TI A longitudinal study of the relationship between the status of bone marrow abnormalities and progression of knee osteoarthritis
SO JOURNAL OF ORTHOPAEDIC SCIENCE
LA English
DT Article
ID transient osteoporosis; subchondral bone; edema; lesions; joint; mri; cartilage; disease
AB Bone marrow abnormalities (BMAs) detected on magnetic resonance imaging (MRI) are suggested to be involved in the pathogenesis of osteoarthritis (OA), and the size of the BMAs is associated with the progression of OA. However, it still remains unclear as to whether the associations of BMA size and OA severity are observed equally or whether they differ from early to advanced stages of OA. In the present study we examined whether BMA enlargement and OA progression differed according to the severity of OA. One hundred and eighty patients with knee OA were enrolled in the present study, and 122 of these patients completed this study. Radiography and knee MRI were done two times in all patients, at the baseline and 6 months or later at the time of patient follow-up. The severity of OA was evaluated by radiography using the Kellgren-Lawrence (K-L) grade. The patients who showed a deterioration in the K-L grade during the follow-up examination (59/122) were defined as the deterioration group. T2-weighted fat-suppressed MR images were used to score the size of the BMAs according to the whole-organ magnetic resonance imaging score (WORMS). A new scoring system, the spacial BMA score (s-score) was defined to assess the size of the BMAs three-dimensionally. In patients with K-L grade 2, the s-score changes during the follow-up period in the deterioration group were significantly increased in comparison to those in the no-change group (P = 0.04), and no significant s-score changes were observed in patients with either K-L grade 1 or 3 (P = 0.07 and 0.57) between the deterioration group and the no-change group during the follow-up examination. In patients with K-L grade 3, the s-score at the baseline in the deterioration group was higher than that in the no-change group (P = 0.05). The relationship between the size and enlargement of BMAs and the progression of OA changed depending upon the severity of OA.

TI Alterations in osteoclast function and phenotype induced by different inhibitors of bone resorption implications for osteoclast quality
SO BMC MUSCULOSKELETAL DISORDERS
LA English
DT Article
ID autosomal recessive osteopetrosis; anhydrase-ii deficiency; cathepsin-k deficiency; matrix metalloproteinases; cysteine-proteinases; carbonic-anhydrase; long-bone; relative contribution; atpase inhibitor; structural basis
AB Background: Normal osteoclasts resorb bone by secretion of acid and proteases. Recent studies of patients with loss of function mutations affecting either of these processes have indicated a divergence in osteoclastic phenotypes. These difference in osteoclast phenotypes may directly or indirectly have secondary effects on bone remodeling, a process which is of importance for the pathogenesis of both osteoporosis and osteoarthritis. We treated human osteoclasts with different inhibitors and characterized their resulting function. Methods: Human CD14 + monocytes were differentiated into mature osteoclasts using RANKL and

M-CSF. The osteoclasts were cultured on bone in the presence or absence of various inhibitors: Inhibitors of acidification (bafilomycin A1, diphyllin, ethoxyzolamide), inhibitors of proteolysis (E64, GM6001), or a bisphosphonate (ibandronate). Osteoclast numbers and bone resorption were monitored by measurements of TRACP activity, the release of calcium, CTX-I and ICTP, as well as by counting resorption pits. Results: All inhibitors of acidification were equally potent with respect to inhibition of both organic and inorganic resorption. In contrast, inhibition of proteolysis by E64 potently reduced organic resorption, but only modestly suppressed inorganic resorption. GM6001 alone did not greatly affect bone resorption. However, when GM6001 and E64 were combined, a complete abrogation of organic bone resorption was observed, without a great effect on inorganic resorption. Ibandronate abrogated both organic and inorganic resorption at all concentrations tested [0.3-100 mu M], however, this treatment dramatically reduced TRACP activity. Conclusions: We present evidence highlighting important differences with respect to osteoclast function, when comparing the different types of osteoclast inhibitors. Each class of osteoclast inhibitors will lead to different alterations in osteoclast quality, which secondarily may lead to different bone qualities.

TI Brake response time before and after total knee arthroplasty: a prospective cohort study
SO BMC MUSCULOSKELETAL DISORDERS
LA English
DT Article
ID total hip; osteoarthritis; prevalence
AB Background: Although the numbers of total knee arthroplasty (TKA) are increasing, there is only a small number of studies investigating driving safety after TKA. The parameter 'Brake Response Time (BRT)' is one of the most important criteria for driving safety and was therefore chosen for investigation. The present study was conducted to test the hypotheses that patients with right-or left-sided TKA show a significant increase in BRT from pre-operative (pre-op, 1 day before surgery) to post-operative (post-op, 2 weeks post surgery), and a significant decrease in BRT from post-op to the follow-up investigation (FU, 8 weeks post surgery). Additionally, it was hypothesized that the BRT of patients after TKA is significantly higher than that of healthy controls. Methods: 31 of 70 consecutive patients (mean age 65.7 +/- 10.2 years) receiving TKA were tested for their BRT pre-op, post-op and at FU. BRT was assessed using a custom-made driving

simulator. We used normative BRT data from 31 healthy controls for comparison. Results: There were no significant increases between pre-op and post-op BRT values for patients who had undergone left-or right-sided TKA. Even the proportion of patients above a BRT threshold of 700 ms was not significantly increased postop. Controls had a BRT which was significantly better than the BRT of patients with right-or left-sided TKA at all three time points. Conclusion: The present study showed a small and insignificant postoperative increase in the BRT of patients who had undergone right-or left-sided TKA. Therefore, we believe it is not justified to impair the patient's quality of social and occupational life post-surgery by imposing restrictions on driving motor vehicles beyond an interval of two weeks after surgery.

TI Effects of Estrogen Deficiency and Low Bone Mineral Density on Healthy Knee Cartilage in Rabbits
SO JOURNAL OF ORTHOPAEDIC RESEARCH
LA English
DT Article
DE ovariectomy; estrogens; osteoporosis; cartilage; animal models
ID articular-cartilage; subchondral bone; experimental-model; animal-models; osteoarthritis; osteoporosis; association; degradation; ovariectomy; population
AB The purpose of this study was to compare the effects of estrogen deficiency and bone mass loss on normal knee cartilage in mature rabbits. Bilateral ovariectomy (OVX) was performed in 13 rabbits, 6 of which also received systemic glucocorticoid for 4 weeks. Seven additional healthy rabbits were used as controls. Bone mineral density (BMD) was measured by dual X-ray absorptiometry in lumbar spine, knee, and subchondral bone of the knee at baseline and 22 weeks after OVX. After sacrifice, the knees were dissected, macroscopy was assessed, and histological cartilage abnormalities were evaluated according to the Mankin score. Correlations of Mankin with BMD at different regions were also performed. When compared to baseline, differences in BMD were only found in spine and knee of the animals receiving glucocorticoids. All the animals subjected to OVX had a significantly higher Mankin score than controls. Mankin was upper in OVX animals receiving glucocorticoids, but differences were not significant. The Mankin score was inversely related with BMD in lumbar spine ($r = -0.67$;$p<0.01$). Although low bone mineral density contributes to the minor osteoarthritic alterations observed in our model, estrogen deficiency itself seems to act directly to induce the main pathogenic effects in healthy cartilage of the rabbit. TI Upper cervical spine injuries: age-specific clinical features
SO JOURNAL OF ORTHOPAEDIC SCIENCE
LA English
DT Article
ID odontoid fractures; elderly-patients; older; osteoarthritis; cord; prevalence; survival; pattern; trauma; axis
AB There are few reports on the age-specific clinical features of upper cervical spine injury. To identify these age-specific changes, we reviewed 103 patients with upper cervical spine injury. We subdivided the patients into four groups according to age: 12 patients were classified as old elderly (a parts per thousand yen75 years), 18 patients as young elderly (65-74 years), 67 patients as young adults (18-64 years), and 6 patients as adolescents (a parts per thousand currency sign17 years). Data were collected on injury etiology, mortality, neurological deficit, distribution and pattern of injury, degenerative changes of each joint in the upper cervical spine and disc in the cervical spine, and osteoporosis of the axis. The proportion of patients with a simple fall as the etiology of their injury showed a statistically significant trend to increase with aging. Although no specific distribution or pattern of injury was statistically elucidated, we were able to detect some common features. A high proportion of the old elderly group (5/12) had a type II odontoid fracture. Body fracture of the axis tends to be frequent in the young elderly and traumatic spondylolisthesis and hyperextension teardrop fracture to be frequent in the young adults. In adolescents, a traffic accident as an unbelted rear seat passenger was the most frequent etiology. Among the 103 patients, 16 died during the initial hospitalization. The mortality rate for upper cervical spine injury was similar in all groups. In the old elderly, stiffness of the lower cervical spine, caused by degenerative changes and osteopenia, might contribute to upper cervical spine

injury in response to low-energy trauma. The disproportion of degenerative change in joints of the upper cervical spine might also contribute to the high frequency of type II odontoid fracture. In young adults, high-energy and hyperextension injury was the most frequent cause of upper cervical spine injury.

DT Article
DE ACL reconstruction; Age; Osteoarthritis; Ligament; Knee

ID patellar tendon-bone; follow-up; acl reconstruction; nonoperative treatment; hamstring tendon; age; knee; level; osteoarthritis; cartilage
AB Anterior cruciate ligament (ACL) deficiency can result in symptomatic functional instability of the knee regardless of the patient's age. We reviewed a single surgeon database of 908 ACL reconstructions carried out in the last 20 years for symptomatic instability. 14 patients were identified who were 55 years or above at surgery (mean: 60 years, range 55-75 years). Patients were evaluated clinically and with clinical outcome scoring and KT-1000 arthrometry assessment. 12 patients (86%) were available to attend for follow-up at a mean 9 years after ACL reconstruction. The median pre-injury Tegner score was 5.5 (range 1-7) and the median pre-operative Lysholm score was 33 (range 15-67). Initially, one patient had a good result but subsequently the patient undergone total knee replacement 5 years after ACL reconstruction. For the remainder, at the most recent review, the median Lysholm score had improved to 79 (range 43-100, $P < 0.05$) although it had deteriorated from the maximum achieved post-op score of 85.5 (range 53-100, $P < 0.05$); and the Tegner score had declined to 3 (range 1-5, $P < 0.05$). KT-1000 testing demonstrated a mean side-to-side difference improvement in laxity from 4.6 +/- A 1.3 mm (range 3-7) to 1.5 +/- A 1.2 mm (range 0-4, $P < 0.05$) and > 2 mm difference in only one knee (for which it was known that the graft had failed at 11 years after ACL reconstruction). At review, the same knee was the only one that demonstrated a pivot shift. ACL reconstruction with autograft in the above-55 patient with minimal osteoarthritis is a safe procedure that returns stability to the knee and permits a return to a reasonable level of activity.

TI Effectiveness of exercise in the treatment of lumbar spinal stenosis, knee osteoarthritis, and osteoporosis
SO AGING CLINICAL AND EXPERIMENTAL RESEARCH
LA English
DT Review
DE Elderly people; exercise; knee osteoarthritis; lumbar spinal stenosis; osteoporosis
ID graded compression; eular recommendations; standing committee; preventing falls; muscle strength; cauda-equina; nerve roots; task-force; management; hip
AB Background and aims: Lumbar spinal stenosis (LSS), osteoarthritis (OA) of the knee, and osteoporosis are major locomotive diseases in the elderly population. The aim of this study was to examine the effectiveness of exercise in these three diseases. Methods: We reviewed the relevant literature, i.e., systematic reviews and meta-analyses searched with Pub Med. Results: There is not sufficient evidence to draw conclusions regarding the effectiveness of exercise for LSS. However, muscle strengthening and aerobic exercises are effective in reducing pain and improving physical function in patients with mild to moderate OA of the knee. On the other hand, aerobics, weight bearing and resistance exercises are effective in increasing the bone mineral density of the spine in postmenopausal women, and walking is effective for the hips. Muscle strengthening, balance training and traditional Chinese Tai Chi reduce the risk of falls in the elderly. Conclusions: Based on a review of the literature, appropriate exercises should be emphasized for elderly patients, especially for those with mild to moderate OA of the knee or osteoporosis. TI Analgesic effect of raloxifene on back and knee pain in postmenopausal women with osteoporosis and/or osteoarthritis
SO JOURNAL OF BONE AND MINERAL METABOLISM
LA English
DT Article
DE Raloxifene; Pain; Skin impedance; Osteoporosis; Osteoarthritis
ID vitamin-d; electroalgometry; risedronate; etidronate; collagen
AB To assess the effect of raloxifene on bone and joint pain, 24 postmenopausal women with back or knee pain or both were randomly divided into two groups, based on the chronological sequence of consultation, to be treated with 60 mg raloxifene and 1 mu g alfacalcidol (RA)/day (group RA) or 1 mu g alfacalcidol alone (A)/day (group A), respectively, for 6 months. Pain following knee loading (KL) by standing up from a chair and bending the knee by squatting, knee and spine loading (KSL) by walking horizontally and ascending and descending stairs, and spine loading (SL) by lying down supine on a bed and leaving the bed to stand was evaluated by electroalgometry (EAM), based on measurement of the fall of skin impedance, and a visual rating scale (VRS), recording subjective pain on a scale of 0-100 between no pain and unbearable pain. The two groups showed no significant difference as to age, indices of mineral metabolism, back and knee pain, and bone status. RA gave a significantly greater analgesic effect than A by both EAM ($P = 0.0158$) and VRS ($P = 0.0268$) on overall comparison of the mean response to all modalities of exercise loading. Paired comparison between pretreatment and posttreatment indicated a significant effect of RA by both EAM ($P = 0.0045$) and VRS ($P = 0.0017$), but not that of A. The analgesic effect was more clearly noted on combined knee-spine loading (KSL) and spine loading (SL) than simple knee loading (KL). Monthly comparison of the analgesic effect indicated a significantly better analgesic effect in the fifth month by VRS. RA effect greater than A was more evident by EAM than VRS and during months 3-6 than during 1-2 months, suggesting a slowly progressive effect of RA. Pain evaluation by EAM and VRS mostly gave parallel results, except for a few occasions such as knee loading and spine loading by sitting up and leaving a bed, when EAM detected a positive

effect but VRS failed to do so. RA appeared to be more effective on bone and joint pain than A in postmenopausal women according to both EAM and VRS measurements.

TI Pretreatment of periosteum with TGF-β1 in situ enhances the quality of osteochondral tissue regenerated from transplanted periosteal grafts in adult rabbits
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE Bone; Cartilage; Chondrogenesis; Joints; Periosteum; Regenerative medicine; Tissue engineering; Transforming growth factor-beta
ID continuous passive motion; mesenchymal stem-cells; autogenous osteoperiosteal grafts; deep cartilage defects; full-thickness defects; joint surface-defects; articular-cartilage; ii collagen; follow-up; repair

AB Objective: To compare the efficacy of in situ transforming growth factor-betal (TGF-beta 1)-pretreated periosteum to untreated periosteum for regeneration of osteochondral tissue in rabbits. Methods: In the pretreatment group, 12 month-old New Zealand white rabbits received subperiosteal injections of 200 ng of TGF-beta 1 percutaneously in the medial side of the proximal tibia, 7 days prior to surgery. Control rabbits received no treatment prior surgery. Osteochondral transverse defects measuring 5 mm proximal to distal and spanning the entire width of the patellar groove were created and repaired with untreated or TGF-beta 1-pretreated periosteal grafts. Post-operatively the rabbits resumed normal cage activity for 6 weeks. Results: Complete filling of the defects with regenerated tissue was observed in both the TGF-beta 1 -pretreated and control groups with reformation of the original contours of the patellar groove. The total histological score (modified O'Driscoll) in the TGF-beta 1-pretreated group, 20(95% Confidence Interval (CI), 19-21), was significantly higher (P=0.0001) than the control group, 18 (16-19). The most notable improvements were in structural integrity and subchondral bone regeneration. No significant differences in glycosaminoglycan or type II collagen content, or equilibrium modulus were found between the surgical groups. The cambium of the periosteum regenerated at the graft harvest site was significantly thicker (P=0.0065) in the TGF-beta 1-pretreated rabbits, 121 mu m (94-149), compared to controls, 74 mu m (52-96), after 6 weeks. Conclusions: This study demonstrates that in situ pretreatment of periosteum with TGF-beta 1 improves osteochondral tissue regeneration at 6-weeks post-op compared to untreated periosteum in 12 month-old rabbits. TI How to measure the impact of musculoskeletal conditions
SO BEST PRACTICE & RESEARCH IN CLINICAL RHEUMATOLOGY
LA English
DT Article
ID rheumatoid-arthritis; death certificate; health-status; mortality; expenditures; burden
AB Musculoskeletal conditions are universally prevalent among all age and gender groups, across all socio-demographic strata of society. Their impact is pervasive yet this is not widely recognised at the level of health policy and priority. Musculoskeletal conditions are a diverse group of disorders with regard to pathophysiology but are linked anatomically and by their association with pain and impaired physical function; encompassing a spectrum of conditions, including inflammatory diseases such as rheumatoid arthritis or gout; age-related conditions such as osteoporosis and osteoarthritis; common conditions of unclear aetiology such as back pain and fibromyalgia; and those related to activity or injuries such as occupational musculoskeletal disorders, sports injuries or the consequences of falls and major trauma. The increasing number of older people and the changes in lifestyle throughout the world with increasing obesity and reduced physical activity mean that the burden on people and society will increase dramatically. The growing awareness of the burden increases the need for accurate measurement and assessment of the burden as well as measurement of the impact of any public health action. This chapter considers theoretical and practical issues relevant to measuring the buden of musculoskeltal conditions in populations, societies and individuals. (C) 2010 Published by Elsevier Ltd.

TI A comparison of conventional maximum intensity projection with a new depth-specific topographic mapping technique in the CT analysis of proximal tibial subchondral bone density
SO SKELETAL RADIOLOGY
LA English
DT Article
DE Subchondral bone; Bone mineral density; Computed tomography; Osteoarthritis; CT-OAM; CT-TOMASD
ID anterior cruciate ligament; articular-cartilage; trabecular bone; knee osteoarthritis; mineral density; computed-tomography; cancellous bone; cortical bone; osteoporosis; joints
AB The objective was to identify subchondral bone density differences between normal and osteoarthritic (OA) proximal tibiae using computed tomography osteoabsorptiometry (CT-OAM) and computed tomography topographic mapping of subchondral density (CT-TOMASD). Sixteen intact cadaver knees from ten donors (8 male:2 female; mean age:77.8, SD:7.4 years) were categorized as normal (n = 10) or OA (n = 6) based upon CT reconstructions. CT-OAM assessed maximum subchondral bone mineral density (BMD). CT-TOMASD assessed average subchondral BMD across three layers (0-2.5, 2.5-5 and 5-10 mm) measured in relation to depth from the subchondral surface. Regional analyses of CT-OAM and CT-TOMASD included: medial BMD, lateral BMD, and average BMD of a 10-mm diameter area that searched each medial and lateral plateau for the highest "focal" density present within each knee. Compared with normal knees, both CT-OAM and CT-TOMASD demonstrated an average of 17% greater whole medial compartment density in OA knees ($p < 0.016$). CT-OAM did not distinguish focal density differences between OA and normal knees ($p > 0.05$). CT-TOMASD focal region analyses revealed an average of 24% greater density in the 0- to 2.5-mm layer (p =

0.003) and 36% greater density in the 2.5- to 5-mm layer (p = 0.034) in OA knees. Both CT-OAM and TOMASD identified higher medial compartment density in OA tibiae compared with normal tibiae. In addition, CT-TOMASD indicated greater focal density differences between normal and OA knees with increased depth from the subchondral surface. Depth-specific density analyses may help identify and quantify small changes in subchondral BMD associated with OA disease onset and progression.

AB Introduction: Obesity is a public health problem, with overweight individuals representing approximately 20% of the adult world population. Postmenopausal status is associated with higher prevalence of obesity, as 44% of postmenopausal women are overweight, among whom 23% are obese. Obesity often co-exists with other diseases, the most important being diabetes mellitus, dyslipidemia and hypertension. Furthermore, obesity increases the risk of gynecologic cancer, cardiovascular disease, venous thromboembolism, osteoarthritis and chronic back pain. Aim: To formulate a position statement on the management of the menopause in obese women. Materials and methods: Literature review and consensus of expert opinion. Results and conclusions: Obese women seeking hormone therapy should be evaluated for their individual baseline risk of developing breast cancer, cardiovascular disease and venous thromboembolism. These risks should be weighed against expected benefit from symptom relief, improved quality of life and osteoporosis prevention. The lowest effective estrogen dose should be used (GEE 0.300-0.400 mg or estradiol 0.5-1 mg orally daily or 25-50 mu g estradiol transdermally). With regard to progestogens, although no RCT data exist, there are observational studies showing that micronized progesterone or dydrogesterone may have a better risk profile with respect to breast cancer risk. There are no RCT data comparing various progestogens with regard to VTE risk. There are observational data, however, suggesting that

micronized progesterone or pregnane derivatives may be associated with a lower VTE Fisk in postmenopausal women taking HT compared to nonpregnane derivatives. There is a rationale in suggesting the use of transdermal HT in obese women, since this route of administration has been associated with a lesser risk of venous thromboembolism than oral therapy. TI The prevalence of osteoporosis in patients with severe hip and knee osteoarthritis awaiting joint arthroplasty
SO AGE AND AGEING
LA English
DT Article
DE osteoporosis; osteoarthritis; hip; knee; bone mineral density; elderly
ID bone-mineral density; elderly-men; women; precision; fractures; arthritis; risk
AB Objective: to determine the prevalence of osteoporosis among patients with osteoarthritis awaiting total knee arthroplasty or total hip arthroplasty aged between 65 and 80 years. Design: cross-sectional observational study. Setting: tertiary referral centre in Newcastle upon Tyne, UK. Subjects: patients with osteoarthritis awaiting total knee hip arthroplasty aged between 65 and 80 years. Methods: lumbar spine, bilateral femoral and forearm bone mineral density (BMD) measurements were obtained using dual-energy X-ray absorptiometry. Results: the cohort consisted of 199 patients with a mean age of 72 years (SD 4), and 113 (57%) were women. The overall rate of osteoporosis at any site was 23% (46/199) and a further 43% (85/199) of patients would have been classified as osteopaenic according to World Health Organization criteria. Osteoporosis was more commonly detected in the forearm (14%) than the lumbar spine (8.5%) and proximal femur of the index side (8.2%). Conclusions: in summary, a significant proportion of patients with end-stage OA have osteoporosis but this diagnosis may be missed unless BMD measurements are performed at sites distant from joints affected by OA.

TI Thromboprophylaxis with the Low-Molecular-Weight Heparin Bemiparin Sodium in Elderly Medical Patients in Usual Clinical Practice The ANCIANOS Study
SO CLINICAL DRUG INVESTIGATION
LA English
DT Article
ID venous thromboembolism; hospitalized-patients; risk-factors; prevention; safety; prophylaxis; thrombosis; efficacy; placebo; care
AB Background: Venous thromboembolism (VTE) is a preventable common disease in geriatric medical patients, causing substantial morbidity and mortality. Objective: To assess the effectiveness and safety of bemiparin sodium thromboprophylaxis in non-surgical elderly medical patients (aged >= 65 years) bedridden for at least 4 days due to acute medical illness. Methods: This was a prospective, observational, multicentre cohort study carried out in patients treated in the setting of geriatric centres (GCs) or hospital-at-home units (HHUs). The study included 507 non-surgical elderly patients recruited from 49 Spanish centres who were administered subcutaneous bemiparin sodium (Hibor (R)) 2500 IU/day or 3500 IU/day, depending on the degree of VTE-risk moderate or high, respectively. Rates of VTE, major and minor bleeding events, thrombocytopenia and deaths that occurred during the 3-month study period were extracted. Results: Seventy-two percent of the subjects were women, and the mean (SD) age was 82 (8) years. Overall, 70.6% (358 patients) were treated in GCs and 29.4% (149 patients) in HHUs. The main causes of immobilization were: heart failure (30.4%), acute infectious disease (29.8%), acute respiratory insufficiency (19.9%), rheumatological disease (i.e. osteoarthritis, rheumatoid arthritis and osteoporosis) [15.4%] and acute cerebrovascular disease (14.4%). Most of the patients (63%) had a high VTE risk and received the highest dose of prophylactic bemiparin sodium (3500 IU/day) for a mean 33 days. The incidence of VTE was 0.6% (three distal deep vein thromboses confirmed by Doppler ultrasound). No cases of pulmonary embolism were reported. There were two (0.4%) major bleeding events, eight (1.6%) minor bleeding events and seven (1.4%) cases of mild thrombocytopenia; no cases of moderate or severe thrombocytopenia were reported. Twenty-four patients (4.7%) developed mild to moderate injection site complications. Twenty-one patients (4.1%) died, but all from causes not related to study medication. Conclusions: Bemiparin sodium thromboprophylaxis for 4-5 weeks was associated with a low incidence of VIE and a low rate of bleeding and other complications in non-surgical elderly patients at risk of VTE, treated either in GCs or in HHUs, in standard clinical practice.

TI 23Na and 2H Magnetic Resonance Studies of Osteoarthritic and Osteoporotic Articular Cartilage
SO MAGNETIC RESONANCE IN MEDICINE
LA English
DT Article
DE osteoarthritis; osteoporosis; Na-23 and H-2 quadrupolar interactions; DQF; TQF
ID quantum-filtered nmr; multinuclear nmr; sodium; mri; glycosaminoglycan; microstructure; spectroscopy; quantitation; orientation; density
AB In this study, the short component of the Na-23 T-2 (T-2f) and the Na-23 and H-2 quadrupolar interactions (nu(Q)) were measured in bone-cartilage samples of osteoarthritic (OA) and osteoporotic (OP) patients. Na-23 nu(Q) was found to increase in osteoarthritic articular cartilage relative to controls. Similar results were found in bovine cartilage following proteoglycan (PG) depletion, a condition that prevails in osteoarthritis. Na-23 nu(Q) and 1/T-2f for articular cartilage obtained from osteoporotic patients were significantly larger than for control and osteoarthritic cartilage. Decalcification of both human and bovine articular cartilage resulted in an increase of Na-23 nu(Q) and 1/T-2f, showing the same trend as the osteoporotic samples. Differences in the ratio of the intensity of the large 2H splitting to that of the small one in the calcified zone were also observed. In osteoporosis, this ratio was twice as large as that obtained for both control and osteoarthritic samples. The H-2 and Na-23 results can be interpreted as due to sodium ions and water molecules filling the void created by the calcium depletion and to calcium ions being located in close association with the collagen fibers. To the best of our knowledge, this is the first study reporting differences of NMR parameters in cartilage of osteoporotic patients. Magn Reson Med 64:653-661, 2010. (C) 2010 Wiley-Liss, Inc.

AB The human skeleton optimizes its microarchitecture by elaborate adaptations to

mechanical loading during development and growth. The mechanisms for adaptation involve a multi-step process of cellular mechanotransduction stimulating bone modelling, and remodeling resulting in either bone formation or resorption. This process causes appropriate microarchitectural changes tending to adjust and improve the bone structure to its prevailing mechanical environment. Normal individual reaches peak bone mass at age between 25 and 30 years, and thereafter bone mass declines with age in both genders. The bone loss is accompanied by microarchitectural deterioration resulting in reduced mechanical strength likely leading to fragility fractures. With aging, inevitable bone loss occurs, which is frequently the cause of osteoporosis; and inevitable bone and joint degeneration happens, which often results in osteoarthrosis. These diseases are among the major health care problems in terms of socio-economic costs. The overall goals of the current series of studies were to investigate the age-related and osteoarthrosis (OA) related changes in the 3-D microarchitectural properties, mechanical properties, collagen and mineral quality of subchondral cancellous and cortical bone tissues. The studies included mainly two parts. For human subjects: aging- (I-IV) and early OA-related (V-VI) changes in cancellous bone properties were assessed. For OA guinea pig models (VII-IX), three topics were studied: firstly, the spontaneous, age-related development of guinea pig OA; secondly, the potential effects of hyaluronan on OA subchondral bone tissues; and thirdly, the effects on OA progression of an increase in subchondral bone density by inhibition of bone remodeling with a bisphosphonate. These investigations aimed to obtain more insight into the age-related and OA-related subchondral bone adaptations. Microarchitectural adaptation in human aging cancellous bone The precision of micro-CT measurement is excellent. Accurate 3-D micro-CT image datasets can be generated by applying an appropriate segmentation threshold. A fixed threshold may be used to obtain reliable volume fraction data, and this fixed threshold may be determined from the Archimedes-based volume fraction of a subgroup of specimens (1). Based on accurately generated micro-CT datasets, agerelated microarchitectural changes of human tibial cancelbus bone have been demonstrated (II, III). Apart from connectivity, all measured microarchitectural properties correlate significantly with age. However, age-related changes in the properties of human tibial cancellous bone do not follow the same pattern, nor do they occur at the same age. The observed increase of anisotropy and the constant nature of connectivity suggest an important bone remodeling mechanism that normal aging tibia may adapt trabecular volume orientation. Namely, that the aging trabeculae align preferentially to the primary loading direction to compensate bone loss (III). Age-related changes in trabecular thickness and structure type become significant first after 80 years of age. The plate-like structure reflects high mechanical stress whereas rod-like structure reflects low mechanical stress (II). Trabecular structure type and bone volume fraction correlates strongly. Trabecular structure type together with anisotropy correlates well with the Young's modulus. The most effective microarchitectural properties for predicting the mechanical properties of cancellous bone seem to differ with age (IV).

Microarchitectural adaptation in human osteoarthrotic subchondral bone In early human OA subchondral cancellous bone, none of the mechanical properties of cancellous bone can be predicted by the measured physical/compositional properties (V). The increased trabecular thickness and density, but relatively decreased connectivity suggests a mechanism of bone remodeling in early OA as a process of filling trabecular cavities. This process leads to a progressive change of trabeculae from rod-like to plate-like, the opposite to that of normal ageing. The increase in bone tissue accompanied with deteriorated microarchitecture in early-stage OA cancellous bone does not account for the loss of mechanical properties, which suggests deterioration in the quality of OA cancellous bone (VI). Microarchitectural adaptation in guinea pig osteoarthrotic subchondral bone Age-related pronounced changes of the microarchitecture and bone matrix composition of the subchondral bone tissues in guinea pig have been demonstrated. These changes do not appear to follow the same pattern as in normal aging and may have different influences on the resulting mechanical properties (VII). Intra-articular injection of hyaluronan effectively protects against cartilage degeneration in guinea pig primary OA. The decrease of subchondral bone density and thickness and change of trabecular structure toward rod-like result in more compliant subchondral bone and thereby reduces cartilage stress during impact loading. Moreover, hyaluronan maintains the mechanical properties of cancellous bone likely through increasing its mineralization. Early administration of hyaluronan is effective for intervention of OA initiation and progression, and short-term early HA treatment is sufficient to maintain treatment effects in OA guinea pig model (VIII). The inhibition of bone remodeling by ALN leads to significant increase of subchondral bone mass and bone mineral content, and marked changes of microarchitecture. Furthermore, the resulting increased bone mass accelerates articular cartilage degeneration at the medial condyle and, to some extent, at the lateral condyle. These results suggest that increased subchondral bone density promotes OA progression and call for circumspection in using bone density enhancing drugs for intervention of primary OA (IX). Conclusion Age-related musculoskeletal diseases increase as a result of increase in the elderly population and a change in lifestyle. Over the last a few decades, much significant research on the properties has been carried out on diseases such as age-related bone fracture, prosthetic loosening, bone remodeling, and degenerative bone diseases on both axial central vertebra and peripheral trabecular bone. We have now achieved a great deal of knowledge on normal aging- and diseases-related changes in bone properties and quality. This knowledge is of major importance for the understanding of degenerative bone diseases, and for the design, fixation, survival of joint prosthesis, functional adaptation of host bone; and for application of biomaterials regarding interface reaction, fracture repair and defect healing. Understanding the microarchitectural properties, mechanical adaptations, and collagen and mineral qualities of subchondral bone tissues highlighted in these studies may help to gain more insights into the pathogenesis of degenerative bone diseases and to target and develop novel approaches for the intervention and

treatment.

TI A Longitudinal Analysis of Urinary Biochemical Markers and Bone Mineral Density in STR/Ort Mice as a Model of Spontaneous Osteoarthritis
SO ARTHRITIS AND RHEUMATISM
LA English
DT Article
ID degenerative joint disease; body-mass index; knee osteoarthritis; cartilage damage; cross-links; mouse knee; x-ray; collagen; osteoporosis; pyridinoline
AB Objective. To investigate the longitudinal changes both in the urinary concentrations of biochemical markers and in bone mineral density (BMD) during disease progression in the STR/Ort mouse model of osteoarthritis (OA). Methods. Male STR/Ort mice were studied, with CBA mice used as nonarthritic controls. Radiographic evaluation and grading of the knee and measurements of urinary C-terminal crosslinking telopeptide of type II collagen (CTX-II), pyridinoline (Pyr), and deoxypyridinoline were performed between 8 weeks and 40 weeks of age. The BMD of the femoral shaft was measured from 20 weeks to 40 weeks of age and adjusted for body weight. Histologic evaluation and grading were performed at 40 weeks of age. STR/Ort mice were divided into 2 subgroups (STR OA and STR non-OA) based on histologic grading. Results. No significant differences between STR/Ort and CBA mice were observed for any biochemical marker or BMD at any time point. Urinary CTX-II levels and BMD in the STR OA subgroup were higher than those in the STR non-OA subgroup before radiographic changes of OA were apparent. Higher urinary Pyr levels in the STR OA subgroup were observed at the advanced stage of OA. Conclusion. Urinary CTX-II could be a useful marker in the early diagnosis and predicting the progression of OA, and urinary Pyr may be a potential marker to assess the severity of OA at an advanced stage. An increase in BMD prior to the establishment of radiographic OA may be related to the induction

of OA.

TI Subchondral bone microstructural damage by increased remodelling aggravates experimental osteoarthritis preceded by osteoporosis
SO ARTHRITIS RESEARCH & THERAPY
LA English
DT Article
ID kappa-b-ligand; experimental knee osteoarthritis; cruciate ligament transection; articular-cartilage; mineral density; trabecular bone; receptor-activator; cancellous bone; ii collagen; model
AB Introduction: Osteoporosis (OP) increases cartilage damage in a combined rabbit model of OP and osteoarthritis (OA). Accordingly, we assessed whether microstructure impairment at subchondral bone aggravates cartilage damage in this experimental model. Methods: OP was induced in 20 female rabbits, by ovariectomy and intramuscular injections of methylprednisolone hemisuccinate for four weeks. Ten healthy animals were used as controls. At week 7, OA was surgically induced in left knees of all rabbits. At 22 weeks, after sacrifice,

microstructure parameters were assessed by micro-computed tomography, and osteoprotegerin (OPG), receptor activator of nuclear factor-kappa B ligand (RANKL), alkaline phosphatase (ALP) and metalloproteinase 9 (MMP9) protein expressions were evaluated by Western Blot at subchondral bone. In addition, cartilage damage was estimated using the histopathological Mankin score. Mann-Whitney and Spearman statistical tests were performed as appropriate, using SPSS software v 11.0. Significant difference was established at $P < 0.05$. Results: Subchondral bone area/tissue area, trabecular thickness and polar moment of inertia were diminished in OPOA knees compared with control or OA knees ($P < 0.05$). A decrease of plate thickness, ALP expression and OPG/RANKL ratio as well as an increased fractal dimension and MMP9 expression occurred at subchondral bone of OA, OP and OPOA knees vs. controls ($P < 0.05$). In addition, the severity of cartilage damage was increased in OPOA knees vs. controls ($P < 0.05$). Remarkably, good correlations were observed between structural and remodelling parameters at subchondral bone, and furthermore, between subchondral structural parameters and cartilage Mankin score. Conclusions: Microstructure impairment at subchondral bone associated with an increased remodelling aggravated cartilage damage in OA rabbits with previous OP. Our results suggest that an increased subchondral bone resorption may account for the exacerbation of cartilage damage when early OA and OP coexist simultaneously in same individuals.

TI Evidence that bone mineral density plays a role in degenerative disc disease: the UK Twin Spine Study
SO ANNALS OF THE RHEUMATIC DISEASES
LA English
DT Article
ID lumbar spine; genetic influences; risk-factors; osteoporosis; osteoarthritis; women; hip; heritability; chingford
AB Objective Osteoarthritis (OA) and osteoporosis are often considered to lie at opposite ends of a spectrum of bone phenotypes. Lumbar degenerative disc disease (LDD) may be associated with low back pain (LBP) and is similar in many

ways to OA. LDD is reported in small studies to be associated with increased spine bone mineral density (BMD). The present work aimed to confirm this association in a large population sample using MRI and explore the relationship further, in particular to determine whether it is mediated genetically. Methods A population based sample (N = 908, age range 32-74 years) of UK female twins having MRI of the lumbar spine was used in this study. LDD traits and summary measures and their relationship with BMD at the lumbar spine and hip were examined using multivariate multiple regression and maximum likelihood based variance decomposition. Results There was a significant positive correlation between LDD and BMD at the lumbar spine and hip, which remained significant after adjustment for confounders. Both traits were highly heritable and the associations between them were mediated genetically. Conclusions A clear, significant and independent association of BMD at hip and lumbar spine with LDD was found which is, in part, genetically mediated. The association with the non-axial site, the hip, is of particular interest and suggests a systemic bone effect. This should encourage the search for pleiotropic genes to help in the understanding of the bone-cartilage relationship. Moreover, genetic variants identified could provide novel therapeutic targets in the management of LBP.

TI Musculoskeletal Complications of Hereditary Hemochromatosis: A Case-Control Study
SO JOURNAL OF RHEUMATOLOGY
LA English
DT Article
DE HEREDITARY HEMOCHROMATOSIS; OSTEOARTHRITIS; OSTEOPOROSIS; CARTILAGE; PHLEBOTOMY; IRON
ID genetic hemochromatosis; iron-overload; hfe gene; arthritis; disease; bone; osteoporosis; arthropathy; mutations; symptoms
AB Objective. Arthropathy that mimics osteoarthritis (OA) and osteoporosis (OP) is considered a classic complication of hereditary hemochromatosis (HH) but has never been investigated in a cross-sectional study. We investigated whether HH is associated with increased prevalence of OA and OP and related factors. Methods. A self-administered questionnaire was completed by 306 patients with HH and 304 age and sex-matched unaffected controls. Results. The mean age of patients was 60.1 +/- 11.3 years, and 47.4% were women. More patients with HH than controls had been given a diagnosis of OA: 50.5% vs 28.9% [adjusted OR (aOR) 2.5, 95% CI 1.8-3.6]. Compared with controls, patients with HH had a higher risk of knee (aOR 5.3, 95% CI 1.1-25.6) and hip replacement prosthesis (aOR 5.2, 95% CI 2.2-11.9). More patients than controls had been diagnosed with OP: 23.3% vs 4.6% (aOR 7.3, 95% CI 3.2-17.0). Patients with FM showed an increased prevalence, although not significant, of wrist (aOR 1.7, 95% CI 0.9-3.0) or vertebral fractures (aOR 1.7, 95% CI 0.8-3.8). The severity of iron overload, as defined by a ferritin level > 1000 mu g/l at diagnosis, was associated with OA (p = 0.0005), OP (p = 0.01), presence of hip prosthesis (p = 0.04), wrist fractures (p = 0.002), and vertebral fractures (p = 0.02). Conclusion. This case-control study strongly suggests a significant association

among HH, OA, and OP. Joint involvement can be severe, especially in patients with substantially elevated ferritin levels. (First Release August 1 2010; J Rheumatol 2010:37:2145-50; doi:10.3899/jrheum.100234)

TI Partial medial meniscectomy and rotational differences at the knee during walking
SO JOURNAL OF BIOMECHANICS
LA English
DT Article
DE Knee; Meniscectomy; Walking gait; Moment; Internal/external rotation
ID arthroscopic partial meniscectomy; cruciate ligament reconstruction; cartilage morphology; matched controls; deficient knee; meniscal tear; gait analysis; acl injury; osteoarthritis; kinematics
AB Loss of meniscal function due to injury or partial meniscectomy is common and represents a significant risk factor for premature osteoarthritis. The menisci can influence the transverse plane movements (anterior-posterior (AP) translation and internal-external (IE) rotation) of the knee during walking. While walking is the most frequent activity of daily living, the kinematic differences at the knee during walking associated with the meniscal injury are not well understood. This study examined the influence of partial medial meniscectomy (PMM) on the kinematics and kinetics of the knee during the stance phase of gait by testing the differences in anterior-posterior translation, internal-external rotation, knee flexion range of movement, peak flexion/extension moments, and adduction moments between the PMM and healthy contralateral limbs. Ten patients (45 +/- 9 years old, height 1.75 +/- 0.06 m, weight 76.7 +/- 13.5 kg) who had undergone partial medial meniscectomy (33 +/- 100 months post-op) in one limb with a healthy contralateral limb were tested during normal walking. The contralateral limb was compared to a matched control group and no differences were found. The primary kinematic difference was a significantly greater external rotation (3.2 degrees) of the tibia that existed through stance phase, with 8 of 10 subjects demonstrating the same pattern. The PMM subjects also exhibited significantly lower peak flexion and extension moments in their PMM limbs. The altered rotational position found likely results in changes of tibio-femoral contact during walking and could cause the type of degenerative changes found in the articular cartilage following meniscal injury. TI Flare-up of hand osteoarthritis caused by zoledronic acid infusion
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE Bisphosphonates; Osteoarthritis; Side effects; Zoledronic acid
ID nitrogen-containing bisphosphonates; in-vitro; alendronate; osteoporosis; synthase; statins; bone
AB Zoledronic acid is effective for osteoporosis at a single annual intravenous dose. It usually causes few adverse effects; the most common are related to acute phase reactions. We reported the case of a 64-year-old woman who presented flare-up of hand osteoarthritis after zoledronic acid infusions. Despite the fact that arthralgia is a common side effect of intravenous bisphosphonates, development of inflammatory signs in osteoarthritic joints is a rare event. We hypothesized that this side effect is caused by a release of cytokines secondary to activation of gamma-delta T lymphocytes.

TI Wnt pathway genes in osteoporosis and osteoarthritis: differential expression and genetic association study
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE Frizzled; Gene expression; LRP5; Osteoarthritis; Osteoporosis; Wnt
ID single-nucleotide polymorphisms; false discovery rate; hip osteoarthritis; articular chondrocytes; signaling pathway; bone; frzb; activation; women; sites
AB In comparison with hip fractures, increased expression of genes in the Wnt pathway and increased Wnt activity were found in bone samples and osteoblast cultures from patients with osteoarthritis, suggesting the involvement of this pathway in subchondral bone changes. No consistent differences were found in the genetic association study. This study aims to explore the allelic variations and expression of Wnt pathway genes in patients with osteoporosis and osteoarthritis.

The expression of 86 genes was studied in bone samples and osteoblast primary cultures from patients with hip fractures and hip or knee osteoarthritis. The Wnt-related activity was assessed by measuring AXIN2 and in transfection experiments. Fifty-five SNPs of the LRP5, LRP6, FRZB, and SOST genes were analyzed in 1,128 patients. Several genes were differentially expressed in bone tissue, with the lowest values usually found in hip fracture and the highest in knee osteoarthritis. Overall, seven genes were consistently upregulated both in tissue samples and in cell cultures from patients with knee osteoarthritis (BCL9, FZD5, DVL2, EP300, FRZB, LRP5, and TCF7L1). The increased expression of AXIN2 and experiments of transient transfection of osteoblasts with the TOP-Flash construct confirmed the activation of Wnt signaling. Three SNPs of the LRP5 gene and one in the LRP6 gene showed marginally significant differences in allelic frequencies across the patient groups, but they did not resist multiple-test adjustment. Genes in the Wnt pathway are upregulated in the osteoarthritic bone, suggesting their involvement not only in cartilage distortion but also in subchondral bone changes.

TI Modified Brix Model Analysis of Bone Perfusion in Subjects of Varying Bone Mineral Density
SO JOURNAL OF MAGNETIC RESONANCE IMAGING
LA English
DT Article
DE bone perfusion; pharmacokinetic model; osteoporosis; microcirculation
ID contrast-enhanced mri; peripheral arterial-disease; marrow fat-content; multiple-myeloma; lumbar spine; osteoporosis; spectroscopy; women; microcirculation; osteoarthritis
AB Purpose: To apply pharmacokinetic modeling to the investigation of bone perfusion in subjects of varying bone mineral density. Materials and Methods: This study re-analyzed previous experimental data. A modified pharmacokinetic model was applied to data obtained from two prior studies of dynamic contrast-enhanced MR imaging of L3 vertebral body in 165 subjects (65 males, 100 females), classified into three groups (normal, osteopenia, and osteoporosis) according to bone mineral density. Three parameters, amplitude A, exchange rate (k(ep)), and elimination rate (k(el)), were obtained by fitting the signal intensity to the pharmacokinetic model. These parameters were compared across the three groups for males and females, respectively. Results: Perfusion parameters, amplitude A was found to be reduced in osteoporotic subjects with additional, though less pronounced, reductions found in the permeability constant (A*k(ep)) and the elimination rate (k(el)). Increased marrow fat content was found in osteoporotic bone, which helped to partially explain the observed reduction in interstitial space. Conclusion: By pharmacokinetic model, bone perfusion can be quantitatively analyzed with alteration in functional parameters related to microcirculation in subjects of varying bone mineral density. Developing bone marrow specific pharmacokinetic models should help to deepen knowledge of physiological and pathological perfusion changes occurring in bone.

TI Simultaneous ultrasound measurement of articular cartilage and subchondral bone
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE Ultrasound; Articular cartilage; Subchondral bone; Proximal tibia; Mechanical properties; pQCT
ID cortical end-plate; cancellous bone; mechanical-property; in-vitro; human calcaneus; frequency; density; osteoarthritis; transmission; quantitation
AB Objective: In osteoarthritis (OA), subchondral sclerosis takes place during cartilage degeneration. High frequency ultrasound (12-55 MHz) has been shown to

diagnose degenerated articular cartilage, while 0.1-1 MHz ultrasound has been applied for clinical characterization of bone and diagnostics of osteoporosis. The aim of the study is to investigate, for the first time, the feasibility of 5 MHz ultrasound for simultaneous analysis of articular cartilage and subchondral bone. Methods: Osteochondral samples (n = 10) were prepared from fresh and visually normal bovine medial tibial plateaus. Acoustic properties of the cartilage and subchondral bone were measured with a scanning ultrasound system using the pulse-echo geometry and compared with biomechanical, histological and compositional reference data. Results: The apparent integrated backscatter (AIB) from internal cartilage showed significant partial correlations with hydroxyproline (Hypro) (r = 0.58, P = 0.000). water content (r = -0.52, P = 0.001) and dynamic modulus (r = 0.57, P = 0.000) of the tissue. Weak but statistically significant correlation was found between the bone AIB and mineral density of the subchondral plate (r = -0.34, P = 0.041). Topographical variations in cartilage thickness could be detected using ultrasound. Composition, thickness and mechanical properties of the cartilage varied significantly across the tibial plateau. For the calculated ultrasound parameters, the variation was significant only between a few locations. Conclusions: Pulse-echo ultrasound geometry at 5 MHz was feasible for simultaneous measurement of the acoustic properties of articular cartilage and subchondral bone. However, the relationships between the ultrasound parameters and properties of cartilage and bone were not as strong as reported earlier in studies focusing only either on bone or cartilage. Simultaneous measurement of both tissues compromises, due to natural curvature of articulating surfaces, the perpendicularity of the incidence of the ultrasound pulse. Obviously, this source of uncertainty should be minimized in order to enable effective clinical use of ultrasound in simultaneous measurement of articular cartilage and subchondral bone. TI Discordance in Femoral Neck Bone Density in Subjects With Unilateral Hip Osteoarthritis
SO JOURNAL OF CLINICAL DENSITOMETRY
LA English
DT Article
DE Bilateral BMD; hip; osteoarthritis
ID mineral density; osteoporosis; fracture; arthritis; women
AB Osteoarthritis (OA) is a common disease that increases in incidence with age and currently affects an estimated 27 million Americans. To determine whether site-specific hip bone mineral density (BMD) measures are confounded by the presence of OA, we measured bilateral hip BMD by dual X-ray absorptiometry in 34 subjects (19 women and 15 men) scheduled for hip replacement for confirmed advanced unilateral hip OA. The femoral neck (FN) BMD ($p = 0.035$) and T-score ($p = 0.017$) for the hip with OA was higher than those of the contralateral hip. There was a difference in osteoporosis classification depending on which hip was considered: for 11 of the 34 subjects (32%), the FN T-score was normal for OA hip, but the contralateral hip was classified as osteopenic (T-score between -1.0 and -2.5). For 1 subject, the FN T-score was normal for OA hip, but the contralateral hip was classified as osteoporotic (T-score below -2.5). Discordance was also present for trochanter values and not for total hip values. These data indicate that advanced hip OA can be associated with a higher bone density at the FN and

trochanter but not at total hip and that the discrepancy between hips at the FN may have an impact on patient treatment decisions.

TI Intra-Articular Injections of Bone Morphogenetic Protein-7 Retard Progression of Existing Cartilage Degeneration
SO JOURNAL OF ORTHOPAEDIC RESEARCH
LA English
DT Article
DE bone morphogenetic protein; osteoarthritis; animal model

ID human articular chondrocytes; endogenous osteogenic protein-1; rabbit knee; proteoglycan synthesis; osteoarthritis; op-1; insulin-like-growth-factor-1; repair; model
AB We investigated the effect of weekly intra-articular injections of bone morphogenetic protein-7 (BMP-7) on prevention of progression of existing cartilage degeneration in an osteoarthritis model in rabbits. An anterior cruciate ligament transection (ACLT) model was used to create a progressive osteoarthritis model. BMP-7 was intra-articular injected weekly into the right knee and PBS into the left knee from 4 weeks after ACLT. Both sides of the knees were compared macroscopically, histologically, immunohistochemically, and by micro CT. Macroscopically, fibrillation in the femoral condyle was observed 4 weeks after ACLT. In the control knees, cartilage degeneration further progressed throughout the 12-week period. In the BMP-7 treated knee, osteoarthritis progression was milder than in the control knees. Histologically, safranin-O staining was decreased in the surgical knees at 4 weeks. Obvious erosions in both medial and lateral condyles were revealed in the control knees at 12 weeks, while cartilage matrix was predominantly retained in the BMP-7 treated knees. The macroscopic and microscopic OA score in the BMP-7 treated knee was better than that in the control in each rabbit. Immunohistochemical analysis demonstrated that both type II collagen and BMP-7 were more expressed in cartilage treated with BMP-7. Micro CT analysis showed that osteophytes were smaller in the BMP-7 treated knee compared to that of the control. Weekly intra-articular injections of BMP-7 inhibited progression of existing cartilage degeneration. (C) 2010 Orthopaedic Research Society. Published by Wiley Periodicals, Inc. J. Orthop. TI Beneficial effects of β-Ecdysone on the joint, epiphyseal cartilage tissue and trabecular bone in ovariectomized rats
SO PHYTOMEDICINE
LA English
DT Article
DE beta-Ecdysone; Ovariectomy; Rat; Joint; Epiphysis; Trabeculae
ID growth-plate chondrocytes; estrogen-receptor-alpha; articular-cartilage; protein-synthesis; x receptor; osteoarthritis; phytoecdysteroids; ultraspiracle; hypertrophy; matrix
AB Ecdysteroids are steroids found in invertebrates and plants. In mammals they have protein anabolic effects. We have recently published antiosteoporotic effects of Tinospora cordifolia (TC) extract and the search for the possible active ingredients yielded the presence of beta-Ecdysone (Ecd). Therefore, we investigated the effects of pure Ecd in ovariectomized rats on morphological changes in joint, epiphyseal cartilage and trabecular tissue. Following ovariectomy rats were fed for 1 month with Ecd containing food at a dose of 52.8 mg/day/animal. Positive and negative control animals received 17-beta Estradiol (E-2, 132 mu g/day/animal) and soy free (sf) food respectively. At sacrifice, specimens consisting of upper tibiae-lower femurs and knee joint were harvested and processed for histomorphometry. The parameters measured included thickness of the joint cartilage, thickness of the whole epiphyseal growth plate and its three

zones. Furthermore, the percentage of trabecular bone in the metaphysis region of tibiae was quantified. Ecd and E-2 induced a significant increase in the thickness of joint cartilage. The whole epiphyseal growth plate and its proliferative and hypertrophic zones were also increased by Ecd whereas E-2 reduced their size. The percentage of trabecular area in the metaphysis of tibia was significantly increased in Ecd and E-2 treated animals. Results provide a plausible explanation for the antiosteoporotic effects of TC. Hence, TC as well as other Ecd producing plants or pure Ecd may be of value in the prevention and treatment of osteoporosis and osteoarthritis which is of increasing importance due to aging and obesity among individuals. DT Review
DE nerve growth factor; review; neurogenic inflammation; rheumatic diseases
ID tumor-necrosis-factor; systemic-lupus-erythematosus; gene-related peptide; affinity neurotrophin receptor; trk protooncogene product; factor messenger-rna; dorsal-root ganglia; mast-cells; factor ngf; tnf-alpha
AB Objectives: The nervous system modulates the immune response in many autoimmune syndromes by neurogenic inflammation. One of the pivotal mediators is nerve growth factor (NGF), which is known for its effects on neuronal survival and growth. There is considerable evidence that NGF acts as an important mediator of many immune responses. This article reviews the role of NGF in rheumatic diseases and strategies for potential therapeutic interventions. Methods: We conducted a

database search using Medline and Medpilot. Eight hundred abstracts containing the keyword NGF and 1 of the following terms were reviewed: arthritis, neurogenic inflammation, rheumatoid arthritis, osteoarthritis, collagen arthritis, arteritis, psoriasis, psoriatic arthritis, Sjogren syndrome, systemic lupus erythematosus, gout, osteoporosis, lower back pain, lumbar disc herniation, nerve root compression, spondyloarthritis, spondylarthropathy, algoneurodystrophy, fibromyalgia, Kawasaki syndrome, polyarteritis nodosa, cytokine, vasculitis, pain, therapy, and antagonist. Articles were analyzed based on relevance and content. Most clinical trials and studies with human specimens were included. Studies with experimental animal models were selected if they contained relevant data. Results: NGF is overexpressed in many inflammatory and degenerative rheumatic diseases. Concentrations differ to some extent and sometimes even show contradictory results. NGF is found in serum, synovial fluid, and cerebrospinal fluid, and tissue specimens. NGF concentrations can be correlated with the extent of inflammation and/or clinical activity in many conditions. In rheumatoid arthritis, NGF levels are significantly higher as compared with osteoarthritis. Conclusions: NGF is a significant mediator and modulator of inflammation. NGF sometimes shows detrimental and sometimes regenerative activity. These findings indicate potential therapeutic interventions using either NGF antagonists or recombinant NGF. DT Review
DE alpha(v)beta(3) antagonists; bisphosphonate; bone disease; cathepsin K; cyclooxygenase-2; MMP; prostaglandin EP4 receptor; secreted Frizzled-related protein; vacuolar H-ATPase
ID nonpeptide alpha(v)beta(3) antagonists; solid-phase synthesis; frizzled-related protein-1; cathepsin-k inhibitors; vacuolar h+-atpase; matrix-metalloproteinase inhibitors; rhinovirus 3c protease; biological evaluation; selective inhibitors; postmenopausal women
AB Importance of the field: Bones play many roles in the body, providing structure, protecting organs, anchoring muscles and storing calcium. Over 100 million people worldwide suffer from bone diseases, mainly osteoporosis, cancer-related bone loss, osteoarthritis and inflammatory arthritis. Osteoporosis itself has no specific symptoms, and the main consequence is the increased risk of bone fractures. Therefore, the prevention of bone diseases is important to maintain the quality of life in the human society. However, treatment options are still insufficient. Areas covered in this review: This review article gives a summary of the low molecular mass modulators of bone diseases targets disclosed in patent applications and articles, mainly during the last 5 years. What the reader will gain: Readers will rapidly gain an overview of these modulators not only for historical targets, but also of emerging and revisited targets. Readers will also be able to see the current research trend and the main players in this field. Take home message: Drug discovery for bone diseases has made progress in the last years. The research area has dynamically shifted from historical targets (bisphosphonate, parathyroid hormone and calcitonin) to newly confirmed targets or targets re-visited which were biologically validated in the past. Cathepsin K inhibitors should be very close to launching in the market.

TI APPLICATIONS OF INTRANASAL LOW INTENSITY LASER THERAPY IN SPORTS MEDICINE
SO JOURNAL OF INNOVATIVE OPTICAL HEALTH SCIENCES
LA English
DT Review
DE Photobiomodulation; homeostasis; nicotinamide adenine dinucleotide; sirtuin 1; sports medicine
ID low-level laser; traumatic brain-injury; onset muscle soreness; sirtuin 1; knee osteoarthritis; mouse model; melatonin; supplementation; inflammation; osteoporosis
AB Function-specific homeostasis (FSH) has been defined as a negative-feedback response of a biosystem to maintain its interior function-specific conditions so that the function is perfectly performed. There is no photobiomodulation of intranasal low intensity laser therapy (ILILT) on a function in its FSH, but ILILT could modulate a function far from its FSH. This rehabilitation has been found to be mediated by the ratio of intracellular nicotinamide adenine dinucleotide (NAD(+)) and its reduced form NADH, NAD(+)/NADH, and then sirtuin 1 (SIRT1). There might be FSH-specific NAD(+)/NADH (FSN) and SIRT1 activity (FSA). ILILT might enhance NAD(+)/NADH and SIRT1 activity until they arrive at FSN and FSA, respectively. The NAD(+)/NADH and SIRT1 activity of related cells of many athletic diseases such as upper respiratory tract infection, asthma, osteoarthritis, exercise-induced muscle damage, wound, traumatic brain injury, and osteoporosis are lower than FSN and FSA, respectively. Therefore, there may be therapeutic effects of ILILT on those athletic diseases. Furthermore, many phenomena and the ILILT mechanism have been integrated to support the prophylaxis effects of ILILT on the swine-origin influenza A (H1N1).

TI Measurement of Foot Bone Mineral Density in Rheumatoid Arthritis: Its Application and Clinical Relevance
SO TURKISH JOURNAL OF RHEUMATOLOGY
LA English
DT Article
DE Foot; bone mineral density; DEXA; rheumatoid arthritis
ID x-ray absorptiometry; 1987 revised criteria; scoring methods; hand; osteoporosis; densitometry; erosions; mass; associations; radiographs
AB Objective: Hand and foot joints are the primary targets in rheumatoid arthritis (RA) and decrease in the periarticular bone mineral density (BMD) is one of the earliest and considerable change in the affected joint. This study aimed to assess the relationship between foot bone mineral density (fBMD) measured by Dual Energy X-ray absorptiometry (DEXA) and BMD at axial sites, disease activity, functional status and quality of life in patients with RA Materials and Methods: 50 patients with RA, 40 age-and sex-matched patients with osteoarthritis (OA) and 14 voluntary healthy individuals were included in the study. C-reactive protein, erythrocyte sedimentation rate (ESR), Ritchie Articular Index (RAI), Health Assesment Questionnare (HAQ), and Foot Function Index (FFI) were measured. X-ray of the feet was scored by Larsen and Sharp/van der Heijde methods. Axial and fBMD were measured by DXA. Results: The results of the present study revealed that Turkish patients with RA carrying SE with HLA-DRB1 genes is significantly related with the production of anti-CCP. The diagnostic sensitivity and specificity of anti-CCP for RA is determined as 73,3% and 100% respectively. Conclusion: These results suggest for the first time that foot BMD measurement by DEXA is a useful and precise method. Foot BMD may reflect both localized and generalized bone loss and may be a potential outcome measure particularly in patients with marked foot involvement. (Turk J Rheumatol 2010; 25: 56-62)

TI Impact of knee and low back pain on health-related quality of life in Japanese women: the Research on Osteoarthritis Against Disability (ROAD)
SO MODERN RHEUMATOLOGY
LA English
DT Article
DE Epidemiology; Knee; Pain; Osteoarthritis; Quality of life
ID middle-aged women; postmenopausal women; vertebral fractures; elderly subjects; bone-marrow; osteoporosis; distress; hip; association; prevalence
AB Although knee and low back pain are major public health issues, little information is available on their impact on the quality of life (QOL). We have investigated the impact of knee and low back pain on the QOL in Japanese women by assessing the associations between knee pain and low back pain and various QOL domains using measures such as the Medical Outcomes Study Short Form-8, EuroQOL, and the Western Ontario and McMaster Universities Osteoarthritis Index. From the 3,040 Japanese women participating in the Research on Osteoarthritis Against Disability (ROAD) study, we analyzed data on 1,369 women > 40 years old (mean age 68.4 years). We further examined the associations of Kellgren-Lawrence (KL) grade at the knee and lumbar spine and the presence of vertebral fracture (VFx) with the magnitude of QOL loss in women with knee pain and low back pain, respectively. Knee pain and low back pain were found to be significantly associated with lower QOL scores among the women comprising the study cohort. In women with knee pain KL = 4, knee osteoarthritis was strongly associated with the magnitude of QOL loss. For women with low back pain, no significant associations were found between KL grade and magnitude of QOL loss, while there was a moderate association between the latter and VFx.

TI Transcriptional regulation of bone and joint remodeling by NFAT
SO IMMUNOLOGICAL REVIEWS
LA English
DT Review
DE NFAT; osteoporosis; osteoarthritis; rheumatoid arthritis; osteoclast; osteoblast
ID activated t-cells; endothelial growth-factor; osteoclast-associated receptor; vasoactive-intestinal-peptide; gastrin-releasing-peptide; ae2 cl-/hco3-exchanger; nuclear-factor; gene-expression; rheumatoid-arthritis; substance-p
AB Osteoporosis and arthritis are highly prevalent diseases and a significant cause of morbidity and mortality worldwide. These diseases result from aberrant tissue remodeling leading to weak, fracture-prone bones or painful, dysfunctional joints. The nuclear factor of activated T cells (NFAT) transcription factor family controls diverse biologic processes in vertebrates. Here, we review the scientific evidence that links NFAT-regulated gene transcription to bone and joint pathology. A particular emphasis is placed on the role of NFATs in bone resorption and formation by osteoclasts and osteoblasts, respectively. In addition, emerging data that connect NFATs with cartilage biology, angiogenesis, nociception, and neurogenic inflammation are explored. The goal of this article is to highlight the importance of tissue remodeling in musculoskeletal disease and situate NFAT-driven cellular responses within this context to inspire future research endeavors.

TI Explaining functioning outcomes across musculoskeletal conditions: a multilevel modelling approach
SO DISABILITY AND REHABILITATION
LA English
DT Article
DE MHADIE; functioning; disability; ICF; musculoskeletal
ID chronic widespread pain; icf core set; international-classification; rheumatoid-arthritis; health icf; patient perspective; disability; validation; rehabilitation; fibromyalgia
AB Purpose. To determine whether changes in health outcomes result from changes in domains of functioning and relevant environmental factors in musculoskeletal conditions. Method. Longitudinal observational study on a convenience sample of 291 patients with low back pain, osteoarthritis, osteoporosis, rheumatoid arthritis and chronic widespread pain. The study was part of the MHADIE project. Data collection was performed at baseline, after 4 and 8 weeks using the ICF Core Sets for the corresponding musculoskeletal conditions. Multilevel models for change were used to determine which ICF categories explain the variability and change over time of the general, physical and mental health according to the SF-36. Results. There are only small fluctuations in the health outcomes. These are related to functions of the locomotor apparatus, such as muscle power, and to activities and participation domains related to them, such as lifting and carrying objects. A large amount of baseline variance is explained with a relatively small number of ICF categories of functioning. Conclusions. This study presents a list of functioning problems and environmental factors relevant to map out both the patterns and the variations in the experience of living with a chronic and painful condition. These are intervention targets common across MSC conditions.

