of progressive load training for the quadriceps muscle (50% up to 80% of 1-RM-one maximum repetition) and proprioception training associated to a drug treatment of osteoporosis and the control group that included 50 patients who only underwent a drug treatment of osteoporosis. The muscular strength, balance, functional mobility, and quality of life were evaluated in the beginning and end of the research. The number of falls was evaluated 24 weeks post-treatment. Eighty-five patients concluded the research. The program promoted a significant difference among the groups for SF-36 in the eight sub-scales (p a parts per thousand currency signaEuro parts per thousand 0.0018), Timed Up & Go Test ($p < 0.0001$), 1-RM test ($p < 0.0001$), Berg Balance Scale ($p < 0.0001$) and also a decrease in the number of falls in the intervention group compared to control (IRR = 0.263, 95% CI 0.10-0.68, $p = 0.0064$). The association of progressive strength training for the quadriceps and the proprioceptive training is effective for the prevention of falls, increasing the muscle power, the static and dynamic balance and increasing the speed of the motor responses, therefore improving the performance of daily activities.

TI In Situ Microindentation for Determining Local Subchondral Bone Compressive Modulus
SO JOURNAL OF BIOMECHANICAL ENGINEERING-TRANSACTIONS OF THE ASME
LA English
DT Article
DE subchondral bone; microindentation; modulus; stiffness; osteoarthritis
ID articular-cartilage; elastic-modulus; osteoarthritis; nanoindentation; osteoporosis; progression
AB Alterations to joint tissues, including subchondral bone, occur With osteoarthritis. A microindentation technique was developed to determine the local compressive modulus of subchondral bone. This test, in conjunction with a cartilage indentation test at the same location, could evaluate changes of these material properties in both tissues. The accuracy of the technique was determined by applying it to materials of known moduli. The technique was then applied to rat tibial plateaus to characterize the local moduli of the subchondral bone. An established nanoindentation method was adopted to determine the modulus of subchondral bone following penetration of the overlying articular cartilage. Three cycles of repeated loadings were applied (2.452 N, 30 s hold). The slope of the load-displacement response during the unloading portion of the third cycle was used to measure the stiffness. Indentation tests were performed on two polyurethane foams and polymethyl-methacrylate for validation (n = 15). Regression analysis was used to compare the moduli with reference values. Subchondral bone moduli of tibial plateaus from Sprague-Dawley rats (n = 5) were measured for central and posterior locations of medial and lateral compartments. An analysis of variance was used to analyze the effects of compartment and test location. The measured moduli of the validation materials correlated with the reference values ($R(2) = 0.993$, $p = 0.05$). In rat tibial plateaus, the modulus of the posterior location was significantly greater than the center location (4.03 +/- 1.00 GPa and 3.35 +/- 1.16 GPa respectively, $p = 0.03$). The medial compartment was not different from the lateral compartment. This method for measuring the subchondral bone in the same location as articular cartilage allows studies of the changes in these material properties with the onset and progression of osteoarthritis. TI What happens to femoral neck bone mineral density after hip resurfacing surgery?
SO JOURNAL OF BONE AND JOINT SURGERY-BRITISH VOLUME
LA English
DT Article
ID x-ray absorptiometry; health survey questionnaire; physical-activity; osteo-arthritis; outcome measure; arthroplasty; fracture; osteoarthritis; osteoporosis; densitometry
AB The major advantage of hip resurfacing is the decreased amount of bone resection compared with a standard total hip replacement. Fracture of the femoral neck is the most common early complication and poor bone quality is a major risk factor. We undertook a prospective consecutive case control study examining the effect of bone mineral density changes in patients undergoing hip resurfacing surgery. A total of 423 patients were recruited with a mean age of 54 years (24 to 87). Recruitment for this study was dependent on pre-operative bilateral femoral bone mineral density results not being osteoporotic. The operated and non-operated hips were assessed. Bone mineral density studies were repeated over a two-year period. The results showed no significant deterioration in the bone mineral density in the superolateral region in the femoral neck, during that period. These findings were in the presence of a markedly increased level of physical activity, as measured by the short-form 36 health survey physical function score.