TI Bone mineral density reference ranges for Australian men: Geelong Osteoporosis Study
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE Bone mineral density; Men; Normative data; Random population-based; Reference range
ID lumbar spine; multicenter osteoporosis; fracture risk; femoral-neck; women; population; osteoarthritis; femur; standardization; prevalence
AB A large population-based random sample of Australian white men was used to provide normative bone mineral density (BMD) data at multiple anatomical sites. The femoral neck BMD data are very similar to those obtained in USA non-Hispanic white males participating in the National Health and Nutrition Examination Survey III (NHANES III). The reference ranges will be suitable for similar populations. To provide normative BMD data for Australian men derived from a large population-based random sample. An age-stratified random sample of men was

recruited from the Australian electoral rolls (n = 1,467 aged 20-97 years). BMD was quantified at multiple sites using Lunar densitometers. Age-related differences in BMD were best predicted by linear relationships at the spine and hip and by quadratic functions at the whole body and forearm. At the spine, a small age-related increase in mean BMD was observed. Although in the subset with no spinal abnormalities, there was a decrease of 0.003 g/cm(2) per year from age 20. At the hip sites, mean BMD decreased at 0.001-0.006 g/cm(2) per year from age 20. At the forearm and whole body, BMD peaked at 41-47 years. Apart from a small difference in men greater than or equal to 80 years, the Australian femoral neck BMD data are not different to those obtained in USA non-Hispanic white males participating in NHANES III and were generally similar to those of large studies from Canada (CaMos) and Spain. These data supply BMD reference ranges at multiple anatomical sites that will be applicable to white Australian men and similar populations such as USA non-Hispanic white men.

DE Knee; MRI; Bone marrow oedema
ID early rheumatoid-arthritis; transient osteoporosis; transitory demineralization; femoral-head; mri; osteoarthritis; osteonecrosis; classification; pattern; lesions
AB Magnetic resonance (MR) imaging is a frequently performed investigation for disease of the knee. Bone marrow oedema (BME) is a common MR finding with a number of causes including trauma, tumour, infection, inflammatory arthropathies and BME syndromes. This article illustrates the range of MR appearances of BME around the knee and describes secondary signs that allow the reader to determine the cause of disease and to distinguish BME from normal marrow signal changes.

TI The delivery of evidence-based preventive care for older Americans with arthritis
SO ARTHRITIS RESEARCH & THERAPY
LA English
DT Article
ID antitumor necrosis factor; congestive-heart-failure; rheumatoid-arthritis; influenza-vaccination; osteoporosis care; factor therapy; bone mass; risk; disease; quality
AB Introduction: Previous research suggests patients with rheumatoid arthritis (RA) may receive suboptimal care with respect to preventive tests and services. We evaluated the proportion of older Americans with RA, psoriatic arthritis (PsA), and osteoarthritis (OA) receiving these services and the specialty of the providers delivering this care. Methods: Using data from 1999 to 2006 from the Medicare Chronic Conditions Warehouse, we identified persons age >/= 65 in the national

5% sample. Over the required five-year observation period, we identified tests and services recommended for older adults and the associated healthcare provider. Services of interest included dual energy x-ray absorptiometry (DXA), influenza and pneumococcal vaccination, hyperlipidemia lab testing, mammography and colonoscopy. Results: After accounting for the sampling fraction, we identified 141,140 RA, 6,300 PsA, and 770,520 OA patients eligible for analysis. Over five years, a majority of RA, PsA, and OA patients were tested for hyperlipidemia (84%, 89% and 87% respectively) and received DXA (69%, 75%, and 52%). Only approximately one-third of arthritis patients received pneumococcal vaccination; 19% to 22% received influenza vaccination each year. Approximately 20% to 35% of arthritis patients never underwent mammography and colonoscopy over five years. Concomitant care from both a rheumatologist and a primary care physician was significantly associated with a greater likelihood of receiving almost all preventive tests and services. Conclusions: Among older Americans on Medicare, the absolute proportion of persons with arthritis receiving various recommended preventive services and screening tests was substantially less than 100%. Improved co-management between primary care and arthritis physicians may in part improve the delivery of preventive care for arthritis patients, but novel systematic interventions in this area are needed.

TI Development of an Instrument to Collect Health Care Resource use Data in the Context of Rehabilitation
SO PHYSIKALISCHE MEDIZIN REHABILITATIONSMEDIZIN KURORTMEDIZIN
LA English
DT Article
DE health resource use; data collection; cost measure; rehabilitation; economic evaluation
ID low-back-pain; rheumatoid-arthritis; economic-evaluation; cost assessment; questionnaire; accuracy; illness; records
AB Purpose: The objective of this paper is to describe the development of an instrument to collect health resource utilization data in rehabilitation research and to discuss lessons learned. Materials and Methods: The questionnaire was developed to collect data about health resource use aiming at the alongside economic evaluations of 5 rehabilitation studies. Considering the health condition of study patients, the specific questions of associated studies and the methodological standards proposed by the "Working Group Methods in Health Economic Evaluation" (MEA), it was decided which health resource use components should be part of the questionnaire and which recall period would be adequate. Health resource use information was assessed in order to calculate direct medical, direct non medical and indirect costs. Results: The standardized self-administered retrospective health resource use assessment questionnaire was answered by a total of 1 042 subjects with one of the following indications: osteoarthritis, osteoporosis, back pain, cancer, fibromyalgia or brain/cranial traumata. Discussion: Although the questionnaire was adapted for each rehabilitation study, it could be learned that the development of a standardized general brief questionnaire to collect health resource use with fixed cost categories is of fundamental importance in order to facilitate comparability across indications and studies in rehabilitation. Conclusions: The instrument to collect health resource utilization provided enough information to calculate direct medical, direct non medical and indirect costs. The core version omitting disease-specific aspects could serve as a starting point towards a standardized and validated, general, self-administered questionnaire suitable for alongside comparative economic evaluations in rehabilitation.

TI Markers of Bone Formation and Resorption Identify Subgroups of Patients with Clinical Knee Osteoarthritis Who Have Reduced Rates of Cartilage Loss
SO JOURNAL OF RHEUMATOLOGY
LA English

DT Article
DE OSTEOARTHRITIS; BONE METABOLISM; MAGNETIC RESONANCE IMAGING; PROGRESSION
ID biochemical markers; turnover markers; marrow lesions; joint damage; iliac crest; progression; collagen; women; osteoporosis; metabolism
AB Objective. To determine whether serum markers of bone formation and resorption, used individually or in combination, can be used to identify subgroups who lose cartilage volume at different rates over 2 years within a knee osteoarthritis (OA) population. Methods. Changes in cartilage volume over 2 years were measured in 117 subjects with knee OA using magnetic resonance imaging. We examined relationships between Change in cartilage volume and baseline serum markers of bone formation [intact N-terminal propeptide of type I procollagen (PINP) and osteocalcin] and resorption [N-telopeptide of type I collagen (NTX-I), C-telopeptide of type I collagen (CTX-I), and C-telopeptide of type I collagen (ICTP). Results. The baseline markers of bone formation, PINP and osteocalcin ($p = 0.02$, $p = 0.01$, respectively), and the baseline markers of bone resorption. CTX-I and NTX-I ($p = 0.02$ for both), were significantly associated with reduced cartilage loss. There were no significant associations between baseline ratios of bone formation to resorption markers and cartilage loss. However, when subjects were divided into subgroups with high or low bone formation markers (based on levels of marker mean or < mean for the population, respectively), in the subgroup with high PINP there was a significant association between increasing bone resorption markers CTX-I and NTX-I and reduced cartilage loss ($p = 0.02$, $p = 0.001$, respectively). Similarly, in the subgroup with high osteocalcin, there was a significant association between increasing CTX-I and NTX-I and reduced cartilage loss ($p = 0.02$, $p = 0.003$, respectively). In contrast, in subgroups with low bone formation markers, no significant associations were obtained between markers of bone resorption and cartilage loss. Conclusion. Overall, the results suggest that higher bone remodeling (i.e., higher serum levels of bone formation and resorption) is associated with reduced cartilage loss. Considering markers of bone formation and resorption together, it is possible to identify subgroups within the OA population who have reduced rates of cartilage loss. TI Urinary metabolomics as a potentially novel diagnostic and stratification tool for knee osteoarthritis
SO METABOLOMICS
LA English
DT Article
DE Metabolomics; Osteoarthritis; Phenotype; Stratification; Biomarker; Histamine
ID histamine; chondrocytes; disease; acid; classification; osteoporosis; metabolism; biomarkers; cartilage; reveals
AB Metabolomics has been used as a tool in disease diagnosis and phenotype prediction. A urinary metabolomic study based on GC-MS in combination with multivariate statistics was used here to classify between knee osteoarthritis (OA) and healthy controls. OPLS-DA of the spectral data showed distinct metabolic profile variations between OA patients and healthy controls and between two OA phenotypes. Differential metabolites reveal up-regulated TCA cycle associated with OA and histamine metabolism disorders accompanied with knee effusion symptoms. This metabolomic method is potentially applicable as a novel strategy for OA diagnosis and patient stratification.

TI Pulsed Electromagnetic Fields Stimulation Affects BMD and Local Factor Production of Rats With Disuse Osteoporosis
SO BIOELECTROMAGNETICS
LA English
DT Article
DE pulsed electromagnetic fields; disuse osteoporosis; bone mineral density; interleukin-6; transforming growth factor-beta 1
ID hormone replacement therapy; double-blind; bone; osteoarthritis; calcitonin; model; risk
AB Pulsed electromagnetic fields (PEMF) have been used widely to treat nonunion fractures and related problems in bone heating, as a biological and physical method. With the use of Helmholtz coils and PEMF stimulators to generate uniform time-varying electromagnetic fields, the effects of extremely low frequency electromagnetic fields on bone m ineral density (BMD) and local factor production in disuse osteoporosis (DOP) rats were investigated. Eighty 4-month-old female Sprague Dawley (SD) rats were randomly divided into intact (INT) group, DOP group, calcitonin-treated (CT) group, and PEMF stimulation group. The right hindlimbs of all the rats were immobilized by tibia-tail fixation except for those rats in the INT group. Rats in the CT group were injected with calcitonin (2 IU/kg, i.p., once a day) and rats in the PEMF group were irradiated with PEMF immediately postoperative. The BMD, serum transforming growth factor-beta 1 (TGF-beta 1), and interleukin-6 (IL-6) concentration of the proximal femur were measured 1, 2, 4, and 8 weeks after treatment. Compared with the CT and DOP groups, the BMD and serum TGF-beta 1 concentration in the PEMF group increased significantly after 8 weeks. The IL-6 concentration in the DOP group was elevated significantly after operation. The PEMF group showed significantly lower IL-6 level than the DOP group. The results found demonstrate that PEMF stimulation can efficiently suppress bone mass loss. We, therefore, conclude that PEMF may affect bone remodeling process through promoting TGF-beta 1 secretion and inhibiting IL-6 expression. Bioelectromagnetics 31:113-119, 2010. TI Local plate/rod descriptors of 3D trabecular bone micro-CT images from medial axis topologic analysis
SO MEDICAL PHYSICS
LA English
DT Article
DE three-dimensional image analysis; x-ray computed tomography
ID skeleton graph analysis; cancellous bone; architecture; quantification; osteoarthritis; decomposition; thickness; models; women; spine
AB Purpose: Trabecular bone microarchitecture is made of a complex network of plate and rod structures evolving with age and disease. The purpose of this article is to propose a new 3D local analysis method for the quantitative assessment of parameters related to the geometry of trabecular bone microarchitecture. Methods: The method is based on the topologic classification of the medial axis of the 3D image into branches, rods, and plates. Thanks to the reversibility of the medial axis, the classification is next extended to the whole 3D image. Finally, the percentages of rods and plates as well as their mean thicknesses are calculated. The method was applied both to simulated test images and 3D micro-CT images of human trabecular bone. Results: The classification of simulated phantoms made of plates and rods shows that the maximum error in the quantitative percentages of plate

and rods is less than 6% and smaller than with the structure model index (SMI). Micro-CT images of human femoral bone taken in osteoporosis and early or advanced osteoarthritis were analyzed. Despite the large physiological variability, the present method avoids the underestimation of rods observed with other local methods. The relative percentages of rods and plates were not significantly different between osteoarthritis and osteoporotic groups, whereas their absolute percentages were in relation to an increase of rod and plate thicknesses in advanced osteoarthritis with also higher relative and absolute number of nodes. Conclusions: The proposed method is model-independent, robust to surface irregularities, and enables geometrical characterization of not only skeletal structures but entire 3D images. Its application provided more accurate results than the standard SMI on simple simulated phantoms, but the discrepancy observed on the advanced osteoarthritis group raises questions that will require further investigations. The systematic use of such a local method in the characterization of trabecular bone samples could provide new insight in bone microarchitecture changes related to bone diseases or to those induced by drugs or therapy. TI Relationship between spine osteoarthritis, bone mineral density and bone turn over markers in post menopausal women
SO BMC WOMENS HEALTH
LA English
DT Article
ID postmenopausal women; disc degeneration; cortical bone; lumbar spine; iliac crest; elderly-men; hip; osteoporosis; fracture
AB Background: Several studies have observed an inverse relationship between osteoporosis and spinal osteoarthritis, the latter being considered as possibly delaying the development of osteoporosis. The aim of this study was to determine the association between individual radiographic features of spine degeneration, bone mineral density (BMD) and bone-turn over markers. Methods: It was a cross sectional study of 277 post menopausal women. BMD of all patients was assessed at the spine and hip using dual-energy X-ray absorptiometry. Lateral spinal radiographs were evaluated for features of disc degeneration. Each vertebral level from L1/2 to L4/5 was assessed for the presence and severity of osteophytes and disc space narrowing (DSN). For Bone turn-over markers, we assessed serum osteocalcin and C-terminal cross-linking telopeptide of type I collagen (CTX). Linear regressions and partial correlation were used respectively to determine the association between each of disc degeneration features, BMD, and both CTX and osteocalcin. Results: Mean age of patients was 58.7 +/- 7.7 years. Eighty four

patients (31.2%) were osteoporotic and 88.44% had spine osteoarthritis. At all measured sites, there was an increase in BMD with increasing severity of disc narrowing while there was no association between severity of osteophytes and BMD. After adjustment for age and BMI, there was a significant negative correlation between CTX and DSN. However, no significant correlation was found between CTX and osteophytes and between osteocalcin and both osteophytes or DSN. Conclusion: In post menopausal women the severity of disc narrowing, but not osteophytes, is associated with a generalized increase in BMD and a decreased rate of bone resorption. These results are consistent with the hypothesis that osteoarthritis, through DSN, has a protective effect against bone loss, mediated by a lower rate of bone resorption. However, spine BMD is not a relevant surrogate marker for the assessment of osteoporosis in the spine in patients with osteoarthritis and debate as to the relationship between OA and OP is still open because of the contradictory data in the literature.

TI Patient factors in the implementation of decision aids in general practice: a qualitative study
SO HEALTH EXPECTATIONS
LA English
DT Article
DE decision aids; focus groups; general practice; onus of responsibility; suitability
ID patients preferences; breast-cancer; involvement; choice; care; participation; conflict; therapy; people; trial
AB Background Decision aids (DAs) have been developed to help patients make treatment decisions. Research shows that they are effective in increasing patients' knowledge of treatment options without raising anxiety or conflict. However, they have not been routinely adopted for use in general practice in the UK and there are few reports addressing strategies to introduce them. Objective To examine patients' views about a variety of DAs for different conditions (heart disease, osteoporosis, osteoarthritis and breast cancer) in order to inform a strategy to introduce them into general practice. Setting and participants General practice patients over the age of 18 years being or having been treated for one of the conditions above. Methods Qualitative study involving 12 focus groups with 77 patients evaluating decision aids relevant to their conditions. A semi-structured interview guide was used to generate discussions about the applicability of the DAs in routine general practice. Results Patients welcomed DAs for their educational and informational content. Reactions to the DAs were influenced by patients' own personal desires for involvement. The main concerns were that the use of DAs would potentially shift the onus of decision making responsibility on to the patient and about the practical challenges to implementation. Conclusions Clinicians will need to make explicit to patients that DAs are an adjunct to routine care and not a replacement, and therefore do not represent a derogation of responsibility. DAs need to be used as an integral part of the communication and support process for patients who want them.

TI Micro-CT and mechanical evaluation of subchondral trabecular bone structure between postmenopausal women with osteoarthritis and osteoporosis
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE Menopause; Micro-CT; Microstructure; Osteoarthritis; Osteoporosis
ID tibial cancellous bone; age-related-changes; femoral-head; microstructure; metabolism; estrogen; model; hip; men; quantification
AB An inverse relationship between osteoarthritis and osteoporosis has been debated over years. The microstructure of the femoral heads from postmenopausal osteoarthritic and osteoporotic women was evaluated with micro-CT. Significant differences were observed in microstructural parameters between them. Different microstructure might relate to the opposite bone defects in osteoarthritis and osteoporosis. This study was undertaken to verify the inverse relationship between osteoarthritis (OA) and osteoporosis (OP) by comparing the structural and mechanical indices. Femoral head specimens were obtained from 17 postmenopausal women (OA, n = 8; OP, n = 9) during hip surgery. The microstructural parameters were measured with micro-CT. Mechanical test was performed after bone cube scanning. Significant difference in bone volume fraction (BV/TV) and trabecular thickness was noted between OA and OP groups. Structure model index decreased in OA, and increased in OP. The higher apparent density (AD) and lower material density (MD) were also shown in OA. Different from OP, positive correlation were noted between connectivity density and mechanical indices in OA. In OA group, BV/TV was associated with Young's modulus and AD, while trabecular number was the only parameter that correlated with MD. However, in OP group, only BV/TV correlated with yield strength, AD, and MD. We observed the difference in microstructure between postmenopausal women with OA and OP, which might relate to the opposite bone defects in OA and OP. BV/TV might play an important role in mechanical properties of the subchondral bone in either OA or OP.

TI Treatment of osteoporosis: recognizing and managing cutaneous adverse reactions and drug-induced hypersensitivity
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Review
DE Anti-osteoporotic treatments; Cutaneous adverse reactions; Hypersensitivity reactions; Osteoporosis
ID toxic epidermal necrolysis; stevens-johnson-syndrome; strontium ranelate; postmenopausal women; systemic symptoms; alendronate; fracture; england; rash; eosinophilia
AB Cutaneous adverse reactions are reported for many treatments including antiosteoporotic agents. This position paper includes an algorithm for their recognition. With early recognition and proper management, including immediate and permanent withdrawal of the culprit agent, accompanied by hospitalization, rehydration, and systemic corticosteroids, if necessary, the prognosis is good. Cutaneous adverse reactions are reported for many therapeutic agents and observed in between 0% and 8% of treated patients depending on the drug. The antiosteoporotic agents are reputed to be safe in terms of cutaneous effects; however, there have been a number of case reports of cutaneous adverse reactions, which merit consideration. This was the subject of a Working Group meeting of the European Society for Clinical and Economic Aspects of Osteoporosis and Osteoarthritis in April 2009, to focus on the impact of cutaneous adverse reactions and drug-induced hypersensitivity in the management of postmenopausal osteoporosis. We prepared this position paper following these discussions, and include an algorithm for their recognition. We reviewed cutaneous adverse reactions observed with antiosteoporotic agents, including information from case reports, regulatory documents, and pharmacovigilance. The cutaneous adverse reactions range from benign reactions including exanthematous or maculopapular eruption (drug rash), photosensitivity, and urticaria to the severe and potentially life-threatening reactions, angioedema, drug rash with eosinophilia and systemic symptoms (DRESS), Stevens Johnson syndrome (SJS), and toxic epidermal necrolysis (TEN). Review of available evidence shows that cutaneous adverse reactions occur with all commonly used antiosteoporotic agents. Notably, there are reports of SJS and TEN for bisphosphonates, and of DRESS and TEN for strontium ranelate. These severe reactions remain very rare (< 1 in 10,000 cases). With early recognition and proper management, including immediate and permanent withdrawal of the culprit agent, accompanied by hospitalization and rehydration and systemic corticosteroids if necessary, the prognosis is good.

TI The effects of bone turnover rate on subchondral trabecular bone structure and cartilage damage in the osteoarthritis rat model
SO RHEUMATOLOGY INTERNATIONAL
LA English
DT Article
DE Iodoacetate; Trabeculae; Osteoarthritis; Rat; Ovariectomy; Bisphosphonate; Bone turnover rate

ID articular-cartilage; knee osteoarthritis; osteoporosis; bisphosphonates; tomography; deficiency; strength; tissue; joints
AB The effects of bone turnover rate on subchondral trabecular changes and cartilage destruction were evaluated in an iodoacetate-induced osteoarthritis rat model. Thirty female rats were randomly divided into three groups as the ovariectomized group, the no-treatment group and the bisphosphonate medication group. Arthritis was induced by a single intra-articular iodoacetate injection into the right tibiofemoral joint. Eight weeks after this injection, tibiofemoral joints on both sides were scanned with a micro-CT. Subchondral trabecular indices were measured on both sides of the tibial lateral condyle epiphysis. In the ovariectomized group, the percentage of bone volume, trabecular thickness and trabecular bone pattern factor of the arthritic sides were lower than those of the control sides, while trabecular separation and structure model index of the arthritic sides were higher than those of the control sides ($p < 0.05$). In the no-treatment group, only trabecular thickness of the arthritic sides was lower than in the control sides ($p < 0.05$). In the bisphosphonate medication group, trabecular indices were no different between the arthritic and control sides. Articular cartilage destruction and severity of arthritis increased significantly in the order: ovariectomized group < no-treatment group < bisphosphonate medication group ($p < 0.05$). After osteoarthritis development, severities of subchondral trabecular changes appeared to be strongly affected by bone turnover rate. Furthermore, a correlation was found between cartilage destruction severity and subchondral trabecular change in the intra-articular iodoacetate-injected osteoarthritis rat model.

TI Normal and threshold values of radiographic parameters for knee osteoarthritis using a computer-assisted measuring system (KOACAD): the ROAD study
SO JOURNAL OF ORTHOPAEDIC SCIENCE
LA English
DT Article
ID women; risk
AB Background. Although radiographic severity of the knee is commonly determined by the Kellgren-Lawrence (KL) grading scale, it does not separately assess joint space narrowing or osteophyte formation. The present study aimed to establish normal and threshold values of radiographic parameters for knee osteoarthritis (OA) using the knee osteoarthritis computer-aided diagnosis (KOACAD) measuring system on a large-scale population-based cohort of the Research on Osteoarthritis/Osteoporosis Against Disability (ROAD) population.

Methods. From a total of 3040 participants in the ROAD study, standing anteroposterior radiographs of the knee were obtained from 2975 subjects (1041 men, 1934 women) in the ROAD cohort, and 5950 knees were evaluated using the KOACAD system to obtain the medial and lateral minimum joint space width (mJSW), medial and lateral joint space area (JSA), osteophyte area (OPA), and femorotibial angle (FTA). These indices were compared with the KL scores, and cutoff values for radiographic knee OA were determined by receiver operating characteristic (ROC) curve analysis. Results. The mean KOACAD parameters for KL = 0 were as follows: medial mJSW 3.70 mm; lateral mJSW 4.77 mm, medial JSA 125.0 mm(2), lateral JSA 140.0 mm(2), OPA 0, and FTA 176.1 degrees in men; for women they were medial mJSW 3.26 mm, lateral mJSW 4.22 mm, medial JSA 100.9 mm(2), lateral JSA 111.0 mm(2), OPA 0, and FTA 174.9 degrees. Threshold values for KL >= 2 provided by ROC curve analysis with area under the curve (AUC) > 0.7 were medial mJSW 2.8 mm and medial JSA 107.3 mm(2) in men and medial mJSW 2.7 mm in women. Those for KL >= 3 were medial mJSW 2.1 mm, medial JSA 81.1 mm(2), OPA 2.4 mm(2), and FTA 179.6 degrees in men; and medial mJSW 2.1 mm, medial JSA 66.6 mm(2), OPA 2.5 mm(2), and FTA 178.1 degrees in women. We then determined the cutoff values for medial knee OA and lateral knee OA. Conclusions. The present study established normal and threshold values of parameters for knee OA using an automated computer-assisted program on plain radiographs.

TI Improving care for people with osteoarthritis of the hip and knee: How has national policy for osteoarthritis been translated into service models in Australia?
SO INTERNATIONAL JOURNAL OF RHEUMATIC DISEASES
LA English
DT Review
DE clinical aspects; education; epidemiology; health services and health care economics; osteoarthritis
ID chronic disease management; quality-of-life; replacement surgery; recommendations; physicians; burden
AB There is strong rationale for improving care for people with chronic conditions, including osteoarthritis (OA). Successful implementation of healthcare reform requires new concepts and directions that are strongly supported by policy, new models of care (service redesign) and changes in day-to-day practice (healthcare provider and patient practice). In this paper we discuss the extent to which policy about management of OA of the hip and knee has been translated into new service models in Australia. A structured search of government and other key health websites in Australia was performed to identify policy, funding initiatives and new services models for managing OA of the hip and knee. This search was supported by a literature review. Musculoskeletal conditions were designated a National Health Priority in Australia in 2002. Under the Better Arthritis and Osteoporosis Care initiative, Australia has developed a national policy for OA care and national evidence-based clinical practice guidelines for management of OA of the hip and knee. Only two well-described examples of new chronic disease management service models, the Osteoarthritis Clinical Pathway (OACP) model and the Osteoarthritis Hip and Knee Service (OAHKS) were identified. Primarily focused within acute care public hospital settings, these have been shown to be feasible and acceptable but have limited data on clinical impact and cost-effectiveness. While policy is extant, implementation has not been systematic and comprehensive. Clinicians have evidence-based recommendations for OA management but are poorly supported by service models to deliver these effectively and efficiently.

DT Article
DE Aging; Bone mineral density; Exercise; Men; Population studies; Risk factors
ID risk-factors; elderly-men; physical-activity; proximal femur; lumbar spine; chinese men; determinants; fracture; hip; osteoporosis
AB Aging alone is not the only factor accounting for poor bone health in older men. There are modifiable factors and lifestyle choices that may influence bone health and result in higher bone density and lower fracture risk even in very old men. Introduction The aim of this cross-sectional analysis was to identify the factors associated with areal bone mineral density (BMD) and their relative contribution in older men. Methods The Concord Health and Ageing in Men Project is a population-based study in Sydney, Australia, involving 1,705 men aged 70-97. Data were collected using questionnaires and clinical assessments. BMD of the hip and spine was measured by dual X-ray absorptiometry. Results In multivariate regression models, BMD of the hip was associated with body weight and bone loading physical activities, but not independently with age. The positive relationship between higher BMD and recreational activities is attenuated with age. Factors independently associated with lower BMD at the hip were inability to stand from sitting, a history of kidney stones, thyroxine use, and Asian birth and at the spine, chronic obstructive pulmonary disease, paternal fracture history, and thyroxine use. Higher body weight, participation in dancing, tennis or jogging, quadriceps strength, alcohol consumption, and statin use were associated with higher hip BMD, while older age, osteoarthritis, higher body weight, and aspirin use were associated with higher spinal BMD. Conclusion Maintaining body weight, physical activity, and strength were positively associated with BMD even in very elderly men. Other parameters were also found to influence BMD, and once these were included in multivariate analysis, age was no longer associated with BMD. This suggests that age-related diseases, lifestyle choices, and medications influence BMD rather than age per se.

TI Raloxifene protects cultured human chondrocytes from IL-1β induced damage: A biochemical and morphological study
SO EUROPEAN JOURNAL OF PHARMACOLOGY
LA English
DT Article
DE Raloxifene; Chondrocyte; Interleukin-1 beta; Proteoglycan; Metalloproteinase-3; Nitric oxide
ID estrogen replacement therapy; human articular chondrocytes; nitric-oxide synthase; nf-kappa-b; receptor modulator; postmenopausal women; cartilage turnover; osteoarthritis; expression; knee
AB It is well known that estrogens are implicated in the pathogenesis of osteoarthritis. Raloxifene is a selective estrogen receptor modulator used in the treatment of osteoporosis, though little is known about the possible effects of raloxifene on cartilage metabolism. The aim of our study was to evaluate the possible in vitro effects of raloxifene in human osteoarthritis chondrocytes cultivated in the presence or absence of Interleukin-1 beta (IL-1 beta) (5 ng/ml). The effects of 0.1 mu M and 1 mu M of raloxifene in the culture medium were assessed using an immuno-enzymatic method for proteoglycans and metalloproteinase-3 (MMP-3), and the Griess method for nitrite. Gene expression of inducible Nitric Oxide Synthase (iNOS) was detected by real-time PCR. A morphological analysis was performed by transmission electron microscopy (TEM).

Cell viability was significantly (P<0.01) reduced by the IL-1 beta. and restored to basal levels by raloxifene at both of the concentrations used. The presence of IL-1 beta led to a significant decrease (P<0.01) in proteoglycan levels as well as a significant increase of MMP-3 and NO (P<0.01). When the cells were co-incubated with IL-1 beta and raloxifene, a significant and dose-dependent increase in proteoglycans and a reduction of MMP-3 and nitric oxide (NO) were detected. iNOS was noticeably expressed in IL-1 beta stimulated chondrocytes, while raloxifene decreased in a very significant manner the gene expression of iNOS at both of the concentrations used. The results of the biochemical evaluation were confirmed by TEM. Our data suggest that raloxifene may have a potential chondroprotective role in osteoarthritis. (C) 2011 Elsevier B.V. TI The increased in vitro osteoclastogenesis in patients with rheumatoid arthritis is due to increased percentage of precursors and decreased apoptosis - The In Vitro Osteoclast Differentiation in Arthritis (IODA) study
SO BONE
LA English
DT Article
DE Rheumatoid arthritis; Bone; Osteoclast; Apoptosis; CD14(+); Osteoclastogenesis; Biomarker; Diagnostic model
ID bone erosion; osteoprotegerin; cells; classification; osteoarthritis; osteoporosis; expression; cytokine; criteria; ligand
AB Increases in local and systemic bone resorption are hallmarks of rheumatoid arthritis (RA). Osteoclasts are implicated in these processes and their enhanced differentiation may contribute to bone destruction. We observed that in vitro osteoclastogenesis varies among healthy individuals and hypothesized that increased osteoclastogenesis could be a marker for the presence of RA. Our objective in the present study was to determine if in vitro osteoclastogenesis from peripheral blood mononuclear cells (PBMCs) was different in patients with RA compared to healthy controls and osteoarthritis (OA) patients. Expression of CD14 in PBMCs was quantified and PBMCs were incubated for 21 days in the presence of the osteoclastogenic cytokines M-CSF and RANKL. Differentiation on cortical bone slices permitted the analysis of bone resorption while apoptotic potential was assessed by terminal deoxynucleotidyl transferase-mediated dUTP nick end labeling. In vitro osteoclastogenesis was higher in PBMCs from RA patients compared to controls, and a similar increase was observed in the percentage of osteoclast precursors in RA patients. Osteoclasts from RA patients showed lower apoptotic rates than osteoclasts from healthy controls. No difference was observed in bone resorption activity between RA patients and controls. Interestingly, the difference in osteoclast number and apoptosis rate allowed the implementation of an algorithm capable of distinguishing patients with RA from controls. In conclusion, our study shows that osteoclast differentiation from PBMCs is enhanced in patients with RA, and this difference can be explained by both a higher percentage of osteoclast precursors in the blood and by the reduced

apoptotic potential of mature osteoclasts. (C) 2010 Elsevier Inc. All rights reserved.

TI Osteocyte Deficiency in Hip Fractures
SO CALCIFIED TISSUE INTERNATIONAL
LA English
DT Article
DE FGF23; Osteocytes; Osteoporosis; PHEX; Sclerostin
ID femoral-neck fracture; bone-formation; sclerostin expression; gene-expression; in-vivo; pth; sost/sclerostin; osteoporosis; modulation; apoptosis
AB Osteocytes play a central role in the regulation of bone remodeling. The aim of this study was to explore osteocyte function, and particularly the expression of SOST, a Wnt inhibitor, in patients with hip fractures. Serum sclerostin levels were measured by ELISA. The expression of several osteocytic genes was studied by quantitative PCR in trabecular samples of the femoral head of patients with hip fractures, hip osteoarthritis and control subjects. The presence of sclerostin protein and activated caspase 3 was revealed by immunostaining. There were no significant differences in serum sclerostin between the three groups. Patients with fractures have fewer lacunae occupied by osteocytes (60 +/- 5% vs. 64 +/- 6% in control subjects, P = 0.014) and higher numbers of osteocytes expressing activated caspase 3, a marker of apoptosis. The proportion of sclerostin-positive lacunae was lower in patients with fractures than in control subjects (34 +/- 11% vs. 69 +/- 10%, P = 2 x 10(-8)). The proportion of sclerostin-positive osteocytes was also lower in patients. RNA transcripts of SOST, FGF23 and PHEX were also less abundant in fractures than in control bones (P = 0.002, 5 x 10(-6), and 0.04, respectively). On the contrary, in patients with osteoarthritis, there was a decreased expression of SOST and FGF23, without differences in PHEX transcripts or osteocyte numbers. Osteocyte activity is altered in patients with hip fractures, with increased osteocyte apoptosis and reduced osteocyte numbers, as well as decreased transcription of osteocytic genes.

Therefore, these results suggest that an osteocyte deficiency may play a role in the propensity to hip fractures.

TI Concise Review: Induced Pluripotent Stem Cells and Lineage Reprogramming: Prospects for Bone Regeneration
SO STEM CELLS
LA English
DT Review
DE Induced pluripotent stem cells; Lineage reprogramming; Bone regeneration; Osteogenic differentiation
ID in-vitro differentiation; osteoblast differentiation; osteogenic differentiation; gene-expression; functional cardiomyocytes; enhances osteogenesis; mesenchymal cells; nuclear transfer; trabecular bone; up-regulation
AB Bone tissue for transplantation therapies is in high demand in clinics. Osteodegenerative diseases, in particular, osteoporosis and osteoarthritis, represent serious public health issues affecting a respectable proportion of the elderly population. Furthermore, congenital indispositions from the spectrum of craniofacial malformations such as cleft palates and systemic disorders including osteogenesis imperfecta are further increasing the need for bone tissue. Additionally, the reconstruction of fractured bone elements after accidents and the consumption of bone parts during surgical tumor excisions represent frequent clinical situations with deficient availability of healthy bone tissue for therapeutic transplantations. Epigenetic reprogramming represents a powerful technology for the generation of healthy patient-specific cells to replace or repair diseased or damaged tissue. The recent generation of induced pluripotent stem cells (iPSCs) is probably the most promising among these approaches dominating the literature of current stem cell research. It allows the generation of pluripotent stem cells from adult human skin cells from which potentially all cell types of the human body could be obtained. Another technique to produce clinically interesting cell types is direct lineage reprogramming (LR) with the additional advantage that it can be

applied directly in vivo to reconstitute a damaged organ. Here, we want to present the two technologies of iPSCs and LR, to outline the current states of research, and to discuss possible strategies for their implementation in bone regeneration. STEM CELLS 2011; 29: 555-563

TI Bone mineral density is cross sectionally associated with cartilage volume in healthy, asymptomatic adult females: Geelong Osteoporosis Study
SO BONE
LA English
DT Article
DE Bone mineral density; Knee structure; Cartilage; Defects; Adult females
ID early radiographic osteoarthritis; knee osteoarthritis; marrow lesions; surface-area; women; defects; risk; compartment; population; fracture
AB Introduction: The association between osteoporosis and osteoarthritis (OA) is controversial. Although previous studies have shown total body, lower limb, spinal and knee BMD and knee cartilage volume to be positively associated, the relationship between other distant site-specific measures of BMD and other knee structures is unknown. The aim of this study was to determine the associations between BMD at eight skeletal sites, and knee structure in asymptomatic young to

middle-aged females without any clinical signs of OA. Methods: One hundred and sixty healthy, asymptomatic females (29-50 yr) underwent magnetic resonance imaging of the knee. BMD was measured at the spine, hip, total body and forearm by dual energy X-ray absorptiometry, and at the calcaneus by quantitative ultrasound. BMD was tested for an association with cartilage volume, defects, and bone marrow lesions (BMLs). Results: Medial cartilage volume was positively associated with BMD at the spine, total body, femoral neck, and Ward's triangle (all $p<0.05$), with non-significant associations in the same direction at the trochanter ($p=0.07$). Findings in the lateral compartment were similar. The presence of medial cartilage knee defects were also associated with BMD at the spine; defects in the lateral compartment were associated with BMD at the forearm (both $p=0.05$). BMD was not associated with the presence of BMLs. No associations were observed with calcaneus BMD. Conclusions: Site-specific BMD is associated with cartilage volume at the knee in asymptomatic young to middle-aged adults, with the direction and effects trending in the same direction. The magnitude of changes correlates with clinically relevant changes. QUS defined calcaneus BMD, showed no associations with knee structure. Although systemic factors may underlie the association between knee cartilage volume and axial/lower limb BMD, these data suggest that common local, possibly biomechanical factors may also play a role. TI Autoimmune disease as a risk factor for globus pharyngeus: a cross-sectional epidemiological study
SO CLINICAL OTOLARYNGOLOGY
LA English
DT Article
ID rheumatoid-arthritis; symptom
AB Objective: To assess the prevalence and severity of globus-type symptoms in individuals who have a prior diagnosis of autoimmune disease. Design: Cross-sectional questionnaire. Participants and setting: One hundred and nine patients with autoimmune disease (rheumatoid arthritis, seronegative spondarthritis, connective tissue disease, systemic vasculitis) and 41 patients with non-autoimmune disease (osteoarthritis/osteoporosis) attending a rheumatology tertiary referral clinic at Norfolk & Norwich University Hospitals NHS Foundation Trust. The results from this study were compared to previous published figures in patients with globus pharyngeus (n = 105) and normal population (n = 174). Main outcome measures: Glasgow Edinburgh Throat Scale questionnaire; Reflux Symptom Index; Anxiety/Depression Scale. Results: Patients with autoimmune disease demonstrate a significantly higher prevalence for 5/10 symptoms on the Glasgow Edinburgh Throat scale score when compared to the non-autoimmune control group ($P < 0.01$). This significant difference increases to 9/10 symptoms when compared to published results for the normal population ($P = 0.01$). No significant difference was found when comparing the autoimmune and non-autoimmune control group reflux symptom index ($P = 0.64$) or anxiety depression scale ($P = 0.71$). Conclusion: Patients with autoimmune disease have a significantly increased prevalence of globus symptoms when compared to the healthy population. A further prospective study is required to decipher the effect of pharmacotherapy as a possible causative factor.

TI Treatment of resistant nonunion of supracondylar fractures femur by megaprosthesis
SO KNEE SURGERY SPORTS TRAUMATOLOGY ARTHROSCOPY
LA English
DT Article
DE Supracondylar fracture; Resistant nonunion; Megaprosthesis; Osteoarthritis; Arthroplasty
ID total knee arthroplasty; distal femoral nonunions; internal-fixation; elderly-patients; salvage; surgery
AB Resistant nonunion of distal femoral fractures in the elderly is a great challenge to treat because it is often associated with multiple problems like poor bone quality, arthritis, disuse osteopenia, joint contractures, and implant failure. We treated ten patients with megaprosthesis and report the outcome. Ten elderly patients of resistant nonunion of distal femoral fractures with arthritis knee were treated with megaprosthesis. The median patient age was 74 years (68-85 years). All these patients had undergone at least two prior operative procedures and were operated by us, 24-33 months following the first index surgery. Modular Resection System was used in all the patients. Eight patients were available for follow-up. Median follow-up period was 4 years. Two patients required extended local wound care for wound skin necrosis. One patient sustained traumatic periprosthetic subtrochanteric fracture following a subsequent trauma. No thromboembolic complications were seen. All knees showed satisfactory alignment and range of motion. Postoperative, median knee society pain score, and knee society function score were 84 (80-88) and 88 (84-92) at last follow-up. Megaprosthesis can be offered as a one-stage salvage procedure for difficult nonunion in distal femoral fractures associated with bone loss, osteoporosis, and secondary knee arthritis. IV.

TI Subtrochanteric fractures after long-term treatment with bisphosphonates: a European Society on Clinical and Economic Aspects of Osteoporosis and Osteoarthritis, and International Osteoporosis Foundation Working Group Report
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE Atypical; Bisphosphonate; Femur; Low trauma; Osteoporosis; Subtrochanteric
ID monthly oral ibandronate; suppressed bone turnover; femoral-shaft fractures; postmenopausal osteoporosis; stress-fractures; alendronate therapy; randomized-trial; zoledronic acid; microdamage accumulation; insufficiency fractures
AB This paper reviews the evidence for an association between atypical subtrochanteric fractures and long-term bisphosphonate use. Clinical case reports/reviews and case-control studies report this association, but retrospective phase III trial analyses show no increased risk. Bisphosphonate use may be associated with atypical subtrochanteric fractures, but the case is yet unproven. A Working Group of the European Society on Clinical and Economic Aspects of Osteoporosis and Osteoarthritis and the International Osteoporosis Foundation has reviewed the evidence for a causal association between subtrochanteric fractures and long-term treatment with bisphosphonates, with the aim of identifying areas for further research and providing recommendations for physicians. A PubMed search of literature from 1994 to May 2010 was performed using key search terms,

and articles pertinent to subtrochanteric fractures following bisphosphonate use were analysed. Several clinical case reports and case reviews report a possible association between atypical fractures at the subtrochanteric region of the femur in bisphosphonate-treated patients. Common features of these 'atypical' fractures include prodromal pain, occurrence with minimal/no trauma, a thickened diaphyseal cortex and transverse fracture pattern. Some small case-control studies report the same association, but a large register-based study and retrospective analyses of phase III trials of bisphosphonates do not show an increased risk of subtrochanteric fractures with bisphosphonate use. The number of atypical subtrochanteric fractures in association with bisphosphonates is an estimated one per 1,000 per year. It is recommended that physicians remain vigilant in assessing their patients treated with bisphosphonates for the treatment or prevention of osteoporosis and advise patients of the potential risks. Bisphosphonate use may be associated with atypical subtrochanteric fractures, but the case is unproven and requires further research. Were the case to be proven, the risk-benefit ratio still remains favourable for use of bisphosphonates to prevent fractures.

TI A Comparison of the Effects of Alendronate and Alfacalcidol on Bone Mineral Density Around the Femoral Implant and in the Lumbar Spine After Total Hip Arthroplasty
SO JOURNAL OF BONE AND JOINT SURGERY-AMERICAN VOLUME
LA English
DT Article
ID postmenopausal osteoporosis; vertebral fractures; double-blind; women; stem; trial; surface; dexa
AB Background: Several previous studies have demonstrated that bone mineral density loss around femoral implants is common, particularly in the proximal part of the femur, soon after total hip arthroplasty. The purpose of the present study was to compare the effects of alendronate and alfacalcidol on bone mineral density loss around the femoral implant and in the lumbar spine after total hip arthroplasty. Methods: The present study included sixty patients with osteoarthritis of the hip who had undergone a primary cementless total hip arthroplasty. We assigned these individuals to treatment with alendronate (n = 20), alfacalcidol (n = 18), or no medication (n = 22). Periprosthetic and lumbar spine bone mineral density was measured one week after surgery, and biochemical markers (bone-specific alkaline phosphatase and serum N-terminal telopeptides of type-1 collagen) were measured before surgery as a reference baseline. Subsequent measurements were performed at twelve, twenty-four, and forty-eight weeks after surgery. The periprosthetic measurement area in the femur was defined as Regions 1 to 7, which are consecutively located around the implant from the greater trochanter to the lesser trochanter and calcar. Results: Bone mineral density in the alendronate group was maintained in all regions. In the alfacalcidol and no-medication groups, bone mineral density in Region 7 was lower than in Regions 3 to 6 throughout the study period ($p < 0.0001$ as a result of repeated measures analysis of variance). Bone mineral density in the lumbar spine in the alendronate and alfacalcidol groups was higher than in the no-medication group at forty-eight weeks. The serum level of N-terminal telopeptides of type-1 collagen in the alendronate group was lower than that in the no-medication group throughout the study period ($p = 0.003$, 0.02 and 0.005). Conclusions: Alendronate prevented bone mineral density loss around femoral implants, particularly in Region 7 (calcar), but alfacalcidol did not show any effects in any regions. However, bone mineral density losses in the lumbar spine were effectively prevented by either alendronate or alfacalcidol.

TI Quality of intertrochanteric cancellous bone as predictor of femoral stem RSA migration in cementless total hip arthroplasty
SO JOURNAL OF BIOMECHANICS
LA English
DT Article
DE Total hip arthroplasty; Bone quality; Osteoporosis; RSA; mu CT
ID follow-up; osteoarthritis; osteoporosis; replacement; prostheses; stability;

precision; survival; density; 2-year
AB In cementless total hip arthroplasty, osteoporosis may jeopardize the achievement of immediate stability and lead to migration of anatomically shaped femoral stems. Poor quality of proximal cancellous bone per se may also affect the rate of osseointegration. In a selected group of female total hip arthroplasty patients (mean age 64 years) with unremarkable medical history, intertrochanteric cancellous bone biopsy was taken from the site of stem implantation. Local bone quality, determined by structural mu CT imaging and destructive compression testing of the biopsy tissue, was used as the predictor of three-dimensional stem migration determined by radiostereometric analysis (RSA) up to 24 months. The patients exhibited major differences in mechanical properties of the intertrochanteric cancellous bone, which were closely related to the structural parameters calculated from mu CT data. Unexpectedly, the major differences observed in the quality of trochanteric cancellous bone had only minor reflections in the RSA migration of the femoral stems. In statistical analysis, the mu CT-based bone mineral density quartile (low, middle, high) was the only significant predictor for stem translation at 24 months ($p = 0.022$) but only a small portion ($R-2=0.16$) of the difference in translation could be explained by changes in bone mineral density quartile. None of the other parameters investigated predicted stem migration in translation or rotation. In conclusion, poor quality of intertrochanteric cancellous bone seems to contribute to the risk of implant migration less than expected. Probably also the importance of surgical preservation of intertrochanteric cancellous bone has been over-emphasized for osseointegration of cementless stem. (C) 2010 Elsevier Ltd. TI Assessing Quality of Care of Elderly Patients Using the ACOVE Quality Indicator Set: A Systematic Review
SO PLOS ONE
LA English
DT Review

ID vulnerable older patients; nursing-hm; community; management; medicare; uk; incontinence; project; adults; falls
AB Background: Care of the elderly is recognized as an increasingly important segment of health care. The Assessing Care Of Vulnerable Elderly (ACOVE) quality indicators (QIs) were developed to assess and improve the care of elderly patients. Objectives: The purpose of this review is to summarize studies that assess the quality of care using QIs from or based on ACOVE, in order to evaluate the state of quality of care for the reported conditions. Methods: We systematically searched MEDLINE, EMBASE and CINAHL for English-language studies indexed by February 2010. Articles were included if they used any ACOVE QIs, or adaptations thereof, for assessing the quality of care. Included studies were analyzed and relevant information was extracted. We summarized the results of these studies, and when possible generated an overall conclusion about the quality of care as measured by ACOVE for each condition, in various settings, and for each QI. Results: Seventeen studies were included with 278 QIs (original, adapted or newly developed). The quality scores showed large variation between and within conditions. Only a few conditions showed a stable pass rate range over multiple studies. Overall, pass rates for dementia (interquartile range (IQR): 11%-35%), depression (IQR: 27%-41%), osteoporosis (IQR: 34%-43%) and osteoarthritis (IQR: 29-41%) were notably low. Medication management and use (range: 81%-90%), hearing loss (77%-79%) and continuity of care (76%-80%) scored higher than other conditions. Out of the 278 QIs, 141 (50%) had mean pass rates below 50% and 121 QIs (44%) had pass rates above 50%. Twenty-three percent of the QIs scored above 75%, and 16% scored below 25%. Conclusions: Quality of care per condition varies markedly across studies. Although there has been much effort in improving the care for elderly patients in the last years, the reported quality of care according to the ACOVE indicators is still relatively low.

DT Article
DE Elderly; Exercise; Benefits; Barriers
ID randomized controlled-trial; promote physical-activity; aerobic exercise; older-adults; cardiovascular-disease; knee osteoarthritis; resistance exercise; public-health; reduced risk; primary-care
AB In older adults, regular exercise provides numerous health benefits that include improvements in blood pressure, coronary artery disease, diabetes, lipid profile, osteoarthritis, osteoporosis, mood, neurocognitive function, and overall morbidity and mortality. This article discusses the benefits of exercise in the elderly and how physicians can help such patients overcome barriers to exercise (eg, sedentary lifestyle, lack of education, coexisting morbidities), and offers some practical exercise prescriptions for both healthy and compromised elderly patients.

TI Gene expression profiling suggests a pathological role of human bone marrow-derived mesenchymal stem cells in aging-related skeletal diseases
SO AGING-US
LA English

DT Article
DE human bone marrow mesenchymal stem cell; aging; osteoporosis; osteoarthritis
ID rat osteoprogenitor cells; tumor-suppressor; mitogenic activity; stromal cells; target gene; differentiation; osteoarthritis; aggrecanolysis; susceptibility; proliferation
AB Aging is associated with bone loss and degenerative joint diseases, in which the aging of bone marrow-derived mesenchymal stem cell (bmMSC)(1) may play an important role. In this study, we analyzed the gene expression profiles of bmMSC from 14 donors between 36 and 74 years old, and obtained age-associated genes (in the background of osteoarthritis) and osteoarthritis-associated genes (in the background of old age). Pathway analysis of these genes suggests that alterations in glycobiology might play an important role in the aging of human bmMSC. On the other hand, antigen presentation and signaling of immune cells were the top pathways enriched by osteoarthritis-associated genes, suggesting that alteration in immunology of bmMSC might be involved in the pathogenesis of osteoarthritis. Most intriguingly, we found significant age-associated differential expression of HEXA, HEXB, CTSK, SULF1, ADAMTS5, SPP1, COL8A2, GPNMB, TNFAIP6, and RPL29; those genes have been implicated in the bone loss and the pathology of osteoporosis and osteoarthritis in aging. Collectively, our results suggest a pathological role of bmMSC in aging-related skeletal diseases, and suggest the possibility that alteration in the immunology of bmMSC might also play an important role in the etiology of adult-onset osteoarthritis.

TI How applicable are clinical practice guidelines to elderly patients with

comorbidities?
SO CANADIAN FAMILY PHYSICIAN
LA English
DT Article
ID practice good medicine; canadian consensus conference; older-people; diagnosis; dementia; management; disease; quality; recommendations; osteoporosis
AB Objective To examine the applicability of 10 common clinical practice guidelines (CPGs) to elderly patients with multiple comorbidities. Design Content analysis of published Canadian CPGs for the following chronic diseases: diabetes, dyslipidemia, dementia, congestive heart failure, depression, osteoporosis, hypertension, gastroesophageal reflux disease, chronic obstructive pulmonary disease, and osteoarthritis. Main outcome measures Presence or absence of 4 key indicators of applicability of CPGs to elderly patients with multiple comorbidities. These indicators include any mention of older adults or people with comorbidities, time needed to treat to benefit in the context of life expectancy, and barriers to implementation of the CPG. Results Out of the 10 CPGs reviewed, 7 mentioned treatment of the elderly, 8 mentioned people with comorbidities, 4 indicated the time needed to treat to benefit in the context of life expectancy, 5 discussed barriers to implementation, and 7 discussed the quality of evidence. Conclusion This study shows that although most CPGs discuss the elderly population, only a handful of them adequately address issues related to elderly patients with comorbidities. In order to make CPGs more patient centred rather than disease driven, guideline developers should include information on elderly patients with comorbidities.

TI Health-Related Quality of Life in Subjects With Low Back Pain and Knee Pain in a Population-Based Cohort Study of Japanese Men The Research on Osteoarthritis Against Disability Study
SO SPINE
LA English
DT Article
DE knee pain; low back pain; osteoarthritis; quality of life; vertebral fracture
ID postmenopausal women; vertebral fractures; elderly subjects; osteoporosis; association; prevalent; hip
AB Study Design. Cross-sectional surveys of health-related quality of life (QOL) in subjects with low back pain and knee pain using a population-based cohort. Objective. The purpose of the present study was to clarify the impact of low back pain and knee pain on QOL in men. In addition, we analyzed the impacts of vertebral fracture (VFx), lumbar spondylosis, and knee osteoarthritis (OA) on the magnitude of QOL loss in men with low back pain and knee pain. Summary of Background Data. Low back pain and knee pain are major public health issues causing disability among the elderly men, but there were no population-based studies to compare the impact of low back pain on QOL with that of knee pain in Japanese men. Methods. From 3040 participants in the Research on Osteoarthritis Against Disability study, data from 767 men older than 40 years who completed questionnaires (mean age = 69.7 years) were examined. To carry out the QOL assessment, the Medical Outcomes Study Short Form 8 (SF-8) and EuroQol (EQ-5D) were used. We examined the association of low back pain and knee pain with QOL. Furthermore, we also examined the presence of VFx and the severity of lumbar spondylosis and knee OA with the magnitude of QOL loss in men with low back pain and knee pain, respectively. Results. The impact of low back pain on QOL was larger than that of knee pain. In men with low back pain, there were few associations between Kellgren-Lawrence grade and QOL, whereas VFx was associated with physical QOL. For men with knee pain, Kellgren-Lawrence grade

equal to 4 knee OA was associated with QOL. Conclusion. This study revealed that low back pain has a larger impact than knee pain on QOL. Furthermore, low back pain with VFx is strongly associated with physical QOL loss.

TI Acute primary total knee arthroplasty for peri-articular knee fractures in patients over 65 years of age
SO INJURY-INTERNATIONAL JOURNAL OF THE CARE OF THE INJURED
LA English
DT Article
DE Knee replacement; Outcome; Fracture; Peri-articular; Elderly
ID distal femoral fractures; elderly-patients; tibial plateau; periarticular fractures; hinge prosthesis; femur; replacement; fixation; stabilization; liss
AB Peri-articular knee fractures in osteoporotic or osteoarthritic bone present a challenge to fixation, mobilisation or non-operative management. We present a series of 15 proximal tibial and 11 distal femoral fractures treated with total knee arthroplasty at over mean follow-up period of 38.8 months. The mean age of the patients was 80 years. The choice of the implant and level of constraint was determined as per the nature of injury and preference of the surgeon dealing with the fracture. Patients were allowed rapid mobilisation with immediate full weight-bearing. Good clinical results were achieved with fracture healing, sound fixation and well-aligned flexible knees. Mean Knee Society knee score was 90.2; Knee Society function score was 35.5; Oxford Knee score was 39.5; and Short Form (SF)-36 physical function score was 37.3 and mental score 50.6. Good correlation was noted between Knee society knee score and SF-36 physical function score (Pearson's 0.76, p = 0.001), suggesting that generic health would dictate the final function achieved, whilst high knee scores suggest the satisfactory results of the operation. Analogous to arthroplasty for hip fractures, this technique should be considered as a treatment option in elderly peri-articular knee fractures with osteoporosis and/or osteoarthritis. AB Introduction: Glucocorticoids are known to attenuate bone formation in vivo leading to decreased bone volume and increased risk of fractures, whereas effects on the joint tissue are less characterized. However, glucocorticoids appear to have a reducing effect on inflammation and pain in osteoarthritis. This study aimed at characterizing the effect of glucocorticoids on chondrocytes, osteoclasts, and osteoblasts. Experimental: We used four model systems to investigate how glucocorticoids affect the cells of the joint; two intact tissues (femoral head- and

cartilage-explants), and two separate cell cultures of osteoblasts (2T3-pre-osteoblasts) and osteoclasts (CD14(+)-monocytes). The model systems were cultured in the presence of two glucocorticoids; prednisolone or dexamethasone. To induce anabolic and catabolic conditions, cultures were activated by insulin-like growth factor I/bone morphogenetic protein 2 and oncostatin M/tumor necrosis factor-alpha, respectively. Histology and markers of bone- and cartilage-turnover were used to evaluate effects of glucocorticoid treatment. Results: Prednisolone treatment decreased collagen type-II degradation in immature cartilage, whereas glucocorticoids did not affect collagen type-II in mature cartilage. Glucocorticoids had an anti-catabolic effect on catabolic-activated cartilage from a bovine stifle joint and murine femoral heads. Glucocorticoids decreased viability of all bone cells, leading to a reduction in osteoclastogenesis and bone resorption; however, bone morphogenetic protein 2-stimulated osteoblasts increased bone formation, as opposed to non-stimulated osteoblasts. Conclusions: Using highly robust in vitro models of bone and cartilage turnover, we suggest that effects of glucocorticoids highly depend on the activation and differential stage of the cell targeted in the joint. Present data indicated that glucocorticoid treatment may be beneficial for articular cartilage, although detrimental effects on bone should be taken into account. (C) 2011 Elsevier Inc. TI The Effect of Weekly Risedronate on Periprosthetic Bone Resorption Following Total Hip Arthroplasty A Randomized, Double-Blind, Placebo-Controlled Trial
SO JOURNAL OF BONE AND JOINT SURGERY-AMERICAN VOLUME
LA English
DT Article
ID femoral components; implant migration; cyclic therapy; ebra-fca; replacement; stem; etidronate; fractures; failure; osteoporosis
AB Background: Bone loss leading to late-occurring periprosthetic femoral fracture is a mode of failure in cementless total hip arthroplasty. The aim of this trial was to investigate the effect of a bisphosphonate, risedronate, on femoral penprosthetic bone resorption following total hip arthroplasty in patients with osteoarthritis of the hip. Methods: We enrolled seventy-three patients between the ages of forty and seventy years who were scheduled to undergo total hip arthroplasty in a single-center, randomized, double-blind, placebo-controlled trial. Subjects were randomly assigned to receive either 35 mg of risedronate (n = 36) or a placebo (n = 37) orally once weekly for six months. The primary end point was the change in bone mineral density in Gruen femoral zones 1 and 7. Bone mineral density scans were made preoperatively and at two days and three, six, twelve, and twenty-four months postoperatively. Secondary end points included migration of the femoral stem and clinical outcome. Results: Seventy of the seventy-three patients (thirty-three in the risedronate group and thirty-seven in the placebo group) were analyzed for the primary end point. The mean bone mineral density in zone 1 was 9.2% higher (95% confidence interval [Cl], 4.2% to 14.1%) in the risedronate group than in the placebo group at six months postoperatively and 7.2% higher (95% CI, 1.0% to 13.3%) at one year. The mean bone mineral density in zone 7 was 8.0% higher (95% CI, 2.7% to 13.4%) in the risedronate group than in the placebo group at six months postoperatively and 4.3% higher (95% CI, -1.5% to 10.1%) at one

year. Migration of the femoral stern, the clinical outcome, and the frequency of adverse events did not differ between the groups. Conclusions: Risedronate taken once weekly for six months following total hip arthroplasty was effective in reducing periprosthetic bone resorption around an uncemented femoral stem up to one year after surgery but had no discernible effect on implant migration or clinical outcome. Future studies of bisphosphonate treatment following total hip arthroplasty should focus on clinically relevant end points such as the risks of fracture and revision arthroplasty.

DE Osteoarthritis (OA); Platelet-rich plasma (PRP); Collagen matrix; Physiological microenvironment; Pro-inflammatory cytokines
ID necrosis-factor-alpha; in-vitro; articular chondrocytes; growth-factors; osteoarthritis; cells; differentiation; matrix; interleukin-1; mechanisms
AB This study was undertaken to evaluate the role of collagen matrix to enhance platelet-rich plasma (PRP) effects on pro-inflammatory cytokine-induced arthritic

model. We have previously demonstrated the highly regenerative roles of PRP to restore disc degeneration and osteoporosis. In this study. PRP modulated by collagen matrix was used as a regenerative and anti-inflammatory mediator to rescue the chondrocyte degeneration induced by pro-inflammatory cytokines IL-1 beta (10 ng/ml)+TNF-alpha (20 ng/ml). First, the mu result indicated that 1 ng/ml TGF-beta 1 in PRP showed an optimal dosage for chondrocytes proliferation. The chondrogenic-specific gene expressions were rescued by PRP from the inhibition of IL-1 beta+TNF-alpha, especially under the modulation of collagen matrix. The inflammatory molecules activated by IL-1 beta+TNF-alpha were also significantly diminished by PRP with collagen matrix. The membrane receptors integrin alpha 1 beta 1 and CD44 were strongly inhibited by IL-1 beta+TNF-alpha, while this inhibition was then recovered by PRP in collagen coating condition. In a 3D model encapsulated with collagen, PRP-induced chondrogenesis were highly enhanced, such as strong restoration of type II collagen and proteoglycan from the inhibition of IL-1 beta+TNF-alpha. The result indicated that collagen matrix enhances the effect of PRP on chondrogenesis in response to pro-inflammatory cytokines. The combination of PRP and collagen matrix might facilitate a physiological microenvironment beneficial for maintaining chondrocyte homeostasis and represents an advanced osteoarthritis therapy for clinical applications. TI Bone Mineral Density Is Not Related to Osteophyte Formation in Osteoarthritis of the Hip
SO JOURNAL OF RHEUMATOLOGY
LA English
DT Article
DE BONE MINERAL DENSITY; DUAL-ENERGY X-RAY ABSORPTIOMETRY; OSTEOARTHRITIS; HIP
ID femoral-neck; iliac crest; joint; osteoporosis; women; replacement; arthroplasty; association; dysplasia; arthritis
AB Objective. Reports have suggested that bone mineral density (BMD) is higher in patients with osteoarthritis (OA) of the hip than in healthy controls. Various types of OA of the hip caused by osteophyte formation were observed on radiographs during progression to the advanced degenerative stage, and the preoperative type of OA was reported to influence the results of surgical treatment. However, the mechanism underlying the development of different types of OA is still unknown. We measured BMD of patients with hip OA and determined whether higher BMD was observed in patients with osteophyte formation than in those without osteophytes. Methods. We measured BMD of the lumbar spine, radius, and calcaneus using dual-energy x-ray absorptiometry in 88 women who were scheduled to undergo total hip arthroplasty for endstage OA. Hips were evaluated for osteophyte formation using Bombelli's classification; 31 were graded as atrophic type, 30 as normotrophic, and 27 as hypertrophic. BMD at different skeletal sites were compared among the 3 types of OA. Results. No significant difference in BMD of the lumbar spine, ultradistal radius, mid-radius, or calcaneus was observed among the atrophic, normotrophic, and hypertrophic types of OA. Conclusion. Our data suggest that osteophyte formation is not related to general BMD. Factors other than general bone status, for example the morphology of the hip joint, need to be analyzed to determine the pathomechanism of osteophyte formation in the osteoarthritic hip. TI Teriparatide as a Chondroregenerative Therapy for Injury-Induced Osteoarthritis
SO SCIENCE TRANSLATIONAL MEDICINE
LA English
DT Article
ID parathyroid-hormone 1-34; endochondral bone-formation; experimental mouse models; knee-joint instability; articular-cartilage; hip osteoarthritis; metalloproteinase inhibitor; chondrocyte differentiation; osteoblast apoptosis; molecular-mechanisms
AB There is no disease-modifying therapy for osteoarthritis, a degenerative joint disease that is projected to afflict more than 67 million individuals in the United States alone by 2030. Because disease pathogenesis is associated with inappropriate articular chondrocyte maturation resembling that seen during normal endochondral ossification, pathways that govern the maturation of articular chondrocytes are candidate therapeutic targets. It is well established that parathyroid hormone (PTH) acting via the type 1 PTH receptor induces matrix synthesis and suppresses maturation of chondrocytes. We report that the PTH receptor is up-regulated in articular chondrocytes after meniscal injury and in osteoarthritis in humans and in a mouse model of injury-induced knee osteoarthritis. To test whether recombinant human PTH(1-34) (teriparatide) would inhibit aberrant chondrocyte maturation and associated articular cartilage degeneration, we administered systemic teriparatide (Forteo), a Food and Drug Administration-approved treatment for osteoporosis, either immediately after or 8 weeks after meniscal/ligamentous injury in mice. Knee joints were harvested at 4, 8, or 12 weeks after injury to examine the effects of teriparatide on cartilage degeneration and articular chondrocyte maturation. Microcomputed tomography revealed increased bone volume within joints from teriparatide-treated mice compared to saline-treated control animals. Immediate systemic administration of teriparatide increased proteoglycan content and inhibited articular cartilage degeneration, whereas delayed treatment beginning 8 weeks after injury induced a regenerative effect. The chondroprotective and chondroregenerative effects of teriparatide correlated with decreased expression of type X collagen, RUNX2 (runt-related transcription factor 2), matrix metalloproteinase 13, and the carboxyl-terminal aggrecan cleavage product NITEGE. These preclinical findings provide proof of concept that Forteo may be useful for decelerating cartilage degeneration and inducing matrix regeneration in patients with osteoarthritis.