TI Differential effects of salt stress on osmotic adjustment and solutes allocation on the basis of root and leaf tissue senescence of two silage maize (Zea mays L.) varieties
SO INDUSTRIAL CROPS AND PRODUCTS
LA English
DT Article
DE Salt stress; Tissue senescence; Osmotic adjustment; Zea mays L.
ID low water potentials; increased proline deposition; glycine betaine; accumulation; plants; wheat; photosynthesis; tolerance; salinity; growth
AB The comparative effects of salt stress on osmotic adjustment and solutes accumulation in relation to root-leaf tissue senescence of two silage maize varieties were examined. Studies were carried out with seedlings of two forage maize varieties (Aristo and Arper) subjected to 0, 34, 68 and 102 mM NaCl for 6 weeks under glasshouse conditions. Osmotic potential (OP), osmotic adjustment (OA) and solutes accumulation were quantified in primary roots and in three leaf stages (young, mature and senescent leaves). Moreover, in order to assess the distribution of proline and glycine betaine during root development, the two components were analyzed at different position from the primary root apex of both varieties. The total dry matter was significantly dropped with increasing salinity and reduction was greater in Aristo than in Arper. Salt stress impact in terms of ionic status was more pronounced in roots than in leaves and in older leaves than younger ones. In this setting, Aristo displayed a more sensitivity than Arper. A close relationship

between the age of root-leaf tissue and proline and glycine betaine allocation, as salinity response. was shown. During the stress treatment, the accumulation of the two components was higher in growing regions of roots and in young leaves. While total free amino acids (FAA) and sugars were accumulated in roots as well as leaves but preferentially in the mature leaves. The capacity of OA was greater in young than in mature and/or senescent leaves and the contribution efficiency of organic solutes to this occurrence tended to be higher in Arper than in Arista. Moreover, glycine betaine and proline appeared to be the main solutes that contributed ably to OA mainly in growing regions followed by sugars and other FAA. Inorganic solutes (K+ and Ca2+), however, did not seem to play an important role in OA since their amounts were often reduced in response to salt tolerance. (C) 2009 Elsevier B.V. TI A Mineral-Rich Extract from the Red Marine Algae Lithothamnion calcareum Preserves Bone Structure and Function in Female Mice on a Western-Style Diet
SO CALCIFIED TISSUE INTERNATIONAL
LA English
DT Article
DE Bone mineralization; Bone strength; Mineral-rich red algae extract; Aquamin; High-fat Western-style diet; Osteoporosis
ID fat-sucrose diet; mechanical-property; knee osteoarthritis; colon-cancer; long-term; osteoporosis; calcium; metabolism; nutrition; copper
AB The purpose of this study was to determine whether a mineral-rich extract derived from the red marine algae Lithothamnion calcareum could be used as a dietary supplement for prevention of bone mineral loss. Sixty C57BL/6 mice were divided into three groups based on diet: the first group received a high-fat Western-style diet (HFWD), the second group was fed the same HFWD along with the mineral-rich extract included as a dietary supplement, and the third group was used as a control and was fed a low-fat rodent chow diet (AIN76A). Mice were maintained on the respective diets for 15 months. Then, long bones (femora and tibiae) from both males and females were analyzed by three-dimensional micro-computed tomography (micro-CT) and (bones from female mice) concomitantly assessed in bone strength studies. Tartrate-resistant acid phosphatase (TRAP), osteocalcin, and N-terminal peptide of type I procollagen (PINP) were assessed in plasma samples obtained from female mice at the time of sacrifice. To summarize, female mice on the HFWD had reduced bone mineralization and reduced bone strength relative to female mice on the low-fat chow diet. The bone defects in female mice on the HFWD were overcome in the presence of the mineral-rich supplement. In fact, female mice receiving the mineral-rich supplement in the HFWD had better bone structure/function than did female mice on the low-fat chow diet. Female mice on the mineral-supplemented HFWD had higher plasma levels of TRAP than mice of the other groups. There were no differences in the other two markers. Male mice showed little diet-specific differences by micro-CT.