TI Predicting subchondral bone stiffness using a depth-specific CT topographic mapping technique in normal and osteoarthritic proximal tibiae
SO CLINICAL BIOMECHANICS
LA English
DT Article
DE Stiffness; Subchondral bone; Bone mineral density; Computed tomography; Osteoarthritis
ID trabecular bone; mechanical-property; knee osteoarthritis; articular-cartilage; cancellous bone; finite-element; femoral-head; density; modulus; osteoporosis
AB Background: Subchondral bone stiffness is thought to be involved in osteoarthritis pathogenesis. Our objective was to determine if a CT imaging technique, which measures density in relation to depth from the subchondral

surface, could predict the stiffness of proximal tibial subchondral bone. A second objective was to determine whether cartilage degeneration (an indicator of osteoarthritis) affected predictions. Methods: Thirteen proximal tibial compartments (4 medial, 9 lateral) from 10 male donors (age: mean 73.2, SD 10.6 years) were scanned using quantitative CT. We assessed average subchondral bone mineral density across different depths (0-2.5, 0-5, 0-10 mm) and layers (2.5-5, 5-10 mm) measured relative to the subchondral surface. We classified cartilage status as normal or degenerated using the International Cartilage Repair Society system. We performed macro indentation testing directly at the subchondral surface, and related stiffness to density measures using power-law regression models adjusted for side, age and cartilage status. We tested the coincidence of normal and degenerated regression models using F test statistics. Findings: Density measures nearest the subchondral bone surface (0-2.5 mm) were most effective at predicting subchondral bone stiffness ($r(2) = 0.67$, $p<0.001$). The predictive ability of depth-specific density measures decreased when density was averaged across larger depths or layers deep to the subchondral surface. Cartilage status did not affect model predictions. Interpretation: Depth-specific density measures have potential use as in vivo imaging tools for characterizing subchondral bone density and estimating stiffness. This information could help explain the role of subchondral bone in osteoarthritis pathogenesis. (C) 2011 Elsevier Ltd. All rights reserved.

TI Effects of Controlled Released BMP-7 on Markers of Inflammation and Degradation During the Cultivation of Human Osteoarthritic Chondrocytes
SO JOURNAL OF BIOMATERIALS APPLICATIONS
LA English
DT Article
DE osteoarthritic chondrocyte; PGLA microspheres; BMP-7; inflammation
ID human articular chondrocytes; osteogenic protein-1 op-1; nf-kappa-b; matrix metalloproteinase-13; proinflammatory cytokine; soluble receptor; gene-expression; tnf-alpha; il-1; proteoglycan
AB The aim of the present study is to investigate the effects of BMP-7 released from polylactide microspheres on the appearance of various catabolic and inflammatory cytokines secreted by osteoarthritic chondrocytes cultivated in a collagen gel. Articular chondrocytes of 15 patients suffering from osteoarthritis are transferred to a collagen type-I gel. Additionally, BMP-7 encapsulated into polylactide microspheres (50 ng BMP-7/mL gel) is added. After 14 days, gene expression and protein appearance of various genes involved in matrix turnover and inflammation are investigated by immunohistochemical staining and RT-PCR and compared to untreated controls. TNF-alpha, MMP-13, IL-6, IL-1 beta, and VEGF gene expressions are decreased in the treatment group. In contrast, BMP-7-induced matrix synthesis is not affected, leaving collagen type-II (Col-II) gene expression to be elevated, while collagen type-I (Col-I) is decreased. In summary, controlled release of low concentrated BMP-7 from polylactide microspheres leads to a decrease in gene expression of the investigated inflammation and matrix degradation markers whereas matrix synthesis is induced.

TI Hand Radiological Damage in Systemic Sclerosis: Comparison with a Control Group and Clinical and Functional Correlations
SO SEMINARS IN ARTHRITIS AND RHEUMATISM
LA English
DT Review
DE systemic sclerosis; hands; radiology
ID disease-activity; arthropathy; criteria
AB Objective: To define the burden of hand radiological damage in systemic sclerosis (SSc) patients, compared with a control group. Methods: Both hands of 167 SSc patients and 168 hands (82 right and 86 left) of age- and gender-matched controls were imaged by conventional radiograph. Two musculoskeletal radiologists semiquantitatively scored the following lesions: tuft acro-osteolysis, tuft calcinosis, joint space narrowings, marginal erosions, surface erosions, collapse arthropathies, periarticular calcifications, and juxta-articular osteoporosis, at the following areas: tufts, distal interphalangeal, proximal interphalangeal, metacarpophalangeal, carpal, and first carpometacarpal joints. Clinical and functional characteristics of the 167 SSc patients were obtained from the Belgian Systemic Sclerosis Cohort database. Results: Tuft acro-osteolysis and calcinosis were the most common findings observed in SSc patients and were almost absent in controls. SSc patients displaying tuft acro-osteolysis/calcinosis suffered from more severe disease. Arthropathies were infrequently detected and mainly consisted of a mixture of osteoarthritis-related changes (joint space narrowing and surface erosions) also observed in controls and of 2 types of rare SSc-associated arthropathies: a rheumatoid arthritis-like pattern, characterized by marginal erosions (n = 7 patients), and a collapse arthropathy (n = 6 patients), characterized by pressure erosions and joint subluxation. Conclusions: Although a rheumatoid arthritis-like or a collapse arthropathy can be observed in SSc patients, arthropathies are less common than previously reported. (C) 2011 Elsevier Inc. TI Antibody-Mediated "Universal" Osteoclast Targeting Platform using Calcitonin as a Model Drug
SO PHARMACEUTICAL RESEARCH
LA English
DT Article
DE drug delivery system; monoclonal antibody; osteoclast; osteoporosis; post-traumatic osteoarthritis; RANK receptor; salmon calcitonin
ID salmon-calcitonin; methyl 4-mercaptobutyrimidate; differentiation factor; postmenopausal women; sulfhydryl-groups; bone-resorption; delivery; cells; rank; osteopetrosis
AB To generate and characterize a specific monoclonal antibody (mAb) against recombinant human RANK receptor and to develop an antiresorptive strategy using this mAb as an osteoclast-targeting platform that selectively targets osteoclast cells whilst delivering an attached (i.e. chemically conjugated) active drug cargo. Using hybridoma technology, we generated a specific monoclonal antibody (mAb) against recombinant human RANK receptor and characterized by SDS PAGE, ELISA, Western Blot and immunocytochemistry, then synthesized osteoclast-targeting bioconjugates of salmon calcitonin (sCT) using this antibody

by generating thiol groups on mAb using 2-Iminothiolane and subsequently reacting them with sCT-PEG-MAL synthesised from sCT and NHS-PEG-MAL. To test the efficacy of the conjugate in vitro, osteoclasts were generated from precursor RAW 264.7 cells by dosing with the cytokines macrophage-colony-stimulating factor (M-CSF), and RANK Ligand (RANKL) and TRAP activity assay, Resorption Pit Assay, TRAP staining were performed. Cytotoxicity of the mAb-sCT conjugate was also evaluated in RAW 264.7 cells; sCT bioactivity and CTR binding potential were evaluated by in vitro intracellular cAMP stimulation assay in human T47D breast cancer cells. Generation of antibody against human RANK receptor was confirmed by SDS PAGE, ELISA and Western Blot. Immunocytochemistry confirmed the osteoclast targeting potential of the antibody. Successful conjugation of the antibody with sCT was confirmed by SDS PAGE and ELISA.Multinucleated osteoclast formation was confirmed by staining for tartrate-resistant acid phosphatase (TRAP). Conjugate functionality was confirmed by TRAP activity and Resorption Pit assay, showing the inhibitory effect on osteoclast differentiation. cAMP assay confirmed the retention of calcitonin bioactivity after conjugation. Our strategy offers the potential for a "universal" osteoclast-targeting platform-one that targets the RANK receptor on osteoclast cells by simply altering the conjugated cargo in order to affect the specific regulation of osteoclast cells.

TI Is Greater Lumbar Vertebral BMD Associated With More Disk Degeneration? A Study Using μCT and Discography
SO JOURNAL OF BONE AND MINERAL RESEARCH
LA English

DT Article
DE LUMBAR SPINE; DISK DEGENERATION; BONE MINERAL DENSITY; DISCOGRAPHY; MCT
ID bone-mineral density; intervertebral-disk; back-pain; osteoporosis; women; osteoarthritis; spine; hip; men; densitometry
AB It is well documented that osteoarthritis is associated with greater BMD in peripheral extremities. Yet the relationship between vertebral BMD and disk degeneration (DD) remains controversial in the lumbar spine, which may be due largely to the inadequacies of BMD and DD measures. Aiming to clarify the association between vertebral BMD and adjacent DD, we studied 137 cadaveric lumbar vertebrae and 209 corresponding intervertebral disks from the spines of 48 white men aged 21 to 64 years. DD was evaluated using discography. The vertebrae were scanned using a micro-computed tomography (mu CT) system to obtain volumetric BMD for the whole vertebra, the vertebral body, the vertebral body excluding osteophytes, and the vertebral body excluding osteophytes and endplates. A random effects model was used to examine the association between the different definitions of vertebral BMD and adjacent DD. No significant association was found between the BMD of the whole vertebra and adjacent DD. However, when the posterior elements were excluded, there was a significant association between greater vertebral body BMD and more severe degeneration in the disk cranial to the vertebra. This association remained after further excluding osteophytes and endplates from the vertebral body BMD measurements. Also, a trend of greater BMD of the vertebral body associated with more adjacent DD was evident. These results clarify the association between vertebral BMD and DD and specifically indicate that it is higher BMD of the vertebral body, not the entire vertebra, that is associated with more severe adjacent DD. This association may be obscured by the posterior elements and is not confounded by osteophytes and endplate sclerosis. (C) 2011 American Society for Bone and Mineral Research.

AB In older men with haemophilia, arthropathy resulting from a lifetime of intra-articular bleeding contributes to the loss of independence and increased morbidity that occurs with age. A regular exercise programme that incorporates aerobics, strength training and balance and flexibility activities is a key component of successful ageing, helping to improve functional mobility and reduce the risk of falls, osteoporosis and osteoporotic fractures. Because of the special challenges associated with haemophilia, which include both the underlying coagulopathy and, in many cases, extensive joint damage, patients beginning an exercise regimen should be referred to appropriately trained physiotherapists (preferably someone associated with a haemophilia treatment centre) for evaluation, education and instruction and follow-up. Various assistive devices may make exercise easier to perform and more comfortable.

TI Obesity Is Not Protective against Fracture in Postmenopausal Women: GLOW
SO AMERICAN JOURNAL OF MEDICINE
LA English
DT Article
DE Fractures; Obesity; Osteoporosis; Postmenopausal
ID body-mass index; bone-mineral density; self-report; osteoporotic fractures; knee osteoarthritis; visceral fat; risk-factors; older men; validity; management
AB OBJECTIVE: To investigate the prevalence and incidence of clinical fractures in obese, postmenopausal women enrolled in the Global Longitudinal study of Osteoporosis in Women (GLOW). METHODS: This was a multinational, prospective, observational, population-based study carried out by 723 physician practices at 17 sites in 10 countries. A total of 60,393 women aged >= 55 years were included. Data were collected using self-administered questionnaires that covered domains that included patient characteristics, fracture history, risk factors for fracture, and anti-osteoporosis medications. RESULTS: Body mass index (BMI) and fracture history were available at baseline and at 1 and 2 years in 44,534 women, 23.4% of whom were obese (BMI >= 30 kg/m(2)). Fracture prevalence in obese women at baseline was 222 per 1000 and incidence at 2 years was 61.7 per 1000, similar to rates in nonobese women (227 and 66.0 per 1000, respectively). Fractures in obese women accounted for 23% and 22% of all previous and incident fractures, respectively. The risk of incident ankle and upper leg fractures was significantly higher in obese than in nonobese women, while the risk of wrist fracture was significantly lower. Obese women with fracture were more likely to have experienced early menopause and to report 2 or more falls in the past year. Self-reported asthma, emphysema, and type 1 diabetes were all significantly more common in obese than nonobese women with incident fracture. At 2 years, 27% of obese women with incident fracture were receiving bone protective therapy, compared with 41% of nonobese and 57% of underweight women. CONCLUSIONS: Our results demonstrate that obesity is not protective against fracture in postmenopausal women and is associated with increased risk of ankle and upper leg fractures. TI Relevance of orthostatic posturography for clinical evaluation of hip and knee joint arthroplasty patients
SO GAIT & POSTURE

LA English
DT Article
DE Postural control; Clinical evaluation; Hip; Knee; Prostheses
ID surface replacement arthroplasty; postural control; balance; osteoarthritis; parameters; stability; sway; society; system; gait
AB In order to verify whether orthostatic posturography (OP) can support clinical assessment of total hip (THA) and knee arthroplasty (TKA), 81 subjects with THA and 100 with TKA were recruited and compared with 59 healthy volunteers. All patients were tested one or two days prior to surgery: 42 subjects (20 THA and 22 TKA) were tested again after six months, and 34 (14 THA and 20 TKA) yet again after 12 months. OP was performed using a Kistler 9286A piezoelectric force plate and the following postural parameters (PPs) were adopted on account of their functional meaning: mean velocity and the root mean square of the distance of the centre of pressure (COP), sway area, and 95% of the CoP power frequency. Eye condition and fatigue related to the test duration were also examined. The three most meaningful PPs were identified and a logarithmic transformation was then applied to these, as well as standardization. Almost all the PP values were higher preoperatively in the patients as compared with the healthy subjects and it was possible to detect many statistically significant differences between patients and healthy subjects. However, when examining the 181 subjects at the preoperative stage, the PPs did not show congruence with the clinical scores as well as they did during follow-up. Therefore, the use of the OP is not recommended to monitor patients undergoing THA or TKA. (C) 2011 Elsevier B.V. All rights reserved.

TI The prevalence of vitamin D deficiency in consecutive new patients seen over a 6-month period in general rheumatology clinics
SO CLINICAL RHEUMATOLOGY
LA English
DT Article
DE Outpatient clinics; Prevalence; Rheumatology; Vitamin D deficiency
ID association; disease
AB The objectives of this study are to assess: (a) the prevalence of vitamin D deficiency among new patients attending rheumatology outpatient departments, (b) the age profile of these low vitamin D patients and (c) whether any diagnostic category had a particularly high number of vitamin D-deficient patients. All new patients seen consecutively in general rheumatology clinics between January to June 2007 inclusive were eligible to partake in this study, and 231 out of 264 consented to do so. Parathyroid hormone, 25-hydroxyvitamin D, creatinine, calcium, phosphate, albumin and alkaline phosphatase levels were measured. We defined vitamin D deficiency as a parts per thousand currency sign53 nmol/l and severe deficiency as a parts per thousand currency sign25 nmol/l. Overall, 70% of

231patients had vitamin D deficiency, and 26% had severe deficiency. Sixty-five percent of patients aged a parts per thousand yen65 and 78% of patients aged a parts per thousand currency sign30 years had low vitamin D levels. Vitamin D deficiency in each diagnostic category was as follows: (a) inflammatory joint diseases/connective tissue diseases (IJD/CTD), 69%; (b) soft tissue rheumatism, 77%; (c) osteoarthritis, 62%; (d) non-specific musculoskeletal back pain, 75% and (e) osteoporosis, 71%. Seasonal variation of vitamin D levels was noted in all diagnostic groups apart from IJD/CTD group, where the degree of vitamin D deficiency persisted from late winter to peak summer. Very high prevalence of vitamin D deficiency was noted in all diagnostic categories ($p = 0.006$), and it was independent of age ($p = 0.297$). The results suggest vitamin D deficiency as a possible modifiable risk factor in different rheumatologic conditions, and its role in IJD/CTD warrants further attention.

TI Spontaneous Osteonecrosis of the Tarsal Navicular in an Adult: Mueller-Weiss

Syndrome
SO JOURNAL OF FOOT & ANKLE SURGERY
LA English
DT Article
DE avascular necrosis; osteonecrosis; bone graft; iliac crest; surgery; tarsus
ID osteoporosis
AB Spontaneous osteonecrosis of the navicular in the adult is known as Mueller-Weiss syndrome, which is a rare disease characterized by a collapse of the lateral portion of the tarsal navicular combined with a medial protrusion of the talar head and peri-navicular osteoarthritis. In this article, we describe a case of spontaneous osteonecrosis of tarsal navicular in a 43-year-old male. Chronic midfoot pain over the dorsomedial aspect of the right foot was resolved after complete removal of the necrotic bone from the tarsal navicular, followed by an autologous bone grafting of the resultant defect. TI An evaluation of the impact of seniors on a rheumatology referral clinic: demographics and pharmacotherapy
SO CLINICAL RHEUMATOLOGY
LA English
DT Article
DE Pharmacotherapy; Rheumatology clinic; Seniors
ID elderly-patients; aggressive treatment; arthritis; population; decisions; care; age
AB The aging population is impacting subspecialty areas outside of geriatrics. Rheumatic diseases increase with age. Therapy for these diseases can add to polypharmacy and negatively impact other comorbidities. This is a retrospective chart review of all patients attending a rheumatology subspeciality clinic over 1 year. Referrals were prescreened and excluded probable degenerative axial and peripheral disease and chronic pain syndromes. Data were collected on demographics, diagnoses, and medications. Two hundred ninety-five new patients were seen. Seventy-eight (26%) were seniors (age, >65 years) with a mean age of 73 years (65-90). Comparing the >65 to <65 age groups, the prevalence of inflammatory arthritides (rheumatoid arthritis (RA), psoriatic arthritis, palindromic rheumatism) was comparable: 48% vs 53%; however, osteoarthritis and polymyalgia

rheumatica were twice as common in the older group. Comorbidities in the >65 age group included hypertension (31%), osteoporosis (27%), diabetes (15%), hypothyroidism (11%), and coronary artery disease (9%). Only one patient had documented dementia. There were no cases of uncontrolled hypertension identified, and all patients were receiving a mixture of anti-hypertensives. Eighty-one percent of osteoporosis patients were on antiresorptives, but only 40% of prednisone users were taking bisphosphonates. For RA, treatment was somewhat comparable between the groups, with all but two patients receiving disease-modifying antirheumatic drugs. Eleven percent were on biologics. Seniors comprise a significant number of referrals. Pharmacotherapy differs in seniors, with more use of prednisone and a probable contribution of polypharmacy. This study highlights the need for reciprocal knowledge by both geriatricians and rheumatologists to optimize the management of these complex patients.

TI Reproducibility of subregional trabecular bone micro-architectural measures derived from 7-Tesla magnetic resonance images
SO MAGNETIC RESONANCE MATERIALS IN PHYSICS BIOLOGY AND MEDICINE
LA English
DT Article
DE Ultra high field; 7 Tesla; MRI; Trabecular bone; Micro-architecture; Knee
ID articular-cartilage; mri; interrelationship; parameters
AB High-resolution magnetic resonance imaging (MRI) of trabecular bone combined with quantitative image analysis represents a powerful technique to gain insight into trabecular bone micro-architectural derangements in osteoporosis and osteoarthritis. The increased signal-to-noise ratio of ultra high-field MR (a parts per thousand yen7 Tesla) permits images to be obtained with higher resolution and/or decreased scan time compared to scanning at 1.5/3T. In this small feasibility study,

we show high measurement precision for subregional trabecular bone micro-architectural analysis performed on 7T knee MR images. The results provide further support for the use of trabecular bone measures as biomarkers in clinical studies of bone disorders.

DE Knee; MR; Subchondral bone; Osteoarthritis; Trabecular bone; Osteoporosis
ID fractal signature analysis; articular-cartilage; mineral density; proximal tibia; 3 tesla; mechanical-property; osteoarthritic knee; joint; interrelationship; reproducibility

AB Changes in weight-bearing subchondral bone are central to osteoarthritis (OA) pathophysiology. Using MR, knee trabecular bone is typically assessed in the axial plane, however partial volume artifacts limit the utility of MR methods for femorotibial compartment subchondral bone analysis. Oblique-coronal acquisitions may enable direct visualization and quantification of the expected increases in femorotibial subchondral trabecular bone. MR acquisition parameters were first optimized at 3 Tesla. Thereafter, five volunteers underwent axial and coronal exams of their right knee. Each image series was evaluated visually and quantitatively. An anatomically standardized region-of-interest was placed on both the medial and lateral tibial plateaus of all coronal slices containing subchondral bone. Mean and maximum marrow signal was measured, and "bone signal" was calculated. The MR acquisition had spatial resolution 0.2 x 0.2 x 1.0 mm and acquisition time 10.5 min. The two asymptomatic knees exhibited prominent horizontal trabeculae in the tibial subchondral bone, while the one confirmed OA knee had disorganized subchondral bone and absent horizontal trabeculae. The subchondral bone signal was 8-14% higher in both compartments of the OA knee than the asymptomatic knees. The weight-bearing femorotibial subchondral trabecular bone can be directly visualized and changes quantified in the coronal-oblique plane. Qualitative and quantitative assessments can be performed using the resultant images and may provide a method to discriminate between the healthy and OA knees. These methods should enable a quantitative evaluation of the role of weight-bearing subchondral bone in the natural history of knee OA to be undertaken.

DE Boron; Calcium fructoborate; Osteoporosis; Osteoarthritis; Anti-inflammatory; Antioxidant
ID polyunsaturated fatty-acids; dietary boron; thermal-stability; boric-acid; extracellular-matrix; cadmium(ii) complex; mineral metabolism; d-fructose; vitamin-d; borate
AB Calcium fructoborate is a boron-based nutritional supplement. Its chemical structure is similar to one of the natural forms of boron such as bis-manitol, bis-sorbitol, bis-fructose, and bis-sucrose borate complexes found in edible plants. In vitro studies revealed that calcium fructoborate is a superoxide ion scavenger and anti-inflammatory agent. It may influence macrophage production of inflammatory mediators, can be beneficial for the suppression of cytokine production, and inhibits progression of endotoxin-associated diseases, as well as the boric acid and other boron sources. The mechanisms by which calcium fructoborate exerts its beneficial anti-inflammatory effects are not entirely clear, but some of its molecular biological in vitro activities are understood: inhibition of the superoxide within the cell; inhibition of the interleukin-1 beta, interleukin-6, and nitric oxide release in the culture media; and increase of the tumor necrosis factor-alpha production. Also, calcium fructoborate has no effects on lipopolysaccharide-induced cyclooxygenase-2 protein express. The studies on animals and humans with a dose range of 1-7 mg calcium fructoborate (0.025-0.175 mg elemental boron)/kg body weight/day exhibited a good anti-inflammatory activity, and it also seemed to have negligible adverse effect on humans.

TI Relationship between gender, bone mineral density, and disc degeneration in the lumbar spine: a study in elderly subjects using an eight-level MRI-based disc degeneration grading system
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE Bone mineral density; Degeneration; Intervertebral disc; Lumbar spine; Osteopenia; Osteoporosis
ID postmenopausal women; osteoporosis; osteoarthritis; fractures; osteopenia; features
AB The study cohort comprised 196 females and 163 males. Lumbar spine bone mineral density (BMD) and magnetic resonance imaging (MRI) were acquired. Females had more severe disc degeneration than males. Lumbar spine lower BMD was associated with less severe disc degeneration. Lumbar disc spaces were more likely to be narrower when vertebral BMD was higher. The purpose of this paper is to study the relationship between gender, BMD, and disc degeneration in the lumbar spine. The study cohort comprised 196 females and 163 males (age range 67-89 years) with no age difference between the two groups. Lumbar spine BMD was measured with dual X-ray densitometry, and MRI was acquired at 1.5 T. A subgroup of 48 males had additional lumbar vertebral quantitative computerized tomography densitometry. Lumbar disc degeneration was assessed using a MRI-based eight-level grading system. Female subjects had more severe disc degeneration than male subjects. After removing age effect, a positive trend was observed between T-score and severity of lumbar disc degeneration. This was significant in female subjects while not significant in male subjects. Lumbar disc spaces were more likely to be narrowed when vertebral BMD was higher. These observations were more significant in the midlumbar region (L3/4 and L4/5) and less so at the thoracolumbar junction. Female subjects tended to have slightly more severe lumbar disc degeneration than male subjects. Lower lumbar spine BMD was associated with less severe disc degeneration.

TI Effect of exercise on bone and articular cartilage in heterozygous manganese superoxide dismutase (SOD2) deficient mice
SO FREE RADICAL RESEARCH
LA English
DT Article
DE Manganese superoxide dismutase; exercise; bone; cartilage; reactive oxygen species
ID mitochondrial oxidative stress; free-radicals; subchondral bone; knockout mice; oxygen; osteoarthritis; expression; damage; antioxidants; activator
AB Reactive oxygen species (ROS) are involved in both bone and cartilage physiology and play an important role in the pathogenesis of osteoporosis and osteoarthritis. The present study investigated the effect of running exercise on bone and cartilage in heterozygous manganese superoxide dismutase (SOD2)-deficient mice. It was hypothesized that exercise might induce an increased production of ROS in these tissues. Heterozygous SOD2-deficient mice should

exhibit an impaired capability to compensate, resulting in an increased oxidative stress in cartilage and bone. Thirteen female wild type and 20 SOD2<SU++/--</SU mice (aged 16 weeks) were randomly assigned to a non-active wild type (SOD2<SU++/++</SUCon, n == 7), a trained wild type (SOD2<SU++/++</SURun, n == 6), a non-active SOD2<SU++/--</SU (SOD2<SU++/--</SUCon, n == 9) and a trained SOD2<SU++/--</SU (SOD2<SU++/--</SURun, n == 11) group. Training groups underwent running exercise on a treadmill for 8 weeks. In SOD2<SU++/--</SU mice elevated levels of 15-F-2t-isoprostane and nitrotyrosine were detected in bone and articular cartilage compared to wild type littermates. In osteocytes the elevated levels of these molecules were found to be reduced after exercise while in chondrocytes they were increased by aerobic running exercise. The observed changes in oxidative and nitrosative stress did neither affect morphological, structural nor mechanical properties of both tissues. These results demonstrate that exercise might protect bone against oxidative stress in heterozygous SOD2-deficient mice.

TI MUSCULOSKELETAL PROBLEMS AND DRUG USE IN THE ELDERLY: PERSPECTIVE OF THE GENERAL PRACTITIONERS
SO TURKISH JOURNAL OF GERIATRICS-TURK GERIATRI DERGISI
LA English
DT Article
DE General Practitioners; Musculoskeletal Disease; Anti-Inflammatory Agents,

Non-Steroidal; Pain
ID pain
AB Introduction: The elderly populates all over the world and in our country, demands of this population from health services are on the rise due to chronic diseases. Prevalance of osteoarthritis, osteoporosis and pain resulting from various musculoskeletal diseases are known to increase with age. Since improving national healthcare services through the enhancement of primary care is a major challenge in many countries; we aimed to investigate the perspective of the general practitioners (GPs) and the problems they encounter while dealing with musculoskeletal problems in the elderly population. Materials and Method: 159 governmental primary health care centers were randomly chosen and involved in the study. The GPs were questioned on the types of health problems they frequently encounter in the elderly population, the groups of drugs they prefer, whether they perform intraarticular or intralesional injections, the type of drugs they prescribe for osteoporosis, the type of drug groups that satisfy their patients most, drugs that the patients might prefer according to the advice of nonmedics and the drugs that elderly patients tend to use without prescriptions. Results: The most frequently used drugs for the musculoskeletal problems in the elderly were nonsteroidal antiinflammatory drugs (NSAIDs), followed by COX-2 specific NSAIDs, and paracetamol. The drugs that satisfy patients most were COX-2 specific NSAIDs, followed by NSAIDs, corticosteroids and paracetamol. 90.4% of the patients demanded for prescription of the drugs that were adviced by nonmedics. The GPs have observed that NSAIDs, antibiotics, vitamins and mineral preparations, cardiovascular system drugs were used by the patients without prescriptions. Conclusion: The GPs are frequently involved in the care of elderly patients with painful problems. NSAIDs are the most frequently used medications for musculoskeletal pain problems. A wide range of medications are used by the elderly patients without prescription.

TI Reference values for hand grip strength, muscle mass, walking time, and one-leg standing time as indices for locomotive syndrome and associated disability: the second survey of the ROAD study
SO JOURNAL OF ORTHOPAEDIC SCIENCE
LA English
DT Article
ID speed; sarcopenia; predictor; mortality; health; age
AB We established reference values for hand grip strength, muscle mass, walking time, and one-leg standing time as indices reflecting components of locomotive syndrome and associated disability using a large-scale population-based sample from the second survey of the Research on Osteoarthritis/Osteoporosis Against Disability (ROAD) cohort. We measured the above-mentioned indices in 2,468 individuals a parts per thousand yen40 years old (826 men, 1,642 women; mean age 71.8 years) during the second visit of the ROAD study. Disability was defined as certified disability according to the long-term care insurance system through public health centres of each municipality. Mean values for hand grip strength (weaker side), muscle mass of the thighs, walking time for 6 m at the usual pace, and the fastest pace for men were 32.7 kg, 7.0 kg, 5.6 s, and 3.7 s, respectively, and those for women were 20.8 kg, 5.2 kg, 5.9 s, and 4.1 s, respectively. The median values for one-leg standing time (weaker side) were 14 s for men and 12 s for women. The prevalence of disability in men aged 65-69, 70-74, 75-79, and a parts per thousand yen80 was 0.0, 1.0, 6.3, and 8.8%, respectively, and in women was 3.4, 3.5, 9.2, and 14.7%, respectively. There were significant associations between the presence of disability and walking time for 6 m at the usual pace and at the fastest pace, and between the presence of disability and walking speed. We established reference values for indices reflecting components of locomotive syndrome, and identified significant associations between walking ability and disability.

TI Partial adherence: a new perspective on health economic assessment in osteoporosis
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE Adherence; Compliance; Cost-effectiveness; Persistence
ID cost-effectiveness; bisphosphonate therapy; drug-therapy; persistence; alendronate; impact; women; risk; prevention; raloxifene
AB Partial adherence in osteoporosis increases the risk for fragility fracture and has considerable impact on cost-effectiveness. This review highlights a number of avenues for further research, such as improved definition of thresholds of compliance and persistence, as well as gap length, offset times, and fraction of benefit. Introduction A number of economic models have been developed to evaluate osteoporosis therapies and support decisions regarding efficient allocation of health care resources. Adherence to treatment is seldom incorporated in these models, which may reduce their validity for decision-making since adherence is poor in real-world clinical practice. Methods An ad hoc working group of the European Society for Clinical and Economic Aspects of Osteoporosis and Osteoarthritis met to review key issues concerning the incorporation of partial adherence in health economic models. Results Observational data have shown that poor adherence is associated with an increase in the risk for fragility fracture. Health economic modelling indicates that full adherence is associated with more quality-adjusted life years gained than partial adherence, as well as higher treatment costs and lower fracture-related costs. Although adherence appears as an important driver of cost-effectiveness, the effect is dependent on a range of other variables, such as offset time, fraction of benefit, fracture risk, fracture efficacy, fracture-related costs, and drug cost, some of which are poorly defined. Current models used to evaluate cost-effectiveness in osteoporosis may oversimplify the contributions of compliance and persistence. Conclusion Partial adherence has a significant impact on cost-effectiveness. Further research is required to optimise thresholds of compliance and persistence, the impact of gap length, offset times, and fraction of benefit.

TI Bone cement penetration pattern and primary stability testing in keeled and pegged glenoid components
SO JOURNAL OF SHOULDER AND ELBOW SURGERY
LA English
DT Article
DE TSA; shoulder; arthroplasty; bone mineral density; micro-CT
ID total shoulder arthroplasty; follow-up; glenohumeral osteoarthritis; rheumatoid-arthritis; shear-strength; replacement; survivorship; fixation; hemiarthroplasty; complications
AB Background: It has been proposed that bone mineral density has an influence on cement penetration in hip and knee arthroplasty. The hypotheses of this study were that: 1) there is a negative correlation between bone mineral density (BMD) and cement penetration in cemented glenoid components; and 2) that implant design has an influence on cement penetration into the glenoid bone. Methods: BMD of 10 pairs of fresh frozen scapulas was measured. Micro-computed tomography (micro-CT) scans in 3 different sections were analyzed after implantation of keeled and pegged glenoid components using a 3(rd)-generation cementing technique with a vacuum mixing system. Cement penetration was analyzed and correlated with BMD. Pull-out strength testing was performed to analyze primary stability. Results: The overall peak BMD was 0.6 [g/cm(2)] (range, 0.33-0.98). A strong negative correlation between BMD and mean cement penetration was found for the peg (R(2) = -.83; P < .003) and for the keel group (R(2) = -.81; P < .005). Mean cement penetration was 78.4 mm(2) (range, 60.6-94.2) in the keel and 113.9 mm 2 (range, 78.2-143.4) in the peg group (P < .0001). In all cases, the components were pulled out of the cement mantle, whereas the bone-cement interfaces remained intact. The mean pull-out strength was 1093N (764-1343N) for keeled and 884N (650-1264N) for pegged components (P < .05). Conclusion: A modern cementing technique, leading to a deep bonding between bone and cement, is crucial to prevent loosening of glenoid components. The findings of this study might help us to better understand the results of follow-up studies of cemented glenoid implants. Our results could be helpful for the choice of implants in patients with poor bone quality like osteoporosis or rheumatoid arthritis. Level of evidence: Basic Science Study. DE Osteoblasts; Wnt/beta-catenin pathway; RANK/RANKL/OPG; Osteoporosis; Osteoarthritis; Rheumatoid arthritis
ID tumor-necrosis-factor; glucocorticoid-induced osteoporosis; bone morphogenetic protein-2; mesenchymal stem-cells; growth-factor-beta; kappa-b ligand; osteoclastogenesis-inhibitory factor; human osteoarthritic osteoblasts; alkaline-phosphatase activity; messenger-ribonucleic-acid
AB Osteoblasts are mononucleated cells that are derived from mesenchymal stem cells and that are responsible for the synthesis and mineralization of bone during initial bone formation and later bone remodelling. Osteoblasts also have a role in the regulation of osteoclast activity through the receptor activator of nuclear factor kappa-B ligand and osteoprotegerin. Abnormalities in osteoblast differentiation and activity occur in some common human diseases such as osteoporosis and osteoarthritis. Recent studies also suggest that osteoblast functions are compromised at sites of focal bone erosion in rheumatoid arthritis.

TI Operative compared to non-operative treatment of displaced intra-articular calcaneal fractures
SO JOURNAL OF RESEARCH IN MEDICAL SCIENCES
LA English
DT Article
DE Calcaneal Fracture; Reconstruction Plate; Rigid Internal Fixation; Open Reduction
ID open reduction; os calcis; outcm
AB BACKGROUND: The aim of this study was to compare outcomes of open reduction and rigid internal fixation of displaced calcaneal fractures with that of non operative treatment. METHODS: Seventy two consecutive patients with displaced intra-articular calcaneal fractures were selected regarding inclusive and exclusive criteria and then were randomly allocated to surgical and non surgical groups. First group underwent open reduction and internal fixation with reconstruction plate and screws fixation and the other group were treated with closed reduction and cast immobilization. Data were collected by clinical observation and a check list. Data was analyzed by chi-square and student's t-test. RESULTS: The results showed significant difference between outcomes of surgical treatment and nonsurgical method (p = 0.001). There were some differences between two methods in terms of decreasing pain [Odd Ratio (OR): 6.72, p = 0.001], swelling (OR: 6.80, p = 0.001), increased range of motion of the joints (p = 0.001), decreased late osteoarthritis (OR: 2.33, p = 0.22) in favor of surgical group. CONCLUSIONS: Open reduction and internal fixation of displaced calcaneal fractures in absence of open fracture, severe osteoporosis, or comminution, poor general condition may be the preferred method of treatment.

TI Subchondral trabecular structural changes in the proximal tibia in an ovine model of increased bone turnover
SO JOURNAL OF ANATOMY
LA English
DT Article
DE microcomputed tomography; osteoarthritis; osteoporosis; subchondral bone; tibial plateau
ID biomechanical property; ovariectomized sheep; computed-tomography; articular-cartilage; cancellous bone; animal-models; l3 vertebra; osteoarthritis; estrogen; microstructure
AB Ovariectomized (OVX) sheep are now considered to be useful models for a variety of metabolic bone disorders. The specific aim of this study was to determine the effects of ovariectomy on the structural parameters and material density of the subchondral bone of the ovine tibial plateau as measured by microcomputed tomography (MicroCT). Twenty-three sheep were examined in this study; 10 of the sheep underwent ovariectomy (OVX), and the remainder (n = 13) were kept as controls (CON). These animals were then sacrificed at 12 months post-operatively. Three-dimensional analyses were performed of osteochondral samples (15 mm deep) which were obtained from the medial tibial plateau using MicroCT. Bone volume fraction of the subchondral trabecular bone was reduced in the ovariectomized sheep as compared to control animals (0.439 vs. 0.483, P = 0.038). Trabeculae were also significantly thinner in the OVX group (0.220 vs. 0.252 mm, P = 0.010), with reduced connectivity density (7.947 vs. 11.524 mm-3, P = 0.014). There was a trend towards lower numbers of individual trabeculae present in the OVX group as compared to controls, but this did not reach significance (2.817 vs. 3.288 mm-1, P = 0.1). There was also increased trabecular separation in the OVX group, which again fell short of significance (0.426 vs. 0.387 mm, P = 0.251). There was no difference in hydroxyapatite concentration (HA) between the two groups

(929 vs. 932 mgHA cm-3, P = 0.687). In conclusion, significant alterations of the trabecular architecture under the tibial plateau were observed following 12 months of oestrogen-deficiency in this ovine model. Despite these marked morphological and structural density differences, the material densities were equal in the two groups.

ID spontaneous osteonecrosis; transient osteoporosis; marathon runners; mri findings; pagets-disease; osteomyelitis; osteoarthritis; competition; prevalence; appearance
AB Magnetic resonance imaging (MRI) is very sensitive for the detection of marrow abnormalities. Bone marrow edema on MRI has been defined as an area of low signal intensity on T1-weighted images, associated with intermediate or high signal intensity findings on T2-weighted images. The bone marrow edema pattern is a nonspecific finding with multiple etiologies. The knee is a common place for bone marrow signal abnormalities to appear on MRI. Besides contusions and fractures from acute trauma, there are a variety of other causes of the bone marrow edema pattern. It is important for the interpreter of the study to be aware of the different etiologies responsible for producing these changes and to be able to narrow the differential diagnosis without mistaking such a pattern for acute trauma or infiltrative tumor. This article concentrates on those entities that produce a bone marrow edema pattern not related to acute trauma including red marrow proliferation, stress, osteochondral lesions, osteonecrosis, bone marrow edema syndrome, arthropathy, infection, Paget's disease, and marrow replacement disorders.

TI siRNA therapy for cancer and non-lethal diseases such as arthritis and osteoporosis
SO EXPERT OPINION ON BIOLOGICAL THERAPY
LA English
DT Review
DE arthritis; gene therapy; musculoskeletal diseases; siRNA
ID tumor-necrosis-factor; adjuvant-induced arthritis; collagen-induced arthritis; gene-therapy; in-vivo; ewings-sarcoma; rheumatoid-arthritis; rna-interference; cathepsin-k; reduces inflammation
AB Importance of the field: Gene silencing mediated by siRNA has been widely investigated as a potential therapeutic approach. The success of these therapies depends on effective systems capable of selectively and efficiently conveying siRNA to targeted cells/organs with minimal toxicity. Areas covered in this review: This review discusses current experimental approaches to siRNA delivery strategies available for arthritis treatment and the management of other musculoskeletal disorders. The review covers literature on the subject from 2000 to 2010. What the reader will gain: In the last decade, extensive improvements have been made to optimize siRNA-based gene therapy and have been tested on several arthritis and orthopedic conditions. However, except for Phase I - II DNA-based gene therapy trials on arthritis, no clinical studies have reported siRNA application in these domains. Take home message: Most musculoskeletal disorders, such as rheumatoid arthritis, osteoarthritis, fracture, aseptic loosening, cartilage and intervertebral disc degeneration are non-fatal and age-related chronic inflammatory conditions, but represent significant morbidity and a socio-economic burden. siRNA-based gene therapy offers treatment opportunities that are less invasive, more effective and less expensive than existing modalities. Future directions for siRNA therapy include

the development of safe and more efficient delivery systems and the selection of optimal gene targets for disease control.

TI Comparison of the effects of elcatonin and risedronate on back and knee pain by electroalgometry using fall of skin impedance and quality of life assessment using SF-36
SO JOURNAL OF BONE AND MINERAL METABOLISM
LA English
DT Article
DE Elcatonin; Risedronate; Pain; Electroalgometry (fall of skin impedance); SF-36
ID health survey; osteoporotic patients; salmon-calcitonin; double-blind; cartilage; bone; osteoarthritis; alendronate; etidronate; fractures
AB Back and knee pain is a widespread health problem and a serious threat to the quality of life (QOL) in middle-aged and older adults, as it frequently accompanies osteoporosis and osteoarthritis. In order to compare the effects of elcatonin and risedronate on such pain, 20 units of elcatonin was intramuscularly injected to 18 patients, and 5 mg of risedronate was orally administered daily to 20 others with similar backgrounds. Exercise-induced pain was analyzed by measuring the fall of skin impedance by electroalgometry (EAM), and subjective pain was recorded by a visual rating system (VRS) on a scale of 0 (no pain) to 100 (unbearable pain). In patients treated with elcatonin, the mean EAM-estimated pain was significantly reduced after 4, 5 and 6 months of treatment, and the VRS score after 3, 5 and 6 months, indicating a significant analgesic effect. In the risedronate group, however, improvement was less remarkable. Two-way analysis of variance using pain as a dependent variable and treatment group and time as independent variables revealed a significantly greater effect of elcatonin over risedronate on both the EAM and VRS scores, and the influence of treatment time on pain was indistinguishable between the two treatment groups. Effect of exercise load on pain was less on knee load than knee and spine load and spine load, but indistinguishable between the two groups. Changes in QOL were evaluated by the SF-36 system. Norm-based scoring showed significant improvements in 3 of 4 categories for elcatonin and in 2 of 4 for risedronate, suggesting comparable effects on the physical aspects of QOL, whereas responses to emotionally and socially directed questions indicated significant improvements in all 4 categories for risedronate, but none for elcatonin, suggesting a more physical than emotional component in elcatonin effects compared to risedronate.

TI Reduced tissue hardness of trabecular bone is associated with severe osteoarthritis
SO JOURNAL OF BIOMECHANICS
LA English
DT Article
DE Trabecular bone; Osteoarthritis; Hardness; Microstructure
ID cancellous bone; femoral-head; subchondral bone; mechanical-property; collagen metabolism; elastic property; lamellae; nanoindentation; osteoporosis; microindentation

AB This study investigated whether changes in hardness of human trabecular bone are associated with osteoarthritis. Twenty femoral heads extracted from subjects without musculoskeletal diseases (subject age: 49-83 years) and twenty femoral heads extracted from osteoarthritic subjects (subject age: 42-85 years) were tested. Sixty indentations were performed along the main trabecular direction of each sample at a fixed relative distance. Two microstructures were found on the indenting locations: packs of parallel-lamellae (PL) and secondary osteons (SO). A 25 gf load was applied for 15 s and the Vickers Hardness (HV) was assessed. Trabecular tissue extracted from osteoarthritic subjects was found to be about 13% less hard compared to tissue extracted from non-pathologic subjects. However, tissue hardness was not significantly affected by gender or age. The SO was 10% less hard than the PL for both pathologic and non-pathologic tissues. A hardness of 34.1 HV for PL and 30.8 HV for SO was found for the non-pathologic tissue. For osteoarthritic tissue, the hardness was 30.2 HV for PL and 27.1 HV for SO. In the bone tissue extracted from osteoarthritic subjects the occurrence of indenting a SO (28%) was higher than that observed in the non-pathological tissue (15%). Osteoarthritis is associated with reduced tissue hardness and alterations in microstructure of the trabecular bone tissue. Gender does not significantly affect trabecular bone hardness either in non-pathological or osteoarthritic subjects. A similar conclusion can be drawn for age, although a larger donor sample size would be necessary to definitively exclude the existence of a slight effect. (C) 2011 Published by Elsevier Ltd.

TI Underestimated Fracture Probability in Patients With Unilateral Hip Osteoarthritis as Calculated by FRAX
SO JOURNAL OF CLINICAL DENSITOMETRY
LA English
DT Article
DE FRAX; hip fracture; osteoarthritis; osteoporosis; total fracture
ID bone-mineral density; articular-cartilage; arthroscopic evidence; postmenopausal women; clinician guide; risk-assessment; osteoporosis; knee; tool; association
AB Osteoporosis (OP) and osteoarthritis (OA) are age-related diseases often considered to be mutually exclusive. We previously found that 25% of women with

advanced OA had occult OP and that femoral neck (FN) bone mineral density (BMD) T-scores were significantly higher for osteoarthritic vs contralateral hips. The FRAX calculator incorporates clinical risk factors and FN BMD T-score to estimate 10-yr total fracture probability and hip fracture probability. In 35 women and men aged 41 yr or older with unilateral hip OA scheduled for hip replacement, we tested whether FRAX fracture probability is underestimated when using data for the OA rather than the contralateral hip. There were between-hip differences for FN BMD T-score ($p < 0.0001$), total fracture probability ($p = 0.0004$), and hip fracture probability ($p = 0.0009$). Use of FN BMD T-scores resulted in OP treatment recommendations for 0% and 11% of subjects compared with 11% and 17% for total fracture probability and hip fracture probability, respectively. In 6-11% of subjects in this series, the FRAX calculator underestimated fracture probability with data for the OA hip. With the increased use of FRAX in clinical use, these data suggest that measurement of BMD at the contralateral hip may yield higher calculated FRAX total and hip fracture probabilities.

TI The effect of hip and knee arthroplasty on oral anti-inflammatory use and the relationship to body mass index: results from the UK general practice research database
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE NSAID; Hip; Knee; Arthroplasty
ID total joint arthroplasty; quality-of-life; osteoarthritis; replacement; obesity; community; arthritis; surgery; weight; pain
AB Objective: To determine the use of oral anti-inflammatory drugs in the year before and the 2 years after primary total hip (THR) or knee (TKR) replacement, and whether this varies according to Body mass Index (BMI). Design: 28,068 THR's and 24,364 TKR's, with five matched controls per case were identified from the General Practitioner Research Database. Anti-inflammatory usage was categorized into

"zero coverage" - no prescribed anti-inflammatory medication and ">80% coverage" - prescribed anti-inflammatory medication for greater than 80% of the days in the year. Secondary subset analysis was performed according to BMI. Results: 1 year post-surgery the proportion of cases on >80% coverage reduced from 21% (95%confidence interval (CI): 20-22%) to 8% (95%CI: 7-10%) for THR and 21% (95%CI: 20-22%) to 13% (95%CI: 11-14%) for TKR, with no ongoing reduction at 2 years. Zero coverage increased at one and both time points. The proportion of THR's on >80% coverage increased with BMI pre-op. The magnitude in reduction post-op was similar across all BMI groups. The proportion of TKR's on >80% coverage pre-op was greatest in extreme BMI categories. The magnitude in reduction post-op was similar across all BMI groups. Conclusion: THR/TKR's reduce the need for anti-inflammatory medication with most benefit observed in the first post-operative year. Increasing BMI affects anti-inflammatory use both in the general population and those undergoing THR/TKR surgery but without strong evidence of a detrimental effect on the benefits of pain relief. TI Accelerated metacarpal bone mineral density loss is associated with radiographic progressive hand osteoarthritis
SO ANNALS OF THE RHEUMATIC DISEASES
LA English
DT Article
ID x-ray radiogrammetry; of-rheumatology criteria; c-reactive protein; classification;

cytokines; disease; women; hip; osteoporosis; inflammation
AB Objective To study the association between metacarpal bone mineral density (BMD) loss and progressive hand osteoarthritis (OA) over 2 years. Methods Using the Kellgren-Lawrence (KL) grading scale and the Osteoarthritis Research Society International Atlas, standardised hand radiographs of 181 patients with primary OA at multiple sites (mean age 60 years, 80% women, mean body mass index 27 kg/m(2)) were assessed for hand OA at baseline (KL >= 2 in two or more hand joints) and progressive hand OA over 2 years (>= 1 point increase in total osteophyte and joint space narrowing score in patients with hand OA at baseline). Changes in BMD were measured over 2 years in metacarpals 2-4 by digital x-ray radiogrammetry. Accelerated BMD loss was defined as loss of >3 mg/cm(2)/year. Logistic regression analyses were performed to assess the associations between BMD loss and progressive hand OA. Results The baseline prevalence of hand OA was 68% and, after 2 years, 32% of these patients had progressive hand OA. Accelerated BMD loss was present in 79% of the patients with progressive hand OA compared with 60% and 57% of the patients with non-progressive hand OA and no hand OA, respectively. BMD loss was independently associated with progressive hand OA compared with non-progressive hand OA with a RR (95% CI) of 2.1 (1.1 to 4.3). Conclusion Accelerated metacarpal BMD loss is associated with progressive hand OA over a period of 2 years; knowledge of common mechanisms may lead to development of therapeutic interventions for hand OA.

TI Perimenopausal risk factors and future health
SO HUMAN REPRODUCTION UPDATE
LA English
DT Review
DE lifestyle at menopause; perimenopausal smoking; breast cancer; chronic diseases in elderly women; post-menopausal bone fractures
ID recreational physical-activity; amyotrophic-lateral-sclerosis; acute myocardial-infarction; breast-cancer risk; body-mass index; parkinsons-disease; mediterranean diet; smoking-cessation; fat distribution; osteo-arthritis
AB BACKGROUND: Lifestyle changes around the time of menopause have the potential to impact on morbidity and eventual mortality. Here we review this topic to identify how such changes may improve health at perimenopause and beyond. METHODS: Searches were performed in Medline and other databases. Each subject summary was presented to the ESHRE Workshop Group, where omissions or disagreements were resolved by discussion. RESULTS: Body weight increases because the decline in physical activity during the perimenopause is greater than the concomitant decline in energy intake. It is imperative to stop smoking before menopause because the risk of acute myocardial infarction rises sharply thereafter. Cardiovascular events can be reduced by managing risk factors, such as hypertension and increased lipids and body weight. Breast cancer risk is increased

to a similar extent by hormone use, decreased physical activity, increased calorie intake and alcohol use, all reflecting lifestyle decisions. Smoking, alcohol and exercise may increase or decrease risk of aging brain disorders, especially dementia and Parkinson's disease, while stress is consistently associated with increased risk and a prudent diet is consistently associated with reduced risk. Osteoarthritis frequency increases after 50 years of age and risk is elevated 3-fold by obesity, while risk of osteoporosis can be minimized by smoking cessation, adequate vitamin D intake and regular weight-bearing exercise. CONCLUSIONS: Lifestyle changes around the time of the perimenopause can reduce the likelihood and severity of heart disease and chronic illness in later years and the cost of care of elderly women.

TI Bone presence between the central peg's radial fins of a partially cemented pegged all poly glenoid component suggest few radiolucencies
SO JOURNAL OF SHOULDER AND ELBOW SURGERY
LA English
DT Article
DE Total shoulder arthroplasty; glenoid loosening; shoulder replacement; glenoid; CT scan; radiolucencies
ID total shoulder arthroplasty; surface replacement arthroplasty; neer hemiarthroplasty; follow-up; osteoarthritis; prosthesis; polyethylene; survivorship; regression
AB Background: Cement penetration problems and/or cement-induced bone necrosis may contribute to glenoid component failures. An all polyethylene component was developed that promotes biologic fixation between radial fins of its central peg and utilizes minimal cement fixation for its peripheral pegs, but it has little published data. We hypothesized better bone presence between the radial fins would be associated with less overall radiolucencies. This study's purpose was to utilize computed tomography (CT) and plain films to assess for bone between the central peg's radial fins and to assess overall component radiolucencies. Materials and methods: Thirty-five of 48 consecutively performed total shoulder arthroplasties (TSA) for primary glenohumeral osteoarthritis were in patients able to participate a minimum 2 years after surgery. All had reamed humeral head bone packed between radial fins of the central peg and minimal cement for the peripheral pegs. Thin cut (0.625 mm) CT scans, standardized plain films, Simple Shoulder Tests (SST), and Constant scores were obtained. A musculoskeletal radiologist calculated Yian CT scores, bone presence between fins on CT, and Lazarus radiolucency scores. Results: At a mean of 43 months, by CT: I) better Yian scores correlated with more bone between fins, and 2) bone was present in 6/6 inter-fin compartments in 23/35 shoulders, averaging 4.5/6 overall. Mean Lazarus radiolucency score was 0.45. Mean SST and Constant scores were 10.3 and 81.3, respectively. Conclusion: TSA utilizing autologous bone in inter-fin compartments of the central peg and minimal peripheral peg cement maintained bone presence a minimum 2 years post-op. More bone imparted fewer overall component radiolucencies. Level of evidence: Level IV, Case Series, Treatment Study. (C) 2011 Journal of Shoulder and Elbow Surgery Board of Trustees.

TI Identification of Major Direct Medical Cost Categories Among Patients with Musculoskeletal Conditions Undergoing Outpatient Rehabilitation
SO PHYSIKALISCHE MEDIZIN REHABILITATIONSMEDIZIN KURORTMEDIZIN
LA English
DT Article
DE cost categories; direct medical cost; rehabilitation; health resources
ID low-back-pain; rheumatoid-arthritis; economic-evaluation; illness; instrument; trials
AB Purpose: The goal of this study was to identify major cost categories of direct medical costs among patients with musculoskeletal conditions undergoing outpatient rehabilitation. Materials and Methods: Minor cost categories were discriminated from major cost categories by ranking the percentage of direct medical costs represented by each category using a cut-off of 5%. Means and 95% confidence intervals of direct medical costs were estimated using 1000 bootstrap samples. Results: Major cost categories for our sample including osteoarthritis, osteoporosis, back pain and fibromyalgia patients were outpatient physician visits, non physician services, medication and inpatient treatment. Since the 95% confidence intervals of estimated means were overlapping, no statistically significant difference can be assumed between the mean direct medical costs estimated solely with major categories and the one estimated with all available categories. Discussion: The development of a standard brief core set of major direct medical cost categories for musculoskeletal conditions is important regarding the standardization of comparative economic evaluations. The major cost categories we identified can serve as candidate categories and make a valuable contribution to the establishment of a standard brief core set of major cost categories for musculoskeletal conditions which should be included in the alongside economic evaluation of rehabilitative interventions. Conclusion: In summary, we have identified a) medication, b) physician visits, c) non physician services use and d) inpatient treatment as major direct medical cost categories for our sample including osteoarthritis, osteoporosis, back pain and fibromyalgia patients.

TI Do musculoskeletal degenerative diseases affect mortality and cause of death after 10 years in Japan?
SO JOURNAL OF BONE AND MINERAL METABOLISM
LA English
DT Article
DE Osteoarthritis of the knee; Lumbar spondylosis; Osteoporosis; Mortality; Cause of death
ID bone-mineral density; osteoporotic fractures; rheumatoid-arthritis; vertebral

fractures; telomere length; osteoarthritis; women; knee; men; association
AB There are several reports from Europe and the United States on mortality from musculoskeletal degenerative diseases; however, no reports have been published from Japan. This study is the first that has examined whether musculoskeletal degenerative diseases affect life prognosis in Japan. As many as 944 persons who were 60 years of age and older and who underwent one or more musculoskeletal checkups (knee, lower back, and bone mineral density examination) were enrolled. Survival and death after 10 years were examined. For each knee, lower back, and bone mineral density examination, subjects were divided into normal and abnormal groups. For each of the examinations (knee, lower back, or bone mineral density), 10-year mortality was compared between the two groups. Also, causes of death were examined after 10 years. As many as 805 subjects survived and 125 died. For those with and without osteoarthritis of the knee, mortality after 10 years was 17 and 10%, respectively. For those with and without lower back abnormalities, mortality after 10 years was 12 and 14%, respectively. For those with or without low bone mineral density, mortality after 10 years was 17 and 10%, respectively. Multivariate analysis adjusted for age, gender, body mass index, and lifestyle revealed that odds ratio of death after 10 years was 2.32 and 2.33 in the presence of osteoarthritis of the knee and a low bone mineral density, respectively, and thus the risk of death after 10 years was significantly high. With regard to the cause of death, cerebrovascular and cardiovascular diseases were most frequently evident in patients with osteoarthritis of the knee. Musculoskeletal degenerative diseases influence mortality after 10 years.

TI Comparison of 2D and 3D bone microarchitecture evaluation at the femoral neck, among postmenopausal women with hip fracture or hip osteoarthritis
SO BONE
LA English
DT Article
DE Femoral neck; Microarchitecture; Microcomputed tomography; Hip osteoarthritis; Hip fracture
ID quantitative computed-tomography; trabecular bone; cancellous bone; proximal femur; mineral density; iliac crest; hr-pqct; osteoporosis; biopsy; risk
AB Objectives: High resolution peripheral quantitative tomography (HR-pQCT) is used more widely to assess microarchitecture, but we are lacking comparisons

between HR-pQCT and histomorphometry, which is considered the gold standard. They have only been assessed on different anatomical regions. The purpose of our study was to assess the microarchitecture and the relative contribution of cortical and trabecular bone in hip fracture with this 3D imaging technique, compared with the 2D histomorphometry. Material and methods: We compared the distribution of cortical and trabecular bone in the ultradistal femoral neck samples (similar to 3 mm thick) obtained after total hip replacement in 21 hip osteoarthritis (HOA, 66 +/- 8 yrs) and 20 hip fracture (HF, 79 +/- 8 yrs) menopausal women by a direct 3D evaluation method (HR-pQCT: XtremeCT, Scanco Medical AG) and by histomorphometry. performed and averaged on three 10 mu m-thick sections 800 mu m apart. Results: Significant correlations were found between both techniques for trabecular bone volume, number, thickness, separation and cortical thickness ($0.51<r'<0.81$, $p<0.01$). The connectivity was also significantly correlated ($r'=0.58$, $p<0.001$) between both techniques, as well as the trabecular bone pattern factor measured in 2D with the structural model index (SMI) measured in 3D ($r'=0.62$, $p<0.001$). However HR-pQCT overestimated the absolute value of most parameters, with higher values being even more overestimated. The agreement between the two techniques was weak for cortical porosity. With the 3D measurements we found that trabecular bone volume was 43% lower in HF than HOA ($p<0.01$), associated with loss of trabecular connectivity (-50%, $p<0.01$) and a more rod-like structure (SMI, 22%, $p<0.01$), mainly at the inferior (34%, $p<0.01$) and posterior (22%, $p<0.05$) quadrants. Cortical thickness was found to be lower in the posterior quadrants (-22%, $p<0.05$) and tended to be lower in HF than in HOA at the inferior quadrant (-14%, $p=0.08$), but it was still the highest at the inferior quadrant in both groups. In conclusion, 3D methods confirmed the alteration of trabecular and cortical bone found by histomorphometry in HF compared with HOA and the frequency of the rod-like structure in HF. TI Therapeutic effects of exercise training in patients with pediatric rheumatic diseases
SO REVISTA BRASILEIRA DE REUMATOLOGIA
LA English
DT Review
DE physical fitness; motor activity; rheumatology; child
ID musculoskeletal pain syndrm; juvenile idiopathic arthritis; joint hypermobility syndrome; physical-activity; functional ability; aerobic exercise; children; fibromyalgia; program; fitness
AB Over the past decades, the role of exercise training in rheumatic diseases has been largely explored. Currently, physical activity is well known to benefit patients with osteoporosis, osteoarthritis, systemic lupus erythematosus, systemic sclerosis, idiopathic inflammatory myopathy, fibromyalgia and rheumatoid arthritis. Therefore, exercise training has been considered a valuable tool for treating rheumatic patients. The therapeutic effects of exercise training have also been investigated in pediatric rheumatic diseases. Collectively, studies have revealed the therapeutic potential of exercise in juvenile idiopathic arthritis, juvenile systemic lupus erythematosus, juvenile dermatomyositis, juvenile fibromyalgia and other causes of chronic pain. The aim of this review is to familiarize the pediatric rheumatologist with the exercise science field; discuss the potential benefits of exercise training in pediatric rheumatic diseases, emphasize both research and clinical perspectives of this promising field; and propose practical models of pre-participation examinations and contraindications to exercise.

TI Risk factors for the incidence and progression of radiographic osteoarthritis of the knee among Japanese
SO INTERNATIONAL ORTHOPAEDICS
LA English
DT Article
ID bone-mineral density; women; prevalence; hip; weight; men
AB This longitudinal study aimed to identify risk factors for the incidence and progression of radiographic knee osteoarthritis (OA). We examined the inhabitants of Miyagawa village aged a parts per thousand yen65 years every two years between 1997 and 2007. Anteroposterior radiographs of both knees were graded for OA using the Kellgren-Lawrence (K/L) grading system. Knee OA was defined as grade a parts per thousand yen2. We recorded the incidence of knee OA among participants in whom both knees changed from K/L grades 0 or 1 to a parts per thousand yen2 over a four-year follow-up period. We also recorded the progression of knee OA using this threshold among patients in whom one or both knees changed from K/L grades 2 or 3 to any higher grade over the follow-up period. Baseline data obtained from standard questionnaires, physical findings and X-rays included age, gender, body mass index (BMI), osteoporosis, Heberden's nodes, knee range of motion (ROM), knee pain and cigarette smoking. The rates of incidence and progression of knee OA among 360 participants (241 women, 119 men) who fulfilled the study criteria were 4.0 and 6.0% per year, respectively. Female gender (odds ratio [OR] 2.849, 95% confidence interval [CI] 1.170-6.944) and high BMI (OR 1.243, 95% CI 1.095-1.411) were significantly associated with the incidence of knee OA, and restricted knee ROM (OR 0.941, 95% CI 0.892-0.992) was significantly associated with knee OA progression. Patients with a low knee ROM relative to grade of radiographic knee OA require more careful follow-up than those with a higher ROM.

TI Active Shape Modeling of the Hip in the Prediction of Incident Hip Fracture
SO JOURNAL OF BONE AND MINERAL RESEARCH
LA English
DT Article
DE ACTIVE SHAPE MODELING; HIP SHAPE; HIP FRACTURE; OSTEOPOROSIS; BONE
ID osteoporotic fractures; proximal femur; radiographic osteoarthritis; femoral

geometry; bone-density; women; risk; men; recognition; progression
AB The objective of this study was to evaluate right proximal femur shape as a risk factor for incident hip fracture using active shape modeling (ASM). A nested case-control study of white women 65 years of age and older enrolled in the Study of Osteoporotic Fractures (SOF) was performed. Subjects (n = 168) were randomly selected from study participants who experienced hip fracture during the follow-up period (mean 8.3 years). Controls (n = 231) had no fracture during follow-up. Subjects with baseline radiographic hip osteoarthritis were excluded. ASM of digitized right hip radiographs generated 10 independent modes of variation in proximal femur shape that together accounted for 95% of the variance in proximal femur shape. The association of ASM modes with incident hip fracture was analyzed by logistic regression. Together, the 10 ASM modes demonstrated good discrimination of incident hip fracture. In models controlling for age and body mass index (BMI), the area under receiver operating characteristic (AUROC) curve for hip shape was 0.813, 95% confidence interval (CI) 0.771-0.854 compared with models containing femoral neck bone mineral density (AUROC = 0.675, 95% CI 0.620-0.730), intertrochanteric bone mineral density (AUROC = 0.645, 95% CI 0.589-0.701), femoral neck length (AUROC = 0.631, 95% CI 0.573-0.690), or femoral neck width (AUROC = 0.633, 95% CI 0.574-0.691). The accuracy of fracture discrimination was improved by combining ASM modes with femoral neck bone mineral density (AUROC = 0.835, 95% CI 0.795-0.875) or with intertrochanteric bone mineral density (AUROC = 0.834, 95% CI 0.794-0.875). Hips with positive standard deviations of ASM mode 4 had the highest risk of incident hip fracture (odds ratio = 2.48, 95% CI 1.68-3.31, p < .001). We conclude that variations in the relative size of the femoral head and neck are important determinants of incident hip fracture. The addition of hip shape to fracture-prediction tools may improve the risk assessment for osteoporotic hip fractures. (c) 2011 American Society for Bone and Mineral Research.

TI Osteoblastogenesis and Adipogenesis Are Higher in Osteoarthritic than in Osteoporotic Bone Tissue
SO ARCHIVES OF MEDICAL RESEARCH
LA English
DT Article
DE PPAR gamma; RUNX2; Gene expression; Fracture; Osteoporosis; Osteoarthritis
ID activated receptor-gamma; ppar-gamma; gene-expression; adipose-tissue; inverse relationship; lipid-metabolism; in-vivo; differentiation; marrow; hypoxia
AB Background and Aims. New data show that increased adipogenesis in bone marrow may decrease osteoblastogenesis, resulting in osteoporosis (OP). Runt-related transcription factor 2 (RUNX2) and peroxisome proliferator-activated receptor gamma (PPAR gamma) are two main transcriptional regulators controlling osteoblastogenesis and adipogenesis from the same precursor cell in bone-the mesenchymal stem cell. Because osteoarthritis (OA) and OP present the opposing bone phenotype, our aim was to determine whether the expression of selected adipogenic genes is lower in OA compared to OP bone tissue. Methods. Bone samples were obtained from gender-matched OP (n = 54) and OA (n = 49) patients undergoing hip arthroplasty. Osteoblastogenesis and adipogenesis were estimated by gene expression analysis of RUNX2, PPAR gamma 2 and their downstream genes. Results. In OA bone, significantly higher expression of PPAR gamma 2 and adiponectin as well as RUNX2, osterix and osteocalcin were obtained, suggesting higher adipogenesis and osteoblastogenesis in OA than in OP. There were no differences in RUNX2/PPAR gamma 2 and osteocalcin/adiponectin ratios between groups, suggesting similar balance of both processes. Higher perilipin 2, angiopoietin-like 4 and fatty-acid binding protein 4 mRNA levels in OP suggest activation of other transcription factors or hypoxic conditions in OP bone. Conclusions. Regulation of bone formation by RUNX2 and PPAR gamma 2 is modified in OA compared to OP, resulting in higher osteoblastogenesis and adipogenesis in OA. Both processes are similarly balanced in OP and OA but less active in OP. (C) 2011 IMSS. Published by Elsevier Inc.

TI FREQUENCY OF RHEUMATIC DISEASES IN PORTUGAL: A SYSTEMATIC REVIEW
SO ACTA REUMATOLOGICA PORTUGUESA
LA English
DT Review
DE Rheumatic Diseases; Burden of Disease; Frequency; Prevalence; Incidence; Portugal
ID bone-mineral density; musculoskeletal diseases; lupus-erythematosus; hip-fractures; prevalence; population; arthritis
AB Objectives: To describe the frequency of rheumatic diseases in Portugal through

a systematic review of published literature, critically appraising available information and identifying data collection gaps. Methods: We systematically reviewed the literature to retrieve data on the occurrence of rheumatic diseases in Portugal through MEDLINE and Index das Revistas Medicas Portuguesas searches, PhD theses, and national health surveys reports. Original articles in English or Portuguese published between 1 January 2000 and 31 December 2010 were included. Results: We retrieved information for the prevalence of rheumatic diseases, osteoarthritis, back pain, work-related musculoskeletal disorders (WRMDs), osteoporosis, fibromyalgia, rheumatoid arthritis, spondyloarthritis and other systemic rheumatic diseases and for the incidence of back pain, osteoporotic fracture and other systemic rheumatic diseases. The prevalence of rheumatic diseases ranged from 16.0% to 24.0% and the prevalence of osteoarthritis was 11.1% (95% confidence intervals (95%CI): 9.4-13.1) in the knee and 5.5% (95%CI: 4.3-7.0) in the hip. Regarding back pain, period prevalence ranged from 8.0% (95%CI: 6.1-10.1) to 29.5% (95%CI: 23.4-36.2) in children and from 12.3% (95%CI: 10.5-14.3) to 51.3% (95%CI: 48.6-53.9) in adults. The prevalence of WRMDs ranged from 5.9% to 84.2% (95%CI: 80.8-87.3). The yearly incidence of osteoporotic fracture (per 100 000) ranged from 93.3 to 481 (95%CI: 407-564) in women and from 31.9 to 154 (95%CI: 106-218) in men. The prevalence of osteoporosis in women ranged from 11.0% to 15.4% (95%CI: 13.4-17.6) and in men from 1.1% to 16.8% (95%CI: 12.2-22.3). The prevalence of fibromyalgia ranged from 3.6% (95%CI: 2.0-5.2) to 3.7% (95%CI: 2.0-5.4). The prevalence estimates of ankylosing spondylitis and of spondyloarthritis were 0.6% and 1.6% (95%CI: 0.8-2.7), respectively. The prevalence of systemic lupus erythematosus was estimated in 0.2% (95%CI: 0.1-0.8). Conclusions: There is a broad spectrum of information available that indicates an important burden of rheumatic diseases in the general Portuguese population. Gaps were identified particularly regarding inflammatory arthropathies and other systemic rheumatic diseases.

TI Quantitative genetic study of the circulating osteopontin in community-selected families
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE Association analysis; IBSP; Mineralization; OPN; SNP; SPP1
ID bone-mineral density; systemic-lupus-erythematosus; receptor activator; serum osteopontin; deficient mice; osteoarthritis; polymorphisms; population; protein; calcification
AB The study assessed contribution of genetic factors to variability of osteopontin (OPN) levels. Evidence of association of OPN levels with polymorphisms in its structural gene and integrin-binding sialoprotein gene loci was obtained. The results motivate research of OPN-related proteins and genes with respect to biomineralization and other biological processes. Introduction OPN is a major phosphoprotein in bone, which plays key role in regulation of bone mineralization process. It is considered as a promising biomarker for osteoarthritis and osteoporosis, and various other pathological conditions. However, the contribution of genetics and other confounding factors to OPN circulating levels variation in general population has never been specifically determined. The main aims of the present study included (1) evaluation of the putative genetic and familial factors' effect on OPN variability and (2) testing the hypothesis that OPN plasma levels are associated with the genetic polymorphisms in its structural gene locus (SPP1) and in integrin-binding sialoprotein gene locus (IBSP). Methods To address these questions, we used a family-based sample of 925 apparently healthy Caucasian individuals. Association of OPN levels with three SNPs in each of the two selected gene loci was explored using pedigree disequilibrium tests. Results Some 58% and 13% of the OPN levels variability were attributable to genetic factors and common spouse environment, respectively. Three SNPs showed nominally significant association with OPN ($p<0.05$). Of these, rs2616262 linked to IBSP promoter region

remained significant after correction for multiple testing (p=0.003). Significant association of this SNP and rs10516799 (distal segment of SPP1) with OPN was confirmed in several statistical tests. Using a special modification of variance component analysis, we examined gene-gene and gene-sex interaction effects, but found non-significant confirmation for these hypotheses. Conclusions Further studies are required to confirm the observed results and to explore the underlying molecular and physiological mechanisms.

TI Nonlinear surrogate modeling of tibio-femoral joint interactions
SO BIOMEDICAL SIGNAL PROCESSING AND CONTROL
LA English
DT Article
DE Surrogate model; Data-driven model; Nonlinear dynamic model; System identification; Tibio-femoral interaction; Ensemble
ID neural-network model; biological-systems; muscle forces; identification; wiener; moments; eeg
AB Musculoskeletal modeling can predict muscle forces and the resulting motion and loading during human ambulatory activities. A better understanding of the

loading environment on hard and soft tissues can enhance our understanding of ligament injury and prevention, tissue engineering, prosthetic design, osteoporosis, and osteoarthritis. The current state-of-the-art in movement simulation is to use simplified representation of the joints, such as representing the knee as a simple hinge joint. The aim of this study is to produce data-driven surrogate models which effectively capture the complex three-dimensional behavior of tibio-femoral joint interactions and that have the ease of use and computational efficiency required for incorporation in existing neuromusculoskeletal simulations. In order to meet our objective, we explored and compared the performance and sensitivity of nonlinear Hammerstein-Wiener, nonlinear autoregressive, and time delay neural network models under different configurations, individually and in ensembles. These models learned from solutions calculated by a validated multibody model of the knee. Inputs to the surrogate models were positions and orientations of the tibia relative to the femur, and the outputs were resulting forces and torques at the tibia with respect to the femur. Models were mixed using mean (sum) rule, weighted mean, and stacked generalization ensemble methods. It was observed that individually, time delay neural network models performed better than other models with normalized mean square errors between 0.0509 and 0.0889 on test data. Among the ensembles, stacked generalization provided the best results reducing test errors by 13-40%. (C) 2010 Elsevier Ltd. All rights reserved.

TI Synopsis and meta-analysis of genetic association studies in osteoporosis for the focal adhesion family genes: the CUMAGAS-OSTEOporosis information system
SO BMC MEDICINE
LA English
DT Article
ID colia1 sp1 polymorphism; genome-wide association; intron 1 polymorphisms; bone-mineral density; publication bias; field synopsis; risk; osteoarthritis; haplotypes; fractures
AB Background: Focal adhesion (FA) family genes have been studied as candidate genes for osteoporosis, but the results of genetic association studies (GASs) are controversial. To clarify these data, a systematic assessment of GASs for FA genes in osteoporosis was conducted. Methods: We developed Cumulative Meta-Analysis of GAS-OSTEOporosis (CUMAGAS-OSTEOporosis), a web-based information system that allows the retrieval, analysis and meta-analysis (for allele contrast, recessive, dominant, additive and codominant models) of data from GASs on osteoporosis with the capability of update. GASs were identified by searching the PubMed and HuGE PubLit databases. Results: Data from 72 studies involving 13 variants of 6 genes were analyzed and catalogued in CUMAGAS-OSTEOporosis. Twenty-two studies produced significant associations with osteoporosis risk under any genetic model. All studies were underpowered (< 50%). In four studies, the controls deviated from the Hardy-Weinberg equilibrium. Eight variants were chosen for meta-analysis, and significance was shown for the variants collagen, type I, alpha(1) (COL1A1) G2046T (all genetic models), COL1A1 G-1997T (allele contrast and dominant model) and integrin beta-chain beta(3) (ITGB3) T176C (recessive and additive models). In COL1A1 G2046T, subgroup analysis has shown significant associations for Caucasians, adults, females, males and postmenopausal women. A differential magnitude of effect in large versus small studies (that is, indication of publication bias) was detected for the variant COL1A1 G2046T. Conclusion: There is evidence of an implication of FA family genes in osteoporosis. CUMAGAS-OSTEOporosis could be a useful tool for current genomic epidemiology research in the field of osteoporosis.

LA English
DT Article
ID knee osteoarthritis; nonvertebral fractures; oral corticosteroids; propensity score; osteoporosis; risedronate; women; prevalence; symptoms; arthroplasty
AB Objective. The association between osteoarthritis (OA) and fractures remains unclear. OA patients have increased bone mass, but no corresponding decrease in fracture rate. This study was undertaken to determine the fracture rates in patients with hip OA undergoing a total hip replacement (THR), as compared with disease-free controls, and to assess the association between bisphosphonate use and postsurgery fracture risk. Methods. We conducted a population-based parallel-cohorts study. All patients in the UK General Practice Research Database undergoing a THR for hip OA between 1986 and 2006 constituted the exposed cohort (n = 14,133). Five disease-free controls were matched with each patient by age, sex, and practice site. Subjects were followed up for 5 years before and after

surgery. Fracture rates and rate ratios (RRs) were estimated using Poisson regression. In addition, bisphosphonate use was identified among patients undergoing THR, and the data, stratified by the presence or absence of a previous fracture and by treatment propensity score, were assessed using fitted Cox models to study the effect of bisphosphonate use on the risk of fracture postsurgery. Results. Patients undergoing a THR had a similar fracture risk as that in controls in the 5 years before THR, but had higher rates postsurgery, which peaked at years 2.5-5 (adjusted RR 1.24, 95% confidence interval [95% CI] 1.02-1.52). Use of bisphosphonates lowered the fracture risk among THR patients who received bisphosphonates as primary prevention (hazard ratio [HR] 0.56, 95% CI 0.38-0.82) and also among THR patients who had experienced a previous osteoporotic fracture (HR 0.48, 95% CI 0.23-0.99). Conclusion. This study identified a 25% increase in fracture risk at 2.5-5 years postsurgery among patients undergoing a THR. Bisphosphonate use reduced the post-THR risk of fracture when administered both as primary prevention and as secondary prevention, by 44% and 52%, respectively. This must be further confirmed in randomized controlled trials.

TI Association between socioeconomic status and bone mineral density in adults: a systematic review
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE Bone density; Hip; Social disadvantage spine; Socioeconomic factors; Systematic review
ID early-life; educational-level; osteoporosis risk; health; mass; hip; pregnancy; women; osteoarthritis; prevalence
AB For most causes of mortality and morbidity, a socioeconomic gradient exists; however, this systematic review identified limited evidence for the role of education on bone mineral density (BMD). Further research is required to build upon the current paucity of data examining influences of socioeconomic status (SES) on BMD, especially in men. For most causes of mortality and morbidity, a socioeconomic gradient exists, although little is understood of the relationship between BMD and SES. We systematically evaluated evidence of SES as a risk factor for low BMD at the clinically relevant sites of hip and spine in adults. We conducted a computer-aided search of Medline, EMBASE, CINAHL, and PsychINFO from January 1, 1966 until December 31, 2008. Reviewed studies investigated the relationship between SES parameters of income, education, and occupation, and the level of BMD. Studies were rated based on their methodological quality, and a best-evidence synthesis was used to summarise the results. One case-control and seven cross-sectional studies were identified for inclusion, of which four cross-sectional studies were high-quality. Best-evidence analysis identified consistent, yet limited, evidence for a positive association between educational attainment and BMD in women. No evidence was available regarding an association between income or occupation and BMD in either gender, or education and BMD in men. Limited good quality evidence exists for the role that education level may play in BMD levels. Cohort studies are required to examine the relationship between individual SES parameters and BMD in order to identify potential intervention targets.

TI Strontium ranelate effect in postmenopausal women with different clinical levels of osteoarthritis
SO CLIMACTERIC
LA English
DT Article
ID cruciate ligament transection; estrogen replacement therapy; subchondral bone; knee osteoarthritis; cartilage degradation; cynomolgus monkeys; cancellous bone; ii degradation; ctx-ii; turnover
AB Methods aEuro integral The analysis included the 2617 postmenopausal women (75 years old) with osteoporosis randomized to strontium ranelate or placebo for a 36-month period. Cartilage degradation was evaluated using a validated urinary marker adjusted for creatinine (CTX-II/cr), whereas bone resorption was assessed by serum CTX-I. The presence of osteoarthritis was determined by individual interviews. Results aEuro integral CTX-II was significantly elevated at baseline in subjects with a history of osteoarthritis (OA++) compared to subjects who did not (OA--) ($p < 0.0001$), whereas CTX-I was unaffected by osteoarthritis status. Strontium ranelate caused a significant decrease from baseline in CTX-II over a 12-month period whatever the osteoarthritis status. Strontium ranelate-treated patients had a significant decrease in CTX-II compared to placebo in both OA++ and OA-- groups up to 12 months, the difference remaining still significant at 36 months in patients from the OA-- group ($p < 0.001$). Conclusions aEuro integral The CTX-II profile of changes over 3 years may reflect efficacy of strontium ranelate against cartilage degradation, with an enhanced beneficial effect in subjects with early or mild clinical osteoarthritis, probably exerting its putative chondroprotective influence in early stages of the disease. Carefully controlled studies in targeted populations with early osteoarthritis are warranted to assess the role of strontium ranelate halting osteoarthritis progression.

TI Does body mass index affect clinical outcome post-operatively and at five years after primary unilateral total hip replacement performed for osteoarthritis? A MULTIVARIATE ANALYSIS OF PROSPECTIVE DATA

SO JOURNAL OF BONE AND JOINT SURGERY-BRITISH VOLUME
LA English
DT Article
ID total joint arthroplasty; perioperative morbidity; risk-factors; obesity; dislocation; prediction
AB Studies describing the effect of body mass index (BMI) on the outcome of total hip replacement have been inconclusive and contradictory. We examined the effect of BMI on medium-term outcome in a cohort of 1617 patients who underwent a primary total hip replacement for osteoarthritis. These patients were followed prospectively for five years with the outcomes of dislocation, revision, duration of surgery and deep and superficial infection studied, as well as collecting Harris hip scores (HHS) and Short-Form 36 (SF-36) questionnaires pre-operatively and at review. A multivariate analysis was performed to see whether BMI is an independent predictor of poor outcome. We found that patients with a BMI of >= 35 kg/m(2) have a 4.42 times higher rate of dislocation than those with a BMI < 25 kg/m(2). Increasing BMI is also associated with superficial infection and poorer HHS and SF-36 scores at five years. These trends remain significant even when multivariate analysis adjusts for age, gender, prosthesis, operating consultant, pre-operative HHS and SF-36, and comorbidities including diabetes mellitus, cardiac disease and osteoporosis. Despite the increased risks, the five-year outcome scores indicate that obese patients have much to gain from total hip replacement. Thus total hip replacement should not be withheld from patients solely on the grounds of an elevated BMI. However, longer-term follow-up of this cohort is required to establish whether adverse outcomes become more evident with time.

TI Relationship Between Hip Bone Mineral Density and Lumbar Disc Degeneration: A Study in Elderly Subjects Using an Eight-Level MRI-Based Disc Degeneration Grading System
SO JOURNAL OF MAGNETIC RESONANCE IMAGING
LA English
DT Article
DE lumbar spine; osteopenia; osteoporosis; bone mineral density; intervertebral disc; degeneration; hip
ID intervertebral disc; postmenopausal women; spinal degeneration; osteoporosis; osteoarthritis; coexistence; fractures; features
AB Purpose: To study the relationship between hip bone mineral density (BMD), lumbar disc degeneration, and lumbar disc space narrowing in elderly subjects. Materials and Methods: The study cohort comprised 196 females and 163 males (age range, 67-89 years) with no age difference between the two groups. Anteroposterior total hip areal BMD was measured with DXA and lumbar spine MRI was acquired using a 1.5 Tesla scanner. Lumbar disc degeneration was assessed using an eight-level grading system wherein each grade represents a stepwise progression from normal disc to severe disc degeneration and disc space narrowing. Results: After controlling for the age effect, no significant relationship was observed between total hip T-score status and severity of disc degeneration. There was no significant difference in total hip BMD in the subjects with or without the disc space narrowing ($P < 0.05$). Female subjects are more likely to have a narrowed disc space than males at all levels, and being statistically significant at L3/4 and L4/5 levels, and with an overall significance of $P = 0.007$. Conclusion:

There was no association observed between hip BMD and lumbar disc degeneration. Elderly females were more likely to have a narrowed lumbar disc space than elderly males.

TI Nuclear medicine techniques in the assessment of alkaptonuria
SO NUCLEAR MEDICINE COMMUNICATIONS
LA English
DT Review
DE alkaptonuria; imaging; nuclear medicine; positron emission tomography-computed tomography
ID bone-mineral density; f-18 fdg pet/ct; rheumatoid-arthritis; disease-activity; scintigraphy; diagnosis; osteoarthritis; arthropathy; tomography; patient
AB Alkaptonuria is a rare autosomal recessive disorder due to a lack of the enzyme homogentisate dioxygenase, leading to ochronosis, a process of accumulation of a melanin-like polymer of homogentisic acid in cartilage and other collagenous structures. Patients develop severe osteoarthropathy that resembles osteoarthritis. Although the diagnosis of alkaptonuria is not particularly challenging in view of the blue-black discolouration of visible connective tissue and the presence of homogentisic acid in urine, the natural history of alkaptonuria remains poorly understood. Patients would benefit immensely from an objective assessment of their disease status and from a clearer understanding of the pathophysiology and associated physical changes. Isotope bone scans, which are commonly used to identify the extent of involvement of bones in cancerous processes, have also been increasingly used for characterizing the extent of arthropathy in conditions such as osteoarthritis and rheumatoid arthritis. Semiquantitative scores based on the extent of involvement of joints have been used to describe the involvement of large joints in the context of symptomatic treatment for osteoarthritis. A similar semiquantitative isotope bone scan score depending on the involvement of the number of large joints in patients with alkaptonuria can be formulated and validated in a suitable cohort of patients. Bone densitometry measurement using dual-energy X-ray absorptiometry scanning is an internationally accepted tool to assess the risk and extent of osteoporosis, and is increasingly used to assess the additional fracture risk in patients with arthropathy. We believe that, currently, nuclear medicine techniques can provide useful information, which can be incorporated into disease severity scores for alkaptonuria. Once the biological basis for alkaptonuria is better understood, it is feasible that nuclear medicine techniques of even greater sensitivity and specificity can be developed, thereby taking advantage of the vast advances in the fields of radiochemistry, radiopharmacy, positron emission tomography-computed tomography and positron emission tomography-magnetic resonance imaging scanning. TI Bone mineral density and joint cartilage: four clinical settings of a complex relationship in osteoarthritis
SO ANNALS OF THE RHEUMATIC DISEASES
LA English
DT Article
ID radiographic knee osteoarthritis; subchondral bone; articular-cartilage; hand osteoarthritis; hip osteoarthritis; elderly-men; osteoporotic fractures; inverse relationship; women; population
AB Experimental and clinical data support the hypothesis that both high and low bone mineral density (BMD) conditions, including osteoporosis, may induce osteoarthritis. However, these conditions do not always predispose to osteoarthritis progression. Four clinical settings could arise from this relationship, and furthermore two phenotypes may be identified whether early osteoarthritis coexists with high or low BMD.

TI The Emerging Role of Dickkopf-1 in Bone Biology: Is It the Main Switch Controlling Bone and Joint Remodeling?
SO SEMINARS IN ARTHRITIS AND RHEUMATISM
LA English
DT Review
DE Dickkopf-1; DKK-1; joint remodeling; rheumatoid arthritis; ankylosing spondylitis; bone; osteoporosis; osteoarthritis; bone mass; Wnt
ID prostate-cancer; circulating dickkopf-1; pagets-disease; rheumatoid-arthritis; serum concentrations; wnt pathway; dkk-1; mass; progression; expression
AB Background: Dickkopf-1 (DKK-1), an inhibitor of the Wnt pathway, has recently emerged as an important player in several critical aspects of bone biology. Methods: We performed an extensive internet search (MEDLINE) using the key words Dickkopf-1 and the abbreviation DICK-1. Results: DKK-1 is a regulator of bone mass with increased expression linked to osteopenia and decreased expression to high bone mass. Moreover, it appears to actively participate in joint remodeling in animal models of arthritis, with increased levels related to bone resorption and decreased levels to new bone formation. Recent studies indicate its possible involvement in the remodeling process of human systemic rheumatic diseases such as rheumatoid arthritis and ankylosing spondylitis. DKK-1 may also play a role in osteoarthritis, metabolic bone disease (osteoporosis and Paget's disease), as well as multiple myeloma-associated bone disease and prostate cancer bone metastases. Conclusions: DKK-1 is a regulator of bone mass and joint remodeling. It may be a promising therapeutic target in osteoporosis; monoclonal antibody-based inhibition of Dkk-1 is already under development for osteoporosis treatment. Its role as a regulator of joint remodeling in animal models requires further exploration in humans. (C) 2011 Elsevier Inc. All rights reserved. Semin Arthritis Rheum 41:170-177

TI Melting bones: The social construction of postmenopausal osteoporosis in Turkey
SO SOCIAL SCIENCE & MEDICINE
LA English
DT Article
DE Turkey; Menopause; Osteoporosis; Risk; Medicalization; Embodied risk; Lifestyle risk; Gender
ID women; menopause; osteoarthritis; experiences; discourses; modernity; knowledge; awareness; medicine; density
AB The increased medicalization of different life stages, including menopause, is a subject studied mostly in the Western context. Examining medicalization in the non-Western world advances discussions of body, identity and health. In this paper. I analyze the discourses around postmenopausal osteoporosis in Turkey, focusing on the different constructions of risk in the medical and popular literature. The empirical basis of the paper draws on ethnographic research done in Istanbul, Turkey between June 2006 and March 2007. The research includes participant observation in gynecology clinics, interviews with clinicians and menopausal women and archival research on the representations of menopause in the Turkish media between 1999 and 2006. Referred to as kemik erimesi (melting of the bones) in colloquial Turkish, osteoporosis has been an essential component in the medicalization of menopause in Turkey. I argue that postmenopausal osteoporosis is defined as a combination of embodied risk, which is related to the definition of menopause as a risky period, and lifestyle risk, demonstrated in discussions around "traditional" vs. "modern" clothing and healthcare habits. The Turkish example emphasizes the importance of local conditions in defining medical risk and complicates the embodied vs. lifestyle risk categories. (C) 2011 Elsevier Ltd. All rights reserved.

TI A woman's journey through the reproductive, transitional and postmenopausal periods of life: Impact on cardiovascular and musculo-skeletal risk and the role of estrogen replacement
SO MATURITAS
LA English
DT Review
DE Cardiovascular risk; Estrogen; Hormone replacement; Menopause; Osteoarthritis; Osteoporosis; Women's health
ID coronary-heart-disease; bone-mineral density; hot flashes; venous thromboembolism; ovarian hormones; womens health; therapy; osteoarthritis; osteoporosis; fractures
AB Sex hormones are fundamental for female development and they are important physiologically to maintain the health and normal functioning of several organs such as the brain, heart and bone. It is now clear that the hormonal changes that occur during a woman's life, particularly her estrogen status, can modulate disease activity. This is especially true for cardiovascular and musculo-skeletal diseases, which are two leading causes of morbidity and mortality in women. With the general aging of the population they represent a serious and growing public health concern. Estrogen synthesis and blood levels fluctuate during a woman's life and in this review three broad periods will be considered: reproductive phase, transition and postmenopausal phase. Generally speaking, women in the reproductive phase of their life are at low risk of cardiovascular and musculo-skeletal disorders. However, the onset of menopause and the loss of ovarian function is associated with a significant increase in the prevalence of diseases such as coronary heart disease, osteoarthritis and osteoporosis. The prevalence of these debilitating diseases continues to increase through the postmenopausal period. Estrogen replacement is an obvious treatment approach to counter the problems associated with the loss of ovarian function and subsequent estrogen deficiency. Overall, oral and transdermal estrogen replacement are similarly effective in relieving menopausal symptoms and disorders that manifest during this period of a woman's life. Transdermal estrogen may be preferable in older women because of its lower thrombogenic potential. In this journey through a woman's life current best evidence relating to cardiovascular and musculoskeletal risk will be reviewed in line with well documented management strategies. TI Oxford unicompartmental knee arthroplasty: medial pain and functional outcome in the medium term

SO JOURNAL OF ORTHOPAEDIC SURGERY AND RESEARCH
LA English
DT Article
ID replacement; prosthesis
AB Background: In our experience results of the Oxford unicompartmental knee replacement have not been as good as had been expected. A common post operative complaint is of persistent medial knee discomfort, it is not clear why this phenomenon occurs and we have attempted to address this in our study. Methods: 48 patients were retrospectively identified at a mean of 4.5 years (range = 3 to 6 years) following consecutive Oxford medial Unicompartmental Knee arthroplasties for varus anteromedial osteoarthritis. The mean age at implantation was 67 years (range 57-86). Of these 48 patients, 4 had died, 4 had undergone revision of their unicompartmental knee replacements and 2 had been lost to follow up leaving 38 patients with 40 replaced knees available for analysis using the 'new Oxford Knee Score' questionnaire. During assessment patients were asked specifically whether or not they still experienced medial knee discomfort or pain. Results: The mean 'Oxford score' was only 32.7 (range = 16 to 48) and 22 of the 40 knees were uncomfortable or painful medially. The accuracy of component positioning was recorded, using standard post operative xrays, by summing the angulation or displacement of each component in two planes from the ideal position (according to the 'Oxford knee system radiographic criteria'). No correlation was demonstrated between the radiographic scores and the 'Oxford scores', or with the presence or absence of medial knee discomfort or pain. Conclusion: In our hands the functional outcome following Oxford Unicompartmental knee replacement was variable, with a high incidence of medial knee discomfort which did not correlate with the postoperative radiographic scores, pre-op arthritis and positioning of the prosthesis.

TI Osteoarthritis Induction Leads to Early and Temporal Subchondral Plate Porosity in the Tibial Plateau of Mice An In Vivo Microfocal Computed Tomography Study
SO ARTHRITIS AND RHEUMATISM
LA English
DT Article
ID articular-cartilage; bone changes; knee-joint; femoral-head; model; osteoporosis; chondrocytes; ct; osteoblasts; quantification
AB Objective. In osteoarthritis (OA), changes occur in both cartilage and subchondral bone. The subchondral bone plate facilitates normal cross-talk between articular cartilage and trabecular subchondral bone, and adaptive changes in the plate due to OA may therefore disturb cross-talk homeostasis. To investigate these changes over time, we examined the cartilage-subchondral bone interface using a combined approach of histologic analysis and in vivo microfocal computed tomography. Methods. Sixteen-week-old male C57BL/6 mice (n = 32) received intraarticular injections of collagenase in 1 joint to induce instability-related OA and received saline injections in the contralateral knee joint (control joint). At 2, 4, 6, 10, and 14 weeks after injection, changes in the tibial subchondral bone plate and subchondral trabeculae were analyzed. Results. Two weeks after injection, collagenase-injected joints had significantly more cartilage damage and osteophytosis than did control joints. Osteoclast activity directly underneath the subchondral bone plate was significantly elevated in collagenase-injected joints compared to control joints (mean +/- SEM osteoclast surface/bone surface 11.07 +/- 0.79% versus 7.60 +/- 0.81%), causing the plate to become thinner and creating a large increase in subchondral bone plate porosity (mean +/- SEM cumulative

porosity volume 0.05 +/- 0.04 x 10(-3) mm(3) in control joints versus 2.52 +/- 0.69 x 10(-3) mm(3) in collagenase-injected joints). Four weeks after injection, the previously formed perforations disappeared, coinciding with a significant rise in osteoblast activity in the subchondral trabecular bone in collagenase-injected joints compared to control joints (mean +/- SEM bone formation rate/bone surface 0.62 +/- 0.13 mu m(3)/mu m(2) per day versus 0.30 +/- 0.03 mu m(3)/mu m(2) per day). Conclusion. The current study is the first to provide quantitative longitudinal data on the dynamic changes in the subchondral bone plate after OA induction. The development of plate perforations may enhance mutual interaction between subchondral trabeculae, bone marrow cells, and the articular cartilage in OA.

TI The Effect of β-Carotene on Lumbar Osteophyte Formation
SO SPINE
LA English
DT Article
DE antioxidants; beta-carotene; dietary intake of antioxidants; lumbar osteophyte formation; vitamin E
ID bone-mineral density; radiographic knee osteoarthritis; vitamin-a intake; alpha-tocopherol; dietary-intake; serum carotenoids; risk; retinol; association; progression
AB Study Design. Cross-sectional cohort study of elderly people. Objective. The relationships of osteophyte formation on plain lumbar radiographs with serum levels of antioxidants (carotenoids, vitamin A, vitamin E) and other factors were investigated to examine whether antioxidants are involved in lumbar spine degeneration. Summary of Background Data. Antioxidants have inhibitory effects on the onset of many diseases. However, the association of lumbar osteophyte formation with antioxidant levels in the general population has not been investigated. Methods. The subjects were 286 people (103 men and 183 women; mean age = 68 years) who underwent resident health screening. Osteophyte formation on lumbar lateral radiographs (Nathan classification), lumbar lordosis angles, sacral inclination angles, serum levels of antioxidants, triglyceride levels, body mass index, osteoporosis, back muscle strength, history of alcohol intake, and smoking history were studied in these subjects. Results. Lumbar osteophyte formation was detected in 48 subjects (17%). Osteophyte formation was significantly more common in elderly persons, men, and subjects with a history of alcohol intake; and had a significant correlation with sacral inclination angle. The levels of alpha-tocopherol, beta-tocopherol, zeaxanthin/lutein, cryptoxanthin, lycopene, alpha-carotene, and beta-carotene were significantly lower in subjects with osteophytes. Logistic regression analysis adjusted for all factors showed that a higher age (odds ratio [OR] = 1.1, 95% confidence interval [CI] = 1.02-1.16; P = 0.02) and a low beta-carotene level (OR = 6.7, 95% CI = 1.39-32.6; P = 0.02) were risk factors for osteophyte formation. Conclusion. The serum levels of carotenoids and vitamin E were significantly lower in subjects with lumbar osteophyte formation, and a low beta-carotene level was the strongest risk factor for lumbar osteophytes. This is the first evidence of an association between carotenoids and lumbar osteophyte formation. This finding suggests that appropriate dietary intake of antioxidants is important for inhibition of lumbar spine degeneration in a rapidly aging society.

DT Article
DE Wilson's disease; Arthralgia; Osteoarthritis; Bone mineral density; Osteoporosis; Fracture; Chondrocalcinosis
ID hepatolenticular-degeneration; osteoarticular changes; skeletal changes; zinc; osteoarthropathy; polyarthritis; abnormality; arthropathy; efficacy; features
AB Wilson's disease (WD) is a rare disease, defined as an autosomal recessive disorder characterised by release of free copper and dramatic accumulation of intracellular hepatic copper with subsequent hepatic and central nervous system abnormalities. Mutations of the ATP7B gene are responsible for the metabolic dysfunction. Small open studies have reported spinal radiological abnormalities including scoliosis, diffuse bone demineralisation, osteochondritis and occasionally fracture. Prevalence of osteoporosis in young adult patients is debated, ranging from 10%, with normal mean Z-score values, to 43% in adults. Past history of spinal or peripheral fractures might be present in 50% of patients. Articular disorders include arthralgias of large joints, such as knee pain, rare effusions, early onset of radiological features of osteoarthritis and associated osteochondritis of the knee joint. Radiological chondrocalcinosis, an unusual feature in young adults, has to be confirmed. Few patients may develop drug-induced lupus with arthralgias, positive anti-nuclear and anti-histone antibodies, secondary to D-penicillamine, the major copper chelator used in WD. In this orphan disease, small retrospective studies cannot allow ascertaining definite WD-related articular and bone manifestations. However, such clinical and radiological abnormalities are occasionally the first symptoms leading to diagnosis. Physicians should be aware that unexplained joint pain and effusion, or even radiological features of osteoarthritis, of the large joints in adolescents could suggest WD and lead to copper survey. TI Burden of Musculoskeletal Disease and Its Determination by Urbanicity, Socioeconomic Status, Age, and Sex: Results From 14,507 Subjects
SO ARTHRITIS CARE & RESEARCH
LA English
DT Article
ID global perspective; public-health; urbanization; disorders; copcord; city
AB Objective. The availability of reliable estimates of the burden of musculoskeletal disease is of considerable importance for policymakers. Methods. This study uses data from the 14,507 participants of the European Health Interview Survey conducted in Austria in 2006/2007 to calculate estimates of the prevalence of osteoarthritis, spinal conditions, and osteoporosis in a population representative of other European Union or Organisation for Economic Co-operation and Development member states. Urbanicity, socioeconomic status, and age and sex were included as determinants of musculoskeletal disease. Results. The prevalence of arthritis was 18.8% (95% confidence interval [95% CI] 18.2-19.4%), of spinal conditions was 38.4% (95% CI 37.6-39.2%), and of osteoporosis was 6.6% (95% CI 6.3-7.0%). The census data showed strong evidence for an association between urbanicity and arthritis (P = 0.012) and osteoporosis (P < 0.001), but not spinal conditions (P = 0.721). Arthritis and spinal conditions were associated with socioeconomic status (P < 0.001 for all). Osteoporosis showed the same associations with age, income, and education. For arthritis, a combined model showed a substantial attenuation of the effect of urbanicity on arthritis prevalence after adjustment for socioeconomic status. Conclusion. These data suggest that the burden of musculoskeletal disease is determined by both urbanicity and socioeconomic status; however, the effect of urbanicity seems to be attributable to differences in socioeconomic status and demographics across geographic regions.

TI Relationship of sclerostin and secreted frizzled protein polymorphisms with bone mineral density: an association study with replication in postmenopausal women
SO MENOPAUSE-THE JOURNAL OF THE NORTH AMERICAN MENOPAUSE SOCIETY
LA English
DT Article
DE Osteoporosis; Sclerostin; SOST; FRZB; Association study; Polymorphisms
ID single-nucleotide polymorphisms; whole-genome association; wnt signaling pathway; gene-expression; osteoporosis; osteoarthritis; sost; strength; standardization; annotation
AB Objective: Secreted frizzled-related protein and sclerostin, encoded by FRZB and SOST genes, respectively, are extracellular Wnt inhibitors that tend to decrease bone formation. The purpose of this study was to explore the association of the sets of polymorphisms capturing common variations of these genes with bone mineral density (BMD). Methods: Twelve polymorphic loci of the FRZB gene and 7 of the SOST gene were genotyped in postmenopausal women from two Spanish regions (Cantabria, n = 1043, and Valencia, n = 342). The polymorphisms included

tagging single nucleotide polymorphisms and single nucleotide polymorphisms with possible functional consequences assessed in silico. Results: The rs4666865 polymorphism of the FRZB gene was associated with spine BMD in the Cantabria cohort in the single-locus (P = 0.008) and the haplotypic analysis. However, the results were not replicated in the Valencia cohort. Several polymorphisms at the 5' region of the SOST gene and, particularly, rs851056 were associated with BMD in women from both cohorts (P = 0.002 in Cantabria and P = 0.005 in Valencia). When the results of both cohorts were combined, the mean (SD) BMD difference across rs851056 genotypes was 47 (0.31) mg/cm(2) (P < 0.001). No differences in FRZB and SOST expression in femoral trabecular bone tissue were detected across genotypes. Conclusions: Polymorphisms in the 5' region of SOST gene are associated with BMD in postmenopausal women. They may contribute to explain, in part, the hereditary influence on bone mass.

TI Association of vitamin D status with knee pain and radiographic knee osteoarthritis
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE Knee osteoarthritis; Gene polymorphism; Epidemiology
ID d-receptor gene; quadriceps weakness; fat distribution; prostate-cancer; serum-levels; cohort; women; polymorphisms; osteoporosis; chondrocytes
AB Objective: The objective of the present study was to explore the association of serum vitamin D concentration and polymorphism in the vitamin D receptor (VDR), with knee pain and radiographic knee osteoarthritis (OA) among men and women

in a large population-based UK cohort study. Methods: Seven hundred and eighty-seven participants in the Hertfordshire Cohort Study (399 men, 388 women; mean age 65.6 +/- 2.7 years) underwent a questionnaire on knee pain and radiographic knee examination. This study examined the association of Fok1, Cdx2 and Apa1 polymorphism in the gene for the VDR and serum 25(OH)D concentration with knee pain and radiographic knee OA by a generalized estimating equations population averaged logistic regression analysis in the Hertfordshire Cohort Study. Results: There were no associations of Fok1, Cdx2 and Apa1 polymorphisms of the VDR with knee OA except for Aa for Apa1 compared with AA [Odds ratio (OR) 0.59, 95% confidence interval (CI) 0.36-0.95, P = 0.031]. While, If for Fok1 (OR 1.60, 95% CI 1.07-2.39, P = 0.022) and AA for Cdx2 polymorphism (OR 2.21, 95% CI 1.07-4.56, P = 0.032) was significantly associated with higher prevalence of knee pain compared with FF for Fok1 and GG for Cdx2, respectively. None of these are statistically significant after adjusting for the three polymorphisms tested. 25(OH)D level was not significantly associated with radiographic knee OA, while, low tertile of 25(OH)D level tended to be associated with knee pain compared with high tertile of 25(OH)D level. Conclusion: The present cross-sectional study using a large-scale population from the Hertfordshire Cohort study indicated that vitamin D may be associated with pain rather than radiographic change, but the evidence for an association between vitamin D genetic variation and pain in knee OA is very weak in the present study. Further replication of our results will be required to elucidate the association of vitamin D and knee OA. (C) 2011 Osteoarthritis Research Society International. Published by Elsevier Ltd. TI Outcomes of primary total knee arthroplasty: the impact of patient-relevant factors on self-reported function and quality of life
SO DISABILITY AND REHABILITATION
LA English
DT Article
DE Knee; osteoarthritis; arthroplasty; quality of life
ID total hip; replacement; osteoarthritis; instrument; surgery; ability; women; womac; men; 15d
AB Purpose. To identify factors associated with functional recovery and outcome 1 year after total knee arthroplasty (TKA). Methods. In the prospective follow-up study, all the patients (n = 75, aged 60-80 years) underwent primary TKA. Assessments were performed preoperatively and 12 months after surgery. The main measures were the Western Ontario and McMaster Universities OA Index (WOMAC) and the 15D. The clinical examination included analyses of comorbidity and a detailed knee examination. Age-standardised population values of the 15D and the Outcome Measures in Rheumatology-Osteoarthritis Research Society International (OMERACT-OARSI) criteria were used as indices of response. Results. Osteoporosis, pain, gender, age and preoperative function of the opposite knee accounted for 29.9% of the variance in the change in the WOMAC function score. A preoperative score of the 15D below the age-standardised population level, pain, higher age and pulmonary disease reduced the possibility to reach the HRQOL level of the general population. Osteoporosis decreased the likelihood of achieving

responder status according to the OMERACT-OARSI criteria. Conclusion. The baseline preoperative score of the 15D strongly associated with the achieved level of HRQOL after TKA. The findings of the present study highlight the multifactorial nature of health status in TKA.

TI Lessons Learned From the Development of Oral Calcitonin: The First Tablet Formulation of a Protein in Phase III Clinical Trials
SO JOURNAL OF CLINICAL PHARMACOLOGY
LA English
DT Review
DE Oral formulation; calcitonin; clinical trial; bone; cartilage
ID human growth-hormone; alpha-amino-acids; in-vivo activity; salmon-calcitonin; intestinal-absorption; bone turnover; cartilage degradation; alendronate treatment;

postmenopausal women; biochemical markers
AB Oral delivery of proteins has been hampered by an array of difficulties. However, promising novel oral delivery systems have been developed. 5-CNAC, formulated with the peptide salmon calcitonin, is in phase III clinical trials for the treatment of osteoporosis or osteoarthritis and could become the first marketed oral peptide. This article reviews key findings and implications from studies undertaken to date with this oral formulation. Findings include these: (1) the optimal calcitonin tablet dose is 0.8 mg; (2) 0.8 mg of oral calcitonin is rapidly absorbed, reaching maximum concentration in 15 to 30 minutes, and is eliminated from plasma with a short half-life-9 to 15 minutes; (3) the 0.8-mg tablet is more highly absorbed than the marketed nasal formulation, with biomarker levels indicating significantly greater efficacy in suppression of bone resorption; (4) drug absorption is increased with dosing at least 10 minutes before a meal rather than postprandially and also with 50 mL of water; (5) the optimal timing of dosing for osteoporosis therapy is in the evening to mitigate the circadian peak in bone resorption; and (6) the oral formulations of synthetic and recombinant calcitonin have similar pharmacokinetic and pharmacodynamic properties. These key findings may aid researchers in the development of other oral formulations.

DT Review
DE Hip osteoarthritis; Trabecular bone; Osteoblast; Gene; wingless MMTV integration (Wnt); TGF-beta signalling
ID osteoblast-like cells; articular-cartilage; growth-factor; trabecular bone; proximal femur; chemotactic response; subchondral bone; mineral density; cancellous bone; messenger-rna
AB The study of primary hip OA is continuing to redefine what was once considered a stagnant pathology as one of dynamic change, occurring over a long period of time involving the many composite tissue types of the joint including the bone. Examination of the inverse relationships evident between OA and fracture cohorts, including individuals with osteoporosis (OP), indicates an imbalance in formation and resorption in the bony component of both pathologies. This review contains an overview of primary OA followed by an assessment of differential gene expression and altered cellular characteristics identified in the bony compartments of primary hip OA, with a focus on the wingless mouse mammary tumor virus integration (Wnt) and TGF-beta signalling pathways. The studies reviewed here suggest that OA is a systemic disease involving the bone and validate the assessment of molecular changes to further investigate this complex disease.

TI The feelgood mutation in zebrafish dysregulates COPII-dependent secretion of select extracellular matrix proteins in skeletal morphogenesis
SO DISEASE MODELS & MECHANISMS

DT Article
ID traffic jams; gene; cartilage; membrane; melanosome; expression; binding;

sec23a; differentiation; osteoarthritis
AB Craniofacial and skeletal dysmorphologies account for the majority of birth defects. A number of the disease phenotypes have been attributed to abnormal synthesis, maintenance and composition of extracellular matrix (ECM), yet the molecular and cellular mechanisms causing these ECM defects remain poorly understood. The zebrafish feelgood mutant manifests a severely malformed head skeleton and shortened body length due to defects in the maturation stage of chondrocyte development. In vivo analyses reveal a backlog of type II and type IV collagens in rough endoplasmic reticulum (ER) similar to those found in coat protein II complex (COPII)-deficient cells. The feelgood mutation hinders collagen deposition in the ECM, but trafficking of small cargos and other large ECM proteins such as laminin to the extracellular space is unaffected. We demonstrate that the zebrafish feelgood mutation causes a single amino acid substitution within the DNA-binding domain of transcription factor Creb3l2. We show that Creb3l2 selectively regulates the expression of genes encoding distinct COPII proteins (sec23a, sec23b and sec24d) but find no evidence for its regulation of sec24c expression. Moreover, we did not detect activation of ER stress response genes despite intracellular accumulation of collagen and prominent skeletal defects. Promoter trans-activation assays show that the Creb3l2 feelgood variant is a hypomorphic allele that retains approximately 50% of its transcriptional activity. Transgenic rescue experiments of the feelgood phenotype restore craniofacial development, illustrating that a precise level of Creb3l2 transcriptional activity is essential for skeletogenesis. Our results indicate that Creb3l2 modulates the availability of COPII machinery in a tissue-and cargo-specific manner. These findings could lead to a better understanding of the etiology of human craniofacial and skeletal birth defects as well as adult-onset diseases that are linked to dysregulated ECM deposition, such as arthritis, fibrosis or osteoporosis.

TI Are temporomandibular joint disk displacements without reduction and osteoarthrosis important determinants of mandibular backward positioning and clockwise rotation?
SO ORAL SURGERY ORAL MEDICINE ORAL PATHOLOGY ORAL RADIOLOGY AND ENDODONTOLOGY
LA English
DT Article
ID lateral cephalometric analysis; resonance-imaging findings; internal derangement; asymptomatic volunteers; symptomatic patients; dental morphology; skeletal; women; prevalence; accuracy
AB Objective. The aim of this study was to estimate whether, in patients with temporomandibular joint (TMJ) arthralgia, the magnetic resonanace imaging (MRI) findings of bilateral TMJ disk displacement without reduction (DDwoR) and/or osteoarthrosis (OA) are determinants of mandibular backward positioning and/or clockwise rotation. Study design. Bilateral MRI of the TMJ was performed in 50 consecutive TMJ arthralgia patients to identify individuals with bilateral TMJ DDwoR and/or OA. Linear and angular cephalometric measurements were taken to apply selected criteria of mandibular backward positioning (FH to Na-Pog < 84 degrees, Na-A-Pog > 5 degrees, and SNB < 75 degrees) and clockwise rotation (FH to OP > 13 degrees, MP to FH > 35 degrees, and S-Gn to FH > 64 degrees).

Logistic regression analysis was used to estimate the association between selected MRI and cephalometric parameters. Results. In the age-and gender-adjusted analyses, significant increases in risk of mandibular backward positioning and clockwise rotation occurred with bilateral DDwoR and OA (9.5:1; P = .040). Conclusion. In patients with TMJ arthralgia the MRI parameters of DDwoR and OA seem to be important determinants of mandibular backward positioning and clockwise rotation. TI Bone mineral densities in patients with developmental dysplasia of the hip
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE Bone mineral density (BMD); Developmental dysplasia of the hip; Dual-energy X-ray absorptiometry (DXA); Osteoarthritis of the hip; Peripheral quantitative computed tomography (pQCT)
ID acetabular dysplasia; osteoarthritis; osteoporosis; age; association; joint
AB Bone mineral density (BMD) of the lumbar spine, ultradistal radius, and calcaneus were significantly higher in the developmental dysplasia of the hip (DDH) patients than in the controls. Therefore, our data suggest that BMDs at different skeletal sites are greater in patients with DDH than in healthy women. DDH has been acknowledged as a potentially preosteoarthritic condition that results in the development of hip osteoarthritis. Patients with DDH have been reported to have abnormal morphology of the pelvis and spine. Additional research, including that of bone quality, needs to be conducted to elucidate the pathogenetic mechanism of this disease. We therefore sought to determine whether BMD differs between healthy women and women with DDH. We measured BMD in 40 women who were scheduled to undergo pelvic osteotomy for DDH (average age, 45.3 years) and in 31 healthy women used as age-matched controls (average age, 47.5 years). BMDs of the lumbar spine, radius, and calcaneus were measured. BMDs of the lumbar spine, ultradistal radius, and calcaneus were significantly higher in the DDH patients than in the controls. Therefore, our data suggest that BMDs at different skeletal sites are greater in patients with DDH than in healthy women.

AB Genetic haemochromatosis is a hereditary disease characterised by tissue iron overload. In Caucasians it is most often due to homozygous C282Y HFE gene mutation, but other genes may be involved. Without treatment by venesections, patients can develop life-threatening visceral damage such as liver cirrhosis and carcinoma, diabetes or heart failure. This treatment has been remarkably successful in preventing these complications, but patients survive with other symptoms of the disease susceptible to impair, sometimes seriously, their quality of life. This is the case of arthropathy and osteoporosis complicating haemochromatosis. In this chapter, focus has been placed on the rheumatological complications of genetic haemochromatosis. DT Article
DE Osteoarthritis; IL-1; Interleukin; Genetic; Association; Polymorphism
ID genome-wide association; bone-mineral density; meulenbelt et-al; gene-cluster; population; susceptibility; heterogeneity; osteoporosis; chingford; article
AB Objective: To clarify the role of common genetic variation in the Interleukin-1 beta (IL1B) and Interleukin-1R antagonist (IL1RN) genes on risk of knee and hip osteoarthritis (OA) and severity of knee OA by means of large-scale meta-analyses. Methods: We searched PubMed for articles assessing the role of IL1B and IL1RN

polymorphisms/haplotypes on the risk of hip and/or knee OA. Novel data were included from eight unpublished studies. Meta-analyses were performed using fixed- and random-effects models with a total of 3595 hip OA and 5013 knee OA cases, and 6559 and 9132 controls respectively. The role of ILRN haplotypes on radiographic severity of knee OA was tested in 1918 cases with Kellgren-Lawrence (K/L) 1 or 2 compared to 199 cases with K/L 3 or 4. Results: The meta-analysis of six published studies retrieved from the literature search and eight unpublished studies showed no evidence of association between common genetic variation in the IL1B or IL1RN genes and risk of hip OA or knee OA (P > 0.05 for rs16944, rs1143634, rs419598 and haplotype C-G-C (rs1143634, rs16944 and rs419598) previously implicated in risk of hip OA). The C-T-A haplotype formed by rs419598, rs315952 and rs9005, previously implicated in radiographic severity of knee OA, was associated with reduced severity of knee OA (odds ratio (OR) = 0.71 95% CI 0.56-0.91; P = 0.006, I(2) = 74%), and achieved borderline statistical significance in a random-effects model (OR = 0.61 95% CI 0.35-1.06 P=0.08). Conclusion: Common genetic variation in the Interleukin-1 region is not associated with prevalence of hip or knee OA but our data suggest that IL1RN might have a role in severity of knee OA. TI Total knee arthroplasty in elderly osteoporotic patients
SO AGING CLINICAL AND EXPERIMENTAL RESEARCH
LA English
DT Article
DE Osteoporosis; TKA
ID follow-up; prosthesis; replacement; 5-year
AB Often in daily practice the choice of a prosthesis does not rise out of considerations about literature evidences, but it seems to be related to the personal experience and "surgical philosophy" of surgeon. The choice of prosthesis in total joint replacement is usually justified by biological and mechanical parameters that the surgeon considers before surgery. Osteoporosis is a disease characterized by a reduced bone mass and a degeneration of the bone tissue; it leads to bone fragility, so to a higher risk of fractures. Bone resistance, as all the changes in the microarchitecture of the bone tissue, is linked to bone density. Because of the bone density variation and/or the changes in the bone micro-architecture, as the bone strength decreases, the risk of fractures increases. It is important to understand all the factors taking part in both normal and abnormal bone remodelling. Osteoporosis does not imply a concrete bone loss, but a change of the bone micro-architecture itself. In these cases the choice of the patient and implant design are very important. In the period between March 1997-July 2002,

we implanted 100 consecutive TKA (total knee arthroplasty) Genesis II in 97 subjects (79 female); mean age was 77.1 years old. All TKA were performed because of primary osteoarthritis of the knee. All patients had complete pain relief and excellent knee score. The surgical and medical complications were in accordance with the published literature. We must consider all existing medical conditions, the state of the knee and local needs of the elderly patient. Thus, within these limits, the total knee can improve the ability of patients to manage the activities of daily living and improve their quality of life. TI DETERMINANTS OF MAJOR DIRECT MEDICAL COST CATEGORIES AMONG PATIENTS WITH OSTEOPOROSIS, OSTEOARTHRITIS, BACK PAIN OR FIBROMYALGIA UNDERGOING OUTPATIENT REHABILITATION
SO JOURNAL OF REHABILITATION MEDICINE
LA English
DT Article
DE healthcare costs; direct service costs; musculoskeletal diseases
ID health-care costs; quality-of-life; rheumatoid-arthritis; predictors; burden; prevalence; instrument; illness; disease; women
AB Objective: To identify determinants of direct medical costs among patients with osteoporosis, osteoarthritis, back pain or fibromyalgia. Design: Cross-sectional study. Participants: Convenience sample of 410 patients undergoing outpatient rehabilitation. Methods: Resource use was assessed with a self-report retrospective questionnaire, and direct medical costs were calculated considering outpatient physician services, non-physician health services, medication and inpatient treatment. Non-parametric bootstrap techniques with 1,000 replications were used to estimate means of costs and their 95% confidence intervals (CI). To identify determinants of costs, a generalized linear model with log link function and gamma distribution, as well as a multivariate logistic regression analysis, were performed. Results: Medical indication ($p < 0.001$), age ($p=0.034$) and the scales of the Short Form-36 (SF-36) role physical ($p<0.001$), physical functioning ($p=0.036$), social functioning ($p=0.047$) and vitality ($p=0.005$) were significant predictors of direct medical costs, whereas the medical indication fibromyalgia (odds ratio (OR)=5.74, 95% CI 2.051-16.066, $p=0.001$), the Short-Form 36 (SF-36) scale role physical (OR=0.988, 95% CI 0.980-0.996, $p = 0.002$) and comorbidity (OR=1.161,95% CI 1.043-1.292, $p = 0.006$) were statistically significant determinants of high direct medical costs beyond the median. Conclusion: Our work confirms

known predictors of direct medical costs and broadens the understanding of determinants of direct medical costs beyond the median.

DT Article
DE DKK-1; M-CSF; Osteoporosis RANKL/OPG; SOST; TGF beta
ID colony-stimulating factor; rheumatoid-arthritis; hypovitaminosis-d; mineral density; expression; metastases; dickkopf-1; mechanism; women
AB This study evaluates cytokines production in bone and bone marrow of patients with an osteoporotic fracture or with osteoarthritis by real time PCR, Western blot and immunohistochemistry. We demonstrate that the cytokine pattern is shifted towards osteoclast activation and osteoblast inhibition in patients with osteoporotic fractures. Introduction Fragility fractures are the resultant of low bone mass and poor bone architecture typical of osteoporosis. Cytokines involved in the control of bone cell maturation and function are produced by both bone itself and bone marrow cells, but the roles of these two sources in its control and the amounts they produce are not clear. This study compares their production in patients with an osteoporotic fracture and those with osteoarthritis. Methods We evaluated 52 femoral heads from women subjected to hip-joint replacement surgery for femoral neck fractures due to low-energy trauma (37), or for osteoarthritis (15). Total RNA was extracted from both bone and bone marrow, and quantitative PCR was used to identify the receptor activator of nuclear factor kB Ligand (RANKL), osteoprotegerin (OPG), macrophage colony stimulating factor (M-CSF), transforming growth factor beta (TGF beta), Dickoppf-1 (DKK-1) and sclerostin (SOST) expression. Immunohistochemistry and Western blot were performed in order to quantify and localize in bone and bone marrow the cytokines. Results We found an increase of RANKL/OPG ratio, M-CSF, SOST and

DKK-1 in fractured patients, whereas TGF beta was increased in osteoarthritic bone. Bone marrow produced greater amounts of RANKL, M-CSF and TGF beta compared to bone, whereas the production of DKK- 1 and SOST was higher in bone. Conclusions We show that bone marrow cells produced the greater amount of pro-osteoclastogenic cytokines, whereas bone cells produced higher amount of osteoblast inhibitors in patients with fragility fracture, thus the cytokine pattern is shifted towards osteoclast activation and osteoblast inhibition in these patients.

TI Distal Humerus Hemiarthroplasty of the Elbow for Comminuted Distal Humeral Fractures in the Elderly Patient
SO JOURNAL OF TRAUMA-INJURY INFECTION AND CRITICAL CARE
LA English
DT Article
DE Distal humerus fracture; Osteoporosis; Arthroplasty; Hemiarthroplasty
ID internal-fixation; open reduction; intraarticular fractures; rheumatoid-arthritis; complex fractures; arthroplasty; replacement; prosthesis; reconstruction

AB Background: The purpose of our study was to evaluate the objective and subjective outcomes, as well as the radiographic results after elbow hemiarthroplasty (HA) for comminuted distal humerus fractures in elderly patients. Methods: Ten female patients with a mean age of 75.2 years were treated with elbow HA either for osteoporotic, comminuted distal humerus fractures (n = 8) or for early failed osteosynthesis of distal humerus fractures (n = 2). The mean follow-up period was 12.1 months. All patients were examined and evaluated using the Mayo Elbow Performance Score and the Disabilities of the Arm, Shoulder, and Hand score. Radiographic postoperative outcomes were assessed performing anteroposterior and lateral radiographs of the injured elbow. Results: According to the Mayo Elbow Performance Score, nine patients achieved "good" to "excellent results" and only one patient revealed a "fair" clinical outcome. The mean Disabilities of the Arm, Shoulder, and Hand score was 11.5 (range, 0-30). The flexion of the affected elbow was 124.5 degrees (range, 95-140 degrees), the extension deficit was 17.5 degrees (range, 5-30 degrees), the pronation was 80.5 degrees (range, 60-90 degrees), and the supination was 79.5 degrees (range, 50-90 degrees). The following postoperative complications were seen: one triceps weakness, one transient ulnar nerve irritation, one superficial wound infection, and two heterotopic ossifications. None of the patients required explantation of the prosthesis. There was no evidence of loosening, radiolucency, or proximal bone resorption, whereas one patient developed progressive osteoarthritis of the proximal ulnar and radial articulation. Conclusions: Elderly patients treated with elbow HA revealed good to excellent short-term clinical outcomes. A high rate of complications occurred but most complications found were minor and reoperation rate was low. Our results must be regarded as a report on our first experience with HA. As cartilage wear is just a question of time especially in active patients, we cautiously recommend HA only for elderly and multimorbid low-demand patients.

TI Total hip arthroplasty and bone fragility
SO AGING CLINICAL AND EXPERIMENTAL RESEARCH
LA English
DT Article
DE Osteoporosis; stem fixation; total hip arthroplasty
AB The number of elderly people is steadily increasing: in the United States it will increase from 12.9% to 20% in 2030 with respect to the total population. Italy, with UK, Denmark and Sweden are the countries with the largest number of octogenarians (about 4% of the population) and it is estimated that this rate will increase by 300% over the next 50 years. The number of people affected by osteoarthritis will increase significantly and therefore the number of total hip arthroplasties will progressively increase. The success of an implant depends firstly by a flawless surgical technique, a correct and stable implant fixation and an optimal preoperative planning that should consider the bone quality of the patient, in order to choose a proper implant design. Different approaches could be followed to achieve adequate fixation: northern Europe surgeons prefer the cemented implant, instead American orthopedics generally use systems that allow a direct biological osteointegration. Elderly patients often present with multiple

local and general problems that could affect significantly the normal course of a prosthetic surgery procedure and its results: they have bone tissue changes that lead to increased bone fragility and, consequently, difficulties to obtain primary stability. Osteoporotic bone is characterized by reduction of bone mass, decrease of cancellous bone trabeculae and by increased porosity of cortical bone. The bone fragility implies a greater risk of iatrogenic intraoperative fractures. Furthermore, difficulties linked to bone stock deficiencies become even more significant in revision surgery, where cortical bone thinning is associated with enlargement of the isthmus thus making more difficult to obtain distal fixation of prosthetic stems. At the moment, the role played by the drugs used for the treatment of osteoporosis during implant osteointegration is still not clearly understood and is still under investigation. (Aging Clin Exp Res 2011; 23 (Suppl. to No. 2): 76-77) (C) 2011, Editrice Kurtis

TI Alendronate and raloxifene affect the osteoprotegerin/RANKL system in human osteoblast primary cultures from patients with osteoporosis and osteoarthritis
SO EUROPEAN JOURNAL OF PHARMACOLOGY
LA English
DT Article
DE Human osteoblast culture; Osteoporosis; Osteoprotegerin/RANKL; Alendronate and raloxifene
ID estrogen-receptor modulators; marrow stromal cells; in-vitro; zoledronic acid; bone-resorption; postmenopausal osteoporosis; bisphosphonate therapy; regulates osteoclast; gene-expression; mechanisms
AB The osteoprotegerin/RANKL system modulates bone remodelling. Alendronate and raloxifene are anti-resorptive drugs effective in osteoporotic disease. They reduce fracture risk, the activity of bone remodelling and increase bone mineral density. It is not known if they can exert a direct effect in osteoblasts via the osteoprotegerin/RANKL system. Our objective was to assess the effects of alendronate and raloxifene among osteoprotegerin production (ELISA), as well as osteoprotegerin and RANKL expression (RT-PCR), in primary cultures of human osteoblasts (hOB). We compared 17 osteoporotic patients with 16 patients affected by osteoarthritis in basal conditions and after incubation with alendronate (10(-6) M), raloxifene (10(-7) M) or 17-beta estradiol (10(-7) M) for 24 h. The statistical analysis was determined by ANOVA. Osteoprotegerin protein secretion in hOB cultures was higher in patients with osteoporosis than osteoarthritis. Osteoprotegerin secretion levels remained unchanged after each treatment. The

osteoporotic group was more sensitive to treatment. Both raloxifene (34%) and estradiol (37%) increased osteoprotegerin mRNA expression, and alendronate (118%) and raloxifene (61%) increased the mRNA expression of RANKL. The RANKL/osteoprotegerin mRNA ratio was higher in osteoporotic than osteoarthritic patients. In the osteoporotic group, the RANKL/osteoprotegerin mRNA ratio was significantly increased after treatment with alendronate (112%) and after treatment with raloxifene (60%). These results indicate a direct action of alendronate and raloxifene on hOB cultures from osteoporotic patients, and the cited drugs are able to modulate the osteoprotegerin/RANKL system. TI Primary total knee arthroplasty in the management of epiphyseal fracture around the knee
SO ORTHOPAEDICS & TRAUMATOLOGY-SURGERY & RESEARCH
LA English
DT Article
DE TKA; Fracture; Knee; Osteoporosis; Elderly
ID distal femoral fractures; total elbow arthroplasty; humeral fractures; tibial plateau; femur
AB Introduction: Over the past few years the use of arthroplasty was broadened to treating complex epiphyseal fractures at the shoulder and elbow joints. Similar trends to treat this type of fractures at the knee are less documented. Based on a multicenter retrospective series study, the aims of this work is to evaluate the short term clinical results of total knee prostheses in the management of comminuted

epiphyseal fractures around the knee, to identify the technical issues and fine tune the indications. Material and methods: Following the initiative of the French Hip and Knee Society (SFHG) and the Traumatology Study Group (GETRAUM), 26 charts from eight different centers in France were included in this multicenter retrospective series. Inclusion criteria were: primary total knee arthroplasty (TKA) in the management of complex articular fractures involving the proximal end of the tibia or distal end of the femur. Surgical features were identified and complications were analyzed. The assessment protocol at last follow-up was standardized and included patient demographic data, analysis of the Parker and IKS scores. Results: During the immediate postoperative period, six patients (23%) reported a general complication and four patients (15%) a local arthroplasty-related complication. At last follow-up (mean 16.2 months), the overall final Parker score was 6.3 (a mean decrease of 1.7) and the mean IKS knee score was 82 points for a mean function score of 54 points. Discussion: Primary TKA is a suitable management option for complex fractures in autonomous elderly patients suffering from knee osteoarthritis. The key technical details of this procedure should be respected and meticulously planned to achieve optimal results and limit the risk of complications. This risk in these acute complex fractures remains higher than after conventional TKA but comparable to that observed after TKA for post-traumatic arthritis. Level of evidence: IV; retrospective cohort study. (C) 2011 Published by Elsevier Masson SAS.