TI Lower bone mineral density of forearm in postmenopausal patients with radiographic hand osteoarthritis
SO RHEUMATOLOGY INTERNATIONAL
LA English
DT Article
DE Osteoarthritis; Hand; Bone mineral density; AUSCAN index; Kellgren-Lawrence grade
ID women; knee; strength; mass; osteoporosis; association; incident; fracture; weight
AB The association between clinical parameters and forearm bone mineral density (BMD) in postmenopausal females with radiographic hand OA has not been determined. We investigated the difference in forearm BMD between radiographic hand OA and non-radiographic hand OA, and also the association between clinical parameters of patients and the level of forearm BMD. A total of 180 postmenopausal patients with hand OA were enrolled in this study. We classified them into two groups according to the Kellgren-Lawrence (K-L) radiological grade, one with radiographic hand OA (K-L grade a parts per thousand yen 2) and the other with non-radiographic OA (K-L grade < 2) as controls. The number of nodal joints, swollen joints and tender joints were determined in the physical examination, and measures of BMD (g/cm(2)), Australian Canadian (AUSCAN) OA hand index, grip strength, pinch strength, and visual analogue scale (VAS) were also estimated. Patients with radiographic hand OA had lower distal radius BMD when compared with controls (0.35 +/- A 0.06 vs. 0.40 +/- A 0.05, P < 0.001). After adjusting for variables such as age, menopausal duration, number of nodal joints, and AUSCAN function index, the difference in BMD between the two groups was also significantly different (0.35 +/- A 0.04 vs. 0.38 +/- A 0.04, P < 0.001). For analysis of risk factors for forearm BMD in hand OA, age and K-L OA grade in total hand OA are considered risk factors, whereas age and menopause duration contribute to the forearm BMD in radiographic hand OA patients (P < 0.001, P =

0.002, respectively). The development of osteoporosis at the distal radius in radiographic hand OA is associated with older age (OR = 1.216, P = 0.002), lower BMI (OR = 0.777, P = 0.004) and lower stiffness in the AUSCAN OA index (OR = 0.505, P = 0.003). This study shows that the BMD levels of the distal radius in patients with radiographic hand OA are significantly lower when compared to those of controls. Forearm BMD levels are positively associated with age and K-L radiological grade in total hand OA, whereas age and menopausal duration are closely related with radiographic hand OA. The presence of osteoporosis in the distal radius in radiographic hand OA may be influenced by age, BMI, and stiffness on the AUSCAN index.

TI The association between hip fracture and hip osteoarthritis: A case-control study

SO BMC MUSCULOSKELETAL DISORDERS
LA English
DT Article
ID bone-mineral density; joint space width; body-mass index; femoral-neck fracture; risk-factors; osteoporotic fractures; replacement; population; falls; chingford
AB Background: There have been reports both supporting and refuting an inverse relationship between hip fracture and hip osteoarthritis (OA). We explore this relationship using a case-control study design. Methods: Exclusion criteria were previous hip fracture (same side or contralateral side), age younger than 60 years, foreign nationality, pathological fracture, rheumatoid arthritis and cases were radiographic examinations were not found in the archives. We studied all subjects with hip fracture that remained after the exclusion process that were treated at Akureyri University Hospital, Iceland 1990-2008, n = 562 (74% women). Hip fracture cases were compared with a cohort of subjects with colon radiographs, n = 803 (54% women) to determine expected population prevalence of hip OA. Presence of radiographic hip OA was defined as a minimum joint space of 2.5 mm or less on an anteroposterior radiograph, or Kellgren and Lawrence grade 2 or higher. Possible causes of secondary osteoporosis were identified by review of medical records. Results: The age-adjusted odds ratio (OR) for subjects with hip fracture having radiographic hip OA was 0.30 (95% confidence interval [95% CI] 0.12-0.74) for men and 0.33 (95% CI 0.19-0.58) for women, compared to controls. The probability for subjects with hip fracture and hip OA having a secondary cause of osteoporosis was three times higher than for subjects with hip fracture without hip OA. Conclusion: The results of our study support an inverse relationship between hip fractures and hip OA.