TI The role of synovial fluid markers of catabolism and anabolism in osteoarthritis, rheumatoid arthritis and asymptomatic organ donors
SO ARTHRITIS RESEARCH & THERAPY
LA English
DT Article
ID leukemia inhibitory factor; articular chondrocytes; osteogenic protein-1; il-6 receptor; serum; cytokines; interleukin-1; expression; knee; osteocalcin
AB Introduction: The purpose of this study was to correlate the level of anabolic and catabolic biomarkers in synovial fluid (SF) from patients with rheumatoid arthritis (RA), patients with osteoarthritis (OA) and asymptomatic organ donors. Methods: SF was collected from the knees of 45 OA, 22 RA patients and 20 asymptomatic organ donors. Eight biomarkers were selected and analyzed by using an enzyme-linked immunosorbent assay: interleukin (IL)-1, IL-6, IL-8 and IL-11; leukemia-inhibitory factor (LIF); cartilage oligomeric protein (COMP); osteocalcin; and osteogenic protein 1 (OP-1). Data are expressed as medians (interquartile ranges). The effects of sex and disease activity were assessed on the basis of the Western Ontario and McMaster Universities index score for patients with OA and on the basis of white blood cell count, erythrocyte sedimentation rate and C-reactive protein level for patients with RA. Results: The mean ages (+/- SD) of the patients were as follows: 53 +/- 9 years for patients with OA, 54 +/- 11 years for patients with RA and 52 +/- 7 years for asymptomatic organ donors. No effect of participants' sex was identified. In the SF of patients with RA, four of five cytokines were higher than those in the SF of patients with OA and those of asymptomatic organ donors. The most significant differences were found for IL-6 and IL-8, where IL-6 concentration in SF of patients with RA was almost threefold higher than that in patients with OA and fourfold higher than that in asymptomatic donor controls: 354.7 pg/ml (1,851.6) vs. 119.4 pg/ml (193.2) vs. 86.97 pg/ml (82.0) ($P < 0.05$ and $P < 0.05$, respectively). IL-8 concentrations were higher in SF of patients with RA than that in patients with OA as well as that in asymptomatic donor controls: 583.6 pg/ml (1,086.4) vs. 429 pg/ml (87.3) vs. 451 pg/ml (170.1) ($P < 0.05$ and $P < 0.05$, respectively). No differences were found for IL-11 in the SF of patients with RA and that of patients with OA, while a 1.4-fold difference was detected in the SF of patients with OA and that of asymptomatic donor controls: 296.2 pg/ml (257.2) vs. 211.6 pg/ml (40.8) ($P < 0.05$). IL-1 concentrations were the highest in the SF of RA patients (9.26 pg/ml (11.1)); in the SF of asymptomatic donors, it was significantly higher than that in patients with OA (9.083 pg/ml (1.6) vs. 7.76 pg/ml (2.6); P <

0.05). Conversely, asymptomatic donor control samples had the highest LIF concentrations: 228.5 pg/ml (131.6) vs. 128.4 pg/ml (222.7) in the SF of patients with RA vs. 107.5 pg/ml (136.9) in the SF of patients with OA ($P < 0.05$). OP-1 concentrations were twofold higher in the SF of patients with RA than those in patients with OA and threefold higher than those in asymptomatic donor control samples (167.1 ng/ml (194.8) vs. 81.79 ng/ml (116.0) vs. 54.49 ng/ml (29.3), respectively; $P < 0.05$). The differences in COMP and osteocalcin were indistinguishable between the groups, as were the differences between active and inactive OA and RA. Conclusions: Activation of selected biomarkers corresponds to the mechanisms that drive each disease. IL-11, LIF and OP-1 may be viewed as a cluster of biomarkers significant for OA; while profiling of IL-1, IL-6, IL-8, LIF and OP-1 may be more significant in RA. Larger, better-defined patient cohorts are necessary to develop a biomarker algorithm for prognostic use.

TI Improving subchondral bone integrity reduces progression of cartilage damage in experimental osteoarthritis preceded by osteoporosis
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE Osteoarthritis; Osteoporosis; Cartilage damage; Subchondral bone impairment; PTH [1-34]
ID cruciate ligament transection; kappa-b ligand; knee osteoarthritis; articular-cartilage; parathyroid-hormone; mineral density; treating osteoarthritis; antiinflammatory drugs; estrogen deficiency; receptor activator
AB Purpose: Impairment of subchondral bone density and quality aggravates cartilage damage in osteoarthritis (OA). Accordingly, we assessed whether improving microstructure and quality at subchondral bone by the bone-forming agent parathyroid hormone (PTH) [1-34] prevent cartilage damage progression in a rabbit model of OA preceded by osteoporosis (OP). Methods: OP was induced in 20 female rabbits. At week 7, these rabbits underwent knee surgery to induce OA and, at week 12, they started either saline vehicle (n = 10) or PTH (n = 10) for 10 weeks. Ten healthy animals were used as controls. At week 22, microstructure was assessed by micro-computed tomography and bone remodelling by protein expression of alkaline phosphatase (ALP), metalloproteinase-9 (MMP9), osteoprotegerin (OPG) and receptor activator of nuclear factor-kappa B ligand (RANKL) at subchondral bone. Cartilage damage was evaluated using Mankin score. Results: PTH reversed the decrease of bone area/tissue area, trabecular thickness, plate thickness, polar moment of inertia, ALP expression and OPG/RANKL ratio, as well as counteracted the increase of fractal dimension and MMP9 expression at subchondral bone of osteoarthritis preceded by osteoporosis (OPOA) rabbits compared to vehicle administration ($P < 0.05$). Likewise, PTH decreased cartilage damage severity in OPOA rabbits. Good correlations were observed between subchondral bone structure or remodelling parameters, and cartilage Mankin score. Conclusions: Improvement of microstructural and remodelling parameters at subchondral bone by PTH [1-34] contributed to prevent cartilage damage progression in rabbits with early OPOA. These findings support the role of subchondral bone in OA. Further studies are warranted to establish the place of bone-forming agents as potential treatment in OA. TI STAINING PLASTIC BLOCKS WITH TRIIODIDE TO IMAGE CELLS AND SOFT TISSUES IN BACKSCATTERED ELECTRON SEM OF SKELETAL AND DENTAL TISSUES
SO EUROPEAN CELLS & MATERIALS
LA English
DT Article
DE Bone; cartilage; osteoid; histopathology; implant interface
ID 3rd metacarpal bone; micro-ct; morphology; density
AB Backscattered electron scanning electron microscopy (BSE SEM) is an invaluable

method for studying the histology of the hard, mineralised components of poly-methyl methacrylate (PMMA) or other resin embedded skeletal and dental tissues. Intact tissues are studied in micro-milled or polished block faces with an electron-optical section thickness of the order of a half to one micron and with the area of the section as big as a whole - large or small - bone organ. However, BSE SEM does not give information concerning the distribution of uncalcified, 'soft', cellular and extracellular matrix components. This can be obtained by confocal microscopy of the same block and the two sorts of images merged but the blocks have to be studied in two microscope systems. The present work shows a new, simple and economic approach to visualising both components by using the triiodide ion in Lugol's iodine solution to stain the block surface prior to the application of any conductive coating - and the latter can be omitted if charging is suppressed by use of poor vacuum conditions in the SEM sample chamber. The method permits the use of archival tissue, and it will be valuable in studies of both normal growth and development and pathological changes in bones and joints, including osteoporosis and osteoarthritis, and tissue adaptation to implants.

TI Subsidence of collarless uncemented femoral stems in total hips replacements performed for trauma
SO INJURY-INTERNATIONAL JOURNAL OF THE CARE OF THE INJURED
LA English
DT Article
DE Total hip replacement; Fractured neck of femur; Femoral stem subsidence
ID displaced intracapsular fracture; internal-fixation; controlled-trial; neck fractures; subcapital fractures; titanium-alloy; long-term; arthroplasty; component; hemiarthroplasty
AB Introduction: Collarless, uncemented, femoral stems give excellent results in elective hip replacements but few studies look at outcomes in trauma patients. The presence of osteoporosis and subsequent widened femoral canal may compromise the mechanical stability of uncemented femoral stems resulting in early subsidence. The aim of this study was to assess whether early subsidence occurred when collarless uncemented stems were used to treat trauma patients. Materials and methods: Post-operative radiographs of 46 patients, mean age 71, who underwent an uncemented, collarless, total hip replacement for trauma, were reviewed. The difference in distance from the calcar to the prosthesis tip between the immediate post operative radiograph and the subsequent follow-up radiograph was calculated and adjusted for magnification. The same procedure was performed on 36 age-matched patients, who underwent elective hip replacements for osteoarthritis. Hospital notes were reviewed to assess for complications and DEXA scans reviewed for trauma patients where available. Results: The mean femoral stem subsidence was significantly greater in the fracture cohort than in elective patients ($p = 0.001$) with mean subsidence of 4.27 mm (range 0.02-22.05 mm) and 1.57 mm (range 0-5.5 mm), respectively. In the fracture cohort there were 4 revisions within 6 months of surgery, 1 for infection and 3 for femoral stem subsidence leading to dislocation. There were no revisions in the elective cohort. Discussion and conclusions: This study showed that collarless uncemented stems subsided significantly more when performed for fractures and had a high early revision rate. We recommend that uncemented collarless should not be used in trauma patients requiring total hip replacement. (c) 2011 Elsevier Ltd. All rights reserved.

robinow-syndrome; bone; ror2; wnt
AB There is a paucity of studies investigating association between ROR2 gene variants and osteoporosis and osteoarthritis-related phenotypes. The published literature suggests that osteoprotegerin (OPG) and receptor activator of nuclear factor-kB ligand (RANKL) are essential for bone metabolism and correlate with osteoarthritis manifestation and progression. The present study provides evidence of the significant association between ROR2 variants and the OPG/RANKL ratio in human plasma. The present results also suggest significant association between ROR2 polymorphisms and severity of radiographic hand osteoarthritis. Despite the importance of the ROR-2 in skeletal physiology, there is a paucity of studies investigating the potential association of ROR2 gene variants with phenotypes relevant to osteoporosis and osteoarthritis. On the other hand, there is a considerable body of literature suggesting that OPG and RANKL and their ratio (OPG/RANKL) are essential for regulating bone resorption. This is also correlated with osteoarthritis manifestation and progression. The present study therefore examines whether ROR2 polymorphisms may be associated with the OPG/RANKL ratio and hand osteoarthritis (HOA). The study was conducted in a family-based sample of 1,515 Caucasian individuals, assessed for radiographic hand osteoarthritis, using the Kellgren/Lawrence score. Of these, 865 individuals were genotyped for 19 SNPs, relatively equally covering the ROR2 locus, and their plasma levels of OPG and RANKL were assayed. The association between the selected SNPs and OPG, along with the OPG/RANKL ratio and HOA, was explored using the pedigree disequilibrium test. Of the total of 57 tests, 16 nominally significant results ($p < 0.05$) were obtained, which is considerably more than the three normally expected for type I error. The significant association signals for all three phenotypes were mapped to the intron 1 region. The most significant results were detected between OPG/RANKL and rs7048756 ($p < 0.0005$) and between adjacent rs4744107 and Kellgren/Lawrence score ($p = 0.006$). The present study provides evidence of the significant association between ROR2 variants and the OPG/RANKL ratio in human plasma and also suggests ROR2 association with HOA.

TI Systematic reviews of t'ai chi: an overview
SO BRITISH JOURNAL OF SPORTS MEDICINE
LA English
DT Review
ID improving aerobic capacity; older-adults; risk-factors; exercise; efficacy; disease; qigong; chuan; falls
AB Several systematic reviews (SRs) have assessed the effectiveness of t'ai chi for many conditions including hypertension, osteoarthritis and fall prevention; however, their conclusions have been contradictory. The aim of this overview was to critically evaluate the SRs of t'ai chi for any improvement of medical conditions or clinical symptoms. English, Chinese and Korean electronic databases were searched for relevant articles, and data were extracted according to predefined criteria, 35 SRs met our inclusion criteria. They were related to the following conditions: cancer, older people, Parkinson's disease, musculoskeletal pain, osteoarthritis, rheumatoid arthritis (RA), muscle strength and flexibility, improving aerobic capacity, cardiovascular disease and risk factors, lowering resting blood pressure, osteoporosis or bone mineral density, type 2 diabetes, psychological health, fall prevention and improving balance, and any chronic conditions. In several instances, the conclusions of these articles were contradictory. Relatively clear evidence emerged to suggest that t'ai chi is effective for fall prevention and improving psychological health and was associated with general health benefits for older people. However, t'ai chi seems to be ineffective for the symptomatic treatment of cancer and RA. In conclusion, many SRs of t'ai chi have recently been published; however, the evidence is convincingly positive only for fall prevention and for improvement of psychological health.

TI Differential Age-Related Bone Architecture Changes between Female and Male STR/Ort Mice
SO EXPERIMENTAL ANIMALS
LA English
DT Article
DE bone architecture; osteoarthritis; STR/Ort
ID tibial torsion; ovariectomized rats; mineral density; trabecular bone; osteoarthritis; knee; cartilage; metabolism; joint; osteoporosis
AB The incidence of spontaneous osteoarthritis (OA) in female STR/Ort mice is much lower than that observed in male STR/Ort mice; however, the reason for the differential incidence of OA between sexes has not been elucidated. Here, we investigated and compared age- and sex-related bone mineral density and architectural changes in male and female STR/Ort mice. Bone architecture and bone mineral density (BMD) of femurs were examined in 5-, 10-, 15-, 20-, and 35-week-old male and female STR/Ort mice by microscopic computed tomography (mu CT). Angular degrees of internal tibial torsion (ADITT) were also measured in mice at 5, 15, and 35 weeks of age. Earlier decreases of cancellous volume and BMD were found in male STR/Ort mice. Using mu CT, an age-related decline of bone marrow space in femoral diaphysis was observed in both males and females but was more dramatic in females. In addition, an earlier increase of ADITT was observed in male STR/Ort mice, suggesting that internal rotation of the tibia may contribute to OA. Age- and sex-related bone architectural changes clearly differ between male and female STR/Ort mice. These differences in bone structure, particularly ADITT, may explain the differential incidence of OA in STR/Ort mice.

TI Voice Symptoms in Patients with Autoimmune Disease: A Cross-sectional Epidemiological Study
SO OTOLARYNGOLOGY-HEAD AND NECK SURGERY
LA English
DT Article
DE voice disorders; autoimmune diseases; voice quality; laryngopharyngeal reflux; disease-modifying antirheumatic drugs; depression; xerostomia; cross-sectional survey
ID systemic-lupus-erythematosus; quality-of-life; rheumatoid-arthritis; risk-factors; prevalence; involvement; association; disorders; dysphonia
AB Objective. To assess the prevalence and severity of voice symptoms in individuals with a diagnosis of autoimmune disease. Study Design. Cross-sectional survey. Setting. Study participants were recruited from a rheumatology tertiary referral clinic at Norfolk and Norwich University Hospital. Subjects and Methods. A cross-sectional questionnaire analyzing 109 patients with autoimmune disease (rheumatoid arthritis, seronegative spondyloarthritis, connective tissue disease) and a control group of 41 patients with non-autoimmune disease (osteoarthritis/osteoporosis). Main outcome measures were the Voice Handicap Index-10 (VHI-10), xerostomia scale, acid reflux inquiry, and anxiety/depression scale. Results. Patients with autoimmune disease were more likely to experience voice symptoms as assessed by the VHI-10 questionnaire (P = .0035). Subgroup analysis showed autoimmune patients were more likely to report voice symptoms regardless of whether they were on a disease-modifying antirheumatic drug (DMARD; P = .0010) or non-DMARD (P = .017), suggesting autoimmune disease may be an independent risk factor from pharmacotherapy. Xerostomia was more common in an autoimmune population compared with the control group (P = .02). A positive correlation between xerostomia and VHI-10 scores was found for the DMARD group (Spearman rank coefficient = 0.49, P < .001). No significant difference in acid reflux inquiry (P = .44) or the anxiety/depression scale (P = .36) was found when comparing the autoimmune and control groups. Conclusion. Patients with autoimmune disease have increased likelihood of voice symptoms when compared with a control population with non-autoimmune disease. Further prospective studies to elucidate the cause of voice disorder would be valuable.

TI Impact of treatments for osteoporosis on cartilage biomarkers in humans
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE Biomarkers; Bisphosphonate; Bone; Calcitonin; Estrogens; Osteoarthritis; Selective estrogen receptor modulators; Strontium ranelate
ID knee osteoarthritis; salmon-calcitonin; postmenopausal women; subchondral bone; ii degradation; ctx-ii; estrogen; chondrocytes; symptoms; turnover
AB The rationale to target bone for treating osteoarthritis (OA) relies on the known cross-talk between subchondral bone and cartilage and the demonstration that subchondral bone resorption occurs at an early stage in the development of OA. Therefore, the possible OA disease-modifying effects of bone antiresorptive agents are of interest. This paper aims to review the published data on the effect of estrogens, selective estrogen receptor modulators, calcitonin, strontium ranelate, and bisphosphonates on cartilage biomarkers levels used as surrogate endpoints in clinical trials. Except for findings for tibolone, most observations indicated that these antiresorptive therapies decreased the urinary levels of CTX-II, a biomarker of type II collagen degradation. These data, which should be cautiously interpreted,

suggest that these drugs might favorably affect cartilage homeostasis.

TI Social Determinants of Bone Densitometry Uptake for Osteoporosis Risk in Patients Aged 50 Yr and Older: A Systematic Review
SO JOURNAL OF CLINICAL DENSITOMETRY
LA English
DT Review
DE Dual-energy X-ray absorptiometry; osteoporosis; social determinants; systematic review; utilization
ID socioeconomic-status; fracture; men; density; care; hip; australia; osteoarthritis; association; management
AB The World Health Organization identifies that osteoporosis is one of the leading health problems in the Western world. An increased risk of fragility fracture is observed in more socially disadvantaged individuals in most Western countries. Dual-energy X-ray absorptiometry (DXA) is currently the procedure of choice to diagnose osteoporosis and assess fracture risk. We systematically reviewed the literature regarding social determinants of DXA utilization for osteoporosis detection in patients aged 50 yr and older using a computer-aided search of MEDLINE, EMBASE, CINAHL, and PsychINFO from January 1994 to December 2010. Five cross-sectional studies, incorporating 16 separate analyses, were identified for inclusion in this review. The best evidence analysis identified limited evidence for a positive association between either income or education with DXA utilization; furthermore, the best evidence analysis found no evidence for an association between either marital status or working status and DXA utilization. Further research is required to identify whether a relationship exists and elucidate reasons for disparities in DXA utilization between different social groups, such as choice and referral processes, as a necessary precursor in identifying modifiable determinants and appropriate strategies to promote preventive screening to identify fracture risk.

TI Medial versus lateral condyle bone mineral density ratios in a cross-sectional study: A potential marker for medial knee osteoarthritis severity
SO ARTHRITIS CARE & RESEARCH
LA English
DT Article
ID x-ray absorptiometry; subchondral bone; proximal tibia; static alignment; cartilage damage; osteo-arthritis; lumbar spine; pain; women; osteoporosis
AB Objective To assess the association of bone mineral density (BMD) of the

femoral and tibial condyles with knee pain and disease severity in women with symptomatic medial knee osteoarthritis (OA). Methods We enrolled 192 women (ages 4190 years) between April 2007 and March 2011. The subjects were divided into 2 groups according to joint space narrowing (JSN) on weight-bearing radiographs. BMD of the lumbar spine, proximal femur, and knee condyles was measured. Medial and lateral condyle BMDs of the femur and tibia as well as the medial versus lateral condyle BMD ratios were measured. Results Mean medial condyle BMDs, medial versus lateral condyle BMD ratios, and visual analog scale (VAS) pain in both the femur and the tibia were higher in the obliteration group compared with the narrowing group ($P < 0.001$ for all). A significant positive correlation was observed between the femoral and tibial condyles in the following parameters: medial condyle BMDs, lateral condyle BMDs, and medial versus lateral condyle BMD ratios ($r = 0.7910.844$). In both the femur and the tibia, medial versus lateral condyle BMD ratios had significant positive correlations with femorotibial angle, medial osteophytes, lateral osteophytes, medial JSN, and VAS pain, and had significant negative correlations with the Knee Society pain and function scores. Conclusion Although this study was a cross-sectional study, the femoral and tibial medial versus lateral condyle BMD ratios increased with more severe knee pain and might be a potential marker for monitoring disease severity in women with symptomatic medial knee OA.

TI Bone mineral density is not related to heterotopic ossification after total hip arthroplasty
SO INTERNATIONAL ORTHOPAEDICS
LA English

DT Article
ID ectopic ossification; osteoarthritis; osteoporosis; replacement; women; risk
AB Heterotopic ossification (HO) after total hip arthroplasty (THA) is a frequent complication that compromises the success of this procedure; however, its precise pathogenesis is unknown. Patient-related risk factors have previously been investigated to predict patients likely to have HO. In this study, we compared bone mineral density (BMD) between patients with and without HO after THA. We measured BMD of the lumbar spine, radius, and calcaneus using dual-energy X-ray absorptiometry in 98 females who were scheduled to undergo THA. Radiographs were graded for the presence of HO according to the criteria of Brooker at a minimum follow-up of two years following THA. BMD were compared between those with HO and those without. In total, HO was observed in 20 of 98 hips. There were no significant differences in age, height, weight, body mass index, and pre-operative total hip score between the HO and non-HO groups. No significant difference was observed in BMD of the lumbar spine, distal radius, mid-radius, and calcaneus between the two groups. Our findings suggest that generalized BMD is not related to the occurrence of HO after THA in women.

TI Assessment of bone mineral density and radiographic texture analysis at the tibial subchondral bone
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE BMD; Osteoarthritis; Subchondral bone
ID fractal signature analysis; knee osteoarthritis; trabecular bone; osteoporosis; cartilage; compartment; incident; marker; damage; oa
AB Microstructural changes of subchondral bone constitute one of the figures characterising osteoarthritis on a structural level. Subchondral bonemineral density may reflect the complex relationship between bone and cartilage submitted to movement and loading. In this review, the authors discussed the interest of tibial subchondral bone mineral density assessment in the perspective of its diagnostic, etiopathogenic and prognostic value in osteoarthritis. In addition, the sources of variability linked to the measurement of tibial subchondral bone mineral density are precised. Trabecular bone structure characterisation by radiographic texture analyses may also represent a new promising tool to evaluate the microarchitectural changes that occur with initiation and progression of osteoarthritis. In this paper, the authors also highlighted the interest of different radiographic texture analyses and their clinical relevance in the field of osteoarthritis.

TI Prevalence of Reported Knee Pain Over Twelve Years in a Community-Based Cohort
SO ARTHRITIS AND RHEUMATISM
LA English
DT Article
ID general-population; osteoarthritis; adults; impact; hip; epidemiology; experience; disability; chingford; women
AB Objective. To describe the temporal patterns of knee pain in a community-based cohort over 12 years. Methods. Data on self-reported knee pain at 4 time points over 12 years were analyzed in participants from the Chingford Women's Study of osteoarthritis (OA) and osteoporosis. Pain status was defined as any pain in the preceding month and pain on most days in the preceding month. This status was used to classify participants according to pain patterns of asymptomatic, persistent, incident, or intermittent pain. Multinomial logistic regression was used to identify baseline predictors for each pain pattern. Results. Among the 489 women with complete followup data, the median age at baseline was 52 years (interquartile range [IQR] 48-58 years), the median body mass index (BMI) was 24.39 kg/m(2) (IQR 22.46-27.20), and 11.7% of the women had a Kellgren/Lawrence radiographic OA severity grade of >= 2 in at least one knee. Among subjects reporting any pain in the preceding month versus those reporting pain on most days in the preceding month, 9% versus 2% had persistent pain, 24% versus 16% had incident pain, and 29% versus 18% had intermittent pain. A higher BMI was predictive of persistent pain (odds ratio [OR] 1.14, 95% confidence interval [95% CI] 1.04-1.25) and incident pain (OR 1.10, 95% CI 1.02-1.18). The presence of radiographic knee OA was predictive of persistent pain (OR 3.70, 95% CI 1.34-10.28; P = 0.012), and reported knee injury was predictive of both persistent pain (OR 4.13, 95% CI 1.34-12.66; P = 0.013) and intermittent pain (OR 4.25, 95% CI 1.81-9.98; P = 0.001). Conclusion. Significant variability in the temporal fluctuation of self-reported knee pain was seen in this community-based prospective study over a period of 12 years, with few women consistently reporting knee pain at each time point. Distinct baseline predictors for each pain pattern were identified and may explain the observed heterogeneity of self-reported knee pain when pain

status is measured at only one time point.

TI Accumulation of metabolic risk factors such as overweight, hypertension, dyslipidaemia, and impaired glucose tolerance raises the risk of occurrence and progression of knee osteoarthritis: a 3-year follow-up of the ROAD study
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE Knee osteoarthritis; Incidence; Progression; Metabolic syndrome; Population-based cohort study
ID body-mass index; hip osteoarthritis; obesity; association; population; women; prevalence; management
AB Objective: To clarify the association between the occurrence and progression of knee osteoarthritis (KOA) with components of metabolic syndrome (MS), including overweight (OW), hypertension (HT), dyslipidaemia (DL), and impaired glucose tolerance (IGT), in a general population. Design: From the large-scale population-based cohort study entitled Research on Osteoarthritis/Osteoporosis Against Disability (ROAD) initiated in 2005, 1,690 participants (596 men, 1,094 women) residing in mountainous and coastal areas were enrolled. Of these, 1,384 individuals (81.9%; 466 men, 918 women) completed the second survey, including knee radiography, 3 years later. KOA was defined as Kellgren-Lawrence (KL) grade >= 2 using paired X-ray films. Based on changes in KL grades between the baseline and second surveys, cumulative incidence and progression of KOA were determined. OW, HT, DL, and IGT at baseline were assessed using standard criteria. Results: The cumulative incidence of KOA among 1,384 completers over 3 years was 3.3%/year, and progression in KL grades for either knee, 8.0%/year. Logistic regression analyses after adjusting for potential risk factors revealed that the odds ratio (OR) for the occurrence of KOA significantly increased according to the number of MS components present (OR vs no component: one component. 2.33; two components, 2.82; >= three components, 9.83). Similarly, progression of KOA significantly increased according to the number of MS components present (OR vs no component: one component, 1.38; two components, 2.29; >= three components: 2.80). Conclusion: Accumulation of MS components is significantly related to both occurrence and progression of KOA. MS prevention may be useful in reducing future KOA risk. TI Factors associated with treatment of women with osteoporosis or osteopenia from a national survey
SO BMC WOMENS HEALTH
LA English
DT Article
ID fracture risk-assessment; bone-density; prevention; care; osteoarthritis; epidemiology; disparity; guidelines; diagnosis; frax(tm)
AB Background: Health outcomes could be improved if women at high risk for osteoporotic fracture were matched to effective treatment. This study determined the extent to which treatment for osteoporosis/osteopenia corresponded to the presence of specific risk factors for osteoporotic fracture. Methods: This retrospective analysis of the United States 2007 National Health and Wellness Survey included women age >= 40 years who reported having a diagnosis of osteoporosis (69% of 3276) or osteopenia (31% of 3276). Patients were stratified by

whether they were or were not taking prescription treatment for osteoporosis/osteopenia. Using 34 patient characteristics as covariates, logistic regression was used to determine factors associated with treatment. Results: Current prescription treatment was reported by 1800 of 3276 (54.9%) women with osteoporosis/osteopenia. The following factors were associated with receiving prescription treatment: patient-reported diagnosis of osteoporosis (versus osteopenia); previous bone mineral density test; >= 2 fractures since age 50; older age; lower body mass index; better physical functioning; postmenopausal status; family history of osteoporosis; fewer comorbidities; prescription insurance coverage; higher total prescription count; higher ratio of prescription costs to monthly income; higher income; single status; previous visit to a rheumatologist or gynecologist; and 1 or 2 outpatient visits to healthcare provider (vs. none) in the prior 6 months. Glucocorticoid, tobacco, and daily alcohol use were risk factors for fracture that were not associated with treatment. Conclusions: There is a mismatch between those women who could benefit from treatment for osteoporosis and those who are actually treated. For example, self-reported use of glucocorticoids, tobacco, and alcohol were not associated with prescription treatment of osteoporosis. Other clinical and socioeconomic factors were associated with treatment (e. g. prescription drug coverage and higher income) or not (e. g. comorbid osteoarthritis and anxiety) and could be opportunities to improve care.

TI Interleukin-1α gene variants influence bone mineral density and the risk of osteoporotic hip fractures in elderly Slovenian people
SO CLINICAL CHEMISTRY AND LABORATORY MEDICINE
LA English
DT Article
DE bone; IL-1 alpha; inflammation; osteoporosis; rs17561; rs2071375
ID postmenopausal osteoporosis; cytokine production; rheumatoid-arthritis; blood cells; expression; polymorphisms; osteoarthritis; association; women
AB Background: Osteoporosis is a skeletal disorder, characterized by low bone mass and microarchitectural deterioration of bone tissue, leading to increased risk of fracture. Recently, the role of age-related pro-inflammatory cytokines, such as interleukin (IL)-1 alpha, in stimulating bone resorption has been suggested. As

osteoporosis has a strong genetic background, the aim of our study was to evaluate the association of two IL-1 alpha gene single nucleotide polymorphisms (SNPs) rs2071375 (+12534G>A) and rs17651 (+4845G>T) with osteoporotic phenotypes as well as to find the association with IL-1 alpha gene expression in human bone tissue. Methods: Gcnotyping was performed in 671 Slovenian participants, 125 elderly men, 490 post- and 56 premenopausal women. Bone mineral density (BMD) at the lumbar spine, femoral neck and total hip were measured. Biochemical markers of bone turnover were measured in women. Results: Significant association of GG/TA haplotype with higher femoral neck and total hip BMD in elderly men and women was shown (p=0.009 and 0.030, respectively). In men, the association of the GG/GG haplotype with higher femoral neck BMD was of limited statistical significance (p=0.050). In women, significant association of studied genetic variants with serum C-terminal crosslinking telopeptides of type I collagen and bone alkaline phosphatase were found (p=0.033 and 0.029, respectively). No influence on IL-1 alpha expression was found. Finally, significantly lower odds ratio for hip fracture associated with the presence of TA haplotype was found (p=0.026). Conclusions: Our results of the association of IL-1 alpha gene single nucleotide polymorphisms (SNPs) rs2071375 (+12534G>A) and rs17651 (+4845G>T) with osteoporotic features indicate its role in pathogenesis of osteoporosis. However, these findings need further functional and clinical confirmation.

TI Parathyroid Hormone-Related Protein: An Update
SO JOURNAL OF CLINICAL ENDOCRINOLOGY & METABOLISM
LA English
DT Article
ID pth-related-protein; nuclear-localization sequence; embryonic mammary-gland; beta-cell proliferation; breast-cancer; growth-plate; smooth-muscle; humoral hypercalcemia; pth/pthrp receptor; skeletal development
AB PTHrP was identified as a cause of hypercalcemia in cancer patients 25 yr ago. In the intervening years, we have learned that PTHrP and PTH are encoded by related genes that are part of a larger "PTH gene family." This evolutionary relationship permits them to bind to the same type 1 PTH/PTHrP receptor, which explains why humoral hypercalcemia of malignancy resembles hyperparathyroidism. This review will outline basic facts about PTHrP biology and its normal physiological functions, with an emphasis on new findings of the past 5-10 yr. The medical and research communities first became aware of PTHrP because of its involvement in a common paraneoplastic syndrome. Now, research into the basic biology of PTHrP has suggested previously unrecognized connections to a variety of disease states such as osteoporosis, osteoarthritis, and breast cancer and has highlighted how PTHrP itself might be used in therapy for osteoporosis and diabetes. Therefore, the story of this remarkable protein is a paradigm for translational research, havinggone from bedside to bench and now back to bedside. (J Clin Endocrinol Metab 97: 2947-2956, 2012)

TI Increased proportion of hypermineralized osteocyte lacunae in osteoporotic and osteoarthritic human trabecular bone: Implications for bone remodeling
SO BONE
LA English
DT Article
DE Hypermineralized osteocyte lacunae; Trabecular bone; Osteoporosis; Osteoarthritis; Quantitative backscattered electron imaging; Energy dispersive X-ray spectrometry
ID femoral-neck; mineralization density; cancellous bone; solute transport; matrix; expression; osteoblast; fracture; mlo-a5
AB Hypermineralized osteocyte lacunae (micropetrosis) have received little research attention. While they are a known aspect of the aging human skeleton, no data are available for pathological bone. In this study, intertrochanteric trabecular bone cores were obtained from patients at surgery for osteoporotic (OP) femoral neck fracture (10F, 4M, 65-94 years), for hip osteoarthritis (OA; 7F, 8M, 62-87 years), and femora at autopsy (CTL; 5F, 11M, 60-84 years). Vertebral trabecular bone cores

were also obtained from the vertebra of autopsy cases (CVB; 3F, 6M, 53-83 years). Specimens were resin-embedded, polished, and carbon coated for quantitative backscattered electron imaging (qBEI), energy dispersive X-ray (EDX) spectrometry, and imaging analysis. Bone mineralization (Wt %Ca) was not different between OP. OA, and CTL; but was greater in femoral CTL than in CVB. The percent of hypermineralized osteocyte lacunae relative to the total number (HL/TL) was greater in OP and OA than in CTL However, relative to bone mineral area, OP was characterised by increased hypermineralized osteocyte lacunar number density (Hd.Lc.Dn), whereas OA was characterised by decreased osteocyte lacunar number density (Lc.Dn) and total osteocyte lacunar number density (Tt.Lc.Dn). Lc.Dn was higher in CVB than in femoral CTL. The calcium-phosphorus ratio (R-Ca/P) was not different between hypermineralized osteocyte lacunae and bone matrix in each group. In addition, this study focused on the phenomenon of osteocyte lacunae hypermineralization using qBEI. Seven morphological types of osteocyte lacunae hypermineralization were described according to the presence of one or several hypermineralized spherites, associated or not with a hypermineralized lacunar ring. This study has described, for the first time, the morphology of hypermineralized osteocyte lacunae in OP and OA human bone. Further studies are suggested to investigate the functional influence of hypermineralized osteocyte lacunae on bone remodeling and bone biomechanical properties. (C) 2011 Elsevier Inc. TI Incidence and risk factors for radiographic lumbar spondylosis and lower back pain in japanese men and women: the ROAD study
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE Spondyloarthritis; Epidemiology; Lower back pain
ID quality-of-life; 5-year follow-up; disc degeneration; osteoarthritis; determinants; progression; population; epidemiology; disability; spine
AB Objective: To determine the incidence of radiographic lumbar spondylosis (LS)and lower back pain, and their risk factors in Japan using a large-scale population from the nationwide cohort Research on Osteoarthritis/osteoporosis Against Disability (ROAD) Study. Methods: Participants in the ROAD study who had been recruited between 2005 and 2007 were followed up with lumbar spine radiography for 3 years. A total of 2,282 paired radiographs (75% of the original sample) were scored using Kellgren and Lawrence (KL) grades, and the incidence and progression rate of radiographic LS was analyzed. The incidence of lower back pain was also examined. In addition, associations between risk factors and incident and progressive radiographic LS as well as incident lower back pain were tested. Results: Given a 3.3-year follow-up, the incidence of KL >= 2 radiographic LS was 50.0% and 34.4% (15.3% and 10.5% per year), while that of KL >= 3 LS was 15.3% and 23.7% (4.6% and 7.2% per year) in men and women, respectively. The progression rate of LS was 20.5% and 27.4% (6.2% and 8.3% per year) in men and in women, respectively. In addition, the incidence of lower back pain was 28.3% and 31.2% (8.6% and 9.5% per year) in men and women. Lower back pain was not significantly associated with incident radiographic LS, while a more severe KL grade at baseline was associated with incident lower back pain. Conclusion: The present longitudinal study revealed a high incidence of radiographic LS in Japan. (C) 2012 Osteoarthritis Research Society International. Published by Elsevier Ltd. TI Caffeine-induced fetal rat over-exposure to maternal glucocorticoid and histone methylation of liver IGF-1 might cause skeletal growth retardation
SO TOXICOLOGY LETTERS
LA English
DT Article

ID longitudinal bone-growth; rna-polymerase-ii; chondrocyte differentiation; corticosterone levels; birth-weight; intrauterine; pregnancy; plate; expression; receptor
AB Several epidemiological investigations, including previous work by our laboratory, indicate that maternal caffeine consumption is associated with intrauterine growth retardation and impaired fetal length growth. Skeletal development is critical for length growth. In the present study, our goals were to determine the effects of prenatal caffeine exposures on fetal skeletal growth and to investigate the mechanisms associated with such effects. Pregnant Wistar rats were injected intragastrically with 120 mg/kg of caffeine intragastrically each day from gestational days 11-20. Maternal prenatal caffeine exposure was associated with decreased fetal femur lengths and inhibited of synthesis of extracellular matrices in fetal growth plates Moreover, caffeine exposure significantly increased the levels of fetal blood corticosterone and decreased IGF-1mRNA expression levels in the liver and growth plate. The expression levels of IGF1 signaling pathway components (IGF-1R, IRS-1, AKT1/2 and Col2A1) were also reduced. In addition, the results of chromatin immunoprecipitation assays indicated that caffeine exposure down-regulated histone methylation of fetal IGF-1 in the liver. These results suggest that prenatal caffeine exposure may inhibit fetal skeletal growth through a mechanism that is associated with increased fetal exposure to maternal glucocorticoids and results in lower IGF-1 signaling pathway activity. Taken together, these results raise important concerns regarding the skeletal growth toxicity of caffeine and potentially indicate the intrauterine origins of adult

osteoporosis and osteoarthritis. (C) 2012 Elsevier Ireland Ltd. All rights reserved.

TI Musculoskeletal Pain in Elderly Patients with Osteoporosis: A Multicenter Study
SO TURKIYE FIZIKSEL TIP VE REHABILITASYON DERGISI-TURKISH JOURNAL OF PHYSICAL MEDICINE AND REHABILITATION
LA English
DT Article
DE Osteoporosis; musculoskeletal diseases; pain; elderly
ID prevalence; disorders; epidemiology; fracture; burden
AB Objective: The aim of this study was to identify the ones with osteoporosis (OP) in elderly patients presenting with musculoskeletal complaints and to evaluate the distribution of region of pain and the medications used for the musculoskeletal disease(s) in these patients. Materials and Methods: 1141 elderly patients who were consecutively admitted to the outpatient clinics in nine different provinces were screened for the diagnosis of OR Age, gender, complaints, diagnosis and current medications related to musculoskeletal system disorder(s) were recorded. Results: 382 elderly (341 female, 41 male) with a mean age of 71.9 +/- 5.3 years had the diagnosis of OR Low (54.5%) and upper back (39.6%) pain were the most common complaints in both sexes. These were followed by knee, hip, cervical and shoulder pain, respectively. Osteoarthritis (36%), lumbar (21%) and cervical spondylosis/stenosis (10%) were the most common musculoskeletal diseases accompanying OR The mean number of drugs used was 3.0 +/- 1.2. The most commonly prescribed anti-osteoporotic agents were bisphosphonates (59%). For the musculoskeletal pain, non-steroidal anti-inflammatory drugs (systemic and/or topical) were used in 46.6% and paracetamol in 24.6% of patients. Conclusion: It is crucial to perform a thorough physical examination to reveal the underlying cause of back pain in elderly osteoporotic patients. Besides, in order to minimize polypharmacy, it should be kept in mind that non-pharmacological approaches can

be used for the management of musculoskeletal diseases. Turk J Phys Med Rehab 2012;58:263-6.

TI Osteoporotic changes of subchondral trabecular bone in osteoarthritis of the knee: a 3-T MRI study
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE Magnetic resonance imaging (MRI); Osteoarthritis of the knee; Osteoporosis; Subchondral bone; Trabecular structure
ID cruciate ligament transection; articular-cartilage; in-vivo; distal radius; microstructure; quantification; degradation; progression; tomography; lesions
AB Subchondral trabecular bone structure was analyzed in knee osteoarthritis (OA) patients using 3-T MRI to investigate structural features of subchondral trabecular bone of knee OA. With OA progression, osteoporotic changes were observed in the lateral joint, showing a higher correlation than sclerotic changes in the medial joint. To investigate structural features of subchondral trabecular bone of knee osteoarthritis (OA). Sixty knees with KL grade 0-4 (all female) were examined. Fast imaging employing steady-state acquisition-cycled phases (FIESTA-c) and FatSat Spoiled gradient recalled acquisition in the steady state (SPGR) images were acquired by 3-T MRI. At four sites (the medial femur, medial tibia, lateral femur, and lateral tibia), subchondral trabecular bone structure was analyzed by FIESTA-c imaging, cartilage area was measured by SPGR imaging, and their correlation was analyzed. In addition, the subjects were classified into four groups from the cartilage area measured by SPGR imaging, and subchondral trabecular bone structure in each group was compared. As cartilage area decreased in the medial joint, bone volume fraction and trabecular thickness in the medial tibia increased, and bone volume fraction, trabecular thickness, number, and connectivity in the lateral femur and lateral tibia decreased (r a parts per thousand yenaEuro parts per thousand 0.4 or a parts per thousand currency signa'0.4, p a parts per thousand currency signaEuro parts per thousand 0.001). Compared to medially, the changes laterally showed a higher correlation. When the medial-lateral ratio of trabecular thickness in the tibia was determined, it had the highest correlation coefficient ($r=-0.7$, $p < 0.001$). These changes were not significantly detected in the early stage. To more sensitively detect OA changes in subchondral trabecular bone structure, a focus on osteoporotic changes in the lateral joint and the medial-lateral ratio would be useful. Detectability of early OA remains unknown, but based on a strong correlation with the degree of OA progression, trabecular structural analysis of subchondral bone may be a useful parameter to evaluate OA severity and

evaluate treatment.

TI Implementation of the simplified stochastic model of ageing for longitudinal osteoarthritis data assessment
SO ANNALS OF HUMAN BIOLOGY
LA English
DT Article
DE Knee osteoarthritis; Kellgren/Lawrence; age-dependent degeneration; maximum likelihood; Monte-Carlo simulation
ID radiographic knee osteoarthritis; anterior cruciate ligament; risk-factors; age; cohort; time; mortality; meniscus; weight; period
AB Background: Occurrence and progression of age-related irreversible degradations of skeletal joints, osteoarthritis (OA), has a stochastic nature. However, it is commonly described using polynomial models, which may not necessarily be optimal. Aim: To implement a stochastic model of gradual accumulation of the distinct changes for estimating individuals' putative age at onset and risk of the process advancing in the OA longitudinal data. Subjects and methods: The model was formulated as a discrete Markov process. It was applied to radiographic knee osteoarthritis (RKOA) data: 243 Kellgren-Lawrence (K/L) and 207 osteophytes (OP) score histories from the 15-year follow-up Chingford study. Results: The model performance was examined in Monte-Carlo simulations. The mean age at onset of knee osteoarthritis was: 53.04 and 53.23 years and the average annual risk of one K/L and one OP grade appearance was: 0.066 and 0.025, respectively. The analysis also suggested that there is 3-4 years difference between the inferred age at onset and the age when knee osteoarthritis becomes detectable on radiograph. Conclusion: The stochastic model provides more accurate description of the empiric data compared with the corresponding polynomial model. The model-based individual's estimates could be used as an important tool to fit age-related patterns of the corresponding diseases and conditions.

TI Incidence and risk factors for radiographic knee osteoarthritis and knee pain in Japanese men and women: A longitudinal population-based cohort study
SO ARTHRITIS AND RHEUMATISM
LA English
DT Article
ID middle-aged women; osteo-arthritis; occupational activity; physical-activity; cartilage volume; natural-history; bone-marrow; body-mass; association; progression
AB Objective To examine the incidence and progression of radiographic knee osteoarthritis (OA) and the incidence of knee pain, and their risk factors in Japan, using the large-scale population of the nationwide cohort study ROAD (Research on Osteoarthritis/osteoporosis Against Disability). Methods Subjects from the ROAD study who had been recruited in 20052007 were followed up with knee radiography 3 years later. A total of 2,262 paired radiographs (74.4% of the original sample) were scored using the Kellgren/Lawrence (K/L) grading system, and the incidence and progression rate of knee OA was examined. The incidence rate of knee pain was also examined. In addition, risk factors were tested for their association with incident and progressive radiographic knee OA and incident knee pain. Results Given the similar to 3.3-year followup, the rate of incident K/L grade =2 radiographic knee OA was 6.9% and 11.9% in men and women, respectively, while that of K/L grade =3 knee OA was 8.4% and 13.9% in men and women, respectively. The rate of progressive knee OA was 17.8% and 22.3% in men and women, respectively. The incident rate of knee pain was 21.2% and 27.3% in men and women, respectively. Female sex was a risk factor for incident K/L grade =2 knee OA, but was not associated with incident K/L grade =3 knee OA or progressive knee OA. Knee pain was a risk factor for incident and progressive knee OA. Previous knee injury was a risk factor for knee pain but not for radiographic knee OA. Conclusion The present longitudinal study revealed a high incidence of radiographic knee OA in Japan.

TI The Role of Telomeres in Musculoskeletal Diseases
SO JOURNAL OF INTERNATIONAL MEDICAL RESEARCH
LA English
DT Review
DE TELOMERE; TELOMERASE; OSTEOARTHRITIS; OSTEOPOROSIS; OSTEOSARCOMA; MUSCULOSKELETAL DISEASES
ID diploid cell strains; in-vitro; chondrocyte senescence; reverse-transcriptase; soft-tissue; replicative senescence; osteosarcoma cells; human osteoblasts; human fibroblasts; down-regulation
AB The telomeric region of repetitive DNA sequences at the end of chromosomes prevents end-to-end fusion of chromosome terminals and deterioration of the double-strand free ends. Because of the 'end-replication problem', telomeres shorten with each round of cell division, resulting in cell senescence. The enzyme telomerase compensates for telomere shortening by elongating telomeric sequences, thereby prolonging the lifespan of the cell. Studies of articular cartilage and bone tissues have indicated that telomere shortening limits normal cell function and proliferation, while the telomere maintenance mechanisms of osteosarcoma cells facilitate escape from cell death and promote immortality. This article reviews the literature on this topic and provides an extensive discussion of the basic molecular biology and roles of telomeres and telomerase in musculoskeletal diseases such as osteoarthritis, osteoporosis and osteosarcoma. Findings to date suggest that telomeres and telomerase may become novel therapeutic targets for the diagnosis, treatment and prevention of musculoskeletal disorders.

TI Reliability and predictability of the centre-edge angle in the assessment of pincer femoroacetabular impingement
SO INTERNATIONAL ORTHOPAEDICS
LA English
DT Article
ID femoral-head; surgical dislocation; hip; cam; osteoarthritis; prevalence; cartilage
AB Purpose The aim of the study was to assess the use of the centre-edge (CE) angle in the assessment of pincer femoroacetabular impingement (FAI) for reliability and predictability in the diagnosis. Methods Between 2004 and 2008, 55 patients underwent surgical treatment for FAI. A control group of 30 was identified among patients attending the emergency department with normal radiographs. Radiographs were assessed by two independent observers both before and after the operation. Nine patients with trauma were excluded. The magnetic resonance arthrogram reports of the remaining 46 patients were assessed for pincer FAI. Nineteen patients were identified and underwent repeat radiographic assessment. All underwent surgical dislocation of hip (SDH), acetabular, with/without femoral osteochondroplasty. Acetabular depth and version were also assessed. The intraclass correlation (ICC) was used to assess reliability of the CE angle. The paired t test and independent groups t test were used to assess the difference between the pincer FAI group, both pre-op and post-op and against controls. Results The control and pincer groups were similar in demographics (p=0.1769). Coxa profunda

was present in 14 patients with eight also having retroverted acetabuli. Of the rest two had retroverted acetabuli and one protrusio. The mean CE angle in the control group was 31.4 degrees, in the pre-op pincer group 46.2 degrees and in the post-op pincer group 38.3 degrees. The ICC for intra-observer correlation was 0.977 and 0.992 pre-op and 0.986 and 0.974 post-op. The ICC for inter-observer correlation was 0.960 and 0.957 pre-op and 0.979 and 0.967 post-op. The p value was <0.001 between the controls, the pre-op and post-op pincer groups. The test characteristics using the CE angle >= 40 is a reasonably good predictor of FAI, with a sensitivity of 84.2% and a specificity of 100%. Conclusions The pincer FAI can be reliably assessed with the CE angle and can be predicted in patients presenting with FAI.

TI Exercise prescription for hospitalized people with chronic obstructive pulmonary disease and comorbidities: a synthesis of systematic reviews
SO INTERNATIONAL JOURNAL OF CHRONIC OBSTRUCTIVE PULMONARY DISEASE
LA English
DT Review
DE pulmonary disease; chronic obstructive; comorbidity; exercise; physical fitness
ID progressive resistance exercise; chronic heart-failure; quality-of-life; acute medical illness; physical-activity; risk-factors; blood-pressure; united-states; copd exacerbations; aerobic exercise
AB Introduction: The prescription of physical activity for hospitalized patients with acute exacerbation of chronic obstructive pulmonary disease (AECOPD) can be complicated by the presence of comorbidities. The current research aimed to synthesize the relevant literature on the benefits of exercise for people with multimorbidities who experience an AECOPD, and ask: What are the parameters and outcomes of exercise in AECOPD and in conditions that are common comorbidities as reported by systematic reviews (SRs)? Methods: An SR was performed using the Cochrane Collaboration protocol. Nine electronic databases were searched up to July 2011. Articles were included if they (1) described participants with AECOPD, chronic obstructive pulmonary disease (COPD), or one

of eleven common comorbidities, (2) were an SR, (3) examined aerobic training (AT), resistance training (RT), balance training (BT), or a combination thereof, (4) included at least one outcome of fitness, and (5) compared exercise training versus control/sham. Results: This synthesis examined 58 SRs of exercise training in people with AECOPD, COPD, or eleven chronic conditions commonly associated with COPD. Meta-analyses of endurance (aerobic or exercise capacity, 6-minute walk distance - 6MWD) were shown to significantly improve in most conditions (except osteoarthritis, osteoporosis, and depression), whereas strength was shown to improve in five of the 13 conditions searched: COPD, older adults, heart failure, ischemic heart disease, and diabetes. Several studies of different conditions also reported improvements in quality of life, function, and control or prevention outcomes. Meta-analyses also demonstrate that exercise training decreases the risk of mortality in older adults, and those with COPD or ischemic heart disease. The most common types of training were AT and RT. BT and functional training were commonly applied in older adults. The quality of the SRs for most conditions was moderate to excellent (>65%) as evaluated by AMSTAR scores. Conclusion: In summary, this synthesis showed evidence of significant benefits from exercise training in AECOPD, COPD, and conditions that are common comorbidities. A broader approach to exercise and activity prescription in pulmonary rehabilitation may induce therapeutic benefits to ameliorate clinical sequelae associated with AECOPD and comorbidities such as the inclusion of BT and functional training.

DT Article
DE Osteoarthritis; Fatty acid; Omega fatty acids; Femoral head; Osteoporosis
ID fish-oil omega-3-fatty-acids; n-9 eicosatrienoic acid; dietary supplementation; docosahexaenoic acid; marrow; osteoporosis; expression; osteoprotegerin; multicenter; secretion
AB We report here differences in the fatty acid profile of cancellous bone matrix, including n-3, n-6, mono- and polyunsaturated, as well as saturated fats, between femoral heads from female OA (n = 8, aged 68-88 years), fractured neck of femur (#NOF) (n = 19, 67-88 years) and autopsy controls (CTRL) (n = 4,85-97 years).

Femoral heads were collected from individuals undergoing orthopaedic surgery for OA or #NOF; the fatty acid profile of sub-samples from the superior principal compressive and superior principal tensile regions were determined by gas chromatography. A total of 42 individual fatty acids were detected at varying concentrations with significant differences between subchondral bone from OA subjects, subchondral bone from #NOF subjects and subchondral bone from CTRL subjects, as well as between the superior principal compressive and superior principal tensile regions (for saturated fats only). Subchondral bone from OA subjects had higher total n-6 (OA = 10.89 +/- 3.17, #NOF = 11.11 +/- 1.83, CTRL = 8.32 +/- 2.05, p = 0.008) and total n-3 (OA = 1.34 +/- 0.38, #NOF = 1.19 +/- 0.18, CTRL = 1.15 +/- 0.48, p = 0.011) percentages than subchondral bone from #NOF subjects and subchondral bone from CTRL subjects, and there was no difference in the n-6:n-3 ratio, nor within the percentage of n-9 fatty acids. Arachidonic acid (OA = 0.42 +/- 0.16, #NOF = 026 +/- 0.06, CTRL = 0.28 +/- 0.06, p = 0.01), and gamma-linolenic acid (OA = 0.11 +/- 0.03, #NOF = 0.05 +/- 0.02, CTRL = 0.04 +/- 0.02, p<0.001) were higher in subchondral bone from OA subjects than subchondral bone from #NOF subjects and subchondral bone from CTRL subjects. In conclusion, there is a wide diversity of fatty acids in cancellous bone matrix from the femoral heads of OA and #NOF, suggesting they may have regulatory effects on inflammatory processes, and their metabolites. This article is part of a Special Issue entitled "Osteoarthritis". (C) 2012 Elsevier Inc. All rights reserved.

TI A fully automated trabecular bone structural analysis tool based on T2*-weighted magnetic resonance imaging
SO COMPUTERIZED MEDICAL IMAGING AND GRAPHICS
LA English
DT Article
DE Segmentation; Active contour; Cancellous bone; Articular joint; Quantitative MRI; Osteoporosis; Osteoarthritis
ID level-set approach; of-the-art; in-vivo; distal radius; mechanical-property; decay characteristics; cartilage interface; articular-cartilage; relaxation-times; medical imagery
AB One major source affecting the precision of bone structure analysis in quantitative magnetic resonance imaging (qMRI) is inter- and intraoperator variability, inherent in delineating and tracing regions of interest along longitudinal studies. In this paper an automated analysis tool, featuring bone marrow segmentation, region of interest generation, and characterization of cancellous bone of articular joints is presented. In evaluation studies conducted at the knee joint the novel analysis tool significantly decreased the standard error of measurement and improved the sensitivity in detecting minor structural changes. It further eliminated the need of time-consuming user interaction, and thereby increasing reproducibility. (C) 2011 Elsevier Ltd. All rights reserved.

TI Targeting Bone Alleviates Osteoarthritis in Osteopenic Mice and Modulates Cartilage Catabolism
SO PLOS ONE
LA English
DT Article
ID estrogen-receptor-alpha; subchondral bone; articular-cartilage; knee osteoarthritis; gene haplotype; murine model; ii collagen; degradation; osteoprotegerin; expression
AB Objective: Subchondral bone modifications occur early in the development of osteoarthritis (OA). The level of bone resorption might impact cartilage remodeling. We therefore assessed the in vivo and in vitro effects of targeting bone resorption in OA and cartilage metabolism. Methods: OA was induced by meniscectomy (MNX) in ovariectomized osteopenic mice (OP) treated with estradiol (E2), pamidronate (PAM), or phosphate buffered saline (PBS) for 6 weeks. We assessed the subchondral bone and cartilage structure and the expression of cartilage matrix proteases. To assess the involvement of bone soluble factors in cartilage metabolism, supernatant of human bone explants pre-treated with E2 or PAM were transferred to cartilage explants to assess proteoglycan release and aggrecan

cleavage. OPG/RANKL mRNA expression was assessed in bone explants by real-time quantitative PCR. The role of osteoprotegerin (OPG) in the bone-cartilage crosstalk was tested using an OPG neutralizing antibody. Results: Bone mineral density of OP mice and osteoclast number were restored by E2 and PAM ($p<0.05$). In OP mice, E2 and PAM decreased ADAMTS-4 and -5 expression, while only PAM markedly reduced OA compared to PBS (2.0+/-0.63 vs 5.2+/-0.95; $p<0.05$). OPG/RANKL mRNA was increased in human bone explants treated with both drugs (2.2-3.7-fold). Moreover, supernatants from bone explants cultured with E2 or PAM reduced aggrecan cleavage and cartilage proteoglycan release (73+/-8.0% and 80+/-22% of control, respectively, $p<0.05$). This effect was reversed with osteoprotegerin blockade. Conclusion: The inhibition of bone resorption by pamidronate in osteopenic mice alleviates the histological OA score with a reduction in the expression of aggrecanases. Bone soluble factors, such as osteoprotegerin, impact the cartilage response to catabolic factors. This study further highlights the importance of subchondral bone in the regulation of joint cartilage damage in OA.

TI The association between erosive hand osteoarthritis and subchondral bone attrition of the knee: the Framingham Osteoarthritis Study
SO ANNALS OF THE RHEUMATIC DISEASES
LA English
DT Article
ID mineral density; general-population; women; osteoporosis; prevalence; mri
AB Objective To examine whether erosive hand osteoarthritis (OA) is associated with knee subchondral bone attrition (SBA) and systemic bone mineral density (BMD). Methods Associations of MRI-defined knee SBA with radiographic erosive hand OA were evaluated in 1253 Framingham participants using logistic regression with generalised estimating equations. We also examined the association between the number of erosive OA finger joints and SBA adjusted for the number of non-erosive OA finger joints. Associations between erosive hand OA and femoral neck BMD were explored in 2236 participants with linear regression. Analyses were adjusted for age, sex and body mass index. Results Participants with erosive hand OA had increased odds of knee SBA (OR = 1.60, 95% CI 1.07 to 2.38). The relation between the number of erosive OA finger joints and SBA became non-significant when adjusted for the number of non-erosive OA joints as a proxy for the burden of disease. There was a non-significant trend towards higher BMD in erosive hand OA compared with participants without hand OA. Conclusions Erosive hand OA was associated with knee SBA, but the relation might be best explained by a heightened burden of disease. No significant relation of erosive hand OA with BMD was found.

TI Efficacy of zoledronic acid in treatment of teoarthritis is dependent on the

disease progression stage in rat medial meniscal tear model
SO ACTA PHARMACOLOGICA SINICA
LA English
DT Article
DE osteoarthritis; zoledronic acid; bisphosphonate; pain; subchondral bone; rat medial meniscal tear model
ID subchondral bone; knee osteoarthritis; articular-cartilage; treating osteoarthritis; osteochondral junction; pain; joint; symptoms; osteoporosis; pathogenesis
AB Aim: To investigate whether the stage of osteoarthritis (OA) progression influenced the efficacy of the third-generation bisphosphonate zoledronic acid in a rat medial meniscal tear model. Methods: Medial meniscal tear (MMT) was surgically induced in adult male Sprague Dawley rats. Zoledronic acid (ZOL, 100 mu g/kg, sc, twice a week) was administered starting immediately, early (from 4 weeks) or late (from 8 weeks) after OA induction. The degeneration of articular cartilage was evaluated with toluidine blue O staining. Subchondral bone remodeling was evaluated with X-ray micro-CT scanning. Joint pain was measured with respect to weight-bearing asymmetry. Calcitonin gene-related peptide (CGRP) expression in dorsal root ganglia (DRGs) was examined using immunofluorescence analysis. The afferent neurons in DRGs innervating the joint were identified by retrograde labeling with fluorogold. Results: Progressive cartilage loss was observed during 12 weeks after OA induction. Subchondral bone remodeling manifested as increased bone resorption at early stage (4 weeks), but as increased bone accretion at advanced stages (8 weeks). Immediately and early ZOL administration significantly improved subchondral microstructural parameters, attenuated cartilage degeneration, reduced weight-bearing asymmetry and CGRP expression, whereas the late ZOL administration had no significant effects. Conclusion: The stage of OA progression influences the efficacy of ZOL in treating joint degeneration and pain. To obtain the maximum efficacy, bisphosphonate treatment should be initiated in rat with early stages of OA pathogenesis.

TI IDENTIFICATION OF TRABECULAR EXCRESCENCES, NOVEL MICROANATOMICAL STRUCTURES, PRESENT IN BONE IN OSTEOARTHROPATHIES
SO EUROPEAN CELLS & MATERIALS
LA English
DT Article
DE Bone remodelling; scanning electron microscopy; osteoarthritis; alkaptonuria
ID scanning-electron-microscopy; ochronotic arthropathy; calcified cartilage; subchondral bone; osteoarthritis; osteoporosis; progression
AB It is widely held that bone architecture is finely regulated in accordance with homeostatic requirements. Aberrant remodelling (hyperdensification and/or cyst formation in the immediately subchondral region) has previously been described in bone underlying cartilage in arthropathies. The present study examined the trabecular architecture of samples of bone, initially in the severe osteoarthropathy of alkaptonuria, but subsequently in osteoarthritis using a combination of light microscopy, 3D scanning electron microscopy and quantitative backscattered electron scanning electron microscopy. We report an extraordinary and previously unrecognised bone phenotype in both disorders, including novel microanatomical structures. The underlying subchondral trabecular bone contained idiosyncratic architecture. Trabecular surfaces had numerous outgrowths that we have termed "trabecular excrescences", of which three distinct types were recognised. The first type arose from incomplete resorption of branching secondary trabeculae arising from the deposition of immature (woven) bone in prior marrow space. These were characterised by very deeply scalloped surfaces and rugged edges. The second type had arisen in a similar way but been smoothed over by new bone deposition. The third type, which resembled coarse stucco, probably arises from resting surfaces that had been focally reactivated. These were poorly integrated with the prior trabecular wall. We propose that these distinctive microanatomical structures are indicative of abnormal osteoclast/osteoblast modelling in osteoarthropathies, possibly secondary to altered mechanical loading or other aberrant signalling. Identification of the mechanisms underlying the formation of trabecular

excrescences will contribute to a better understanding of the role of aberrant bone remodelling in arthropathies and development of new therapeutic strategies.