TI Sclerostin and the Regulation of Bone Formation: Effects in Hip Osteoarthritis and Femoral Neck Fracture
SO JOURNAL OF BONE AND MINERAL RESEARCH
LA English
DT Article
DE SCLEROSTIN; OSTEOCYTE; BONE REMODELING; OSTEOARTHRITIS; OSTEOPOROSIS
ID van-buchem-disease; cancellous bone; mechanical strain; cortical porosity; bmp antagonist; up-regulation; iliac crest; sost gene; in-vivo; osteocytes
AB Remodeling imbalance in the elderly femoral neck can result in thin cortices and porosity predisposing to hip fracture. Hip osteoarthritis protects against intracapsular hip fracture. By secreting sclerostin, osteocytes may inhibit Wnt signaling and reduce bone formation by osteoblasts. We hypothesised that differences in osteocytic sclerostin expression might account for differences in osteonal bone-formation activity between controls and subjects with hip fracture or hip osteoarthritis. Using specific antibody staining, we determined the osteocytic expression of sclerostin within osteons of the femoral neck cortex in bone removed from subjects undergoing surgery for hip osteoarthritis (hOA: 5 males, 5 females, 49 to 92 years of age) or hip fracture fixation (FNF: 5 males, 5 females, 73 to 87 years of age) and controls (C: 5 males, 6 females, 61 to 90 years of age). Sclerostin expression and distances of each osteocyte to the canal surface and cement line were assessed for all osteonal osteocytes in 636 unremodeled osteons chosen from fields (similar to 0.5 mm in diameter) with at least one canal staining for alkaline phosphatase (ALP), a marker of bone formation. In adjacent sections, ALP staining was used to classify basic multicellular unit (BMUs) as quiescent or actively forming bone (ALP(+)). The areal densities of scl(-) and scl(+) osteocytes (number of cells per unit area) in the BMU were inversely correlated and were strong determinants of ALP status in the BMU. In controls and hip fracture patients only, sclerostin-negative osteocytes were closer to osteonal surfaces than positively stained cells. Osteon maturity (progress to closure) was strongly associated with the proportion of osteonal osteocytes expressing sclerostin, and sclerostin expression was the chief determinant of ALP status. hOA patients had 18% fewer

osteocytes per unit bone area than controls, fewer osteocytes expressed sclerostin on average than in controls, but wide variation was seen between subjects. Thus, in most hOA patients, there was increased osteonal ALP staining and reduced sclerostin staining of osteocytes. In FNF patients, newly forming osteons were similar in this respect to hOA osteons, but with closure, there was a much sharper reduction in ALP staining that was only partly accounted for by the increased proportions of osteonal osteocytes staining positive for sclerostin. There was no evidence for a greater effect on ALP expression by osteocytes near the osteonal canal. In line with data from blocking antibody experiments, osteonal sclerostin appears to be a strong determinant of whether osteoblasts actively produce bone. In hOA, reduced sclerostin expression likely mediates increased osteoblastic activity in the intracapsular cortex. In FNF, full osteonal closure is postponed, with increased porosity, in part because the proportion of osteocytes expressing sclerostin increases sharply with osteonal maturation. 0 2010 American Society for Bone and Mineral Research.

AB Objective: The signaling protein p38 mitogen-activated protein kinase is required for inflammatory signaling in chondrocytes that regulates matrix metalloproteinase (MMP) production. We sought to determine the role of specific p38 isoforms in chondrocyte catabolic signaling in response to IL-1 beta and fibronectin fragments (Fn-f). Methods: Human articular chondrocytes isolated from normal ankle cartilage from tissue donors or from osteoarthritic knee cartilage obtained during knee replacement were stimulated with IL-1 beta or Fn-f, with or without pretreatment with p38 inhibitors (SB203580 or BIRB796) or growth factors (IGF-1 and OP-1). p38 isoform phosphorylation was measured by antibody array and immunoblotting. MMP-13 expression was measured by real-time polymerase chain reaction (PCR), enzyme-linked immunosorbent assay (ELISA), and immunoblotting. Chondrocytes were transfected with plasmids expressing constitutively active (CA) p38 gamma or with adenovirus expressing dominant negative (DN) p38 gamma. Results: Stimulation of chondrocytes with either IL-1 beta or Fn-f led to enhanced phosphorylation of p38 alpha and p38 gamma, with little phosphorylation of p38 beta or p38 delta isoforms. p38 alpha localized to the nucleus and p38 gamma to the cytosol. Inhibition of both p38 alpha and p38 gamma with BIRB796 resulted in less inhibition of MMP-13 production in response to IL-1 beta or FN-f than did inhibition of only p38 alpha with SB203580. Transfection with CA p38 gamma resulted in decreased MMP-13 production while transduction with DN p38 gamma resulted in increased MMP-13 production. IGF-1 and OP-1 pretreatment inhibited p38 alpha phosphorylation but not p38y phosphorylation. Conclusions: p38 gamma is activated by catabolic stimulation of human articular chondrocytes, but interestingly suppresses MMP-13 production. Treatments that increase p38 gamma activation may be of therapeutic benefit in reducing chondrocyte production of MMP-13. (C) 2010 Osteoarthritis Research Society International. TI Differing patterns of peripheral blood leukocyte telomere length in rheumatologic diseases

SO MUTATION RESEARCH-FUNDAMENTAL AND MOLECULAR MECHANISMS OF MUTAGENESIS
LA English
DT Article
DE Telomere; Inflammation; Rheumatoid arthritis; Psoriatic arthritis; Ankylosing spondylitis; Osteoarthritis; Osteoporosis
ID systemic-lupus-erythematosus; connective-tissue diseases; mononuclear-cells; mammalian-cells; t-cells; recombination; elongation; reduction; arthritis; cancer
AB Telomeres progressively shorten with repeated somatic tissue cell division, their length being an indicator of cellular ageing. Telomeric dysfunction may be implicated in a variety of diseases. We measured mean telomere length in peripheral blood leukocytes (PBL) from patients with various rheumatologic diseases. Mean PBL telomere length was measured using real-time quantitative polymerase chain reaction (Q-PCR) assay in a control population (n = 130; age range: 3-94 years) and in subjects diagnosed with rheumatoid arthritis (RA; n = 86; age range: 31-82 years), psoriatic arthritis (PA; n = 56; age range: 26-79 years) and ankylosing spondylitis (AS; n = 59; age range: 21-75 years). These diseases are associated with chronic systemic inflammatory activity. Telomere length was also quantified in subjects with osteoarthritis (OA: n = 34; age range: 43-82 years) and osteoporosis (OP: n = 35: age range: 59-95 years), diseases without a chronic systemic inflammatory component. Telomere length in OA showed no differences from age-matched controls ($p = 0.234$), but was significantly shorter in OP ($p = 0.001$). Telomere length was significantly longer than controls in RA ($p = 0.015$), PA ($p < 0.001$) and AS ($p < 0.001$). Different patterns in telomere length from PBL are evidenced in rheumatologic pathologies, possibly dependent on the presence or absence of chronic systemic inflammation. (C) 2009 Elsevier B.V.