TI Clinical characteristics influence in vitro action of 1,25-dihydroxyvitamin D3 in human marrow stromal cells
SO JOURNAL OF BONE AND MINERAL RESEARCH
LA English
DT Article
DE MARROW STROMAL CELLS; OSTEOBLAST DIFFERENTIATION; AGE; VITAMIN D; eGFR
ID human bone-marrow; mesenchymal stem-cells; vitamin-d deficiency; age-related decline; 3-dimensional collagen sponges; osteogenic differentiation; parathyroid-hormone; osteoporosis; growth; women
AB Vitamin D is important for bone health, with low vitamin D levels being associated with skeletal fragility and fractures. Among its other biological activities, 1,25-dihydroxyvitamin D (1,25(OH)2D), stimulates the in vitro differentiation of human marrow stromal cells (hMSCs) to osteoblasts, which can be monitored by increases in alkaline phosphatase enzyme activity or osteocalcin gene expression. In this study, we tested the hypotheses that age and clinical attributes of subjects influence in vitro responsiveness of hMSCs to 1,25(OH)2D3. In a cohort of subjects whose hMSCs were isolated from bone marrow discarded during hip replacement surgery for osteoarthritis, there were significant inverse correlations with age for bone mineral density, renal function, body mass index, fat mass index, and lean mass index (n?=?3653). There were significant correlations with serum 25(OH)D for serum parathyroid hormone (PTH), body mass index, fat mass index, and lean mass index (n?=?4750). In vivoin vitro correlation analyses indicated that there were significantly greater in vitro effects of 1,25(OH)2D3 to stimulate osteoblast differentiation in hMSCs obtained from subjects who were younger than 65 years of age, or who had serum 25(OH)D = 20?ng/mL, elevated serum PTH, or better renal function, assessed by estimated glomerular filtration rate. The greater in vitro stimulation of osteoblast differentiation by 1,25(OH)2D3 in hMSCs from vitamin D-deficient subjects suggests that vitamin D replenishment may lead to more vigorous bone formation in subjects at risk. (c) 2012 American Society for Bone and Mineral Research.

TI Radiographic osteoarthritis and pain are independent predictors of knee cartilage loss: a prospective study
SO INTERNAL MEDICINE JOURNAL
LA English
DT Article
DE radiograph; MRI; cartilage; trial
ID older-adult cohort; subchondral bone; progression; volume; joint; extrusion; women; men
AB Background: There is controversy about whether pain and radiographic osteoarthritis (ROA) predict subsequent cartilage loss. The aim of this study was to describe the relationship between ROA, pain and cartilage loss in the knee. Methods: We studied randomly selected subjects at baseline and approximately 2.9 years later (n = 399). The presence of ROA was assessed at baseline with a standing anteroposterior semiflexed radiograph scored using the Osteoarthritis Research Society International atlas for osteophytes (OP) and joint space narrowing (JSN). Pain was assessed by the Western Ontario McMaster Osteoarthritis Index. Subjects' medial and lateral tibial cartilage volumes were determined by magnetic resonance imaging at both time points. Results: In cross-sectional analysis, both medial and lateral tibial cartilage volumes were lower in those with ROA. Any medial ROA predicted medial tibial cartilage loss (3.2% (standard deviation (SD) 5.6) vs 1.9% (SD 5.3) per annum) while any lateral ROA predicted both medial (4.0% (SD 6.0) vs 2.2% (SD 5.3) per annum) and lateral (3.5% (SD 5.8) vs 1.6% (SD 4.2) per annum) tibial cartilage loss (all $P < 0.05$). In multivariate analysis, JSN and OP at both medial and lateral sites had independent dose- response associations with tibial cartilage loss

at both sites. Pain was an independent predictor of lateral, but not medial, tibial cartilage loss after taking ROA into account. Conclusions: Subjects with ROA (either JSN or OP) and, to a lesser extent, pain lose cartilage faster than subjects without ROA and the more severe the ROA the greater the rate of loss. These findings have implications for the design of clinical trials.

TI Impact of treatments for osteoporosis on osteoarthritis progression
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE Anti-osteoporotic treatments; Bone remodeling; Osteoarthritis; Osteoporosis; Sub-chondral bone
ID knee osteoarthritis; inhibition; risedronate; alendronate; symptoms; model; strontium; markers; rabbit
AB Subchondral bone is involved in the development of osteoarthritis, with an excess in bone resorption at an early stage and increased bone formation thereafter. Experimental and observational studies suggest that acting on bone can change progression of osteoarthritis. Clinical prospective controlled studies failed to confirm this result. Appropriate identification of patients at high risk of developing cartilage deterioration is a key issue for the analysis of impact of treatments for osteoporosis on osteoarthritis progression.

TI Endogenous parathyroid hormone is associated with reduced cartilage volume in vivo in a population-based sample of adult women
SO ANNALS OF THE RHEUMATIC DISEASES
LA English
DT Article
ID articular-cartilage; pth/pthrp receptor; osteoarthritis; bone; sensitivity; degradation; females; disease
AB Objectives Animal and in vitro studies suggest that parathyroid hormone (PTH) may affect articular cartilage. However, little is known of the relationship between PTH and human joints in vivo. Design Longitudinal. Setting Barwon Statistical Division, Victoria, Australia. Participants 101 asymptomatic women aged 35-49 years (2007-2009) and without clinical knee osteoarthritis, selected from the population-based Geelong Osteoporosis Study. Risk factors Blood samples obtained 10 years before (1994-1997) and stored at -80 degrees C for random batch analyses. Serum intact PTH was quantified by chemiluminescent enzyme assay. Serum 25-hydroxyvitamin D (25(OH) D) was assayed using equilibrium radioimmunoassay. Models were adjusted for age, bone area and body mass index; further adjustment was made for 25(OH) D and calcium supplementation. Outcome Knee cartilage volume, measured by MRI. Results A higher lnPTH was associated with reduced medial-but not lateral-cartilage volume (regression coefficient +/- SD, p value: -72.2 +/- 33.6 mm(3), p=0.03) after adjustment for age, body mass index and bone area. Further sinusoidal adjustment (-80.8 +/- 34.4 mm(3), p=0.02) and 25(OH) D with seasonal adjustment (-72.7 +/- 35.1 mm(3), p=0.04), calcium supplementation and prevalent osteophytes did not affect the results. Conclusions A higher lnPTH might be detrimental to knee cartilage in vivo. Animal studies suggest that higher PTH concentrations reduce the healing ability of cartilage following minor injury. This may be apparent in the presence of increased loading, which occurs in the medial compartment, placing the medial cartilage at higher risk for injury.

TI RANKL synthesized by articular chondrocytes contributes to juxta-articular bone loss in chronic arthritis
SO ARTHRITIS RESEARCH & THERAPY
LA English
DT Article
ID kappa-b ligand; osteoclast differentiation factor; collagen-induced arthritis; rheumatoid-arthritis; receptor activator; synovial tissue; osteoprotegerin ligand; inflammatory arthritis; in-vitro; t-cells
AB Introduction: The receptor activator nuclear factor-kappaB ligand (RANKL) diffuses from articular cartilage to subchondral bone. However, the role of chondrocyte-synthesized RANKL in rheumatoid arthritis-associated juxta-articular bone loss has not yet been explored. This study aimed to determine whether RANKL produced by chondrocytes induces osteoclastogenesis and juxta-articular bone loss associated with chronic arthritis. Methods: Chronic antigen-induced

arthritis (AIA) was induced in New Zealand (NZ) rabbits. Osteoarthritis (OA) and control groups were simultaneously studied. Dual X-ray absorptiometry of subchondral knee bone was performed before sacrifice. Histological analysis and protein expression of RANKL and osteoprotegerin (OPG) were evaluated in joint tissues. Co-cultures of human OA articular chondrocytes with peripheral blood mononuclear cells (PBMCs) from healthy donors were stimulated with macrophage-colony stimulating factor (M-CSF) and prostaglandin E-2 (PGE(2)), then further stained with tartrate-resistant acid phosphatase. Results: Subchondral bone loss was confirmed in AIA rabbits when compared with controls. The expression of RANKL, OPG and RANKL/OPG ratio in cartilage were increased in AIA compared to control animals, although this pattern was not seen in synovium. Furthermore, RANKL expression and RANKL/OPG ratio were inversely related to subchondral bone mineral density. RANKL expression was observed throughout all cartilage zones of rabbits and was specially increased in the calcified cartilage of AIA animals. Co-cultures demonstrated that PGE(2)-stimulated human chondrocytes, which produce RANKL, also induce osteoclasts differentiation from PBMCs. Conclusions: Chondrocyte-synthesized RANKL may contribute to the development of juxta-articular osteoporosis associated with chronic arthritis, by enhancing osteoclastogenesis. These results point out a new mechanism of bone loss in patients with rheumatoid arthritis.

TI Phenotypic Characterization of Osteoarthritic Osteocytes from the Sclerotic Zones: A Possible Pathological Role in Subchondral Bone Sclerosis
SO INTERNATIONAL JOURNAL OF BIOLOGICAL SCIENCES
LA English
DT Article
DE osteocyte; osteoarthritis; subchondral bone; sclerosis; DMP1 and SOST
ID matrix protein-1 dmp1; articular-cartilage; increased expression; osteoblasts; cells; apoptosis; osteoporosis; microcracks; osteoclasts; resorption
AB Subchondral bone sclerosis is a well-recognised manifestation of osteoarthritis (OA). The osteocyte cell network is now considered to be central to the regulation of bone homeostasis; however, it is not known whether the integrity of the osteocyte cell network is altered in OA patients. The aim of this study was to investigate OA osteocyte phenotypic changes and its potential role in OA subchondral bone pathogenesis. The morphological and phenotypic changes of osteocytes in OA samples were investigated by micro-CT, SEM, histology, immunohistochemistry, TRAP staining, apoptosis assay and real-time PCR studies. We demonstrated that in OA subchondral bone, the osteocyte morphology was altered showing rough and rounded cell body with fewer and disorganized dendrites compared with the osteocytes in control samples. OA osteocyte also showed dysregulated expression of osteocyte markers, apoptosis, and degradative enzymes, indicating that the phenotypical changes in OA osteocytes were accompanied with OA subchondral bone remodelling (increased osteoblast and osteoclast activity) and increased bone volume with altered mineral content. Significant alteration of osteocytes identified in OA samples indicates a potential regulatory role of osteocytes in subchondral bone remodelling and mineral metabolism during OA pathogenesis.

TI Destructive discovertebral degenerative disease of the lumbar spine
SO SKELETAL RADIOLOGY
LA English
DT Article
DE Lumbar spine; Bone debris; Discovertebral osteoarthritis; Rapidly progressive osteoarthritis; Destructive osteoarthritis; Osteoporosis
ID subchondral insufficiency fracture; rheumatoid-arthritis; hip; osteoarthritis; joint; head
AB The uncommon variant of degenerative hip joint disease, termed rapidly progressive osteoarthritis, and highlighted by severe joint space loss and osteochondral disintegration, is well established. We present a similar unusual subset in the lumbar spine termed destructive discovertebral degenerative disease (DDDD) with radiological features of vertebral malalignment, severe disc resorption, and "bone sand" formation secondary to vertebral fragmentation. Co-existing metabolic bone disease is likely to promote the development of DDDD of the lumbar spine, which presents with back pain and sciatica due to nerve root compression by the "bone sand" in the epidural space. MRI and CT play a complimentary role in making the diagnosis.

TI Does mild cognitive impairment affect the occurrence of radiographic knee osteoarthritis? A 3-year follow-up in the ROAD study
SO BMJ OPEN
LA English
DT Article
ID mini-mental state; risk-factors; progression; population; dementia; disease; cohort; life; ad
AB Objective: To determine whether mild cognitive impairment (MCI) increases the risk of occurrence or progression of radiographic knee osteoarthritis (KOA) in a general population. Design: Population-based cohort study. Setting: Residents in mountain and seaside areas of Wakayama Prefecture, Japan. Participants: 1690 participants (596 men, 1094 women; mean age 65.2 years old) were enrolled from the large-scale cohort for the Research on Osteoarthritis (OA)/osteoporosis Against Disability (ROAD) study initiated in 2005 to investigate epidemiological features of OA in Japan. Of these, 1384 individuals (81.9%; 466 men, 918 women) completed the second survey including knee radiography 3 years later. Primary outcome measures: Radiographic KOA was defined as Kellgren-Lawrence (KL) grade >= 2 using paired x-ray films. Incidence of KOA during follow-up defined on radiographs as KL grade >= 2, progression of KOA defined as a higher KL grade (either knee) at follow-up compared with baseline. MCI defined as a summary mini-mental state examination (MMSE) score <= 23. Associations between MCI and incidence or progression of KOA were analysed. Results: The annual cumulative incidence of

KOA was 3.3%; for progression of OA it was 8.0%. On logistic regression analysis adjusted for age, gender, regional differences, body mass index, grip strength (worse side), smoking, alcohol consumption, regular exercise and history of knee injury, baseline MMSE summary score was significantly associated with the incidence of KOA (+ 1 MMSE score; OR 0.83, p=0.010). Baseline MCI was also significantly associated with the incidence of KOA (vs non-occurrence of KOA; OR 4.90, p=0.027). There was no significant association between MMSE scores, the presence of MCI and progression of KOA (+ 1 MMSE score; OR 0.96, p=0.232; vs non-progression of KOA; OR 1.38, p=0.416). Conclusions: MCI significantly increases the risk of incident radiographic KOA, but not the progression of KOA.

TI Cross-sectional analysis of association between socioeconomic status and utilization of primary total hip joint replacements 2006-7: Australian Orthopaedic Association National Joint Replacement Registry
SO BMC MUSCULOSKELETAL DISORDERS
LA English
DT Article
DE Hip joint replacement; Socioeconomic status; Utilization; Australia
ID elective total hip; knee osteoarthritis; medicare beneficiary; occupational activity; geelong-osteoporosis; physical demands; united-states; adult women; rates; population
AB Background: The utilization of total hip replacement (THR) surgery is rapidly increasing, however few data examine whether these procedures are associated with socioeconomic status (SES) within Australia. This study examined primary THR across SES for both genders for the Barwon Statistical Division (BSD) of Victoria, Australia. Methods: Using the Australian Orthopaedic Association National Joint Replacement Registry data for 2006-7, primary THR with a diagnosis of osteoarthritis (OA) among residents of the BSD was ascertained. The Index of Relative Socioeconomic Disadvantage was used to measure SES; determined by matching residential addresses with Australian Bureau of Statistics census data. The data were categorised into quintiles; quintile 1 indicating the most disadvantaged. Age-and sex-specific rates of primary THR per 1,000 person years were reported for 10-year age bands using the total population at risk. Results: Females accounted for 46.9% of the 642 primary THR performed during 2006-7. THR utilization per

1,000 person years was 1.9 for males and 1.5 for females. The highest utilization of primary THR was observed in those aged 70-79 years (males 6.1, and females 5.4 per 1,000 person years). Overall, the U-shaped pattern of THR across SES gave the appearance of bimodality for both males and females, whereby rates were greater for both the most disadvantaged and least disadvantaged groups. Conclusions: Further work on a larger scale is required to determine whether relationships between SES and THR utilization for the diagnosis of OA is attributable to lifestyle factors related to SES, or alternatively reflects geographic and health system biases. Identifying contributing factors associated with SES may enhance resource planning and enable more effective and focussed preventive strategies for hip OA.

TI Relative and Combined Effects of Ethanol and Protein Deficiency on Bone Manganese and Copper
SO BIOLOGICAL TRACE ELEMENT RESEARCH
LA English
DT Article
DE Manganese; Copper; Ethanol; Malnutrition; Bone
ID postmenopausal women; dietary manganese; mineral density; trace minerals; zinc; osteoporosis; metabolism; magnesium; selenium; rats
AB Both manganese and copper may affect bone synthesis. Bone content of both metals can be altered in alcoholics, although controversy exists regarding this matter. To analyse the relative and combined effects of ethanol and a low protein diet on bone copper and manganese, and their relationships with bone structure and metabolism, including trabecular bone mass (TBM), osteoid area (OA), osteocalcin (OCN), insulin-like growth factor-1 (IGF-1), parathyroid hormone (PTH), urinary hydroxyproline (uHP) and vitamin D. Adult male Sprague-Dawley rats were divided into four groups. The control rats received a 18% protein-containing diet; a second group, an isocaloric, 2% protein-containing diet; a third one, an isocaloric, 36% ethanol-containing diet and a fourth, an isocaloric diet containing 2% protein and 36% ethanol. After sacrifice, TBM and OA were histomorphometrically assessed; bone and serum manganese and copper were determined by atomic absorption spectrophotometry, and serum OCN, IGF-1, PTH, uHP and vitamin D by radioimmunoassay. Ethanol-fed rats showed decreased TBM and bone manganese. Significant relationships existed between bone manganese and TBM, serum IGF-1 and OCN. Ethanol leads to a decrease in bone manganese, related to decreased bone mass and bone synthesis. No alterations were found in bone copper.

AB Objective: This study compared human primary osteoblasts derived from hip osteoarthritis (OA) cases against controls (CTLs) to investigate candidate OA disease genes, twist homologue 1 (TWIST1), wingless MMTV integration site family member 5B (WNT5B), transforming growth factor-beta (TGF beta 1) and SMAD family member 3 (SMAD3), during osteoblast differentiation, relative to calcium apposition and elemental mineral composition. Materials & methods: Primary osteoblast cultures were generated from intertrochanteric trabecular bone samples from five female primary hip OA cases and five age-matched female CTLs. During a 42-day differentiation time-course, alizarin red stains, energy-dispersive X-ray spectroscopy and real-time RT-polymerase chain reaction (PCR) were used to quantify calcium, elemental composition and gene expression, respectively. Data were analysed using linear mixed effects models and Pearson correlation matrices. Results: Significant differences, correlations and associations were found in OA and CTL osteoblasts between gene and mineral measures. The calcium: phosphorous (Ca:P) ratio was significantly more varied in OA compared to CTL. Calcium apposition, mineral composition as well as TWIST1 and TGF beta 1 mRNA expression changed significantly over time. TWIST1 mRNA expression was elevated and correlated with SMAD3 mRNA levels in the OA cohort during the time-course. Associations were observed between tissue non-specific alkaline phosphatase (TNAP), osteocalcin (OCN), TWIST1, TGF beta 1, SMAD3 mRNA levels and mineral measures in OA against CTL. Temporal differences between SMAD3 mRNA expression and mineral composition were also found in OA. Conclusions: Dysregulated expression of TWIST1, TGF beta 1 and SMAD3 mRNA observed in OA bone is reflected in the functionality of the osteoblast when these cells are cultured ex vivo. The results presented here are consistent with at least part of the aetiology of primary hip OA deriving from altered intrinsic properties of the osteoblast. TI Osteoporotic profiles in elderly patients with symptomatic lumbar spinal canal stenosis
SO INDIAN JOURNAL OF ORTHOPAEDICS
LA English
DT Article
DE Bone mineral density; bone turnover marker; hypovitaminosis D; lumbar spinal stenosis; osteoporosis
ID quality-of-life; bone-mineral density; vitamin-d; postmenopausal women; fracture risk; hip fracture; mortality; turnover; impact; osteoarthritis
AB Background: The osteoporosis and lumbar canal stenosis, in elderly patients are under diagnosed and under reported. We report a cross sectional study to demonstrate the osteoporotic profile in patients with lumbar spinal stenosis (LSS) and to determine the proportion of patients with LSS who need to be treated for osteoporosis. Materials and Methods: One hundred and six postmenopausal

patients with symptomatic LSS were evaluated for osteoporotic profile, which included lumbar and hip bone mineral density (BMD), serum vitamin D concentration, bone resorption and formation markers. Demographic and disease related variables were analyzed to identify the association with the risk of osteoporosis or osteopenia. Statistical analysis used were multivariate logistic regression with a forward stepwise procedure. Results: Twenty-four patients (22.6%) had osteoporosis and 60 (56.6%) had osteopenia. Overall, 84 patients (79.2%) with symptomatic LSS had osteoporosis or osteopenia. Fifty-nine patients (55.6%) had hypovitaminosis D. All bone turnover makers [alkaline phosphatase, osteocalcin, urinary-N-terminal telopeptide (u-NTx)] were demonstrated to be within normal range. Only age was associated with the risk of osteoporosis or osteopenia in the hip region. In the lumbar spine, all variables were not associated with osteoporosis or osteopenia. 44 patients (41.5%) required treatment for osteoporosis as per risk factors for osteoporosis. According to the guidelines from the Health Insurance Review Agency, however, only 20 patients (18.8% required) qualified for reimbursement for osteoporosis medications. Conclusions: LSS is associated with osteopenia, osteoporosis, and hypovitaminosis D, which should prompt careful screening and treatment in cases of osteoporosis and osteoarthritis.

TI Impact of Health Literacy in Patients with Chronic Musculoskeletal Disease-Systematic Review
SO PLOS ONE
LA English
DT Review
ID older-adults; arthritis; communication; outcm
AB Objectives: To estimate the prevalence of low health literacy, and evaluate the impact of low health literacy on outcomes in patients with chronic musculoskeletal conditions. Data Sources: We searched Embase, Pubmed, PsycInfo, and CINAHL in January 2011 for relevant studies, restricted to English-language articles. Study Selection and Data Extraction: Studies were included if they measured health literacy and/or reported on the link between outcomes and health literacy levels in patients with osteoporosis, osteoarthritis, or rheumatoid arthritis. We assessed risk of bias from participant selection, methods of measuring health literacy and functional outcomes, missing data, and potential for confounding. Data Synthesis: We reviewed 1863 citations and judged 8 studies to be relevant. Most were cross-sectional in nature, and five were based in the United States. Diversity in measurements, participant characteristics, and settings meant that results had to be synthesized narratively. Prevalence of low health literacy varied from 7% to 42%. Of the five studies that reported on musculoskeletal outcomes, only one showed an association (unadjusted) between low health literacy and greater pain and limitations in physical functioning. However, other studies, including those with

multivariate analyses, found no significant relationship between health literacy and measures of pain or disease specific questionnaires. One clinical trial found short-term improvements in the mental health of patients with musculoskeletal conditions after an intervention to improve health literacy. Limitations: Most of the studies were cross-sectional in nature, which precludes interpretation of a causal relationship. The sample sizes may not have been sufficiently large to enable detection of significant associations. Conclusions: The current evidence does not show a consistent association between low health literacy and poorer functional outcomes in patients with chronic musculoskeletal conditions. In the absence of a definite link, efforts to develop interventions to improve health literacy would not necessarily improve health service or patient-related outcomes.

TI Genetic deletion of low-density lipoprotein receptor-related protein 5 increases cartilage degradation in instability-induced osteoarthritis
SO RHEUMATOLOGY
LA English
DT Article
DE WNT; wingless-type MMTV integration site family; LRP5; low-density lipoprotein receptor-related protein 5; OA; osteoporosis; bone; cartilage
ID articular-cartilage; subchondral bone; mice; lrp5; chondrocytes; activation; damage; mouse; leads
AB Methods. Total body bone mineral parameters were measured by dual-energy X-ray absorptiometry. Trabecular and cortical bone parameters of tibia and femur were assessed ex vivo by peripheral quantitative CT. Osteoarthritic changes were induced in Lrp5(-/-) and wild-type C57Bl/6J mice using the surgically induced destabilization of the medial meniscus model and the chemically induced papain and collagenase model. The severity of joint disease was investigated by histological analysis of the knee joints. Results. Bone mineral density and weight were significantly decreased in Lrp5(-/-) C57Bl/6J mice compared with their wild-type littermates. Surgically induced destabilization of the knee joint resulted in significantly increased cartilage degradation in the medial tibia of Lrp5(-/-) mice compared with wild-type control mice. In the medial femur, a similar trend was found but did not reach statistical significance. In the papain- and collagenase-induced models, these differences were not observed. Inflammation scores were comparable between wild-type and Lrp5(-/-) mice. Conclusion. These data show that loss of function of Lrp5 increases cartilage degradation in mild instability-induced OA models in mice. Low bone mass density could have contributed to this effect.

TI The relationship between osteoclastogenic and anti-osteoclastogenic pro-inflammatory cytokines differs in human osteoporotic and osteoarthritic bone tissues
SO JOURNAL OF BIOMEDICAL SCIENCE
LA English
DT Article
DE Interleukins; Interferons; TNF-alpha; TGF-beta 1; beta(3) integrin; Cathepsin K; OSCAR
ID tnf-alpha; estrogen deficiency; receptor activator; gene-expression; trabecular bone; proximal femur; tgf-beta; rankl; interleukin-6; differentiation
AB Background: Pro-inflammatory cytokines possess osteoclastogenic or anti-osteoclastogenic activities. They influence osteoclasts directly or via the receptor activator of nuclear factor kappa B (RANK), RANK ligand (RANKL) and osteoprotegerin (OPG) system. Recent evidence suggests that inflammation may play a role in osteoporosis (OP) and osteoarthritis (OA). We aimed therefore to determine whether there is a difference between both groups: first, in the expression of the osteoclastogenic and anti-osteoclastogenic cytokines, second, in correlation of these cytokines with bone mineral density (BMD) and levels of bone turnover markers (BTM) and third, in correlation between the expression of these cytokines and osteoclast specific genes and RANK/RANKL/OPG genes. Methods: Human bone samples from 54 age and sex matched patients with OP or OA were collected during hip arthroplasty surgery. The expression of 25 genes encoding pro-inflammatory cytokines, their receptors, osteoclast specific genes and

RANK/RANKL/OPG genes was measured using quantitative real-time PCR. Total hip, femoral neck and lumbar spine BMD and BTM in blood samples were measured. The comparison between OP and OA was assessed using Student's t-test or Mann-Whitney U test and correlations between gene expression, BMD and BTM were determined using nonparametric correlation. Results: The results demonstrated a higher expression of interleukin (IL)-6 and IL-1 alpha in OP, and interferon (IFN)-gamma in OA ($p < 0.0005$). Negative correlations of total hip BMD with tumor necrosis factor-alpha (TNF-alpha) in OA and with RANKL/RANK in OP were found ($p < 0.05$). Significant correlations with BTM were shown for IL-1 alpha and IFN-gamma in OP (rho = 0.608 and -0.634) and for TNF-alpha, IL-6 and transforming growth factor-beta 1 (TGF-beta 1) in OA (rho = 0.591, -0.521 and 0.636). Results showed OP specific negative correlations (IFN-gamma with ITGB3, IFN-beta 1 with CTSK, tartrate resistant acid phosphatase (TRAP), CALCR, RANK, RANKL, IL-1 alpha with CTSK, OPG, IL-17A with CALCR) and positive (TGF-beta 1 with CTSK, TRAP, RANK), and OA specific negative (IL-1 alpha with osteoclast associated immunoglobulin-like receptor (OSCAR), TNF-alpha with RANK, RANKL, OPG) and positive (IL-6 with RANK, RANKL, OPG) correlations. Conclusions: Our results demonstrate that the relationship between osteoclastogenic and anti-osteoclastogenic pro-inflammatory cytokines differs in human OP and OA bone and could present an important factor for characteristics of OP and OA bone phenotypes.

TI Inhibition of cathepsin K reduces cartilage degeneration in the anterior cruciate ligament transection rabbit and murine models of osteoarthritis
SO BONE
LA English
DT Article
DE Osteoarthritis; Cathepsin K inhibition; Articular cartilage; Subchondral bone; Osteophytes
ID subchondral bone; articular-cartilage; meniscectomized models; deficient mice; animal-model; expression; resorption; osteoporosis; collagen; mouse
AB Objective: To investigate the disease modifying effects of cathepsin K (CatK) inhibitor L-006235 compared to alendronate (ALN) in two preclinical models of

osteoarthritis (OA). Methods: Skeletally mature rabbits underwent sham or anterior cruciate ligament transection (ACLT)-surgery and were treated with L-006235 (L-235, 10 mg/kg or 50 mg/kg, PO, daily) or ALN (0.6 mg/kg, s.c., weekly) for 8-weeks. ACLT joint instability was also induced in CatK(-/-) versus wild type (wt) mice and treated for 16-weeks. Changes in cartilage degeneration, subchondral bone volume and osteophyte area were determined by histology and mu-CT. Collagen type I helical peptide (HP-I), a bone resorption marker and collagen type II C-telopeptide (CTX-II), a cartilage degradation marker were measured. Results: L-235 (50 mg/kg) and ALN treatment resulted in significant chondroprotective effects, reducing CTX-II by 60% and the histological Mankin score for cartilage damage by 46% in the ACLT-rabbits. Both doses of L-235 were more potent than ALN in protecting against focal subchondral bone loss, and reducing HP-I by 70% compared to vehicle. L-235 (50 mg/kg) and ALN significantly reduced osteophyte formation in histomorphometric analysis by 55%. The Mankin score in ACLT-CatK(-/-) mice was similar to 2.5-fold lower than the ACLT-wt mice and was not different from sham-CatK(-/-). Osteophyte development was not different among the groups. Conclusion: Inhibition of CatK provides significant benefits in ACLT-model of OA, including: 1) protection of subchondral bone integrity, 2) protection against cartilage degradation and 3) reduced osteophytosis. Preclinical evidence supports the role of CatK as a potential therapeutic target for the treatment of OA. (C) 2012 Elsevier Inc. All rights reserved.

TI The effect of risedronate (17.5 mg/week) treatment on quality of life in Japanese women with osteoporosis: a prospective observational study
SO JOURNAL OF BONE AND MINERAL METABOLISM
LA English
DT Article
DE EQ-5D; FRAX; Comorbid factors; Ischemic heart disease; Osteoarthritis
ID type-2 diabetes-mellitus; long-term risk; fracture risk; involutional osteoporosis; rheumatoid-arthritis; postmenopausal women; vertebral fractures; hip; metaanalysis; impact
AB A prospective observational study to test the effects of risedronate 17.5 mg/week treatment on quality of life (QOL) of 1,363 Japanese female patients with osteoporosis showed QOL improvement after 12 weeks of administration. Comorbid factors such as ischemic heart disease, hip osteoarthritis, and higher values of FRAX blunted the effects of QOL of the treatment. Few studies have investigated the effect of osteoporosis treatment on QOL in relationship to comorbid factors other than osteoporosis and fracture. Efficacy was determined by changes over time in EQ-5D at baseline, at 12 and 24 weeks, and at the final assessment. Factors affecting changes in EQ-5D were evaluated with a multivariate analysis. Safety was determined by assessing the incident rate of adverse events. The improvement of EQ-5D compared to baseline was observed as significant after 12 weeks of treatment ($p < 0.001$). The greatest improvement was observed in the dimension of "pain/discomfort" by the multivariate analysis ($p < 0.001$). Factors affecting QOL improvement were FRAX value without BMD, age, glucocorticoid use, ischemic heart disease, hip osteoarthritis, and pain. The incidence rate of drug-related adverse events was 4.72 % (95 % confidence interval 3.63-6.02 %). Risedronate at 17.5 mg/week improved the QOL in patients with osteoporosis among Japanese women, and comorbidity factors decreased the effects.

TI Should risk of bone fragility restrict weight control for other health reasons in postmenopausal women? - A ten year prospective study
SO MATURITAS
LA English
DT Article
DE Dual X-ray absorptiometry; Obesity; Osteoporosis; Postmenopause; Weight change
ID body-mass index; sex-differences; obesity; perimenopausal; overweight; fractures; diagnosis; cohort; hrt; men
AB Background: The aim of the present study was to investigate the health risks of excess body weight in the light of its protective effects on bone fragility. Methods: Femoral neck and lumbar spine dual X-ray absorptiometry was performed for 1970 Finnish women with a mean baseline age of 58.8 years (range 53.1-65.7 years) in 1994 and 2004. Women were categorized according to baseline BMI into normal <25 kg/m2, overweight 25-29.9 kg/m(2) and obese >= 30 kg/m(2). Weight change (kg) was categorized into tertiles. Co-morbidities, not allowed to be present at baseline, was based on self-reports. Osteoporosis was defined as femoral neck or spinal (L2-L4) T-score <-2.5 SD at 10-year follow-up or <-2.0 SD + low trauma energy follow-up fracture. Uni- and multivariate logistic regression models were used to estimate the 10-year risk of incident health disorders. Adjustment for age, number of diseases, alcohol intake and smoking was used in the multivariate models. Results: Obesity (Ob) and overweight (Ow) were related with higher 10-year risk of hypertension (OR = 2.6 (Ob)/OR = 1.7 (Ow), p < 0.001), coronary artery disease (OR = 1.6, p < 0.05/OR = 1.2, p = NS), diabetes (OR = 11.7/OR = 5.3, p < 0.001), osteoarthritis (OR = 1.4, p < 0.05/OR = 1.1, p = NS), chronic back pain (OR = 1.6,p = 0.007/OR = 1.2,p = NS) and poor self-rated health (OR = 2.4,p < 0.05/OR = 1.5, p = NS) and lower risk of osteoporosis (OR = 0.13/OR = 0.28, p < 0.001). Weight change of less than +1 kg was associated 1.8 and 2.6 times lower 10-year risk of having hypertension and breast cancer than weight change over 6.2 kg. Among obese women the absolute risk increase of hypertension was 17%, of diabetes 12%, and absolute risk reduction of osteoporosis 14% in comparison to BMI <25 kg/m(2). Conclusions: Health related risks of high BMI outweigh its protective effects on bone. Weight gain increases the risk hypertension and breast

cancer. (C) 2011 Elsevier Ireland Ltd. All rights reserved.

TI Association of Rsa polymorphism of the estrogen receptor-β gene with rheumatoid arthritis
SO RHEUMATOLOGY INTERNATIONAL
LA English
DT Article
DE Polymorphism; Rheumatoid arthritis; Sex; Estrogen receptor-beta
ID disease-activity; bone loss; therapy; alpha; osteoporosis; severity; agonist; repeat; women; risk
AB To investigate the possible influence of the single nucleotide polymorphism (SNP) of the estrogen receptor-beta gene, rs1256049 (Rsa) in exon 5, on the frequency of rheumatoid arthritis (RA), 263 RA patients and 174 control subjects with osteoarthritis (OA) were recruited. Rsa polymorphism was detected using a PCR-RFLP, Polymerase Chain Reaction-Restriction Fragment Length Polymorphism method. The occurrence of both mutant allele (G) and genotype (GG) were significantly higher in RA than in OA patients (allele P = 0.008, OR: 1.501, 95%CI: 1.12-2.02). In RA patients, GG genotype frequency was higher in severe RA patients than mild RA patients. Moreover, there was significant difference between severe

RA patients and OA patients (P = 0.009), also the allele distribution was significant different between severe RA, mild RA, and OA patients (P = 0.025, 95%CI = 0.61-0.93). With respect to gender, GG genotype was statistically more frequent in female RA patients than that of OA, while such an association was not observed in men. Above all, the presence of the GG genotype could be a risk factor for RA and such trend might be different in gender, although additional larger scale study is needed.

TI A proteomic study of protein variation between osteopenic and age-matched control bone tissue
SO EXPERIMENTAL BIOLOGY AND MEDICINE
LA English
DT Article
DE osteoporosis; proteomics; proteins; carbonic anhydrase; phosphoglycerate kinase; apolipoprotein
ID renal tubular-acidosis; induced metabolic-acidosis; carbonic-anhydrase-ii; mineral density; gene-expression; women; osteoporosis; fractures; serine; substitutions
AB The focus of this study was to identify changes in protein expression within the bone tissue environment between osteopenic and control bone tissue of human femoral neck patients with osteoarthritis. Femoral necks were compared from osteopenic patients and age-matched controls. A new method of bone protein extraction was developed to provide a swift, clear view of the bone proteome. Relative changes in protein expression between control and osteopenic samples were quantified using difference gel electrophoresis (DIGE) technology after affinity chromatographic depletion of albumin and IgG. The proteins that were determined to be differentially expressed were identified using standard liquid chromatography mass spectrometry (LC/MS/MS) and database searching techniques. In order to rule out blood contamination, blood from age-matched osteoporotic, osteopenic and controls were analyzed in a similar manner. Image analysis of the DIGE gels indicated that 145 spots in the osteopenic bone samples changed at least +/- 1.5-fold from the control samples ($P < 0.05$). Three of the proteins were identified by LC/MS/MS. Of the proteins that increased in the osteopenic femurs, two were especially significant: carbonic anhydrase I and phosphoglycerate kinase 1. Apolipoprotein A-I was the most prominent protein that significantly decreased in

the osteopenic femurs. The blood samples revealed no significant differences between groups for any of these proteins. In conclusion, carbonic anhydrase I, phosphoglycerate kinase 1 and apolipoprotein A-I appeared to be the most significant variations of proteins in patients with osteopenia and osteoarthritis.

TI Defining physiologically "normal" vitamin D in African Americans
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE African American; Osteoporosis; Parathyroid hormone; Racial differences; Thresholds; Vitamin D
ID d-endocrine system; parathyroid-hormone; racial-differences; hypovitaminosis-d; d insufficiency; d inadequacy; white; prevalence; calcium; women
AB The relationship between serum 25(OH)D and intact parathyroid hormone (iPTH) was evaluated in the Multicenter Osteoarthritis Study (MOST). No further change in iPTH was observed for African Americans with 25(OH)D levels above 20 ng/ml, suggesting that compared to Caucasians, lower vitamin D targets for sufficiency may be appropriate for African Americans. Vitamin D levels a parts per thousand yen30 ng/ml are commonly considered "normal" based upon maximal

suppression of iPTH; however, this has recently been challenged and the optimal 25(OH)D level among non-Caucasians is unclear. We evaluated the cross-sectional relationship between serum 25(OH)D and iPTH in a sample of Caucasian and African American adults. We used baseline serum samples of participants from the Multicenter Osteoarthritis Study (MOST) for this analysis and used three methods to model the relationship between 25(OH)D and iPTH: ordinary least squares regression (OLS), segmented regression and Helmert contrasts. Among Caucasians (n = 1,258), 25(OH)D and iPTH ranged from 4 to 51 ng/ml and 2 to 120 pg/ml and from 3 to 32 ng/ml and 3 to 119 pg/ml in African Americans (n = 423). We observed different thresholds between African Americans and Caucasians using each analytic technique. Using 25(OH)D as a categorical variable in OLS, iPTH was statistically higher at lower 25(OH)D categories than the 24-32 ng/ml referent group among Caucasians. However, in African Americans, the mean iPTH was only significantly higher at 25(OH)D levels below 15 ng/ml. Using segmented regression, iPTH appeared to stabilize at a lower 25(OH)D level in African Americans (19-23 ng/ml) compared to in Caucasians (> 32 ng/ml). Helmert contrasts also revealed a lower threshold in African Americans than Caucasians. Among MOST participants, the 25(OH)D thresholds at which no further change in iPTH was observed was approximately 20 ng/ml in African Americans versus approximately 30 ng/ml in Caucasians, suggesting optimal vitamin D levels in Caucasians may not be applicable to African Americans.

TI The rate of hip osteoarthritis in patients with proximal femoral fractures versus

hip contusion
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE Osteoarthritis; Osteoporosis; Osteoporotic fractures; Proximal femoral fractures
ID bone-mineral density; osteoporosis; women; femur
AB We found no difference in the rate of radiological hip osteoarthritis in the injured hip when comparing 349 patients with proximal femoral fractures and 112 patients with hip contusion. There was, however, a tendency for more osteoarthritis in patients with trochanteric fractures than in patients with femoral neck fractures. Osteoarthritis (OA) and osteoporotic fractures are two age-related disorders associated with considerable morbidity. There is a clinical impression of an inverse relation between osteoarthritis and osteoporosis, and a protective effect of OA against osteoporotic fractures has been proposed. We performed a case-control study in 461 subjects. Cases (n = 349) were patients aged 50 years or above who sustained a proximal femoral fracture from November 2003 to October 2004, registered prospectively in the department's fracture register. Controls (n = 112) were patients aged 50 years or above with the diagnosis of hip contusion, recruited from the hospital's discharge register. Radiographic OA was scored according to Kellgren and Lawrence (K&L), and minimal joint space (MJS) was measured in both hips when possible. A K&L grade II or higher or an MJS less than 2.5 mm was defined as OA. Both in the hip fracture group and in the contusion group mean, the MJS was 3.5 mm on the injured side (p = 0.79). In the fracture group, 31/250 (12%) had MJS < 2.5 mm and 16/112 (14%) in the contusion group (p = 0.18). In the fracture group, 40/250 (16%) had a K&L OA grade II or higher, and in the contusion group 20/112 (18%) persons had a K&L OA grade II or higher (p = 0.66). There was a tendency for a higher incidence of OA in patients with trochanteric fractures compared with patients with cervical fractures. We found no differences on the injured side in the rate of hip OA between hip fracture patients and hip contusion patients.

TI Correlations between structural and mechanical properties of human trabecular femur bone
SO ACTA OF BIOENGINEERING AND BIOMECHANICS
LA English
DT Article
DE osteoporosis; osteoarthritis; mechanical properties; microtomography
ID cancellous bone; architecture; strength; histomorphometry; parameters; dependence; behavior; tissue
AB In this article, the author presents mathematical relationships between the structural and mechanical properties of cancellous human bone tissue obtained by experimental analysis of specimens. Bone tissue material can adjust its internal structure to the existing loading conditions. The mechanical properties affect the structural properties but changes in structural properties likewise cause changes in the mechanical properties of the tissue. In normal tissue, the processes of tissue construction, destruction, and reconstruction are mutually balanced and complementary; if that balance is disturbed, lesions can occur. Therefore, normal bone tissue and pathologically changed tissue (osteoporosis and osteoarthrosis) coming from the area of human femoral head were examined. The structural properties of cancellous tissue specimens were determined non-destructively for three-dimensional reconstructions with the use of modern micro-CT methods. The mechanical properties of the specimens were determined by an uniaxial compression test in three orthogonal directions. Next, in order to specify the compressive strength, a failure test was conducted in the direction perpendicular to the neck-shaft angle of the hip joint.

TI Orthogenomics: An Update
SO JOURNAL OF THE AMERICAN ACADEMY OF ORTHOPAEDIC SURGEONS
LA English
DT Review
ID bone-mineral density; genome-wide association; pagets-disease; osteoarthritis; susceptibility; variants; ossification; gene; frzb; hip
AB The study of genomics in orthopaedics has considerably lagged behind such study in other medical disciplines. Seminal work from other lines of medical research demonstrates the importance of genomic information in the evolution of personalized medicine. Common techniques for studying genome-phenotype associations include single nucleotide polymorphism, haplotype, and quantitative trait loci analysis. The few genome-based studies in major orthopaedic and related conditions have focused on osteoporosis, osteoarthritis, neuropathy and nerve compression, spinal deformity, trauma and inflammatory response, and pain and analgesia. The nascent field of orthogenomics, newly defined here as the application of genomic study to orthopaedic practice, has produced findings that could affect the practice of orthopaedics. However, more work is required, and the findings must be distilled and harnessed into applicable and achievable steps to improve clinical orthopaedic practice.

TI Risk of hip fracture with hip or knee osteoarthritis: a systematic review
SO CLINICAL RHEUMATOLOGY
LA English
DT Review
DE Hip fracture; Hip fracture risk; Osteoarthritis; Systematic review
ID bone-mineral density; subchondral bone; pain; osteoporosis; epidemiology; arthritis; falls; gait; need; end
AB Osteoarthritis (OA) and hip fracture are two common musculoskeletal disorders associated with substantial societal and personal burden. The objective of this systematic review was to determine the association between hip or knee OA and

risk of hip fractures in people aged 45 years and older as compared to people aged 45 years and older who do not have OA. We searched CINAHL, Cochrane Database of Systematic Reviews, Embase, OVID Medline, PUBMED, and SCOPUS for studies published up to July 2010 and conducted forward searches of included studies using Web of Science. Two reviewers independently screened articles for inclusion, extracted data, and evaluated the risk of bias of included studies using the Newcastle-Ottawa Scale. Eleven articles were included. Three investigated individuals with knee OA, two included adults with knee or hip OA, and six investigated adults with hip OA. We did not combine the hip OA or the knee OA studies in a meta-analysis due to the heterogeneity in: study populations and covariates adjusted for in estimates of association. Hip OA may be related to a decreased risk of hip fracture when considering crude estimates of association or estimates of association adjusted for a limited number of covariates, although not all studies found support for the presence of this association. The association between knee OA and hip fracture remains unclear. The presence of OA in the hip or knee should not act as an indication that assessment for hip fracture risk is unnecessary.

TI Bone Turnover Markers Failed to Predict the Occurrence of Osteonecrosis of the Femoral Head-A Preliminary Study
SO JOURNAL OF CLINICAL LABORATORY ANALYSIS
LA English
DT Article
DE 25-hydroxy-cholecalciferol; bone specific alkaline phosphatase; beta crosslaps; osteocalcin; parathormone; Osteonecrosis of the femoral head; bone turnover marker
ID total hip-arthroplasty; biochemical markers; postmenopausal women; mineral density; heterotopic ossification; degradation-products; osteoporosis; risk; osteolysis; management
AB Background: The early detection of osteonecrosis of the femoral head (ONFH) is difficult, but important for prevention of destruction of the femoral head. The objective of this study was to determine whether the occurrence of osteonecrosis of the femoral head (ONFH) correlates with changes in bone turnover markers. Methods: In 40 patients undergoing primary total hip arthroplasty (THA), different bone turnover markers and hormones (bone specific alkaline phosphatase, osteocalcin, beta cross-laps, 25-hydroxy-cholecalciferol, and parathormone) gained from blood were determined on the morning of the surgery. Twenty-two patients needed a THA due to progressed ONFH. In 18 cases blood was gained from patients with the indication for a THA given due to advanced osteoarthritis (AO) of the hip. Results: Bone specific alkaline phosphatase, osteocalcin, beta cross-laps, and parathormone did not show any deviation from standard values, neither for the group of osteonecrosis nor for the osteoarthritis group.
25-Hydroxy-cholecalciferol revealed on average decreased values without significant differences between both groups ($P < 0.05$). The tested bone turnover markers and hormones failed to predict the occurrence of ONFH. Thus, the focus has to be put on different parameters to find a specific parameter that possibly predicts the risk of ostenecrosis and that is suited to follow up ONFH. J. Clin. Lab. Anal. 26:55-60, 2012. (C)2012 Wiley Periodicals, Inc.

TI Management of Glucocorticoid-Induced Osteoporosis
SO CALCIFIED TISSUE INTERNATIONAL
LA English
DT Article
DE Glucocorticoid; FRAX; Bone therapy; Osteoporosis; Fracture
ID bone-mineral density; corticosteroid-induced osteoporosis; vertebral fracture risk; methylprednisolone pulse therapy; low-dose prednisone; double-blind; oral corticosteroids; postmenopausal women; long-term; inhaled corticosteroids
AB This review summarizes the available evidence-based data that form the basis

for therapeutic intervention and covers the current status of glucocorticoid-induced osteoporosis (GIOP) management, regulatory requirements, and risk-assessment options. Glucocorticoids are known to cause bone loss and fractures, yet many patients receiving or initiating glucocorticoid therapy are not appropriately evaluated and treated. An European Society for Clinical and Economic Aspects of Osteoporosis and Osteoarthritis workshop was convened to discuss GIOP management and to provide a report by a panel of experts. An expert panel reviewed the available studies that discussed approved therapeutic agents, focusing on randomized and controlled clinical trials reporting on bone mineral density and/or fracture risk of at least 48 weeks' duration. There is no evidence that GIOP and postmenopausal osteoporosis respond differently to treatments. The FRAX algorithm can be adjusted according to glucocorticoid dose. Available antiosteoporotic therapies such as bisphosphonates and teriparatide are efficacious in GIOP management. Several other agents approved for the treatment of postmenopausal osteoporosis may become available for GIOP. It is advised to stop antiosteoporotic treatment after glucocorticoid cessation, unless the patient remains at increased risk of fracture. Calcium and vitamin D supplementation as an osteoporosis-prevention measure is less effective than specific antiosteoporotic treatment. Fracture end-point studies and additional studies investigating specific subpopulations (pediatric, premenopausal, or elderly patients) would strengthen the evidence base and facilitate the development of intervention thresholds and treatment guidelines.

TI Low osteocalcin/collagen type I bone gene expression ratio is associated with hip fragility fractures
SO BONE
LA English
DT Article
DE Osteocalcin; Apolipoprotein E; Osteoporosis; Bone mechanical behavior; Fragility fractures
ID apolipoprotein-e; mineral density; osteoporotic fractures; elderly-women; undercarboxylated osteocalcin; phylloquinone vitamin-k-1; mechanical-property; postmenopausal women; biochemical markers; circulating levels
AB Introduction: Osteocalcin (OC) is the most abundant non-collagenous bone protein and is determinant for bone mineralization. We aimed to compare OC bone expression and serum factors related to its carboxylation in hip fragility fracture and osteoarthritis patients. We also aimed to identify which of these factors were associated with worse mechanical behavior and with the hip fracture event. Methods: In this case-control study, fragility fracture patients submitted to hip replacement surgery were evaluated and compared to a group of osteoarthritis patients submitted to the same procedure. Fasting blood samples were collected to assess apolipoproteinE (apoE) levels, total OC and undercarboxylated osteocalcin (ucOC), vitamin K. LDL cholesterol, triglycerides and bone turnover markers. The frequency of the apo epsilon 4 isoform was determined. Femoral epiphyses were collected and trabecular bone cylinders drilled in order to perform compression mechanical tests. Gene expression of bone matrix components was assessed by quantitative RT-PCR analysis. Results: 64 patients, 25 submitted to hip replacement surgery due to fragility fracture and 39 due to osteoarthritis, were evaluated. Bone OC/collagen expression (OC/COL1A1) ratio was significantly lower in hip fracture

compared to osteoarthritis patients (p<0.017) adjusted for age, gender and body mass index. Moreover, OC/COL1A1 expression ratio was associated with the hip fracture event (OR similar to 0; p = 0.003) independently of the group assigned, or the clinical characteristics. Apo epsilon 4 isoform was more frequent in the hip fracture group (p = 0.029). ucOC levels were higher in the fracture group although not significantly (p = 0.058). No differences were found regarding total DC (p = 0.602), apoE (p = 0.467) and Vitamin K (p = 0.371). In hip fracture patients, multivariate analysis, adjusted for clinical characteristics, serum factors related to DC metabolism and gene expression of bone matrix proteins showed that low OC/COL1A1 expression ratio was significantly associated with worse trabecular strength (beta = 0.607; p = 0.013) and stiffness (beta = 0.693; p = 0.003). No association was found between ucOC and bone mechanics. Moreover, in osteoarthritis patients, the multivariate analysis revealed that serum total DC was negatively associated with strength (beta = -0.411; p = 0.030) and stiffness (beta = -0.487; p = 0.009). Conclusion: We demonstrated that low bone OC/COL1A1 expression ratio was an independent predictor of worse trabecular mechanical behavior and of the hip fracture event. These findings suggest that in hip fracture patients the imbalance of bone OC/COL1A1 expression ratio reflects disturbances in osteoblast activity leading to bone fragility. (C) 2012 Elsevier Inc. TI Long-term treatment of osteoporosis in postmenopausal women: a review from the European Society for Clinical and Economic Aspects of Osteoporosis and Osteoarthritis (ESCEO) and the International Osteoporosis Foundation (IOF)
SO CURRENT MEDICAL RESEARCH AND OPINION
LA English
DT Review
DE Bisphosphonate; Calcium; Denosumab; Fracture; Long-term treatment; Osteoporosis; SERM; Strontium ranelate; Vitamin D
ID vitamin-d supplementation; vertebral fracture risk; continuing outcomes relevant; hormone replacement therapy; invasive breast-cancer; nonvertebral fractures; randomized-trial; atrial-fibrillation; strontium ranelate; hip fracture
AB Introduction: Postmenopausal osteoporosis is a chronic disease requiring treatment that balances long-term fracture efficacy against risk. Methods: We reviewed the efficacy and safety of calcium and vitamin D, the selective estrogen receptor modulators (SERMs), the bisphosphonates, denosumab, and strontium ranelate in studies of 3 years or longer. Results: Six trials lasted for 5 years, and seven went beyond that. The evidence beyond 5 years is generally weak, mainly

due to methodological issues (open-label design, small samples, or absence of placebo control). Although calcium and vitamin D appear to be beneficial, the data are insufficient to evaluate benefits and risk beyond 3 years. The fracture efficacy of SERMs beyond 5 years is not known, though increases in bone mineral density (BMD) appear to be maintained. The SERMs have good long-term safety, including protective effects against breast cancer. The bisphosphonates have established fracture efficacy to 3 years, and 4 or 5 years with alendronate and risedronate. The evidence beyond 5 years indicates sustained increases in BMD. The safety of the bisphosphonates does not appear to be modified with time, with the possible exceptions of atypical subtrochanteric fracture and other events of unknown frequency. Denosumab has been tested up to 5 years, with continued increased in BMD and no reported safety issues. There is evidence for fracture efficacy of strontium ranelate, and sustained increases in BMD over 10 years. Strontium ranelate has good long-term safety. Conclusion: Robust long-term studies are relatively rare for the osteoporosis treatments, and generally show maintenance of BMD and, for some agents, an additional reduction in fracture incidence.

TI Does ultrasonographic foetal head position prior to induction of labour predict the outcome of delivery?
SO EUROPEAN JOURNAL OF OBSTETRICS & GYNECOLOGY AND REPRODUCTIVE BIOLOGY
LA English
DT Article
DE Induction of labour; Occipitoposterior position; Foetal head position; Mode of delivery; Prediction; Ultrasonography; Labour presentation
ID occiput posterior position; intrapartum sonography; epidural analgesia; vaginal delivery
AB Objective: To examine the capacity of pre-induction sonographic assessment of occipital position of the foetal head to predict the outcome of delivery, and to assess whether sonographic foetal head position before induction of labour is related to foetal presentation at delivery. Study design: A prospective cohort study was conducted in the Maxima Medical Centre, The Netherlands. We included consecutive women in whom labour was induced. Immediately prior to induction a

transabdominal ultrasound was performed to determine the position of the foetal occiput. The primary outcome was mode of delivery. We recorded maternal demographics, labour and delivery characteristics, maternal and neonatal outcomes. The association between position of the foetal head before induction of labour and the occurrence of caesarean section was addressed using univariable and logistic regression analysis. Results: From the 50 of the 183 foetuses that started labour in occipitoposterior position, 11 persisted in occipitoposterior position until birth, whereas from the 120 foetuses that were in occipitoanterior position before induction, three children were born in an occipitoposterior position. Although we found a difference in caesarean section rate between OP position and OA position of the foetal head at sonography prior to induction, this was not statistically significant (14% versus 6.7%, OR 2.3,95% CI 0.78-6.7). Conclusion: Our study demonstrates that OP position prior to labour induction does not affect mode of delivery. Sonographic assessment of the position of the foetal head prior to labour induction should not be introduced in clinical practice.

TI Subchondral bone as a key target for osteoarthritis treatment

SO BIOCHEMICAL PHARMACOLOGY
LA English
DT Article
DE Subchondral bone; Osteoarthritis; Pathogenesis; Antiresorptives; New therapies
ID anterior cruciate ligament; estrogen replacement therapy; meniscectomized guinea-pig; knee osteoarthritis; articular-cartilage; strontium ranelate; prostaglandin e-2; salmon-calcitonin; trabecular bone; mineral density
AB Osteoarthritis (OA), the most common form of arthritis, is a debilitating and progressive disease that has become a major cause of disability and impaired quality of life in the elderly. OA is considered an organ disease that affects the whole joint, where the subchondral bone (SB) plays a crucial role. Regardless of whether SB alterations precede cartilage damage or appear during the evolution of the disease, SB is currently recognised as a key target in OA treatment. In fact, bone abnormalities, especially increased bone turnover, have been detected in the early evolution of some forms of OA. Systemic osteoporosis (OP) and OA share a paradoxical relationship in which both high and low bone mass conditions may result in induction and/or OA progression. Recent findings suggest that some drugs may be useful in treating both processes simultaneously, at least in a subgroup of patients with OA and OP. This review focuses on the role of SB in OA pathogenesis, describing relevant underlying mechanisms involved in the process and examining the potential activity as disease-modifying anti-osteoarthritic drugs (DMOADs) of certain SB-targeting agents currently under study. TI Oral Calcitonin
SO CURRENT OSTEOPOROSIS REPORTS
LA English
DT Article
DE Calcitonin; Oral; Osteoporosis; Fracture; Osteoarthritis
ID alpha-amino-acids; salmon-calcitonin; postmenopausal women; bone; efficacy; osteoporosis; formulation; delivery; agents
AB Both injectable and nasal spray calcitonins have been utilized in the treatment of postmenopausal osteoporosis for over 25 years. More widespread use of calcitonin in the treatment of osteoporosis has been hampered in part due to poor patient acceptability and compliance and the inability of patients to take this medication as an oral pill. In recent years, an oral preparation of calcitonin has been developed that combines the active peptide hormone with a caprylic acid derivative to enhance bioavailability. Clinical trials with oral calcitonin in patients with osteoarthritis are currently being conducted. A recent phase 3 study failed to demonstrate significant vertebral fracture reduction, and as a result the clinical

program for oral calcitonin in osteoporosis is under review for further consideration.

TI Improving musculoskeletal health: Global issues
SO BEST PRACTICE & RESEARCH IN CLINICAL RHEUMATOLOGY
LA English
DT Article
DE Musculoskeletal health; Prevention; Human resources; Arthritis; Osteoporosis; Road traffic injuries; Developing countries; Health workers
ID human-immunodeficiency-virus; risk-factors; classification criteria; undergraduate education; knee osteoarthritis; rheumatic-diseases; american-college; united-states; hip fracture; prevalence
AB Musculoskeletal (MSK) disorders are among the leading reasons why patients

consult a family or primary health practitioner, take time off work and become disabled. Many of the MSK disorders are more common in the elderly. Thus, as the proportion of the elderly increases all over the world, MSK disorders will make a greater contribution to the global burden of disease. Epidemiological studies have shown that the spectrum of MSK disorders in developing countries is similar to that seen in industrialised countries, but the burden of disease tends to be higher due to a delay in diagnosis or lack of access to adequate health-care facilities for effective treatment. Musculoskeletal pain is very common in the community while fibromyalgia is being recognised as part of a continuum of chronic widespread pain rather than a narrowly defined entity. This will allow research to improve our understanding of pain in a variety of diffuse pain syndromes. The availability of newer more effective therapies has resulted in efforts to initiate therapy at an earlier stage of diseases. The new criteria for rheumatoid arthritis, and the diagnosis of axial and peripheral involvement in spondyloarthritis, permit an earlier diagnosis without having to wait for radiological changes. One of the major health challenges is the global shortage of health workers, and based on current training of health workers and traditional models of care for service delivery, the global situation is unlikely to change in the near future. Thus, new models of care and strategies to train community health-care workers and primary health-care practitioners to detect and initiate the management of patients with MSK disorders at an earlier stage are required. There is also a need for prevention strategies with campaigns to educate and raise awareness among the entire population. Lifestyle interventions such as maintaining an ideal body weight to prevent obesity, regular exercises, avoidance of smoking and alcohol abuse, intake of a balanced diet and nutrients to include adequate calcium and vitamin D, modification of the work environment and avoidance of certain repetitive activities will prevent or ameliorate disorders such as osteoarthritis, osteoporosis, rheumatoid arthritis, gout and MSK pain syndromes including low back pain and work-related pain syndromes. These prevention strategies also contribute to reducing the prevalence and outcome of diseases such as hypertension, cardiovascular diseases, diabetes and respiratory diseases. Thus, prevention strategies require urgent attention globally. (C) 2012 Elsevier Ltd. All rights reserved.

TI Oleanolic acid exerts an osteoprotective effect in ovariectomy-induced osteoporotic rats and stimulates the osteoblastic differentiation of bone mesenchymal stem cells in vitro
SO MENOPAUSE-THE JOURNAL OF THE NORTH AMERICAN MENOPAUSE SOCIETY
LA English
DT Article
DE Oleanolic acid; Ovariectomy; Stem cell microarray; Bone mesenchymal stem cell; Osteoporosis
ID gene-expression; different phases; notch; markers; number; agents; vivo; wnt
AB Objective: Oleanolic acid (OA) and its glycosides have been reported to prevent

bone loss by inhibiting the formation of osteoclasts. However, because bone formation and resorption are balanced processes in bone metabolism, no studies have described the effect of OA on osteogenesis. The aim of the present study was to evaluate the osteoprotective effect of OA in rats with ovariectomy (OVX)-induced osteoporosis and to search for the molecular targets of OA in bone mesenchymal stem cells (bMSCs). Methods: Two-month-old female mice that underwent OVX were treated with OA (20 mg/kg a day). After 2 weeks and after 3 months, bone mass was evaluated by micro-CT, morphometry, and immunohistochemical detection. In addition, the expression of 256 genes was measured via microarray and confirmed by real-time reverse transcription-polymerase chain reaction. The effects of OA on the activities of bMSCs were also observed in vitro using alkaline phosphatase and cell proliferation assays. Results: Micro-CT displayed only a tendency for bone loss at 2 weeks but a decrease in bone mass at 3 months after OVX. OA treatment increased osteoblast number, increasing osteocalcin and runt-related protein 2 protein levels in vivo and facilitating the osteoblastic differentiation of bMSCs in vitro at doses of 10(-6) and 10(-5) M. Gene expression profile analysis revealed that OVX caused a marked dysregulation of gene expression, especially at 2 weeks, some of which was rescued by OA. Few of these genes overlapped, but their functions were involved in the Notch signaling pathway between two phases of the osteoporotic process. Conclusions: OA exerts an osteoprotective effect in OVX-induced osteoporotic rats and stimulates the osteoblastic differentiation of bMSCs in vitro. The molecular mechanism of this effect might be related to the Notch signaling pathway and requires further investigation.

TI Prevalence of symptomatic lumbar spinal stenosis and its association with physical performance in a population-based cohort in Japan: the Wakayama Spine Study
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE Magnetic resonance imaging; Prevalence; Lumbar spinal stenosis; Cross-sectional
ID myelography; diagnosis; people; adults; pain; age; hip
AB Objective: The purpose of this study was to investigate the prevalence of symptomatic lumbar spinal stenosis (LSS) and to clarify the association between symptomatic LSS and physical performance using magnetic resonance imaging (MRI) in a population-based cohort. Design: This cross-sectional study was performed as a part of the Research on Osteoarthritis/osteoporosis Against Disability (ROAD) in Japan and 1,009 subjects (335 men, 674 women, mean age 66.3 years, age range 21-97 years) were analyzed. An experienced orthopedic surgeon obtained the medical history and performed the physical testing for all participants. Symptomatic LSS diagnostic criteria required the presence of both symptoms and radiographic LSS findings. A 6-m walking time, chair standing time, and one-leg standing time were obtained from all participants. Results: The prevalence of symptomatic LSS was 9.3% (95% confidence interval [CI]: 7.7-11.3) overall, 10.1% (CI: 7.4-13.8) in men and 8.9% (CI: 7.0-11.3) in women. There was a difference in the prevalence with increasing age by gender. The LSS prevalence showed little difference with age greater than 70 years for men, but the LSS prevalence for women was higher with increasing age. Among physical performance measures, 6-m walking time at a maximal pace was significantly associated with symptomatic LSS (P = 0.03). Conclusion: The prevalence of symptomatic LSS was approximately 10% in a cohort resembling the general Japanese population. A 6-m walking time at a maximal pace was a more sensitive index than walking at a usual pace in assessing decreased physical performance associated with symptomatic LSS. ID subchondral vascular system; endothelial growth-factor; knee osteoarthritis; cartilage degradation; rat model; metalloproteinase inhibitor; endochondral ossification; chondrocyte phenotype; structural arthritis; biochemical markers
AB Osteoarthritis (OA) is a major cause of pain and disability in the aging population, but its pathogenesis remains incompletely understood. Alterations beneath the articular cartilage at the osteochondral junction are attracting interest as possible mediators of pain and structural progression in OA. Osteochondral changes occur early during the development of OA and may aggravate pathology elsewhere in the joint. Loss of osteochondral integrity removes the barrier between intra-articular and subchondral compartments, exposing subchondral bone and its nerves to abnormal chemical and biomechanical influence. Osteochondral plasticity results in a merging of tissue compartments across the junction. Loss of the clearly differentiated demarcation between bone and articular cartilage is associated with invasion of articular cartilage by blood vessels and sensory nerves, and advancing endochondral ossification. Increased subchondral bone turnover is intimately associated with these alterations at the osteochondral junction. Cells signal across the osteochondral junction, and this cross-talk may be both a consequence of, and contribute to these pathological changes. Bone turnover, angiogenesis and nerve growth are also features of other diseases such as osteoporosis and cancers, for which therapeutic interventions are already advanced in their development. Here we review pathological changes at the osteochondral junction and explore their potential therapeutic implications for OA. This article is part of a Special Issue entitled "Osteoarthritis". AB Osteoporosis is a global health problem characterized by low bone mass and an increase in bone fragility. It is now well accepted that dietary factors play a central role in bone development and health. Diet that lacks adequate minerals is considered to be a risk factor for osteoporosis. The food supplement, Aquamin, is a natural, multi-mineral derived from the red algae Lithothamnion corallioides, rich in calcium, magnesium and 72 other trace minerals. The aim of this study was to evaluate the effect of Aquamin on osteoblastic behaviour and mineralisation in a pre-osteoblastic cell line. Cell number and metabolic activity were assessed using Hoescht DNA and AlamarBlue assays respectively. Osteogenic differentiation was measured using an alkaline phosphatase assay while mineralisation was determined using von Kossa and alizarin red staining. It is reported here that Aquamin promotes increased mineralisation in osteoblast cell culture. These data suggest that the nutritional supplement Aquamin plays an important role in promoting bone formation and may be useful in treating bone diseases such as osteoporosis. TI Bilateral tibial stress fractures: a case report
SO EUROPEAN JOURNAL OF ORTHOPAEDIC SURGERY AND TRAUMATOLOGY
LA English
DT Article
DE Knee pain; Osteoporosis; Spontaneous; Stress fracture; Tibial
ID leg pain; periosteal
AB A stress fracture can be defined as a fracture of a bone caused by repeated (rather than sudden) mechanical stress. They have been reported in almost all bones of the body, with the lower extremity weight bearing bones, especially the tibia, tarsals and metatarsals, being affected most often. These injuries have a broad spectrum of severity and prognosis. Although the pathology of this injury is understood, the aetiology is less agreed upon. This can make it difficult for clinicians to diagnose and treat this common injury. Stress fractures of the proximal tibiae are common in elderly patients with osteoarthritis, and they are also reported in children. Here, we report an unusual case of an otherwise fit, young, adult male who presented with bilateral insufficiency stress fractures occurring simultaneously in both proximal tibiae. Stress fractures should be a differential diagnosis in any young, fit adult who presents with spontaneous knee pain.

TI A Correlation Exists Between Subchondral Bone Mineral Density of the Distal Radius and Systemic Bone Mineral Density
SO CLINICAL ORTHOPAEDICS AND RELATED RESEARCH
LA English
DT Article
ID skeletal structural adaptations; mechanical usage satmu; redefining wolff law; predicting osteoporosis; postmenopausal women; hand osteoarthritis; colles fracture; grip strength; young-adults; follow-up
AB Intraarticular distal radius fractures are common and risk articular congruity owing to disruption of the subchondral bone. Studies regarding microstructure and mechanical properties of the distal radius, however, focus only on the cortical and trabecular bones in the metaphysis and not on the subchondral bone. This study was conducted to (1) quantify the regional bone mineral density of the subchondral plate in the distal radius; (2) analyze the topographic distribution pattern of the subchondral bone mineral density; and (3) evaluate the correlation between the subchondral bone mineral density and the potentially related clinical factors of age, height, weight, BMI, systemic bone mineral densities, socio-occupational classification, and hand osteoarthritis grading. Eighty postmenopausal women with a mean age of 68 years (range, 52-88 years) were enrolled in this study. Digital images of the distal radii of the subjects were scanned by conventional CT and processed to provide the regional bone mineral density of the subchondral plate using a CT osteoabsorptiometry technique. The estimated subchondral bone mineral density was analyzed to evaluate the topographic pattern and its correlation with various clinical factors, including age, height, weight, BMI, degree of hand osteoarthritis, socio-occupational class, and systemic bone mineral density measured in the lumbar spine and hip. During topographic analysis of a densitometric map, a bicentric distribution of the subchondral bone mineral density was found. Among the clinical factors, only the systemic bone mineral density measured by dual-energy x-ray absorptiometry in the femur neck and lumbar spine had a significant correlation with the subchondral bone mineral density of the distal radius. Systemic bone mineral density correlates substantially with the subchondral bone mineral density of the distal radius as a constitutional factor, whereas other local factors arising from the gravitational load or joint reaction force are not associated with the subchondral bone mineral density of the distal radius. Level II, prognostic study. See Guidelines for Authors for a complete description of levels of evidence.

DT Article
ID beta-substituted cyclohexanecarboxamide; bone-resorption; medicinal chemistry; drug discovery; i collagen; design; target; lysosomotropism; lipophilicity; osteoporosis
AB Directed screening of nitrile compounds revealed 3 as a highly potent cathepsin K inhibitor but with cathepsin S activity and very poor stability to microsomes. Synthesis of compounds with reduced molecular complexity, such as 7, revealed key SAR and demonstrated that baseline physical properties and in vitro stability were in fact excellent for this series. The tricycle carboline P3 unit was discovered by hypothesis-based design using existing structural information. Optimization using small substituents, knowledge from matched molecular pairs, and control of lipophilicity yielded compounds very close to the desired profile, of which 34 (AZD4996) was selected on the basis of pharmacokinetic profile.

TI Low BMD affects initial stability and delays stem osseointegration in cementless total hip arthroplasty in women A 2-year RSA study of 39 patients
SO ACTA ORTHOPAEDICA
LA English
DT Article
ID weight-bearing; proximal femur; femoral stems; follow-up; bone; radiostereometry; osteoarthritis; replacement; migration; implants
AB Background and purpose Immediate implant stability is a key factor for success in cementless total hip arthroplasty (THA). Low bone mineral density (BMD) and age-related geometric changes of the proximal femur may jeopardize initial stability and osseointegration. We compared migration of hydroxyapatite-coated femoral stems in women with or without low systemic BMD. Patients and methods 61 female patients with hip osteoarthritis were treated with cementless THA with anatomically designed hydroxyapatite-coated femoral stems and ceramic-ceramic bearing surfaces (ABG-II). Of the 39 eligible patients between the ages of 41 and 78 years, 12 had normal systemic BMD and 27 had osteopenia or osteoporosis. According to the Dorr classification, 21 had type A bone and 18 had type B. Translational and rotational migration of the stems was evaluated with radiostereometric analysis (RSA) up to 2 years after surgery. Results Patients with low systemic BMD showed higher subsidence of the femoral stem during the first 3 months after surgery than did those with normal BMD (difference = 0.6, 95% CI: 0.1-1.1; p = 0.03). Low systemic BMD (odds ratio (OR) = 0.1, CI: 0.006-1.0; p = 0.02), low local hip BMD (OR = 0.3, CI: 0.1-0.7; p = 0.005) and ageing (OR = 1.1, CI: 1.0-1.2; p = 0.02) were risk factors for delayed translational stability. Ageing and low canal flare index were risk factors for delayed rotational stabilization (OR = 3, CI: 1.1-9; p = 0.04 and OR = 1.1, CI: 1.0-1.2; p = 0.02, respectively). Harris hip score and WOMAC score were similar in patients with normal systemic BMD and low systemic BMD. Interpretation Low BMD, changes in intraosseous dimensions of the proximal femur, and ageing adversely affected initial stability and delayed osseointegration of cementless stems in women.

TI Serum intact-parathyroid hormone level following total knee arthroplasty
SO JOURNAL OF ORTHOPAEDIC SURGERY
LA English
DT Article
DE arthroplasty, replacement, knee; osteoarthritis, knee; osteoporosis, postmenopausal; parathyroid hormone
AB Purpose. To evaluate short-term parathyroid hormone (PTH) secretion following total knee arthroplasty (TKA). Methods. 119 Caucasian postmenopausal women aged 49 to 81 (mean, 69.8) years who underwent TKA for end-stage knee osteoarthritis were included. Serum levels of intact-PTH, calcium, phosphorus, and creatinine were evaluated pre-and post-operatively (on days -1 and 7). Creatinine clearance was also calculated. Results. In 67 of the patients, serum intact-PTH levels decreased after TKA; this sample proportion was not significant (p=0.82). In 16 of the patients, such levels elevated abnormally (above normal range). In the remaining 36 patients, such levels elevated within the normal range. Therefore, the mean serum intact-PTH level of all patients increased slightly after TKA (45.4 vs. 45.3, p=0.162). The serum intact-PTH level did not correlate to body weight (r=-0.045, p=0.624), patient age (r=-0.061, p=0.508), serum creatinine level (r=0.084, p=0.366), and clearance of creatinine (r=-0.037, p=0.692). Conclusion. In most postmenopausal women, the serum intact-PTH level decreased moderately following TKA, but in some, the level was abnormally elevated. This may interfere the prosthesis incorporation process.

TI Tai Chi and yoga as complementary therapies in rheumatologic conditions
SO BEST PRACTICE & RESEARCH IN CLINICAL RHEUMATOLOGY
LA English
DT Article
DE Complementary therapy; Tai Chi; Yoga; Rheumatologic disease; Musculoskeletal; Rheumatoid arthritis; Osteoarthritis; Osteoporosis; Fibromyalgia; Outcomes
ID bone-mineral density; quality-of-life; knee osteoarthritis; muscle strength; disease-activity; iyengar yoga; older-adults; arthritis; exercise; pilot
AB Tai Chi and yoga are complementary therapies which have, during the last few decades, emerged as popular treatments for rheumatologic and musculoskeletal diseases. This review covers the evidence of Tai Chi and yoga in the management of rheumatologic diseases, especially osteoarthritis of the knee, hip and hand, and rheumatoid arthritis. There is evidence that Tai Chi and yoga are safe, and some evidence that they have benefit, leading to reduction of pain and improvement of physical function and quality of life in patients. Recommendations for Tai Chi in knee osteoarthritis have recently been issued by the American College of Rheumatology. To allow broader recommendations for the use of Tai Chi and yoga in rheumatic diseases, there is a need to collect more evidence researched with larger randomised controlled trials. LA English
DT Article
DE Foetal head position; Second stage of labour; Intrapartum ultrasound; Validation
ID digital examination; transabdominal sonography; operative delivery; cohort
AB Objectives: To compare the diagnosis of the foetal head position in the second stage of labour by ultrasound scan performed by a novice sonographer and by clinical assessment, to that of an expert sonographer (gold standard): and to evaluate the acceptability of ultrasound in the second stage of labour to women and clinicians. Study design: This is a case series. We recruited sixty women delivering in a university hospital in Dublin, Ireland. An abdominal scan was performed by a novice and an expert ultrasonographer and a clinical assessment was performed by an obstetrician or midwife. Each assessor was blinded to the findings of the others. The main outcome measures were errors in the diagnosis of the foetal head position and acceptability of abdominal ultrasound in the second stage of labour. Results: The ultrasound findings of the novice and expert ultrasonographers were consistent in 52 (87%) cases for the foetal head position; 80% accuracy for the first ten scans performed by the novice (median time 150 s) and 90% for the last ten scans (median time 10 s). The novice made no occipito-anterior/occipito-posterior (OA/OP) errors. The clinical diagnosis of the foetal head position was incorrect in 25 (42%) cases; 8(13%) OA/OP errors. Women and clinicians did not consider the ultrasound assessment to be intrusive.

Conclusion: An abdominal scan by a novice ultrasonographer is an accurate and acceptable method of diagnosing the foetal head position in the second stage of labour and may have a role to play in assessment prior to instrumental delivery. (C) 2012 Elsevier Ireland Ltd. All rights reserved.

TI Variability of morphometric parameters of human trabecular tissue from coxo-arthritis and osteoporotic samples
SO ANNALI DELL ISTITUTO SUPERIORE DI SANITA
LA English

DT Article
DE microtomography; bone morphometry; osteoarthritis; osteoporosis
ID cancellous bone; computed-tomography; surface; volume; osteoarthritis; quality; density
AB Morphometric and architectural bone parameters change in diseases such as osteoarthritis and osteoporosis. The mechanical strength of bone is primarily influenced by bone quantity and quality. Bone quality is defined by parameters such as trabecular thickness, trabecular separation, trabecular density and degree of anisotropy that describe the micro-architectural structure of bone. Recently, many studies have validated microtomography as a valuable investigative technique to assess bone morphometry, thanks to micro-CT non-destructive, non-invasive and reliability features, in comparison to traditional techniques such as histology. The aim of this study is the analysis by micro-computed tomography of six specimens, extracted from patients affected by osteoarthritis and osteoporosis, in order to observe the tridimensional structure and calculate several morphometric parameters.

TI Achievements during the Bone and Joint Decade 2000-2010
SO BEST PRACTICE & RESEARCH IN CLINICAL RHEUMATOLOGY
LA English
DT Article
DE Orthopedics; Bjd; Joint surgery; Arthroscopic surgery; Bioengineering; Robotics; Registries; Musculuskeletal pain; Osteoarthritis; Osteoporosis
ID total hip-arthroplasty; surgery
AB Musculoskeletal diseases continue to produce major disability around the world. Advances in therapy - particularly for the inflammatory diseases - have the potential to eradicate the inflammation and thus prevent joint destruction. Surgical advances include minimally invasive and computer-assisted robotic surgery, and advances in arthroscopic surgery. The development of new musculoskeletal tissues - tendons, cartilage and bone using nanotechnology and stem cells - has the potential to revolutionise the way we approach these chronic destructive diseases as well as major trauma. With the rapid increase in these conditions with an ageing population, new models of care will need to be developed to ensure that the right care is delivered at the right time by the most appropriately trained health professional and at a reasonable cost. The Bone and Joint Decade has played a significant role in focussing researchers, clinicians and health educators on these diseases and also in drawing them to the attention of Governments around the globe. While there is still much to be done, the journey has commenced and will continue into the future with education, research and service delivery into these important conditions being further enhanced. TI Prevalence of Cervical Cord Compression and Its Association With Physical Performance in a Population-Based Cohort in Japan The Wakayama Spine Study
SO SPINE
LA English
DT Article
DE cervical cord compression; population-based study; MRI; physical performance
ID asymptomatic subjects; surgical-treatment; myelopathy; spondylosis; disability; outcm; signs; gait; mri; age
AB Study Design. A population-based magnetic resonance imaging (MRI) study of the cervical spine. Objective. This study was undertaken in order to investigate the prevalence of cervical cord compression (CCC) and to examine the association between CCC and physical performance measures in a population-based cohort established in Japan. Summary of Background Data. Population-based cohort studies of the prevalence of CCC, although essential for clarification of the

prevalence of slowly progressive disease and specification of the time of incidence of CCC, are not available. Methods. This cross-sectional study was performed as a part of the Research on Osteoarthritis/osteoporosis Against Disability study, a large-scale population-based cohort study in Japan. From 1011 inhabitants who underwent MRI examinations, images of the cervical spine of 977 subjects (324 men and 653 women, mean age of 66.4 yr) were evaluated. CCC was assessed by sagittal T2-weighted MRI and was defined as spinal cord compression. The prevalence of CCC and its association with myelopathic signs (hyper-reflexia of the patellar tendon and Hoffmann and Babinski reflexes) were examined. In addition, physical performance measures (grip and release test, grip strength, 6-m walking time, step length, chair-stand time, and one-leg standing time) were tested. Results. The prevalence of CCC was 24.4% and was significantly higher in men (29.3% in men and 21.9% in women, P = 0.011). The prevalence of CCC was higher with increasing age in both sexes. CCC was not significantly associated with any myelopathic signs but was significantly associated with grip and release test, 6-m walking time, step length, and chair-stand time. Conclusion. In this MRI study, the prevalence of CCC was examined. The present results indicate that CCC correlates with physical performance measures from an early stage of the disease before myelopathic signs appear.

TI Transcriptional profile of native CD271+ multipotential stromal cells: Evidence for multiple fates, with prominent osteogenic and wnt pathway signaling activity
SO ARTHRITIS AND RHEUMATISM
LA English
DT Article
ID mesenchymal stem-cells; human bone-marrow; hip osteoarthritis; in-vivo; expression; differentiation; age; hematopoiesis; regeneration; maintenance
AB Objective Controversy surrounds the identity and functionality of rare bone marrowderived multipotential stromal cells (BM-MSCs), including their differentiation capabilities, their relationship to pericytes and hematopoiesis-supporting stromal cells, and the relevance of their culture-expanded progeny in studies of skeletal biology and development of cell-based therapies. The aim of this study was to clarify the nature of candidate BM-MSCs by profiling transcripts that reflect different aspects of their putative

functions in vivo. Methods Rare, sorted BM-derived CD45-/low CD271bright (CD271) cells were analyzed using 96-gene expression arrays focused on transcripts relevant to mesenchymal-lineage differentiation (toward bone, cartilage, fat, or muscle), hematopoietic and stromal support, and molecules critical to skeletal homeostasis. These cells were compared to matched CD45+ CD271- hematopoietic-lineage cells, culture-expanded MSCs, and skin fibroblasts. When feasible, transcription was validated using flow cytometry. Results CD271 cells had a transcriptional profile consistent with the multiple fates of in vivo MSCs, evident from the observed simultaneous expression of osteogenic, adipogenic, pericytic, and hematopoiesis-supporting genes (e.g., SP7 [osterix], FABP4 [fatty acid binding protein 4], ANGPT1 [angiopoietin 1], and CXCL12 [stromal cellderived factor 1], respectively). Compared to culture-expanded MSCs and fibroblasts, CD271 cells exhibited greater transcriptional activity, particularly with respect to Wnt-related genes (>1,000-fold increased expression of FRZB [secreted frizzled-related protein 3] and WIF1 [Wnt inhibitory factor 1]). A number of transcripts were identified as novel markers of MSCs. Conclusion The native, BM-derived in vivo MSC population is endowed with a gene signature that is compatible with multiple functions, reflecting the topographic bone niche of these cells, and their signature is significantly different from that of culture-expanded MSCs. This indicates that studies of the biologic functions of MSCs in musculoskeletal diseases, including osteoporosis and osteoarthritis, should focus on in vivo MSCs, rather than their culture-adapted progeny.

TI Changes in Serum Levels of Cartilage Oligomeric Matrix Protein after Estrogen and Alendronate Therapy in Postmenopausal Women
SO GYNECOLOGIC AND OBSTETRIC INVESTIGATION
LA English
DT Article
DE Cartilage oligomeric matrix protein; Osteoarthritis; Estrogen; Alendronate; Menopause
ID hormone-replacement-therapy; knee osteoarthritis; subchondral bone; articular-cartilage; radiographic progression; ovariectomized rats; model; markers; degradation; association
AB Background: Cartilage oligomeric matrix protein (COMP) is a biomarker for joint destruction and its serum levels are used for assessing therapeutic efficacy. This study aims to compare changes in serum COMP levels in postmenopausal women with osteopenia/osteoporosis receiving estrogen and alendronate. Methods: A total of 62 postmenopausal women diagnosed with osteopenia or osteoporosis were treated with either estrogen (17 beta-estradiol 1 mg, n = 30) or bisphosphonate (alendronate 5 mg, n = 32) for 6 months. The controls were healthy postmenopausal women (n = 30). Serum COMP and osteocalcin levels were measured at baseline and after 6 months of treatment. Results: Estrogen decreased levels of COMP at 6 months compared to baseline levels (-8.35 +/- 19.38%), whereas the bisphosphonate and control groups resulted in no significant changes (-5.50 +/- 18.69 and 1.49 +/- 25.34%, respectively). Concentrations of osteocalcin decreased significantly in both treatment groups (estrogen 25.60 +/- 24.42% and alendronate 13.76 +/- 23.89%, respectively). There was a significant positive correlation between changes after 6 months in COMP and osteocalcin (R = 0.48, p = 0.002). Conclusions: Postmenopausal women treated with estrogen showed

significantly decreased levels of COMP after 6 months. Estrogen might provide a further treatment modality in the prevention of joint destruction. Copyright (c) 20125. Karger AG, Basel

TI Fracture risk in the femoral hip region: A finite element analysis supported experimental approach
SO JOURNAL OF BIOMECHANICS
LA English
DT Article
DE Femoral hip; FEA; Dual-energy X-ray absorptiometry; Fracture risk indicator
ID proximal femur fractures; bone; osteoporosis; density; osteoarthritis; pathogenesis; strength; sites; falls; neck
AB The decrease of bone mineral density (BMD) is a multifactorial bone pathology, commonly referred to as osteoporosis. The subsequent decline of the bone's micro-structural characteristics renders the human skeletal system, and especially the hip, susceptible to fragility fractures. This study represents a systematic attempt to correlate BMD spectrums to the mechanical strength characteristics of the femoral neck and determine a fracture risk indicator based on non-invasive imaging techniques. The BMD of 30 patients' femurs was measured in vivo by Dual-energy X-ray absorptiometry (DXA). As these patients were subjected to total hip replacement, the mechanical strength properties of their femurs' were determined ex-vivo using uniaxial compression experiments. FEA simulations facilitated the correlation of the DXA measurements to the apparent fracture risk, indicating critical strain values during complex loading scenarios. (C) 2012 Elsevier

TI Smoking is a predictor of worse trabecular mechanical performance in hip fragility fracture patients
SO JOURNAL OF BONE AND MINERAL METABOLISM

metaanalysis
AB Clinical risk factors (CRFs) are established predictors of fracture events. However, the influence of individual CRFs on trabecular mechanical fragility is still a subject of debate. In this study, we aimed to assess differences, adjusted for CRFs, between bone macrostructural parameters measured in ex-vivo specimens from hip fragility fracture patients and osteoarthritis patients, and to determine whether individual CRFs could predict trabecular bone mechanical behavior in hip fragility fractures. Additionally, we also looked for associations between the 10-year risk of major and hip fracture calculated by FRAX and trabecular bone mechanical performance. In this case-control study, a group of fragility fracture patients were compared with a group of osteoarthritis patients, both having undergone hip replacement surgery. A clinical protocol was applied in order to collect CRFs [body mass index (BMI), prior fragility fracture, parental history of hip fracture, long-term use of oral glucocorticoids, rheumatoid arthritis, current smoking, alcohol consumption, age and gender]. The 10-year probability of fracture was calculated. Serum bone turnover markers were determined and dual X-ray absorptiometry performed. Femoral head diameter was evaluated and trabecular bone cylinders were drilled for mechanical testing to determine bone strength, stiffness and toughness. We evaluated 40 hip fragility fracture and 52 osteoarthritis patients. Trabecular bone stiffness was significantly lower ($p = 0.042$) in hip fragility fracture patients when compared to osteoarthritic individuals, adjusted for age, gender and BMI. No other macrostructural parameter was statistically different between the groups. In hip fragility fracture patients, smoking habits (beta = -0.403; $p = 0.018$) and female gender (beta = -0.416; $p = 0.008$) were independently associated with lower stiffness. In addition, smoking was also independently associated with worse trabecular strength (beta = -0.323; $p = 0.045$), and toughness (beta = -0.403; $p = 0.018$). In these patients, the 10-year risk of major ($r = -0.550$; $p = 0.012$) and hip fracture ($r = -0.513$; $p = 0.021$) calculated using only CRFs was strongly correlated with femoral neck bone mineral density but not with mechanical performance. Our data showed that among fragility fracture patients active smoking is a predictor of worse intrinsic trabecular mechanical performance, and female gender is also independently associated with lower stiffness. In this population, the 10-year risk of fracture using CRFs with different weights only reflects bone mass loss but not trabecular mechanical properties.

TI The Comorbidity Conundrum: A Focus on the Role of Noncardiovascular Chronic Conditions in the Heart Failure Patient
SO CURRENT CARDIOLOGY REPORTS
LA English
DT Article
DE Anemia; Chronic conditions; Comorbidities; Chronic obstructive pulmonary disease; Diabetes; Depression; Obesity; Thyroid dysfunction; Osteoarthritis; Osteoporosis; Renal dysfunction; Heart failure
ID obstructive pulmonary-disease; multiple chronic conditions; older patients; depressive symptoms; united-states; beta-blockers; risk-factor; mortality; prevalence; drug
AB The rapid aging of the US population combined with improvements in modern medicine has created a new public health concern of comorbidity, a chronic condition that co-exists with a primary illness. Over 141 million Americans suffer from one or more comorbid conditions. In the heart failure (HF) patient, this comorbidity burden is particularly high, with over 40% of patients having five or more chronic conditions. These comorbidities can vary from being a risk factor to a cause of HF progression or even a precipitating factor for decompensation. Comorbidities, particularly the noncardiovascular conditions, have been associated with greater health resource utilization, poor health outcomes, and increased mortality. To minimize the negative impact that these comorbidities have on patient outcomes, appropriate attention should be paid to identifying, prioritizing, and managing each condition; minimizing medication complexity and polypharmacy; and improving overall coordination of care between providers and patients.

AB With the aging of the work force, occupational health nurses must prepare for encounters with clients who are challenged by osteoarthritis or osteoporosis. Clients should be encouraged to exercise safely to promote functioning at home and work. This article reviews recent literature on the benefits of exercise for workers with osteoarthritis, osteoporosis, or both.

TI Lack of Exercise Is a Major Cause of Chronic Diseases
SO COMPREHENSIVE PHYSIOLOGY
LA English
DT Article
ID body-mass index; all-cause mortality; time physical-activity; growth-factor-i; negative-energy balance; life-style intervention; modifiable risk-factors; human skeletal-muscle; fatty liver-disease; nutrition examination survey
AB Chronic diseases are major killers in the modern era. Physical inactivity is a primary cause of most chronic diseases. The initial third of the article considers: activity and prevention definitions; historical evidence showing physical inactivity is detrimental to health and normal organ functional capacities; cause versus treatment; physical activity and inactivity mechanisms differ; gene-environment interaction (including aerobic training adaptations, personalized medicine, and co-twin physical activity); and specificity of adaptations to type of training. Next, physical activity/exercise is examined as primary prevention against 35 chronic conditions [accelerated biological aging/premature death, low cardiorespiratory fitness (VO(2)max), sarcopenia, metabolic syndrome, obesity, insulin resistance, prediabetes, type 2 diabetes, nonalcoholic fatty liver disease, coronary heart disease, peripheral artery disease, hypertension, stroke, congestive heart failure, endothelial dysfunction, arterial dyslipidemia, hemostasis, deep vein thrombosis,

cognitive dysfunction, depression and anxiety, osteoporosis, osteoarthritis, balance, bone fracture/falls, rheumatoid arthritis, colon cancer, breast cancer, endometrial cancer, gestational diabetes, pre-eclampsia, polycystic ovary syndrome, erectile dysfunction, pain, diverticulitis, constipation, and gallbladder diseases]. The article ends with consideration of deterioration of risk factors in longer-term sedentary groups; clinical consequences of inactive childhood/adolescence; and public policy. In summary, the body rapidly maladapts to insufficient physical activity, and if continued, results in substantial decreases in both total and quality years of life. Taken together, conclusive evidence exists that physical inactivity is one important cause of most chronic diseases. In addition, physical activity primarily prevents, or delays, chronic diseases, implying that chronic disease need not be an inevitable outcome during life. (C) 2012 American Physiological Society. TI 3-T MRI assessment of osteophyte formation in patients with unilateral anterior cruciate ligament injury and reconstruction
SO SKELETAL RADIOLOGY
LA English
DT Article
DE Osteophytes; Knee joint; Osteoarthritis; Anterior cruciate ligament rupture; MRI
ID knee osteoarthritis; high prevalence; meniscal lesions; soccer players; scoring system; risk-factors; cartilage; interobserver; reliability; validity
AB To define the number and distribution of osteophytes (OPs) in bilateral knee MRI (magnetic resonance imaging) of patients with unilateral anterior cruciate ligament (ACL) rupture. Bilateral knee MRIs of 20 patients with unilateral ACL rupture and reconstruction were retrospectively analyzed for OPs. OPs were graded following the KOSS (knee OA scoring system) classification and their compartmental distribution was assessed following the WORMS (Whole-Organ Magnetic Resonance Imaging Score) classification. All examined knees revealed OPs. Knees with ACL rupture showed significant ($p < 0.001$) higher total numbers of OPs (mean 11.6; SD +/- 4.4) than knees with intact ACL (mean 5.1; SD +/- 2.3). Knees with ACL rupture showed increased OP formation in all knee compartments with predominance of marginal OPs in the lateral femorotibial compartment especially on the tibia. Our results show that after knee injury with ACL rupture and reconstruction, all knee compartments were involved in post-traumatic increase of OP formation. The most affected compartment was the lateral femorotibial compartment on the tibial side.

TI Hypovitaminosis D and response to cholecalciferol supplementation in patients with autoimmune and non-autoimmune rheumatic diseases
SO RHEUMATOLOGY INTERNATIONAL
LA English
DT Article
DE Hypovitaminosis D; 25(OH)vitamin D supplementation; Inflammatory autoimmune diseases; Osteoarthritis
ID vitamin-d deficiency; serum-levels; 25-hydroxyvitamin d; healthy-subjects; d metabolites; population; arthritis; association; consequences; nutrition
AB Recent reports suggest a role of hypovitaminosis D in the pathogenesis of inflammatory autoimmune diseases (ARD); we investigated 25(OH)vitamin D plasma level before and after supplementation in ARD and NARD (non-ARD: osteoporosis and/or OA) patients. We retrospectively evaluated 572 consecutive clinical records of adult patients at immuno-rheumatology and rehabilitative units of our institution from January 2006 to October 2009. We excluded patients with vitamin D supplementation or renal failure, primary hyperparathyroidism, liver failure. We recorded 25(OH)vitamin D plasma concentration of 245 patients together with other clinical data. We then evaluated 25(OH)vitamin D plasma concentration of 100 (43 ARD and 57 NARD) patients previously included who underwent 750-1,000 UI/die 25(OH)vitamin D supplementation for at least 6 months. Appropriate statistical analysis was performed. The median 25(OH)vitamin D concentration was not significantly different between 119 ARD [33.4 (IQR 22.5-54.9) nmol/l] and 126 NARD patients 32.9 (IQR 18.7-50.2). In stepwise logistic regression, female sex (F:13.7), winter-spring season (F:5.6) and older age (F:5.3), but not ARD, predicted plasma 25(OH)vitamin D < 75 nmol/l. Cholecalciferol

supplementation increased 25(OH)vitamin D plasma concentration equally in both ARD and NARD; however, only 29/100 patients reached a plasma level a parts per thousand yen75 nmol/l without differences between ARD and NARD (chi(2) = n.s.). Hypovitaminosis D is common in rheumatic patients. Sex and age but not ARD are risk factors for this condition. 750-1,000 UI/die of cholecalciferol is not sufficient to normalize plasma level in these patients. Increase of plasma 25(OH)vitamin D after treatment is not influenced by the presence of an inflammatory autoimmune disease.

TI Differential responsiveness to 17β-estradiol of mesenchymal stem cells from postmenopausal women between osteoporosis and osteoarthritis
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE E2 (17 beta-estradiol); Mesenchymal stem cells; Osteoarthritis; Osteogenic potential; Osteoporosis
ID subchondral bone plate; femoral-head; proliferation; estrogen; marrow; age; estradiol; mscs
AB Differential osteogenic potential and responsiveness to 17 beta-estradiol (E2) of mesenchymal stem cells (MSCs) were found between postmenopausal women with osteoporosis (OP) and osteoarthritis (OA). These results suggest differential biological mechanisms of estrogen deficiency in regulation of bone remodeling between OP and OA. OP and OA are two common disorders in postmenopausal women. The inverse relationship has been suggested between OP and OA, but their mechanisms that relate to estrogen deficiency are not fully understood. The aim of this study was to compare the differential responsiveness to E2 of MSCs from osteoporotic versus osteoarthritic donors. Twenty postmenopausal patients, ten with osteoporotic hip fractures and ten with hip osteoarthritis, were included into this study. MSCs were derived from cancellous bones of femoral heads from OA and OP donors and cultured in osteogenic and adipogenic medium with or without E2 added. The alkaline phosphatase (ALP) activity, calcium content, calcified nodules, lipid droplets, messenger RNA (mRNA) expression of ALP, osteocalcin (OC), collagen 1 alpha (COL1 alpha), peroxisome proliferators-activated receptor

gamma 2 (PPAR gamma 2) and lipoprotein lipase (LPL) were measured and compared between two groups with OP and OA. In osteogenic medium, ALP activity, calcium content and mRNA expression of OC and COL1 alpha in MSCs from OA were significantly higher than those from OP group. In adipogenic condition, there was no significant difference in lipid droplets formation and mRNA expression of PPAR gamma 2 and LPL between OP and OA groups. With E2 added in osteogenic medium, ALP activity, calcium content and OC mRNA were significantly higher in OP group than in OA group, whereas E2 had no significant effect on lipid droplet formation and mRNA expression of PPAR gamma 2 and LPL. Differential osteogenic potential and responsiveness to E2 of MSCs were found between postmenopausal women with OP and OA. These results may provide information for clinical application of MSCs in the differential setting of estrogen deficiency.

TI Comparative high-resolution pQCT analysis of femoral neck indicates different bone mass distribution in osteoporosis and osteoarthritis
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE Femoral fracture; Femoral neck; Osteoarthritis; Osteoporosis; pQCT
ID quantitative computed-tomography; mineral density; hip osteoarthritis; cancellous bone; trabecular bone; proximal femur; cortical porosity; knee; strength; women
AB Osteoarthritis is linked to a reduced risk of femoral fracture despite osteoporosis. Different bone distribution in the femoral neck in osteoarthritis and fracture was revealed using a peripheral quantitative computed tomography (pQCT) comparative analysis. Our findings sustain the presence of an adaptive mechanism of bone structure providing fracture protection in osteoarthritis. Although osteoarthritis is associated with reduced femoral fracture risk, it does not protect from bone loss. We investigated whether adaptive mechanisms are present at the arthritic joint, leading to reduced fracture risk, despite the presence of low bone mass density. We performed pQCT comparative analyses of human femoral neck specimens derived from 32 postmenopausal women who received hip prostheses for osteoarthritis (n = 19) or femoral fracture (n = 13) by applying an

in-house automated software to extract bone structure descriptors, characterize trabecular and cortical bone distribution, and evaluate their mutual relationships. The cortical bone volume and trabecular thickness were significantly ($p < 0.05$) higher in the osteoarthritis group than in the fracture group. Trabecular bone volume was also significantly ($p < 0.05$) higher in the osteoarthritis group than the fracture group at the inferior and anterior quadrants. Significance was maintained after adjusting for age, cortical bone volume, and cortical porosity thickness. Multiple linear regression analysis showed that thickness, volume, and apparent density of the trabecular region significantly ($p < 0.05$) correlated with the same cortical descriptors in osteoarthritis, but no significant relationship was found in the fracture group. Age differentially affected the mutual relationships in the two groups, showing a significant correlation with trabecular thickness in both groups and with apparent trabecular density only in femoral fracture group. Starting from these differences in the structural descriptors, our study sustains the presence of a compensatory mechanism in osteoarthritis to preserve the mechanical competence of bone structure, despite the loss of trabecular bone, underlying lower fracture risk.

TI Knee Pain in Patients With Cancer After Chemotherapy, Radiotherapy, and Bone Marrow Transplantation

SO ORTHOPEDICS
LA English
DT Article
ID avascular necrosis; septic arthritis; rheumatoid-arthritis; prostate-cancer; therapy; osteonecrosis; osteoporosis; risk; metastasis; infections
AB The causes of knee pain in patients with cancer with are different from those without cancer, and the purpose of this study was to evaluate these differences. Thirty-six patients with cancer who had knee pain who had undergone 1 or more modalities of treatment, including chemotherapy, radiotherapy, and bone marrow transplant, for a primary diagnosis of cancer were compared with a cohort of 40 patients without cancer who had knee pain. All patients were evaluated clinically and underwent radiographic examination, and some underwent computed tomography or magnetic resonance imaging examination. Among patients with a primary diagnosis of cancer, the most common diagnosis was lymphoma (n=10), and the most common causes of knee pain were avascular necrosis of bone, osteoarthritis, insufficiency fractures, and septic arthritis. In 5 patients, the classical signs of a septic knee were not present. Other causes of knee pain included meniscus tear and anterior cruciate ligament rupture with instability. The most common diagnosis in patients without cancer was osteoarthritis of the knee. No patient without cancer was diagnosed with avascular necrosis, metastatic lesion, or insufficiency fracture. Two patients without cancer were diagnosed with septic arthritis of the knee. This study showed that the causes of knee pain in patients with cancer are different from those without cancer. Septic arthritis may present without the classical clinical signs in patients with cancer, and a high index of suspicion should be maintained for it.

TI Use of OROS® hydromorphone in the treatment of osteoarthritis and osteoporosis: A pooled analysis of three non-interventional studies focusing on different starting doses
SO WIENER KLINISCHE WOCHENSCHRIFT
LA English
DT Article
DE OROS (R); hydromorphone; opioid; osteoarthritis; osteoporosis; dosing
ID chronic nonmalignant pain; chronic noncancer pain; opioid-naive patients; release oxycodone; formulation; efficacy; cancer; noninferiority; tolerability; management
AB OBJECTIVE: To determine the effect of a lower starting dose of OROSA (R) hydromorphone compared with a higher starting dose. DESIGN: Data from the first 15 days of treatment were compared in a combined analysis of three prospective, non-interventional studies. SETTING: Non-interventional, carried out in daily routine settings. PATIENTS: Patients had chronic severe pain due to osteoarthritis or from fragility fractures related to osteoporosis. INTERVENTIONS: OROS-ANA-4001 and OROS-ANA-4002 had a daily starting dose of 8 mg of OROSA (R) hydromorphone; OROS-ANA-4003 had a daily starting dose of 4 mg. MAIN OUTCOME MEASURE(S): A post-hoc analysis to assess the effect of a low starting dose of OROSA (R) hydromorphone on tolerability, pain control, and treatment satisfaction overall and for subgroups of opioid-na < ve patients versus patients previously treated with opioids, and patients aged > 65 years versus patients aged a parts per thousand currency sign65 years. RESULTS: Treatment satisfaction and pain control improved in all studies; treatment satisfaction improved in a higher percentage of patients in the lower starting dose group.

Gastrointestinal disorders were the most frequent treatment-emergent adverse events. Incidence of nausea was comparable between studies. Incidence of constipation, vomiting, fatigue, and pruritus was less frequent with the lower starting dose. In elderly and opioid-na < ve patients, a lower starting dose was associated with lower overall incidence of adverse events, treatment-related adverse events, and those leading to discontinuation. CONCLUSIONS: A lower starting dose was associated with better tolerability and a lower number of treatment terminations at a comparable level of pain control with high treatment satisfaction.

TI Craniovertebral junction pathology in high cervical disc disease
SO BRITISH JOURNAL OF NEUROSURGERY
LA English
DT Article
DE atlanto-axial osteoarthritis; high cervical disc prolapse; Nurick's grade; stress level
ID increased signal intensity; of-the-literature; spondylotic myelopathy; basilar invagination; surgical approach; spinal-cord; mr-images; osteoarthritis; compression; herniation
AB Objective. To establish predisposing factors of high cervical disc degeneration (HCDD) with an emphasis on the presence or absence of craniovertebral junction (CVJ) pathology by a retrospective analysis of clinical and radiologic parameters of patients operated at our institute. Methods. Thirty-seven patients of C3-4 prolapsed intervertebral disc (PIVD) were compared with 45 patients of C5-6 PIVD. Nurick's grade was used for clinical assessment. Radiological parameters like congenital and osteoarthritic changes at CVJ along with measurement of stress levels in flexion and extension on X-rays were done. Results. Mean age of C3-4 PIVD patients (48.16 years, range 26-65 years) was significantly higher than C5-6 PIVD patients (38.13 years, range 21-55 years) ($p < 0.001$). CVJ pathology was seen in significantly higher proportion in patients with C3-4 PIVD (18/37) in comparison to C5-6 PIVD (4/45) ($p < 0.001$). C3-4 PIVD patients presented with a poorer pre-op and post-op Nurick's grade. T2 hyperintense intramedullary signal change was seen in 91.8% (34/37) of C3-4 PIVD patients as compared to 66.67% (30/45) of C5-6 PIVD patients ($p < 0.001$). Conclusion. CVJ pathology is a predisposing factor for HCDD. HCDD presents in a poorer Nurick's grade compared to lower cervical PIVD and majority of the patients have T2 hyperintense intramedullary signal changes in MRI. Presence of T2 hyperintense intramedullary signal changes is associated with poorer pre-op clinical status and poorer post-op outcome.

TI Osteocyte recruitment declines as the osteon fills in: Interacting effects of osteocytic sclerostin and previous hip fracture on the size of cortical canals in the femoral neck
SO BONE
LA English
DT Article
DE Sclerostin; Osteocyte; Osteon; Bone remodelling; Osteoporosis; Fractured neck of femur
ID bone-formation; cancellous bone; osteoblast function; 3d structure; density; cortex; expression; osteoarthritis; activation; mechanism
AB There is little information on the distribution of osteocytes within the individual cortical osteon, but using direct 3-D imaging in a single subject, Hannah et al. found a gradient with a two-fold higher density of cells adjacent to the cement line compared to near the canal. Since a limiting factor for bone formation might be the availability of osteoblasts due to their recruitment as osteocytes, we studied distributions of osteonal osteocytes in frozen sections of the femoral neck cortex. Osteocytes were stained with an anti-sclerostin antibody and counter-stained with toluidine blue. Adjacent sections were stained for alkaline phosphatase (ALP). Each osteonal osteocyte was categorised as being sclerostin-positive (scl +) or negative (scl-). ImageJ was used to measure the perimeter and area of each osteon and canal, while special purpose routines were used to measure the minimum distances

of each osteocyte from the cement line and the canal. Canal area was strongly correlated with osteon area. Osteocytes were most dense close to the cement line; and their areal density within the matrix declined up to three-fold between the cement line and the canal, depending on osteon diameter. Large and small osteons had similar densities of osteocytes close to the cement line, but fractured neck of femur cases had significantly lower densities of osteocytes close to the canal. Higher osteocyte density close to the canal was associated with ALP expression. It is concluded that entombment of osteocytes newly drawn from the osteoblast pool into the mineralising matrix is independent of preceding bone resorption depth. As osteonal mulling proceeds, osteocyte formation declines more rapidly than matrix formation, leading to a progressive reduction in osteocyte density. A shrinking supply of precursor osteoblasts due to previous osteocyte recruitment, apoptosis, or both could produce this effect. In a statistically significant contrast, sclerostin negative osteocytes adjacent to the canal had the expected effect of reducing canal size in controls but this was not seen in hip fracture. This demonstrated the failure of osteonal osteoblasts to sustain bone formation through a complete remodelling cycle in osteoporosis, perhaps due to insufficient osteoblasts remaining capable of mineralized matrix formation. The failure of osteocytic sclerostin suppression to associate with bone formation in these osteons might alternatively be explained by downstream interference with sclerostin's effect on wnt signalling. TI Prospective Treatment of Age-Related Diseases by Slowing Down Aging
SO AMERICAN JOURNAL OF PATHOLOGY
LA English
DT Review
ID extends life-span; caloric restriction; cell-cycle; transplant recipients; insulin-resistance; mtor inhibitor; oral rapamycin; senescence; sirolimus; progression
AB Atherosclerosis, hypertension, obesity, diabetic complications, cancer, benign prostate hyperplasia, Alzheimer and Parkinson diseases, age-related macular

degeneration, osteoarthritis, osteoporosis, and seborrheic keratosis are strongly associated with aging, implying a common underlying process. Each disease is treated separately and, in most cases, symptomatically. Suppression of aging itself should delay or treat all age-related diseases, thus increasing healthy life span and maximal longevity. But, is it possible to slow down aging? Recent evidence indicates that the target of rapamycin signaling pathway is involved in cellular senescence and organismal aging. Preclinical and clinical studies demonstrated the therapeutic effects of rapamycin in diverse age-related diseases. One simple reason why a single drug is indicated for so many age-related diseases is that it inhibits the aging process. TI Tumour necrosis factor receptor superfamily member 11B polymorphisms and association with knee osteoarthritis in women
SO INTERNATIONAL JOURNAL OF IMMUNOGENETICS
LA English
DT Article
ID bone-mineral density; osteoprotegerin gene; postmenopausal women; candidate genes; opg; osteoporosis; population; cartilage; men
AB We examined single-nucleotide polymorphisms (SNPs) across the tumour necrosis factor receptor superfamily member 11B (TNFRSF11B) gene and knee OA. We identified alleles in a VNTR region in intron 3 that was observed exclusively in women OA cases (P = 0.007, Pc = 0.042). Our results reveal that a previously unreported association between a VNTR genotype in TNFRSF11B and knee OA in women.

TI Role of DNA methylation in the regulation of the RANKL-OPG system in human bone
SO EPIGENETICS
LA English

DT Article
DE DNA methylation; osteoporosis; bone remodeling; osteoblasts
ID kappa-b ligand; receptor activator; 1,25-dihydroxyvitamin d-3; osteoprotegerin opg; gene-expression; messenger-rna; in-vitro; osteoclastogenesis; cells; protein
AB Osteoblasts are specialized cells that form new bone and also indirectly influence bone resorption by producing factors that modulate osteoclast differentiation. Although the methylation of CpG islands plays an important role in the regulation of gene expression, there is still scanty information about its role in human bone. The aim of this study was to investigate the influence of CpG methylation on the transcriptional levels of two osteoblast-derived critical factors in the regulation of osteoclastogenesis: the receptor activator of nuclear factor NF kappa B ligand (RANKL) and its soluble decoy receptor osteoprotegerin (OPG). Quantitative methylation specific PCR (qMSP) and pyrosequencing analysis in various cell types showed that the methylation of regulatory regions of these genes, in the vicinity of the transcription start sites, repressed gene transcription, whereas an active transcription was associated with low levels of methylation. In addition, treatment with the DNA demethylating agent 5-azadeoxycitidine promoted a 170-fold induction of RANKL and a 20-fold induction of OPG mRNA expression in HEK-293 cells, which showed hypermethylation of the CpG islands and barely expressed RANKL and OPG transcripts at baseline. Transcriptional levels of both genes were also explored in bone tissue samples from patients with hip fractures and hip osteoarthritis. Although RANKL transcript abundance and the RANKL: OPG transcript ratio were significantly higher in patients with fractures than in those with osteoarthritis (RANKL: 0.76 +/- 0.23 vs. 0.24 +/- 0.08, p = 0.012; RANKL: OPG: 7.66 +/- 2.49 vs. 0.92 +/- 0.21, p = 0.002), there was no evidence for differential methylation across patient groups. In conclusion, the association between DNA methylation and the repression of RANKL and OPG expression strongly suggests that methylation-dependent mechanisms influence the transcription of these genes, which play a critical role in osteoclastogenesis. However, other mechanisms appear to be involved in the increased RANKL/OPG ratio of patients with osteoporotic fractures.

TI Exercise therapy for bone and muscle health: an overview of systematic reviews
SO BMC MEDICINE
LA English
DT Review
DE fibromyalgia; low back pain; neck pain; shoulder pain; osteoarthritis; rheumatoid arthritis; ankylosing spondylitis; osteoporosis; pain; physical function
ID nonspecific neck pain; low-back-pain; rheumatoid-arthritis; musculoskeletal; risk; interventions; osteoarthritis; management; criteria; quality
AB Background: Musculoskeletal conditions (MSCs) are widely prevalent in present-day society, with resultant high healthcare costs and substantial negative effects on patient health and quality of life. The main aim of this overview was to synthesize evidence from systematic reviews on the effects of exercise therapy (ET) on pain and physical function for patients with MSCs. In addition, the evidence for the effect of ET on disease pathogenesis, and whether particular components of exercise programs are associated with the size of the treatment effects, was also explored. Methods: We included four common conditions: fibromyalgia (FM), low back pain (LBP), neck pain (NP), and shoulder pain (SP), and four specific musculoskeletal diseases: osteoarthritis (OA), rheumatoid arthritis (RA), ankylosing spondylitis (AS), and osteoporosis (OP). We first included Cochrane reviews with the most recent update being January 2007 or later, and then searched for non-Cochrane reviews published after this date. Pain and physical functioning were selected as primary outcomes. Results: We identified 9 reviews, comprising a total of 224 trials and 24,059 patients. In addition, one review addressing the effect of exercise on pathogenesis was included. Overall, we found solid evidence supporting ET in the management of MSCs, but there were substantial differences in the level of research evidence between the included diagnostic groups. The standardized mean differences for knee OA, LBP, FM, and SP varied between 0.30 and 0.65 and were significantly in favor of exercise for both pain and function. For NP, hip OA, RA, and AS, the effect estimates were generally smaller and not always significant. There was little or no evidence that ET can influence disease pathogenesis. The only exception was for osteoporosis, where there was evidence that ET increases bone mineral density in postmenopausal women, but no

significant effects were found for clinically relevant outcomes (fractures). For LBP and knee OA, there was evidence suggesting that the treatment effect increases with the number of exercise sessions. Conclusions: There is empirical evidence that ET has beneficial clinical effects for most MSCs. Except for osteoporosis, there seems to be a gap in the understanding of the ways in which ET influences disease mechanisms.

TI Effects of PTH [1-34] on synoviopathy in an experimental model of osteoarthritis preceded by osteoporosis
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE Osteoarthritis; Osteoporosis; Synovitis; Cartilage damage

ID synovial-membrane inflammation; rheumatoid-arthritis; parathyroid-hormone; tissue inhibitor; crucial role; in-vivo; cartilage; expression; macrophages; knee
AB Purpose: Synoviopathy contributes to cartilage degradation in osteoarthritis (OA). Intermittent parathyroid hormone (PTH) [1-34] administration inhibits terminal differentiation of human chondrocytes and prevents cartilage damage. We aimed to determine whether PTH [1-34] could modify synovial changes in experimental OA preceded by osteoporosis (OP). Methods: Twenty osteoporosis (OP) rabbits underwent knee surgery to induce OA. They were administered either saline vehicle or PTH for 10 weeks. Ten healthy rabbits were used as controls. Following sacrifice, synovial changes were assessed by Krenn synovitis score, immunohistochemistry for macrophages (RAM-11), B and T lymphocytes, type I collagen, parathyroid hormone 1 receptor (PTH1R), and anti-proliferating cell nuclear antigen (PCNA). Synovial mRNA levels of Col1A1, IL-1 beta cyclooxygenase 2 (COX-2), matrix-degrading metalloproteinases (MMP-9, MMP-13), and monocyte chemotactic protein-1 (MCP-1), as well as protein expression of PTH1R were also determined. Cartilage damage was analyzed by Mankin score. Results: OPOA + vehicle rabbits showed an increase in synovitis score vs controls (P = 0.003), mainly due to synovial hyperplasia and fibrosis, while PTH reduced these changes (P = 0.017). Mankin and Krenn scores were well correlated in all groups (r = 0.629, P = 0.012). Immunostaining for RAM-11 and B lymphocytes was increased (P <= 0.05), whereas PTH1R protein levels tended to be higher in OPOA + vehicle animals vs controls. PTH did not modify RAM-11 staining or PTH1R levels; however, it restored PTH1R localization to the vicinity of synovial vessels. PTH also decreased type I collagen, MCP-1, and MMP-13 expression (P < 0.05), as well as PCNA staining compared to vehicle-treated OPOA rabbits. Conclusions: In our model of OA aggravated by previous OP, synoviopathy correlated well with cartilage damage. Intermittent PTH [1-34] administration ameliorated both hyperplasia and fibrosis.

TI Effect of co-morbidities on fracture risk: Findings from the Global Longitudinal

Study of Osteoporosis in Women (GLOW)
SO BONE
LA English
DT Article
DE Fracture risk; Co-morbidities; Parkinson's disease; Multiple sclerosis; FRAX
ID bone-mineral density; population-based cohort; parkinsons-disease; cardiovascular-disease; celiac-disease; older men; association; metaanalysis; epidemiology; turnover
AB Introduction: Greater awareness of the relationship between co-morbidities and fracture risk may improve fracture-prediction algorithms such as FRAX. Materials and methods: We used a large, multinational cohort study (GLOW) to investigate the effect of co-morbidities on fracture risk. Women completed a baseline questionnaire detailing past medical history, including co-morbidity history and fracture. They were re-contacted annually to determine incident clinical fractures. A co-morbidity index, defined as number of baseline co-morbidities, was derived. The effect of adding the co-morbidity index to FRAX risk factors on fracture prevention was examined using chi-squared tests, the May-Hosmer test, c index and comparison of predicted versus observed fracture rates. Results: Of 52,960 women with follow-up data, enrolled between October 2006 and February 2008, 3224 (6.1%) sustained an incident fracture over 2 years. All recorded co-morbidities were significantly associated with fracture, except for high cholesterol, hypertension, celiac disease, and cancer. The strongest association was seen with Parkinson's disease (age-adjusted hazard ratio [HR]: 2.2; 95% CI: 1.6-3.1; P<0.001). Co-morbidities that contributed most to fracture prediction in a Cox regression model with FRAX risk factors as additional predictors were: Parkinson's disease, multiple sclerosis, chronic obstructive pulmonary disease, osteoarthritis, and heart disease. Conclusion: Co-morbidities, as captured in a co-morbidity index, contributed significantly to fracture risk in this study population. Parkinson's disease carried a particularly high risk of fracture; and increasing co-morbidity index was associated with increasing fracture risk. Addition of co-morbidity index to FRAX risk factors improved fracture prediction. (C) 2012 Elsevier Inc. All rights reserved.

AB The ever increasing use of magnetic resonance imaging in clinical practice has led to the recognition of a new entity, bone marrow lesions (BMLs). These lesions are characterized by excessive water signals in the marrow space and have emerged as a central component of many different diseases affecting the musculoskeletal system. BMLs have in particular been associated with a wide variety of inflammatory and non-inflammatory rheumatologic conditions and are not only considered significant sources of pain, but also linked to the worsening of patient prognosis in many disease states. In this review, we summarize the current knowledge on BMLs with an emphasis on the clinical and histological features of this entity in inflammatory and non-inflammatory disease and provide a unifying hypothesis based on the appearance with various imaging technologies. We also try to pair this hypothesis with the apparent beneficial effects of various treatment regimens, mainly within the group of bone antiresorptive drugs (calcitonin, bisphosphonates) on symptoms associated with BMLs.

AB Introduction: The purpose of this study was to assess the natural history of bone bruise and bone mineral density (BMD) after traumatic hip dislocations and conservatively treated acetabular fractures. Our hypothesis was that poor bone quality can influence degree of bone bruise and, in time, cause degenerative changes. Materials and methods: Eight consecutive patients with traumatic hip dislocations and five patients with conservatively treated fractures in the femoral head and/or acetabulum were included. Magnetic resonance imaging (MRI) was obtained after 1, 17, 42, 82 and 97 weeks. Dual-emission X-ray absorptiometry (DXA) measurements were made after 10 days and 2 years. Sizes of bone bruise lesions were measured and classified. At the 2-year follow-up, Harris hip score (HHS) was calculated and signs of radiological osteoarthritis (OA) registered. Results: The bone bruise changes were small and all changes resolved within 42 weeks in all, except for three patients; one with a small Pipkin fracture had segmental avascular necrosis (AVN) of the femoral head, one had persisting1-3 mm small spots of bone bruises in the femoral head and the third had <1 cm lesions in both the femoral head and the acetabulum. The lesions were bigger in the femoral head in the hip dislocations and more pronounced in the acetabulum in the fractured acetabuli. We found no significant changes in BMD in four regions of interest (ROIs) after 2 years. No patients developed OA, and all had excellent HHS except for the one patient with AVN. Conclusion: The post-traumatic bone bruise changes in the dislocated hips and the fractured acetabuli were small and transient compared to findings of other authors examining traumatised knees. The patients

had excellent function and no OA after 2 years if they did not develop AVN. In our small sample of relatively young patients with normal age-adjusted BMD, no post-traumatic osteopenia was observed. This might differ in the elderly with poorer bone quality; further studies are needed to assess that. (c) 2012 Elsevier Ltd. All rights reserved.

TI Efficacy and safety of oral strontium ranelate for the treatment of knee osteoarthritis: rationale and design of randomised, double-blind, placebo-controlled trial
SO CURRENT MEDICAL RESEARCH AND OPINION
LA English
DT Article
DE DMOAD; Joint space width; Knee osteoarthritis; Knee radiograph; Randomized clinical trial; Strontium ranelate; Structure-modifying treatment
ID cartilage degradation; biochemical markers; chondroitin sulfate; health-status;

progression; hip; women; bone; radiographs; glucosamine
AB Objective: The osteoporosis drug strontium ranelate dissociates bone remodelling processes. It also inhibits subchondral bone resorption and stimulates cartilage matrix formation in vitro. Exploratory studies in the osteoporosis trials report that strontium ranelate reduces biomarkers of cartilage degradation, and attenuates the progression and clinical symptoms of spinal osteoarthritis, suggesting symptom-and structure-modifying activity in osteoarthritis. We describe the rationale and design of a randomised trial evaluating the efficacy and safety of strontium ranelate in knee osteoarthritis. Research design, methods, and results: This double-blind, placebo-controlled trial (98 centres, 18 countries) includes ambulatory Caucasian men and women aged >= 50 years with primary knee osteoarthritis of the medial tibiofemoral compartment (Kellgren and Lawrence grade 2 or 3), joint space width (JSW) 2.5 to 5 mm, and knee pain on most days in the previous month (intensity >= 40mm on a visual analogue scale). Patients are randomly allocated to three groups (strontium ranelate 1 or 2 g/day, or placebo). Follow-up is expected to last 3 years. The primary endpoint is radiographic change in JSW from baseline in each group versus placebo. The main clinical secondary endpoint is WOMAC score at the knee. Safety is assessed at every visit. It is estimated that 1600 patients are required to establish statistical significance with power >90% (0.2mm +/- 10% between-group difference in change in JSW over 3 years). Recruitment started in April 2006. The results are expected in spring 2012. Clinical trial registration: The trial is registered on www.controlled-trials.com (number ISRCTN41323372). Conclusions: This randomised, double blind, placebo-controlled study will establish the potential of strontium ranelate in improving structure and symptoms in patients with knee osteoarthritis.

TI Difference in Subchondral Cancellous Bone Between Postmenopausal Women With Hip Osteoarthritis and Osteoporotic Fracture Implication for Fatigue Microdamage, Bone Microarchitecture, and Biomechanical Properties
SO ARTHRITIS AND RHEUMATISM
LA English
DT Article
ID human trabecular bone; human cortical bone; damage morphology; marrow lesions; articular-cartilage; mineral density; femoral-head; tissue; age; pathogenesis
AB Objective. Osteoarthritis (OA) and osteoporosis (OP) of the hip rarely occur in the same patient. The purpose of this study was to determine whether this difference might be attributable to the different quantity and quality of subchondral cancellous bone in the two conditions. Methods. Subchondral cancellous bone from the femoral head was obtained at the time of hip arthroplasty from 60 postmenopausal women, 30 with OA and 30 with OP. In each group, 10 specimens were subjected to compressive fatigue loading and 20 were left non-loaded. Specimens were examined by compressive mechanical testing, micro-computed tomography scanning, fluorescence microscopy, and

nanoindentation techniques. Results. Both the ultimate stress and the elastic modulus of cancellous bone from OA patients were significantly higher than those of cancellous bone from OP patients ($P < 0.05$). Compared to cancellous bone from OP patients, the bone volume fraction and trabecular thickness were significantly increased, but bone matrix mineralization was significantly decreased, in cancellous bone from OA patients ($P < 0.05$ for each comparison). The microcrack density was significantly higher in OP cancellous bone than in OA cancellous bone ($P < 0.001$), irrespective of fatigue loading. In addition, fatigue loading resulted in a significant increase in microcrack density in both OA and OP cancellous bone ($P < 0.001$). There was no significant difference in nanoindentation elastic modulus and hardness between cancellous bone from OA and OP patients, as well as between bones with and without fatigue loading. Conclusion. The difference in mechanical properties between OA and OP cancellous bone is attributed to different bone mass and bone structure. OP cancellous bone is susceptible to fatigue damage due to insufficient structure. However, increased bone volume and plate-like structure provide OA cancellous bone a superior capacity to resist fatigue damage.

TI Triglyceride metabolism in bone tissue is associated with osteoblast and osteoclast differentiation: a gene expression study

SO JOURNAL OF BONE AND MINERAL METABOLISM
LA English
DT Article
DE Lipolysis; Lipogenesis; Free fatty acid; Bone tissue
ID messenger-rna; fatty-acids; adiponectin; osteoarthritis; proliferation; adipocytes; fracture; density; lipase; ratio
AB The role of bone marrow adipocytes in bone tissue is not yet understood. Adipocytes express enzymes for metabolism of free fatty acids and adipokines such as adiponectin, which have been shown to exert different effects on bone cells. Our aim was to find out whether triglyceride (TG) metabolism in bone tissue is associated with osteoblast and osteoclast differentiation by gene expression analysis of lipoprotein lipase (LPL), hormone sensitive lipase (HSL), fatty acid synthase (FASN), adiponectin, RUNX2, RANK, RANKL and OPG. Bone tissue was obtained from patients undergoing hip arthroplasty due to osteoporosis (OP) (50) or osteoarthritis (OA) (48) or from healthy autopsy controls (14). Lower bone mineral density and microstructural parameters were observed in OP compared to OA. The FASN expression did not differ between groups suggesting similar de novo lipogenesis. Lower LPL and HSL in OP suggest lower FFA release and uptake in OP bone tissue. Adiponectin expression was lower in OP than in OA and a trend was seen for controls. These results suggest OP bone has lower TG metabolism than OA and normal bone. In OP bone, lower osteoblastogenesis and higher osteoclast formation were observed and correlation analysis suggests adiponectin, LPL and HSL are associated with higher osteoblastogenesis and lower osteoclastogenesis. This study gives insights into TG metabolism in the human bone microenvironment. We conclude that OP bone tissue exhibits lower osteoblastogenesis, higher osteoclastogenesis and lower TG metabolism compared to OA or healthy controls.

TI Ω-3 fatty acid supplement use in the 45 and Up Study Cohort
SO BMJ OPEN
LA English
DT Article
DE COMPLEMENTARY MEDICINE; NUTRITION & DIETETICS; PUBLIC HEALTH
ID alternative medicine cam; n-3 fatty-acids; cardiovascular-disease; fish-oil; complementary; risk; association; cancer
AB Objective There has been a dramatic increase in the use of dietary supplements in Western societies over the past decades. Our understanding of the prevalence of -3 fatty acid supplement consumption is of significance for future nutrition planning, health promotion and care delivery. However, we know little about -3 fatty acid supplement consumption or users. This paper, drawing upon the largest

dataset with regard to -3 fatty acid supplement use (n=266848), examines the use and users of this supplement among a large sample of older Australians living in New South Wales. Design A cross-sectional study. Data were analysed from the 45 and Up Study, the largest study of healthy ageing ever undertaken in the Southern Hemisphere. Setting New South Wales, Australia. Participants 266848 participants of the 45 and Up Study. Primary and secondary outcome measures Participants' use of -3, demographics (geographical location, marital status, education level, income and level of healthcare insurance) and health status (quality of life, history of smoking and alcohol consumption, health conditions) were measured. Results Of the 266848 participants, 32.6% reported having taken -3 in the 4weeks prior to the survey. Use of -3 fatty acid supplements was higher among men, non-smokers, non-to-mild (alcoholic) drinkers, residing in a major city, having higher income and private health insurance. Osteoarthritis, osteoporosis, high cholesterol and anxiety and/or depression were positively associated with -3 fatty acid supplement use, while cancer and high blood pressure were negatively associated with use of -3 fatty acid supplements. Conclusions This study, analysing data from the 45 and Up Study cohort, suggests that a considerable proportion of older Australians consume -3 fatty acid supplements. There is a need for primary healthcare practitioners to enquire with patients about this supplement use and for work to ensure provision of good-quality information for patients and providers with regard to -3 fatty acid products.

AB Study Design. Basic pain study using osteoporotic rodent models. Objective. To examine alterations in distribution of pain-related neuropeptides after compressive force on osteoporotic vertebrae and their chronic pain-related properties. Summary of Background Data. We previously reported significantly increased production of calcitonin gene-related peptide (CGRP), a marker of inflammatory pain, in the dorsal root ganglia (DRG) of vertebrae in osteoporosis-model ovariectomized (OVX) rats. Here, we hypothesized that longitudinal compressive force on vertebrae can affect osteoporotic pain properties, which has not been examined yet. Methods. OVX rats were used as the osteoporosis model. Female Sprague-Dawley rats were prepared and Fluoro-Gold (FG) neurotracer was applied to the periosteal surface of the Co5 vertebra. After FG labeling, the animals were divided into 4 groups: Control, Control + compression, OVX, and OVX + compression. The Control groups were not ovariectomized. In the compression groups, K-wires were stabbed transversely through Co4 and Co6 with Co5 compressed longitudinally by rubber bands bridged between the 2. One, 2, 4, and 8 weeks after surgery, bilateral S1 to S3 DRGs were excised for immunofluorescence assays. Expression of CGRP and activating transcription factor

3, a marker of neuronal injury, were compared among the 4 groups. Results. Sustained upregulation of CGRP in DRG neurons was observed after compression of the Co5 vertebra, and Co5 compression caused significant increase in CGRP production in DRG neurons, whereas a greater level of activating transcription factor 3 upregulation was observed in DRGs in OVX rats after dynamic vertebral compression 8 weeks after surgery, implying potential neuropathic pain. Conclusion. There was sustained upregulation of CGRP and activating transcription factor 3 in DRGs in osteoporotic model rats compared with controls, and levels were further enhanced by dynamic vertebral compression. These findings imply that dynamic compression stress on vertebrae can exacerbate osteoporotic pain by inducing both inflammatory and neuropathic pain mediators.

TI Impact of diabetes and its treatments on skeletal diseases
SO FRONTIERS OF MEDICINE
LA English
DT Review
DE diabetes; bone; osteoporosis; osteoarthritis
ID glycation end-products; bone-mineral density; factor-kappa-b; fracture risk; osteoblast differentiation; hemodialyzed patients; thiazolidinedione use; postmenopausal women; endocrine regulation; parathyroid-hormone
AB Diabetes mellitus is an enormous menace to public health globally. This chronic disease of metabolism will adversely affect the skeleton if not controlled. Both type 1 diabetes mellitus (T1DM) and type 2 diabetes mellitus (T2DM) are associated with an increased risk of osteoporosis and fragility fractures. Bone mineral density is reduced in T1DM, whereas patients with T2DM have normal or slightly higher bone density, suggesting impaired bone quality is involved. Detrimental effects of T1DM on the skeleton are more severe than T2DM, probably because of the lack of osteo-anabolic effects of insulin and other pancreatic hormones. In both T1DM and T2DM, low bone quality could be caused by various means, including but not limited to hyperglycemia, accumulation of advanced glycosylation end products (AGEs), decreased serum levels of osteocalcin and parathyroid hormone. Risk for osteoarthritis is also elevated in diabetic population. How diabetes accelerates the deterioration of cartilage remains largely unknown. Hyperglycemia and glucose derived AGEs could contribute to the development of osteoarthritis. Moreover, it is recognized that oral antidiabetic medicines affect bone metabolism and turnover as well. Insulin is shown to have anabolic effects on bone and hyperinsulinemia may help to explain the slightly higher bone density in patients with T2DM. Thiazolidinediones can promote bone loss and osteoporotic fractures by suppressing osteoblastogenesis and enhancing osteoclastogenesis. Metformin favors bone formation by stimulating osteoblast differentiation and protecting them against diabetic conditions such as hyperglycemia. Better knowledge of how diabetic conditions and its treatments influence skeletal tissues is in great need in view of the growing and aging population of patients with diabetes mellitus.

DE osteoarthritis; antiosteoporotic agent; strontium ranelate; medial meniscal tear; articular cartilage; subchondral bone; SOX9
ID articular-cartilage; mechanical-property; nanoindentation; chondrocytes; disease; sox9; osteoporosis; osteoblasts; inhibition; expression
AB Aim: To investigate whether strontium ranelate (SR), a new antiosteoporotic agent, could attenuate cartilage degeneration and subchondral bone remodeling in osteoarthritis (OA). Methods: Medial meniscal tear (MMT) operation was performed in adult SD rats to induce OA. SR (625 or 1800 mg.kg(-1).d(-1)) was administered via gavage for 3 or 6 weeks. After the animals were sacrificed, articular cartilage degeneration was evaluated using toluidine blue 0 staining, SOX9 immunohistochemistry and TUNEL assay. The changes in microarchitecture indices and tissue mineral density (TMD), chemical composition (mineral-to-collagen ratio), and intrinsic mechanical properties of the subchondral bones were measured using

micro-CT scanning, confocal Raman microspectroscopy and nanoindentation testing, respectively. Results: The high-dose SR significantly attenuated cartilage matrix and chondrocyte loss at 6 weeks, and decreased chondrocyte apoptosis, improved the expression of SOX9, a critical transcription factor responsible for the expression of anabolic genes type II collagen and aggrecan, at both 3 and 6 weeks. Meanwhile, the high-dose SR also significantly attenuated the subchondral bone remodeling at both 3 and 6 weeks, as shown by the improved microarchitecture indices, TMD, mineral-to-collagen ratio and intrinsic mechanical properties. In contrast, the low-dose SR did not significantly change all the detection indices of cartilage and bone at both 3 and 6 weeks. Conclusion: The high-dose SR treatment can reduce articular cartilage degeneration and subchondral bone remodeling in the rat MMT model of OA.

TI An increased rate of falling leads to a rise in fracture risk in postmenopausal

women with self-reported osteoarthritis: a prospective multinational cohort study (GLOW)
SO ANNALS OF THE RHEUMATIC DISEASES
LA English
DT Article
ID bone-mineral density; radiographic osteoarthritis; knee osteoarthritis; osteoporotic fractures; lifetime risk; older-adults; elderly-men; hip; association; pain
AB Objectives Patients with osteoarthritis have increased bone mass but no decrease in fractures. The association between self-reported osteoarthritis and incident falls and fractures was studied in postmenopausal women. Methods The Global Longitudinal Study of Osteoporosis in Women is a prospective multinational cohort of 60 393 non-institutionalised women aged >= 55 years who had visited primary care practices within the previous 2 years. Questionnaires were mailed at yearly intervals. Patients were classified as having osteoarthritis if they answered yes to the question, 'Has a doctor or other health provider ever said that you had osteoarthritis or degenerative joint disease?', and this was validated against primary care records in a subsample. Information on incident falls, fractures and covariates was self-reported. Cox and Poisson models were used for incident fractures and number of falls, respectively, to compute hazard ratios (HRs) and rate ratios (RRs) for baseline osteoarthritis status. Results Of 51 386 women followed for a median of 2.9 years (interquartile range 2.1-3.0), 20 409 (40%) reported osteoarthritis. The adjusted HR for osteoarthritis predicting fracture was 1.21 (95% CI 1.13 to 1.30; p<0.0001) and the adjusted RR for falls was 1.24 (95% CI 1.22 to 1.26; p<0.0001). However, the association between osteoarthritis and fracture was not significant after adjustment for incident falls (HR 1.06 (95% CI 0.98 to 1.15; p=0.13)). Conclusions Postmenopausal women with self-reported osteoarthritis have a 20% increased risk of fracture and experience 25% more falls than those without osteoarthritis. These data suggest that increased falls are the causal pathway of the association between osteoarthritis and fractures.

TI Correlation of meniscal T2*with multiphoton microscopy, and change of articular cartilage T2 in an ovine model of meniscal repair
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE MRI; Meniscus; Cartilage; UTE
ID healthy-subjects; knee; time; mri; bone; osteoarthritis; thickness; sheep; joint
AB Objective: To correlate meniscal T2* relaxation times using ultra-short echo time (UTE) magnetic resonance imaging (MRI) with quantitative microscopic methods, and to determine the effect of meniscal repair on post-operative cartilage T2 values. Design: A medial meniscal tear was created and repaired in the anterior horn of one limb of 28 crossbred mature ewes. MR scans for morphological evaluation, meniscal T2* values, and cartilage T2 values were acquired at 0, 4 and 8 months post-operatively for the Tear and Non-Op limb. Samples of menisci from both limbs were analyzed using multiphoton microscopy (MPM) analysis and biomechanical testing. Results: Significantly prolonged meniscal T2* values were found in repaired limbs than in control limbs, $P < 0.0001$. No regional differences of T2* were detected for either the repaired or control limbs in the anterior horn. Repaired limbs had prolonged cartilage T2 values, primarily anteriorly, and tended to have lower biomechanical force to failure at 8 months than Non-Op limbs. MPM autofluorescence and second harmonic generation data correlated with T2* values at 8 months ($rho = -0.48$, $P = 0.06$). Conclusions: T2* mapping is sensitive to detecting temporal and zonal differences of meniscal structure and composition. Meniscal MPM and cartilage T2 values indicate changes in tissue integrity in the presence of meniscal repair. (C) 2013 Osteoarthritis Research Society International. Published by Elsevier Ltd. TI Degenerative changes at the lumbar spine-implications for bone mineral density measurement in elderly women
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE BMD; Degenerative changes; Diagnosis; DXA; Lumbar spine; Osteoporosis
ID x-ray absorptiometry; osteoporotic fractures; postmenopausal women; men; site; disc; osteoarthritis; densitometry; prevalence; arthrosis
AB Degenerative changes of the lumbar spine may lead to misinterpretation of bone mineral density (BMD) measurements and cause underdiagnosis of osteoporosis. This longitudinal study of 1,044 women, 75 years at inclusion and followed for 10 years, shows that identification of apparent degenerative changes on the dual energy X-ray absorptiometry (DXA) scan can increase the proportion diagnosed. In the elderly, degenerative manifestations in the lumbar spine may result in falsely elevated BMD values, consequently missing a large proportion of those with osteoporosis. Our aim was to determine the distribution and impact of degenerative changes on lumbar spine DXA over time and its clinical implications. Participants were 1,044 women from the population-based Osteoporosis Risk Assessment cohort. All women were 75 years old at invitation and followed up after 5 years (n = 715) and 10 years (n = 382). Degenerative changes were evaluated visually on the DXA image for each vertebra L1 to L4 (intraobserver precision kappa values of 0.66-0.70). At baseline, apparent degenerative changes were more frequent in the inferior segments of the lumbar spine [5 % (L1), 15 % (L2), 26 % (L3), and 36 % (L4)] and increased over time. At 10 years, the prevalences were 20 % (L1), 39 % (L2), 59 % (L3), 72 % (L4), resulting in a significant increase in overall BMD. In women without apparent degenerative changes, BMD remained stable between 75 and 85 rather than an expected bone loss. At baseline, 37 % had osteoporosis (BMD < -2.5) at L1-L4; exclusion of women with apparent degenerative changes increased this proportion to 47 %. Using L1-L2, which was less prone to degenerative changes, 46 % of women were classified as osteoporotic regardless of degenerative changes. Degenerative changes were very common in elderly women, accelerated disproportionately over time, were increasingly frequent from vertebrae L1 to L4, and had significant impact on diagnosing osteoporosis. This suggests that routine reporting of spine BMD at L1-L2 would add valuable information for reassessment and monitoring.

TI Management of the occiput posterior presentation: A single institute experience
SO JOURNAL OF OBSTETRICS AND GYNAECOLOGY RESEARCH
LA English
DT Article
DE cesarean section; manual rotation; obstetric labor complications; persistent occiput posterior; posture change
ID transverse positions; labor
AB Aim: We have examined the risk factors and management processes of the persistent occiput posterior (pOP) position by analyzing medical records from our hospital. Material and Methods: Medical records and delivery notes from January 2007 to December 2009 were reviewed and 103 patients were identified as having the pOP position during active labor. A total of 1054 patients who had occiput anterior (OA) deliveries were used as control. Results: There was no significant difference in population background between the pOP and control groups. Fifty-eight (56%) cases of pOP were identified before the birth of the fetal head whereas 45 were found to be in pOP at the birth. Among these cases identified as pOP before the birth, 30 (52%) patients underwent an attempt to rotate pOP to OA manually. A total of 14 (47%) attempts were successful and delivered OA vaginally. Of 16 cases whose attempts failed, five (31%) had cesarean delivery and 11 had vaginal OP delivery. The overall cesarean rate in this group was 16.7%. Twenty-eight patients who did not have any corrective intervention had a significantly higher rate of cesarean section (60.7%, P < 0.001 by ?2 analysis). The advanced head station and the wider dilatation resulted in a successful manual rotation. Conclusions: Attempts to correct pOP by manual rotation have better results when the head is in the mid-pelvis. Also, posture change reduces cesarean section rate. The current data suggest attempts to correct pOP to OA reduce cesarean section rate.

TI Relationship of Bone Mineral Density to Progression of Knee Osteoarthritis
SO ARTHRITIS AND RHEUMATISM
LA English
DT Article
ID radiographic osteoarthritis; subchondral bone; hip; osteoporosis; risk; risedronate; symptoms; incident; fracture; women
AB Objective To evaluate the longitudinal relationship between bone mineral density (BMD) and BMD changes and the progression of knee osteoarthritis (OA), as measured by cartilage outcomes. Methods We used observational cohort data from the Vitamin D for Knee Osteoarthritis trial. Bilateral femoral neck BMD values as well as knee magnetic resonance imaging (MRI) scans in each subject were obtained at baseline and subsequently at 12 months and 24 months. The change in total cartilage volume and tibial and femoral cartilage thickness was measured by manual cartilage segmentation of 2 sequential knee MRI scans in each subject. Multivariable linear regression models were used to examine the associations of baseline BMD and BMD change with the cartilage outcomes, adjusting for baseline age, sex, body mass index, malalignment, and vitamin D treatment. Model fit and assumptions were validated. Results A total of 127 subjects were eligible for analysis. Longitudinal BMD loss was associated with loss of cartilage volume (= 1.25 per 0.1 gm/cm2, P = 0.02) and loss of tibial cartilage thickness (= 0.028, P = 0.03). BMD loss of a magnitude greater than the least significant change (<-4.7%) was associated with 1.02% cartilage volume loss per year (P = 0.005), 0.014 mm femoral cartilage thickness loss (P = 0.04), and 0.021 mm tibial cartilage thickness

loss per year (P = 0.009). There were no significant associations between baseline BMD and any of the cartilage outcomes. Conclusion Longitudinal BMD loss is associated with progressive cartilage loss in knees with OA. Further work to clarify the basis of this relationship could reveal novel therapeutic targets for knee OA.

TI Value of biomarkers in osteoarthritis: current status and perspectives
SO ANNALS OF THE RHEUMATIC DISEASES
LA English
DT Review
DE Osteoarthritis; Outcomes research; Inflammation
ID synovial-fluid levels; c-reactive protein; biochemical markers; knee osteoarthritis; radiographic osteoarthritis; rheumatoid-arthritis; ctx-ii; biological markers;

aggrecan fragments; proteomic analysis
AB Osteoarthritis affects the whole joint structure with progressive changes in cartilage, menisci, ligaments and subchondral bone, and synovial inflammation. Biomarkers are being developed to quantify joint remodelling and disease progression. This article was prepared following a working meeting of the European Society for Clinical and Economic Aspects of Osteoporosis and Osteoarthritis convened to discuss the value of biochemical markers of matrix metabolism in drug development in osteoarthritis. The best candidates are generally molecules or molecular fragments present in cartilage, bone or synovium and may be specific to one type of joint tissue or common to them all. Many currently investigated biomarkers are associated with collagen metabolism in cartilage or bone, or aggrecan metabolism in cartilage. Other biomarkers are related to non-collagenous proteins, inflammation and/or fibrosis. Biomarkers in osteoarthritis can be categorised using the burden of disease, investigative, prognostic, efficacy of intervention, diagnostic and safety classification. There are a number of promising candidates, notably urinary C-terminal telopeptide of collagen type II and serum cartilage oligomeric protein, although none is sufficiently discriminating to differentiate between individual patients and controls (diagnostic) or between patients with different disease severities (burden of disease), predict prognosis in individuals with or without osteoarthritis (prognostic) or perform so consistently that it could function as a surrogate outcome in clinical trials (efficacy of intervention). Future avenues for research include exploration of underlying mechanisms of disease and development of new biomarkers; technological development; the omics' (genomics, metabolomics, proteomics and lipidomics); design of aggregate scores combining a panel of biomarkers and/or imaging markers into single diagnostic algorithms; and investigation into the relationship between biomarkers and prognosis.

TI Isolated GH Deficiency due to a GHRH Receptor Mutation Causes Hip Joint Problems and Genu Valgum, and Reduces Size but not Density of Trabecular and Mixed Bone
SO JOURNAL OF CLINICAL ENDOCRINOLOGY & METABOLISM
LA English
DT Article
ID growth-factor-i; hormone-receptor; mineral density; radiographic osteoarthritis; young-adults; igf-i; prevalence; collagen; serum; children
AB Context: The GH/IGF-I axis is important for bone growth, but its effects on joint function are not completely understood. Adult-onset GH-deficient individuals have often reduced bone mineral density (BMD). However, there are limited data on BMD in adult patients with untreated congenital isolated GH-deficient (IGHD). We have shown that adult IGHD individuals from the Itabaianinha, homozygous for the c.57 + 1G>A GHRHR mutation, have reduced bone stiffness, but BMD and joint status in this cohort are unknown. Objective: The goal is to study BMD, joint function, and osteoarthritis score in previously untreated IGHD adults harboring the c.57 + 1G>A GHRHR mutation. Design: This is a cross-sectional study. Methods: Areal BMD by dual-energy X-ray absorptiometry was measured in 25 IGHD and 23 controls (CO). Volumetric BMD (vBMD) was calculated at the lumbar spine and total hip. Joint function was assessed by goniometry of elbow, hips, and knees. X-rays were used to measure the anatomic axis of knee and the severity of osteoarthritis, using a classification for osteophytes (OP) and joint space narrowing (JSN). Results: Genu valgum was more prevalent in IGHD than CO. The osteoarthritis knees OP score was similar in both groups, and knees JSN score showed a trend to be higher in IGHD. The hips OP score and JSN score were higher in IGHD. Areal BMD was lower in IGHD than CO, but vBMD was similar in the two groups. Range of motion was similar in elbow, knee, and hip in IGHD and CO. Conclusions: Untreated congenital IGHD due to a GHRHR mutation causes hip joint problems and genu valgum, without apparent clinical significance, reduces bone size, but does not reduce vBMD of the lumbar spine and hip.

TI Epidemiological Survey of Quantitative Ultrasound in Risk Assessment of Falls in Middle-Aged and Elderly People
SO PLOS ONE
LA English
DT Article
ID dwelling older-adults; hip fracture; multifactorial intervention; prediction; women; osteoporosis; fragility; calcaneus; density; outdoor
AB The risk assessment of falls is important, but still unsatisfactory and time-consuming. Our objective was to assess quantitative ultrasound (QUS) in the

risk assessment of falls. Our study was designed as epidemiological cross-sectional study occurring from March 2009 to February 2010 by community survey at a medical center. The participants were collected from systemic sample of 1,200 community-dwelling people (Male/Female = 524/676) 40 years old and over in Yunlin County, Mid-Taiwan. Structural questionnaires including socioeconomic status, living status, smoking and drinking habits, exercise and medical history were completed. Quantitative ultrasound (QUS) at the non-dominant distal radial area (QUS-R) and the left calcaneal area (QUS-C) were measured. The overall prevalence of falls was 19.8%. In men, the independently associated factors for falls were age (OR: 1.04; 95%CI: 1.01 similar to 1.06), fracture history (OR: 1.89; 95%CI: 1.12 similar to 3.19), osteoarthritis history (OR: 3.66; 95%CI: 1.15 similar to 11.64) and speed of sound (OR: 0.99; 95%CI: 0.99 similar to 1.00; p<0.05) by QUS-R. In women, the independently associated factors for falls were current drinking (OR: 3.54; 95%CI: 1.35 similar to 9.31) and broadband ultrasound attenuation (OR: 0.98; 95%CI: 0.97 similar to 0.99; p<0.01) by QUS-C. The cutoffs at -2.5<T-score<-1 derived using QUS-R (OR: 2.85; 95%CI: 1.64 similar to 4.96; p<0.01) in men or T-score <=-2.5 derived using QUS-C (OR: 2.72; 95%CI: 1.42 similar to 5.21; p<0.01) in women showed an independent association with falls. The lowest T-score derived using either QUS-R or QUS-C was also revealed as an independent factor for falls in both men (OR: 2.13; 95%CI: 1.03 similar to 4.43; p<0.05) and women (OR: 2.36; 95%CI: 1.13 similar to 4.91; p<0.05). Conclusions: Quantitative ultrasounds, measured either at the radial or calcaneal area, are convenient tools by which to assess the risk of falls in middle-aged and elderly people.

TI Health economics in the field of osteoarthritis: An Expert's consensus paper from the European Society for Clinical and Economic Aspects of Osteoporosis and Osteoarthritis (ESCEO)
SO SEMINARS IN ARTHRITIS AND RHEUMATISM
LA English
DT Review
DE Review; Cost-effectiveness; Cost-utility; Osteoarthritis; Arthroplasty; Economics; Methods
ID quality-of-life; evidence based recommendations; cost-effectiveness analysis; eular-standing-committee; total joint arthroplasty; total knee arthroplasty; task-force; rheumatoid-arthritis; total hip; selective inhibitors
AB Objectives: There is an important need to evaluate therapeutic approaches for osteoarthritis (OA) in terms of cost-effectiveness as well as efficacy. Methods: The ESCEO expert working group met to discuss the epidemiological and economic evidence that justifies the increasing concern of the impact of this disease and reviewed the current state-of-the-art in health economic studies in this field. Results: OA is a debilitating disease; it is increasing in frequency and is associated with a substantial and growing burden on society, in terms of both burden of illness and cost of illness. Economic evaluations in this field are relatively rare, and those that do exist, show considerable heterogeneity of methodological approach (such as indicated population, comparator, decision context and perspective, time horizon, modeling and outcome measures used). This heterogeneity makes comparisons between studies problematic. Conclusions: Better adherence to guidelines for economic evaluations is needed. There was strong support for the definition of a reference case and for what might constitute "standard optimal care" in terms of best clinical practice, for the control arms of interventional studies. TI Epidemiological Investigation of Osteoarthritis in Middle-Aged Mongolian and Senior Residents of the Inner Mongolia Autonomous Region
SO IRANIAN RED CRESCENT MEDICAL JOURNAL
LA English
DT Article
DE Osteoarthritis; Physical Examination; Hypertension
ID quality-of-life; knee osteoarthritis; follow-up; hip; progression; population; kellgren; lesions; impact; cohort
AB Background: To investigate the prevalence and characteristics of osteoarthritis (OA) in Mongolian middle-aged and senior residents of the Inner Mongolia

autonomous region, compared with the prevalence of OA in different regions, to understand the OA-associated factors and provide theoretical evidences for intervention and prevention. Objectives: Thereby the prevalence, distribution characteristics and correlative factors of OA in Mongolian middle-aged and senior residents in the Inner Mongolia autonomous region were investigated in this study. Materials and Methods: Rural and urban residents in Hohhot, Baotou and Erdos were selected using stratified, multi-stage and cluster random sampling. 2000 residents aging over 45 filled out questionnaires, underwent specialized physical and X-ray examinations. The factors affecting OA were analyzed by the multivariate unconditional logistic regression. Results: Obtained total of 1877 questionnaires were completed. 93% of the residents were unaware of OA-related issues. The prevalence of radiological OA and clinical OA (neck OA: 36.72%; waist OA: 44.02%; knee OA: 12.43%; hand OA: 6.83%) were 62.17% and 56.15%, respectively. Urban residents were more subjected to cervical spine (chi(2) = 8.92, P = 0.005) and less to lumbar spine disease (chi(2) = 10.32, P = 0.004) compared to rural ones. The prevalence of OA in knees and hands of females (chi(2) = 8.65, P = 0.003) was significantly higher than males (chi(2)= 4.37, P= 0.042). The prevalence of OA in postmenopausal females was slightly higher than males (chi(2) = 3.86, P = 0.052), with no statically significant difference. The risks of OA obviously increased with age. The residents with hypertension, diabetes and atherosclerosis were more subjected to OA. Conclusions: The prevalence of OA in Mongolian middle- aged and senior residents in part of the Inner Mongolia autonomous region was similar to the other ethnic groups. The prevalence of OA was affected by age, gender, location, hypertension, diabetes, atherosclerosis and osteoporosis. The residents need further educations about OA prevention and treatment.

TI Alendronate protects against articular cartilage erosion by inhibiting subchondral bone loss in ovariectomized rats
SO BONE
LA English
DT Article
DE Osteoporosis; Osteoarthritis; Alendronate; Subchondral bone; Cartilage; Ovariectomy
ID cruciate ligament transection; knee osteoarthritis; strontium ranelate; controlled-trial; model; osteoporosis; progression; estrogen; increases; severity
AB Osteoporosis (OP) and osteoarthritis (OA) are major health problems in the increasing elderly population, particularly in postmenopausal women, but their relationship remains unclear. The present study investigated whether alendronate (ALN), a potent inhibitor of bone resorption, could protect articular cartilage from degeneration in a combined animal model of OP and OA induced by ovariectomy (OVX). Seventy-eight seven-month-old female Sprague-Dawley rats were assigned into five experimental groups: (1) sham-operated with vehicle treatment, (2) sham-operated with ALN treatment, (3) OVX with vehicle treatment, (4) ALN treatment starting at OVX, and (5) ALN treatment starting at eight weeks after OVX. Histological and micro-CT analyses, together with urine collagen degradation markers, indicated that early ALN treatment completely prevented both subchondral bone loss and cartilage surface erosion induced by OVX. Although late ALN treatment also inhibited subchondral bone loss and significantly reduced cartilage erosion in the OVX rats, these tissues did not completely recover even after 10-weeks of ALN treatment. Quantitative RT-PCR analyses showed that the

protective effect of ALN correlated with increased ratio of OPG/RANKL in both subchondral bone and cartilage. Moreover, whereas OVX caused upregulation of expression of matrix metalloproteinases MMP-13 and MMP-9 in the articular cartilage and chondrocytes in the interface between the articular cartilage and subchondral bone, respectively, early ALN treatment blocked whereas late ALN treatment attenuated the upregulation of these catabolic enzymes in the corresponding tissues. Together, these data indicate that the subchondral bone loss plays an important role in OA pathogenesis in the combined OP and OA model and suggest that treatment timing is an important factor for the effectiveness of anti-resorptive drug therapy of combined OP and OA. AB TVEIT, M., B. E. ROSENGREN, F. NYQUIST, J. NILSSON, and M. K. KARLSSON. Former Male Elite Athletes Have Lower Incidence of Fragility Fractures Than Expected. Med. Sci. Sports Exerc., Vol. 45, No. 3, pp. 405-410, 2013. Purpose: Physical activity during growth is associated with high peak bone mass and may, as a result, prevent osteoporosis later in life. It is therefore possible that athletic

activity during youth could lower the risk of fragility fractures in old age. Although this is currently unclear and based on evaluations of surrogate skeletal end point variables in former athletes, we hypothesized that this is not the case. Methods: In a retrospective matched controlled cohort study design, we calculated the lifetime incidence of fractures from the results of a mailed questionnaire sent to 709 former male elite athletes with a mean age of 69 yr (range = 50-93 yr) who had given up regular sports activity a mean of 34 yr (range = 1-63 yr) earlier, and to 1368 matched controls. Estimates of time to first fracture were analysed using Poisson regression, and for analyses of covariance, Cox Regression was used. Data are presented as rate ratios (RR) with 95% confidence interval (CI). Results: After retirement from sports, the former athletes had an RR of 0.70 (0.52-0.93) for any fracture, an RR of 0.50 (0.27-0.89) for any fragility fracture, and an RR of 0.29 (0.09-0.74) for distal radius fractures. When adjusting for occupation, smoking, alcohol, disease, and medication the hazard ratio (HR) of any fracture after an active career was 0.73 (95% CI = 0.54-0.99) and the hazard ratio of any fragility fracture after age 50 yr was 0.63 (95% CI = 0.35-1.16). Conclusions: In men, elite sports during adolescence are associated with a lower fracture risk after career end. The former athletes were overall healthier, which may have influenced the results.

TI Associations of vertebral deformities and osteoarthritis with back pain among Japanese women: the Hizen-Oshima study
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article

DE Back pain; Epidemiology; Osteoporosis; Vertebral deformity; Vertebral osteoarthritis
ID quality-of-life; lumbar disc degeneration; radiographic features; fractures; osteoporosis; prevalence; epidemiology; disability; men
AB We examined the spinal distribution of the types of vertebral deformities and the associations of vertebral deformities and osteoarthritis with back pain in Japanese women. Midthoracic and upper lumbar vertebrae were more susceptible to deformity. Vertebral deformity and osteoarthritis were frequent and were associated with back pain. Vertebral fractures due to osteoporosis and osteoarthritis are both common and significant health problems in aged people. However, little is known about the descriptive epidemiology of the individual deformity types and the relative clinical impact in women in Japan. Lateral radiographs were obtained from 584 Japanese women ages 40 to 89 years old. Deformities were defined as vertebral heights of more than 3 standard deviations (SDs) below the normal mean. Osteoarthritis was defined as Kellgren-Lawrence (KL) grade 2 or higher. Information on upper or low back pain during the previous month was collected by questionnaire. We compared the spinal distribution of the three types of vertebral deformities (wedge, endplate, and crush) typical of fractures and examined the associations of number and type of vertebral deformities and osteoarthritis with back pain. Fifteen percent of women had at least one vertebral deformity and 74% had vertebral osteoarthritis. The prevalence of upper or low back pain was 30.1%. Deformities were most common in the midthoracic and upper lumbar regions and wedge was the frequent type, followed by endplate and crush. Multiple logistic regression analysis showed that the odds of back pain was 3.0 (95% CI 1.5-6.3) times higher for women with a single wedge deformity and 3.2 (95% CI 1.0--0.6) times higher for women with two or more wedge deformities, compared to women with no wedge deformity. Vertebral osteoarthritis was associated with back pain (OR 1.8, 95% CI 1.1-2.9), independent of other covariates including age and deformities. Our results in this group of Japanese women are similar to and consistent with results reported previously in other populations of Japanese and Caucasians.

TI MR imaging findings of medial tibial crest friction
SO EUROPEAN JOURNAL OF RADIOLOGY
LA English
DT Article
DE Medial tibial condyle; Friction syndrome; MR imaging/diagnosis; Bone marrow edema; Medial knee pain
ID spontaneous osteonecrosis; knee pain; asymptomatic knees; stress-fracture;

meniscal tears; marrow edema; prevalence; osteoarthritis; osteoporosis; diagnosis
AB Objective: Medial tibial condyle bone marrow edema (BME), associated with soft tissue edema (STe) surrounding the medial collateral ligament, was incidentally observed in MRI examinations of young and athletic individuals. The aim of the present study was to 1. Prospectively investigate the association between these findings and coexistence of localized pain, and 2. Explore the possible contribution of the tibial morphology to its pathogenesis. Methods: The medial tibial condyle crest was evaluated in 632 knee MRI examinations. The angle and depth were measured by two separate evaluators. The presence of STe and BME was recorded. A third evaluator blindly assessed the presence of pain at this site. Results: BME associated with STe was found in 24 patients (with no history of previous trauma, osteoarthritis, tumor or pes anserine bursitis). The mean crest angle was 151.3 degrees (95%CI 147.4-155.3 degrees) compared to 159.4 degrees (95%CI 158.8-160 degrees) in controls (Mann-Whitney test, P < 0.0001). MRI findings were highly predictive of localized pain (sensitivity 92% specificity 99%, Fisher's exact test, P < 0.0001). Conclusion: Friction at the medial tibial condyle crest is a painful syndrome. MRI is a highly specific and sensitive imaging modality for its diagnosis.

TI Active Vitamin D prevents anti-osteogenic effect of AGEs on human osteoblasts
SO OSTEOLOGIE
LA English
DT Article
DE AGEs; vitamin D; osteoblasts; mRNA expression
ID glycation end-products; nf-kappa-b; d-receptor; gene-expression; rheumatoid-arthritis; disease-activity; d deficiency; bone; osteoporosis; associations
AB Objective: To investigate whether 1,25-dihydroxyvitamin D-3 (1,25D(3)) is able to prevent advanced glycation end products (AGE)-induced alterations of osteoblasts (OB). Methods: Human OB were isolated and cultured from bone tissue of ten patients with knee osteoarthritis and joint replacement. Cells from passages three to seven were treated with control bovine serum albumin (Co-BSA), AGE-BSA or AGE-BSA supplemented with 1,25D(3) in two different concentrations (medium concentrations: 5 mg/ml AGE-BSA and Co-BSA, respectively; 100 pmol/l and 500 pmol/l 1,25D(3)). mRNA and protein expression of bone alkaline phosphatase (bALP), collagen type 1 (Col1) and osteocalcin (OC) were investigated by real-time PCR and Western Blot-analysis, respectively. Results: AGE-BSA reduced mRNA expression of bALP, Col1 and OC in comparison to Co-BSA significantly. Addition of 1,25D(3) in both concentrations completely prevented the AGE-BSA-induced suppression and resulted in a further increase of mRNA and protein expression of bALP, Col1 and OC. Discussion: 1,25D(3) in a physiological concentration prevents anti-osteogenic effects of AGEs on human OB. Therefore, 1,25D(3) treatment should be beneficial in diseases associated with AGE accumulation, impaired bone formation and vitamin D deficiency such as senile osteoporosis and rheumatoid arthritis.

TI How to define responders in osteoarthritis
SO CURRENT MEDICAL RESEARCH AND OPINION
LA English
DT Review
DE Magnetic resonance imaging; Osteoarthritis; Pain; Responder; Structure-modifying drug; X-ray
ID total joint replacement; patient reported outcm; total knee arthroplasty; total hip-arthroplasty; double-blind; glucosamine sulfate; biochemical markers; cartilage loss; chondroitins 4; risk-factors
AB Background: Osteoarthritis is a clinical syndrome of failure of the joint accompanied by varying degrees of joint pain, functional limitation, and reduced quality of life due to deterioration of articular cartilage and involvement of other joint structures. Scope: Regulatory agencies require relevant clinical benefit on symptoms and structure modification for registration of a new therapy as a disease-modifying osteoarthritis drug (DMOAD). An international Working Group of the European Society on Clinical and Economic Aspects of Osteoporosis and

Osteoarthritis (ESCEO) and International Osteoporosis Foundation was convened to explore the current burden of osteoarthritis, review current regulatory guidelines for the conduct of clinical trials, and examine the concept of responder analyses for improving drug evaluation in osteoarthritis. Findings: The ESCEO considers that the major challenges in DMOAD development are the absence of a precise definition of the disease, particularly in the early stages, and the lack of consensus on how to detect structural changes and link them to clinically meaningful endpoints. Responder criteria should help identify progression of disease and be clinically meaningful. The ideal criterion should be sensitive to change over time and should predict disease progression and outcomes such as joint replacement. Conclusion: The ESCEO considers that, for knee osteoarthritis, clinical trial data indicate that radiographic joint space narrowing >0.5mm over 2 or 3 years might be a reliable surrogate measure for total joint replacement. On-going research using techniques such as magnetic resonance imaging and biochemical markers may allow the identification of these patients earlier in the disease process.

TI Postmenopausal women with osteoporosis and osteoarthritis show different microstructural characteristics of trabecular bone in proximal tibia using high-resolution magnetic resonance imaging at 3 tesla
SO BMC MUSCULOSKELETAL DISORDERS
LA English
DT Article
ID age-related-changes; distal radius; computed-tomography; mineral density; cancellous bone; biomechanical property; inverse relationship; femoral-neck; iliac crest; in-vivo
AB Background: Osteoporosis (OP) and osteoarthritis (OA) are two common musculoskeletal disorders that affect the quality of life in aged people. An inverse relationship between OP and OA was proposed four decades ago. However, the difference in microstructure of the trabecular bone of these two disorders by high-resolution MRI (HR-MRI) has not been compared. The primary objective of the study is to explain the actual relationship between OA and OP based on

differences between bone microstructure of these two diseases. The secondary objectives are to find out the significance of Euler number and its relationship with other structural parameters, and important role of HR-MRI to reveal the microstructure of trabecular bone directly. Methods: Totally, 30 women with OP and 30 women with OA (n = 60) were included in this study. Primary OA of hip, knee, as well as spinal arthrosis were diagnosed according to plain X-ray film findings. Osteoporosis was defined based on the latest criteria of World Health Organization (WHO). Structural and textural parameters derived from HR-MRI images of proximal tibia were calculated and compared with special software. Results: There were significant differences in apparent bone volume fraction, trabecular thickness, mean roundness, Euler number, entropy and inverse different moment between OP and OA patients. In OP group, apparent trabecular separation (Tb.Sp), inertia, absolute value and contrast were positively correlated with Euler number, whereas apparent trabecular number (Tb.N), mean trabecular area, inverse difference and inverse different moment were negatively correlated. Apparent trabecular bone volume fraction (BV/TV), mean trabecular area, mean trabecular perimeter and mean skeleton length negatively correlated with Euler number in OA group. Inverse different moment was the texture parameter, which influenced bone mineral density (BMD) of femoral neck, meanwhile contrast influenced BMD of both great trochanter and Ward's triangle in OP group. While in OA group, Euler number was the exclusive parameter, which affected BMD of femoral neck and Ward's triangle. Conclusions: We found significant differences in microstructure parameters derived from HR-MRI images between postmenopausal women with OP and OA. It convincingly supports the hypothesis that there might be an inverse relationship between OP and OA.

TI Baboons as a Model to Study Genetics and Epigenetics of Human Disease
SO ILAR JOURNAL
LA English
DT Article
DE cardiovascular disease; diabetes; genomics resources; hypertension; intrauterine growth restriction; metabolic syndrome; obesity; osteoporosis
ID maternal nutrient restriction; quantitative trait locus; sodium-lithium countertransport; ldl-cholesterol concentration; cross-species replication; ester transfer protein; bone-mineral density; messenger-rna levels; genome-wide scan; pedigreed baboons
AB A major challenge for understanding susceptibility to common human diseases is determining genetic and environmental factors that influence mechanisms underlying variation in disease-related traits. The most common diseases afflicting the US population are complex diseases that develop as a result of defects in multiple genetically controlled systems in response to environmental challenges. Unraveling the etiology of these diseases is exceedingly difficult because of the many genetic and environmental factors involved. Studies of complex disease genetics in humans are challenging because it is not possible to control pedigree structure and often not practical to control environmental conditions over an extended period of time. Furthermore, access to tissues relevant to many diseases from healthy individuals is quite limited. The baboon is a well-established research

model for the study of a wide array of common complex diseases, including dyslipidemia, hypertension, obesity, and osteoporosis. It is possible to acquire tissues from healthy, genetically characterized baboons that have been exposed to defined environmental stimuli. In this review, we describe the genetic and physiologic similarity of baboons with humans, the ability and usefulness of controlling environment and breeding, and current genetic and genomic resources. We discuss studies on genetics of heart disease, obesity, diabetes, metabolic syndrome, hypertension, osteoporosis, osteoarthritis, and intrauterine growth restriction using the baboon as a model for human disease. We also summarize new studies and resources under development, providing examples of potential translational studies for targeted interventions and therapies for human disease.

DT Article
DE microstructure; biological parameters; collagen fibrils; biomechanics; micro-CT; scanning electron microscopy
ID trabecular bone; postmenopausal women; gender; microarchitecture; microstructure; mass; osteoarthritis; stiffness; estrogen; fracture
AB Background With aging, the human fracture risk gradually increase. This is mainly due to the corresponding changes of the biomechanical parameters of human bone presents with aging. We measured the microstructural parameters of lumbar bone from women in several age groups by micro-computed tomography and scanning electron microscopy. We observed changes in lumbar cancellous bone mineral density and in biomechanical parameters with aging to elucidate the relationship between age and risk of fracture. We provide theoretical support for human pathology, fracture risk increased with age and the individualized of each age group. Methods Thirty-two fresh L3 vertebral bodies were donated from 32 women, aged 20-59 years and were divided into four age groups: 20 to 29 years (group A); 30 to 39 years (group B); 40 to 49 years (group C); and 50 to 59 years (group D). Conventional lumbar separation was performed by removing soft tissue and subsidiary structures, leaving only the vertebral body. The vertebral body was cut into halves along the median sagittal plane, maintaining the upper and lower end-plates of each half, and used for biomechanical, morphological, and density measurements. Results Comparing group A to B, the rod-like trabecular thickness (Tb.Th) decreased; the trabecular spacing (Tb.Sp) increased; the plate-like Tb.Th decreased; bone mineral density, tissue mineral density, bone volume fraction, and bone surface fraction decreased, and the elastic modulus and the ultimate stress

decreased (all changes P<0.05). Similar significant (P<0.05) trends were obtained when comparing group C to D. With aging, the collagen cross-linking capacity declined, the thickness of the collagen fibrils was variable (ranging from almost the same to loose, sparse, or disordered), and the finer collagen fibrils between the thick filaments were disorganized. Conclusions In women aged 20 to 59 years, the rod-like and plate-like Tb.Th of the vertebral body decreased, while Tb.Sp increased. Additionally, the density, elastic modulus, and ultimate stress of the cancellous bone decreased with age. These associated changes in bone microstructure, density, and biomechanics with age may lead to an increasing risk of osteoporosis and fracture.

TI Profiles of vitamin D insufficiency and deficiency in Japanese men and women: association with biological, environmental, and nutritional factors and coexisting disorders: the ROAD study
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE Epidemiology; Population-based study; Prevalence; Risk factor; Vitamin D deficiency; Vitamin D insufficiency
ID serum 25-hydroxyvitamin-d levels; ultraviolet-b; d inadequacy; prevention; hyperparathyroidism; osteoporosis; fractures; risk
AB Assessments of serum 25-hydroxyvitamin D levels in 1,683 Japanese from a population-based cohort revealed prevalences of vitamin D insufficiency and deficiency were 81.3 and 1.2 %, respectively. Vitamin D deficiency was significantly associated with female sex, examined month, current smoking, lack of regular walking, higher intact parathyroid hormone (iPTH), and poor daily vitamin D intake. To clarify the characteristics of subjects with vitamin D insufficiency and deficiency among men and women in the general Japanese population. We initiated research on osteoarthritis/osteoporosis against disability (ROAD), a large-scale population-based cohort study, in 2005-2007. Blood examination was performed to measure serum 25-hydroxyvitamin D (25D) and iPTH levels and biochemical markers of bone turnover in 1,683 participants (595 men, 1,088 women). Participants completed an interviewer-administered questionnaire, measurements of bone mineral density, and x-ray examination. Vitamin D deficiency and insufficiency were defined by serum 25D levels < 10 and a parts per thousand yen10 but < 30 ng/mL, respectively. The prevalence of vitamin D insufficiency and

deficiency was 81.3 and 1.2 %, respectively. Multinominal logistic regression analyses using potentially confounding variables revealed vitamin D insufficiency was significantly associated with age (+1 year, relative risk ratio, 0.98; 95 % confidence interval, 0.96-0.99), gender (women vs. men, 2.28; 1.59-3.30), residing areas (coastal area vs. mountainous area, 0.58; 0.41-0.81), examined month (October, November, December vs. January, 0.51; 0.34-0.76), and serum levels of iPTH (+1 pg/mL, 1.02; 1.01-1.03). Vitamin D deficiency was significantly characterised by female sex (20.5; 3.1-136.7), examined month (0.28; 0.09-0.95), current smoking habit (6.39; 1.78-23.0), lack of regular outside walking (3.96; 1.34-11.7), higher iPTH (1.02; 1.01-1.03) and poor daily vitamin D intake (+10 mu g/day, 0.48; 0.24-0.93). A high prevalence of vitamin D insufficiency and a low prevalence of vitamin D deficiency were found in Japanese men and women, and the characteristics of vitamin D status were clarified.

TI Osteoarthritic versus osteoporotic bone and intra-skeletal variations in normal bone: Evaluation with μCT and bone histomorphometry
SO JOURNAL OF ORTHOPAEDIC RESEARCH
LA English
DT Article
DE osteoarthritis; osteoporosis; controls; mu CT; histomorphometry
ID trabecular bone; postmenopausal women; hip osteoarthritis; orchiectomized rat;

cancellous bone; fracture; microarchitecture; association; index; femur
AB Several studies have shown that in contrast to osteoporosis (OP), osteoarthritis (OA) is characterized by high bone mineral density (BMD). Bone strength not only depends on mineral content as determined by dual X-ray absorptiometry (DXA), but also on bone microarchitecture. We studied intertrochanteric bone from normal controls and OA and OP patients by bone histomorphometry (BHM) and microcomputed tomography (mu CT) as well as DXA in order to first, test the differences between OA and OP comparing both groups to healthy controls, second, to assess variations between three different skeletal sites in controls and third, to determine the level of agreement between mu CT, BHM, and DXA. Analysis was performed on 115 samples from OA and OP patients, and controls. We found significant differences between OA and OP samples in structural parameters and in the osteoid fraction ($p<0.05$). The majority of the intra-skeletal differences were shown between lumbar spine and femoral head samples ($p<0.05$). Significant agreements were found between mu CT and BHM and DXA ($r=0.320.45$, $p<0.05$). Our findings suggest differences in intertrochanteric bone between OA and OP, the age-related intra-skeletal variations and a correlation between microscopic and macroscopic bone evaluation methods. TI Bone marrow mesenchymal stem cells: Fat on and blast off by FGF21
SO INTERNATIONAL JOURNAL OF BIOCHEMISTRY & CELL BIOLOGY
LA English
DT Article
DE Bone marrow mesenchymal stem cell; Osteoblast; Adipocyte; FGF21; PPAR gamma
ID gamma; osteoclastogenesis; differentiation; rosiglitazone; osteoblast; catenin; tissue; chondrocytes; progenitors; cartilage
AB Bone marrow mesenchymal stem cells (BMMSCs) are multipotent marrow stromal cells with the ability to differentiate into a variety of cell types required for tissue regeneration including osteoblasts and chondrocytes. Thus, they hold tremendous potential as powerful therapeutic strategies for the prevention and treatment of degenerative disorders including osteoporosis and osteoarthritis. The differentiation of BMMSCs into competing lineages such as osteoblasts and marrow adipocytes is regulated by various environmental cues and intrinsic signaling pathways. Here I highlight recent advances in the understanding of BMMSC function and regulation, including the interaction between BMMSCs with the hematopoietic/immune system, and the identification of novel modulators of BMMSC differentiation such as the metabolic hormone fibroblast growth factor 21 (FGF21). These new findings will further elucidate the dynamic regulation of BMMSCs in the pathophysiological control of skeletal homeostasis, and facilitate the clinical applications of BMMSCs in regenerative medicine. TI Differential features of muscle fiber atrophy in osteoporosis and osteoarthritis

SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE Akt; Muscle atrophy; Osteoarthritis; Osteoporosis; Sarcopenia; Type II fibers
ID bone-mineral density; signaling pathways; sarcopenia; hip; mechanisms; diagnosis; mass; fractures; arthritis; women
AB We demonstrated that osteoporosis is associated with a preferential type II muscle fiber atrophy, which correlates with bone mineral density and reduced levels of Akt, a major regulator of muscle mass. In osteoarthritis, muscle atrophy is of lower extent and related to disease duration and severity. Osteoarthritis (OA) and osteoporosis (OP) are associated with loss of muscle bulk and power. In these diseases, morphological studies on muscle tissue are lacking, and the underlying mechanisms of muscle atrophy are not known. The aim of our study was to evaluate the OP- or OA-related muscle atrophy and its correlation with severity of disease. Muscle levels of Akt protein, a component of IGF-1/PI3K/Akt pathway, the main regulator of muscle mass, have been determined. We performed muscle biopsy in 15 women with OP and in 15 women with OA (age range, 60-85 years). Muscle fibers were counted, measured, and classified by ATPase reaction. By statistical analysis, fiber-type atrophy was correlated with bone mineral density (BMD) in the OP group and with Harris Hip Score (HHS) and disease duration in the OA group. Akt protein levels were evaluated by Western blot analysis. Our findings revealed in OP a preferential type II fiber atrophy that inversely correlated with patients' BMD. In OA, muscle atrophy was of lower extent, homogeneous among fiber types and related to disease duration and HHS. Moreover, in OP muscle, the Akt level was significantly reduced as compared to OA muscles. This study shows that in OP, there is a preferential and diffuse type II fiber atrophy, proportional to the degree of bone loss, whereas in OA, muscle atrophy is connected to the functional impairment caused by the disease. A reduction of Akt seems to be one of the mechanisms involved in OP-related muscle atrophy.

TI Microstructural alterations of femoral head articular cartilage and subchondral bone in osteoarthritis and osteoporosis
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE Osteoarthritis; Osteoporosis; Cartilage alterations; Subchondral cortical bone; Subchondral trabecular bone
ID cancellous bone; mechanical-property; mri; morphology; plate
AB Objective: Explore whether osteoporosis (OP) in humans influences the morphological status of the articular cartilage and the subchondral bone. Explore the relationship between the macroscopic aspect of the articular surface and the rate of microscopic changes of both the cartilage and the subchondral bone in OP and osteoarthritis (OA). Methods: Femoral heads after total hip replacement were obtained from patients with OP or hip OA (OP, n = 56; OA, n = 12). Cartilage degeneration was assessed using the Mankin grading system whereas subchondral

bone was evaluated using histomorphometry and Micro-computed Tomography (mu CT) scanning system. Thickness of the cartilage layers and subchondral cortical bone (SCB) was measured. Results: Samples with higher total Mankin score have significantly reduced cartilage thickness. Mankin score differed between all OP specimens. In OP samples with lower Mankin scores the thickness of SCB shows a trend of an increase caused by increased levels of bone remodeling. In OP samples with higher Mankin scores we observed thinning of SCB. Structural indices of subchondral trabecular bone (STB) were significantly lower in OP than in OA samples. Conclusion: Thinning of SCB, found in OP samples with higher Mankin scores could be related with the progression of the cartilage degeneration indicating an early-stage OA. Increased levels of bone remodeling and evidently changed morphology of subchondral bone found in OP samples with lower Mankin score indicated that bony bed level must have a role in the progression of the cartilage degeneration. TI Friend or foe: high bone mineral density on routine bone density scanning, a review of causes and management
SO RHEUMATOLOGY
LA English
DT Review
DE DXA; BMD; high bone mass; osteopetrosis; osteoarthritis
ID c-associated osteosclerosis; autosomal-dominant osteopetrosis; idiopathic skeletal hyperostosis; albers-schonberg-disease; energy x-ray; buschke-ollendorff-syndrome; camurati-engelmann-disease; latency-associated peptide; domain-specific mutations; clcn7 gene-mutations
AB A finding of high BMD on routine DXA scanning is not infrequent and most commonly reflects degenerative disease. However, BMD increases may also arise secondary to a range of underlying disorders affecting the skeleton. Although low BMD increases fracture risk, the converse may not hold for high BMD, since elevated BMD may occur in conditions where fracture risk is increased, unaffected

or reduced. Here we outline a classification for the causes of raised BMD, based on identification of focal or generalized BMD changes, and discuss an approach to guide appropriate investigation by clinicians after careful interpretation of DXA scan findings within the context of the clinical history. We will also review the mild skeletal dysplasia associated with the currently unexplained high bone mass phenotype and discuss recent advances in osteoporosis therapies arising from improved understanding of rare inherited high BMD disorders.

TI The mid-term efficacy of intra-articular hyaluronic acid injections on joint structure: a nested case control study
SO MODERN RHEUMATOLOGY
LA English
DT Article
DE Hyaluronic acid; Nested case control study; Joint structure; Knee pain
ID individual radiographic features; randomized clinical-trial; knee osteoarthritis; sodium hyaluronate; hylan g-f-20; double-blind; triamcinolone hexacetonide; molecular-weight; pain; hyalgan(r)
AB Objective Intra-articular (IA) injection of hyaluronic acid (HA) has been shown to relieve osteoarthritis (OA)-related pain and improve joint structure within a 1-year period. We examined the mid-term (2-year) efficacy of IA-HA in Japanese subjects by using a large-scale population-based cohort of the Research on Osteoarthritis/Osteoporosis Against Disability study. Methods We performed a nested case control study of 60 case control pairs matched for age (within 1 year), sex, Kellgren and Lawrence grade, and history of knee pain. The mean follow-up period after IA-HA series was 2.9 years in case patients. We examined the association of IA-HA with knee radiographic severity and knee pain. To estimate radiographic severity of OA, six distinct features-joint space area and the minimum joint space width at medial and lateral sides, osteophyte area, and tibiofemoral angle-were measured using a fully automatic computer-assisted program. Results Comparison of the radiographic parameters between case patients and controls showed that the medial and lateral joint space areas were significantly bigger in case patients than in controls. After constructing a multi-variate logistic regression model to examine the correlation of knee pain, IA-HA, and radiographic features, we found that unlike radiographic features, IA-HA was protectively associated with the presence of pain. Conclusion IA-HA might effectively improve joint structure and relieve pain in patients with knee OA.

TI Physical performance, bone and joint diseases, and incidence of falls in Japanese men and women: a longitudinal cohort study
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE Falls; Longitudinal study; Osteoarthritis; Pain; Walking speed
ID dwelling elderly-people; knee osteoarthritis; radiographic osteoarthritis; osteoporotic fractures; older-adults; risk-factors; lumbar spondylosis; recurrent falls; back-pain; community
AB This study examined whether physical performance and bone and joint diseases were risk factors for falls in 745 men and 1,470 women from the Research on Osteoarthritis/osteoporosis Against Disability (ROAD) study (mean, 69.7 years). Slower walking speed was a risk factor for falls in men and women. Knee pain was a risk factor for falls in women. The objective of the present study was to clarify the incidence of falls by sex and age and to determine whether physical performance and bone and joint diseases are risk factors for falls in men and women using a large-scale population-based cohort of the ROAD. A total of 745 men and 1,470

women were analyzed in the present study (mean age, 68.5 years). A questionnaire assessed the number of falls during 3 years of follow-up. Grip strength and walking speed were measured at baseline. Knee and lumbar spine radiographs were read by Kellgren-Lawrence (KL) grade; radiographic knee osteoarthritis and lumbar spondylosis were defined as KL = 3 or 4. Knee and lower back pain were estimated by an interview. During a mean follow-up of 3 years, 141 (18.9 %) men and 362 (24.6 %) women reported at least one fall. Slower walking speed was a risk factor for falls in men (0.1 m/s decrease; odds ratio [OR], 1.15; 95 % confidence interval [CI], 1.09-1.23) and women (0.1 m/s decrease; OR, 1.05; 95 % CI, 1.01-1.10). Knee pain was also a risk factor for falls (OR, 1.38; 95 % CI, 1.03-1.84) in women, but lower back pain was not. We examined the incidence and risk factors for falls in men and women. Slower walking speed was a risk factor for falls in men and women. Knee pain was a risk factor for falls in women.

TI Phospholipases of Mineralization Competent Cells and Matrix Vesicles: Roles in Physiological and Pathological Mineralizations
SO INTERNATIONAL JOURNAL OF MOLECULAR SCIENCES
LA English
DT Review
DE bone; cartilage; osteoarthritis; osteoporosis; phospholipases; rheumatoid arthritis; sphingomyelinase; osteoblasts; osteoclasts; chondrocytes; Smooth muscle cells; matrix vesicle; mineralization; vascular calcification
ID protein-kinase-c; osteoblast-like cells; platelet-activating-factor; nf-kappa-b; phosphatidylcholine-specific phospholipase; fibroblast-growth-factor; tumor-necrosis-factor; group-ii phospholipase-a2; arachidonic-acid release; catalytically inactive protein
AB The present review aims to systematically and critically analyze the current knowledge on phospholipases and their role in physiological and pathological mineralization undertaken by mineralization competent cells. Cellular lipid metabolism plays an important role in biological mineralization. The physiological mechanisms of mineralization are likely to take place in tissues other than in bones and teeth under specific pathological conditions. For instance, vascular calcification in arteries of patients with renal failure, diabetes mellitus or atherosclerosis recapitulates the mechanisms of bone formation. Osteoporosis-a bone resorbing disease-and rheumatoid arthritis originating from the inflammation in the synovium are also affected by cellular lipid metabolism. The focus is on the lipid metabolism due to the effects of dietary lipids on bone health. These and other phenomena indicate that phospholipases may participate in bone remodelling as evidenced by their expression in smooth muscle cells, in bone forming osteoblasts, chondrocytes and in bone resorbing osteoclasts. Among various enzymes involved, phospholipases A(1) or A(2), phospholipase C, phospholipase D, autotaxin and sphingomyelinase are engaged in membrane lipid remodelling during early stages of mineralization and cell maturation in mineralization-competent cells. Numerous experimental evidences suggested that phospholipases exert their action at various stages of mineralization by affecting intracellular signaling and cell differentiation. The lipid metabolites-such as arachidonic acid, lysophospholipids, and sphingosine-1-phosphate are involved in cell signaling and inflammation reactions. Phospholipases are also important members of the cellular machinery engaged in

matrix vesicle (MV) biogenesis and exocytosis. They may favour mineral formation inside MVs, may catalyse MV membrane breakdown necessary for the release of mineral deposits into extracellular matrix (ECM), or participate in hydrolysis of ECM. The biological functions of phospholipases are discussed from the perspective of animal and cellular knockout models, as well as disease implications, development of potent inhibitors and therapeutic interventions.

TI Orthogeriatrics - considerations in caring for older orthopaedic patient
SO PERIODICUM BIOLOGORUM
LA English
DT Article
DE geriatrics; aging physiology; orthopaedics
ID adult-acquired flatfoot; calcaneal osteotomy; bone-density; osteoarthritis; knee; osteoporosis; pain; metaanalysis; replacement; deficiency
AB Patients over the age of 65 are the fastest growing segment of the population, and it is estimated that it comprises 12.5% of the entire population in the developed countries. Advances in medicine, science and healthy lifestyles have promoted substantially increased lifespans, as well as better quality of life with more physical activity. On the other hand, aging is associated with a variety of physiologic changes that affect orthopedic care. Due to natural involution processes older adults may not have the physiologic reserves necessary to promote healing or to prevent or recover from complications. Degenerative diseases and

injuries sustained from trauma in combination with physiologic changes and comorbidity in the aged pose a significant health problem in older adults and a major treatment challenge for an orthopaedic surgeon. This review summarizes some of these unique challenges in care for older orthopaedic patient.

TI Association between Estrogen Receptor α Gene (ESR1) PvuII (C/T) and XbaI (A/G) Polymorphisms and Hip Fracture Risk: Evidence from a Meta-Analysis
SO PLOS ONE
LA English
DT Article
ID bone-mineral density; osteoporosis; women; cancer; osteoarthritis; heterogeneity; disease; reduce
AB Background and Objective: Genetic factors are important in the pathogenesis of fractures. Notably, estrogen receptor alpha(ESR1) has been suggested as a possible candidate gene for hip fractures; however, published studies of ESR1 gene polymorphisms have been hampered by small sample sizes and inconclusive or ambiguous results. The aim of this meta-analysis is to investigate the associations between two novel common ESR1 polymorphisms (intron 1 polymorphisms PvuII-rs2234693: C > T and XbaI-rs9340799: A > G) and hip fracture. Methods: Crude odds ratios (ORs) with 95% confidence intervals (CIs) were used to evaluate the strength of the association. Results: Five case-control and three cohort studies were assessed, including a total of 1,838 hip fracture cases and 14,972 healthy controls. This meta-analysis revealed that the PvuII T allele is a highly significant risk factor for hip fracture susceptibility, with an effect magnitude similar in male and pre-menopausal and post-menopausal female patients. In stratified analysis based on ethnicity, the PvuII T allele remained significantly correlated with increased risk of hip fracture in Caucasian populations; this correlation, however, was not found in Asian populations. Unlike the PvuII polymorphism, we did not find significant differences in the XbaI (A > G) polymorphism allele or genotype distributions of hip fracture patients and controls. We also found no obvious association between the XbaI polymorphism and hip fracture in any of the racial or gender subgroups. Conclusion: Our findings show that the ESR1 PvuII T allele may increase the risk of hip fracture and that the XbaI polymorphism is not associated with hip fracture.

TI Misclassification of incident conditions using claims data: impact of varying the period used to exclude pre-existing disease
SO BMC MEDICAL RESEARCH METHODOLOGY
LA English
DT Article
DE Incidence; Prevalence; Misclassification; Look back; Medical claims; Medicare
ID medicare claims; elderly population; adverse events; united-states; mortality; breast; beneficiary; prevalence; fractures
AB Background: Estimating the incidence of medical conditions using claims data often requires constructing a prevalence period that predates an event of interest, for instance the diagnosis of cancer, to exclude those with pre-existing conditions from the incidence risk set. Those conditions missed during the prevalence period may be misclassified as incident conditions (false positives) after the event of interest. Using Medicare claims, we examined the impact of selecting shorter versus longer prevalence periods on the incidence and misclassification of 12 relatively common conditions in older persons. Methods: The source of data for this study was the National Cancer Institute's Surveillance, Epidemiology, and End Results cancer registry linked to Medicare claims. Two cohorts of women were included: 33,731 diagnosed with breast cancer between 2000 and 2002, who had >= 36 months of Medicare eligibility prior to cancer, the event of interest; and 101,649 without cancer meeting the same Medicare eligibility criterion. Cancer patients were followed from 36 months before cancer diagnosis (prevalence period) up to 3 months after diagnosis (incidence period). Non-cancer patients were followed for up to 39 months after the beginning of Medicare eligibility. A sham date was inserted after 36 months to separate the prevalence and incidence periods. Using 36 months as the gold standard, the prevalence period was then shortened in 6-month increments to examine the impact on the number of conditions first detected during the incidence period. Results: In the breast cancer cohort,

shortening the prevalence period from 36 to 6 months increased the incidence rates (per 1,000 patients) of all conditions; for example: hypertension 196 to 243; diabetes 34 to 76; chronic obstructive pulmonary disease 29 to 46; osteoarthritis 27 to 36; congestive heart failure 20 to 36; osteoporosis 22 to 29; and cerebrovascular disease 13 to 21. Shortening the prevalence period has less impact on those without cancer. Conclusions: Selecting a short prevalence period to rule out pre-existing conditions can, through misclassification, substantially inflate estimates of incident conditions. In incidence studies based on Medicare claims, selecting a prevalence period of >= 24 months balances the need to exclude pre-existing conditions with retaining the largest possible cohort.

TI Disease patterns of rheumatology outpatients seen in a tertiary hospital serving a multi- ethnic, urban Asian population in Singapore
SO INTERNATIONAL JOURNAL OF RHEUMATIC DISEASES
LA English
DT Article
DE Asia; hospital; outpatient clinics; rheumatic diseases; Singapore
ID national database; arthritis; association; mortality; register
AB AimsTo describe the spectrum of diseases seen in an outpatient setting in the Singapore General Hospital, the largest tertiary referral centre in Singapore. MethodsIn this cross-sectional study, medical records of patients scheduled for an appointment at the rheumatology specialist outpatient clinics over a 4-month period (10 August 2010-31 December 2010) were reviewed. Primary diagnoses documented by the attending physician at the latest visit were recorded. ResultsAmong 4180 patients (29.5% male; mean [SD] age: 53.5 [15.1] years; 77.0% Chinese, 8.0% Malay, 8.8% Indian and 6.2% others), the spectrum of diseases seen was as follows [disease - definite n (%), probable n (%)]: Arthritis: rheumatoid arthritis - 958 (22.9%), 68 (1.6%); osteoarthritis - 452 (10.8%), 39 (0.9%); crystal arthritis - 417 (10.0%), 18 (0.4%); spondyloarthritis - 227 (5.4%), 61 (1.5%); psoriatic arthritis - 158 (3.8%), 9 (0.2%); other inflammatory arthritis - 153 (3.7%), 94 (2.2%); Connective tissues diseases: systemic lupus erythematosus - 412 (9.9%), 26 (0.6%); vasculitis - 105 (2.5%), 22 (0.5%); Sjogren's syndrome - 81 (1.9%), 32 (0.8%); overlap syndromes - 73 (1.8%); scleroderma - 50 (1.2%), 4 (0.1%); undifferentiated connective tissue diseases - 45 (1.1%), 106 (2.5%); myositis - 41 (1.0%), 12 (0.3%); antiphospholipid syndrome - 22 (0.5%), 7 (0.2%); polymyalgia rheumatica - 16

(0.4%); Others: soft tissue rheumatism - 155 (3.7%); osteoporosis - 61 (1.5%); other non-rheumatologic conditions - 189 (4.5%); other rheumatologic conditions - 67 (1.6%). ConclusionRheumatoid arthritis, osteoarthritis and crystal arthritis were the three most common rheumatological diseases seen in a tertiary referral centre serving a multi-ethnic urban Asian population in Singapore.
