TI Vitamin C effects on 5-hydroxymethylcytosine and gene expression in osteoblasts and chondrocytes: Potential involvement of PHD2
SO PLOS ONE
LA English
DT Article
ID bone-mineral density; ascorbic-acid; proteasomal degradation; alkaline-phosphatase; osterix expression; prolyl hydroxylase; in-vitro; differentiation; collagen; activation
AB Vitamin C (ascorbic acid, AA) is a well-known regulator of bone and cartilage metabolism. However, the mechanisms of AA's action in these tissues are only partly understood. In this study, we confirmed that AA contributes to bone and cartilage metabolism by showing decreased articular cartilage and trabecular bone in AA-deficient spontaneous fracture (sfx) mutant mice. In vitro, we found that AA exerts differential effects on chondrocyte and osteoblast differentiation. Since AA is known to increase levels of 5-hydroxymethylcytosine (5-hmC) and induce DNA demethylation via the ten-eleven translocases (TETs), and since prolyl hydroxylase domain-containing protein 2 (PHD2), a known mediator of AA's effects in these tissues, is part of the same enzyme family as the TETs, we next investigated whether increases in 5-hmC might mediate some of these effects. All TETs and PHDs are expressed in chondrocytes and osteoblasts, and PHD2 is localized in both

the cytoplasm and nucleus of the cell, lending plausibility to the hypothesis of altered 5-hmC content in these cells. We found that AA treatment increased levels of 5-hmC in both cell types globally, notably including promoter regions of osteoblast differentiation genes. Furthermore, inhibition of PHD2 decreased 5-hmC levels in chondrocyte differentiation gene promoters, and knockdown of Phd2 in chondrocytes reduced global 5-hmC levels, suggesting for the first time that PHD2 may itself directly mediate increases in 5-hmC in chondrocyte and osteoblast genes. Further investigation of this mechanism could lead to novel therapeutic approaches to treat debilitating diseases such as osteoarthritis and osteoporosis.

TI Increased Risk of Musculoskeletal Disorders and Mental Health Problems in Retired Professional Jockeys: A Cross-Sectional Study
SO INTERNATIONAL JOURNAL OF SPORTS MEDICINE
LA English
DT Article
DE osteoarthritis; osteoporosis; anxiety; depression; athlete; chronic disease
ID body-mass index; weight; sport; age; prevalence; osteoarthritis; comorbidity; concussion; depression; height
AB To examine the prevalence of chronic disease and mental health problems in retired professional, male jockeys compared to an age-matched reference population. A cross-sectional study comparing data from a cohort of retired professional jockeys with an age-matched general population sample. Male participants (age range: 50-89 years old) were used to compare health outcomes of self-reported physician-diagnosed conditions: heart disease, stroke, diabetes, hypertension, osteoporosis, osteoarthritis, depression and anxiety between study populations. Conditional logistic regression models were used to estimate associations between study groups and health outcome. In total, 810 participants (135 retired professional male jockeys and 675 participants from the reference population) were included, with an average age of 64.7 +/- 9.9 years old. Increased odds of having osteoporosis (OR=6.5, 95%CI 2.1-20.5), osteoarthritis (OR=7.5, 95%CI 4.6-12.2), anxiety (OR=2.8, 95%CI 1.3-5.9) and depression (OR=2.6, 95%CI 1.3-5.7) were seen in the retired professional jockeys. No differences were found for the remaining health outcomes. Retired professional jockeys had increased odds of musculoskeletal disease and mental health problems compared to the general population. Understanding the prevalence of chronic disease and mental health problems in retired professional jockeys will help inform screening and intervention strategies for jockeys.

TI Practical guidance for engaging patients in health research, treatment guidelines and regulatory processes: results of an expert group meeting organized by the World Health Organization (WHO) and the European Society for Clinical and Economic Aspects of Osteoporosis, Osteoarthritis and Musculoskeletal Diseases (ESCEO)
SO AGING CLINICAL AND EXPERIMENTAL RESEARCH
LA English
DT Review
DE Outcomes research; Patient engagement; Patient preference; Regulatory process; Treatment guidelines
ID discrete-choice experiment; public involvement; drug development; core set; preferences; engagement; partners
AB There is increasing emphasis on patient-centred research to support the development, approval and reimbursement of health interventions that best meet patients' needs. However, there is currently little guidance on how meaningful patient engagement may be achieved. An expert working group, representing a wide range of stakeholders and disciplines, was convened by the European Society for Clinical and Economic Aspects of Osteoporosis, Osteoarthritis and Musculoskeletal Diseases (ESCEO) and the World Health Organization (WHO). Through a structured, collaborative process the group generated practical guidance to facilitate optimal patient engagement in clinical development and regulatory decisions. Patient engagement is a relational process. The principles outlined in this report were based on lessons learned through applied experience and on an

extensive dialogue among the expert participants. This practice guidance forms a starting point from which tailoring of the approach to suit different chronic diseases may be undertaken.

TI Open-Source Remote Gait Analysis: A Post-Surgery Patient Monitoring Application
SO SCIENTIFIC REPORTS
LA English
DT Article
ID cruciate ligament reconstruction; transitional care; anterior; osteoarthritis; kinematics; asymmetry; mechanics; strength; kinetics; walking
AB Critical to digital medicine is the promise of improved patient monitoring to allow assessment and personalized intervention to occur in real-time. Wearable sensor-enabled observation of physiological data in free-living conditions is integral to this vision. However, few open-source algorithms have been developed for analyzing and interpreting these data which slows development and the realization of digital medicine. There is clear need for open-source tools that analyze free-living wearable sensor data and particularly for gait analysis, which provides important biomarkers in multiple clinical populations. We present an open-source analytical platform for automated free-living gait analysis and use it to investigate a novel, multi-domain (accelerometer and electromyography) asymmetry measure for quantifying rehabilitation progress in patients recovering from surgical reconstruction of the anterior cruciate ligament (ACL). Asymmetry indices extracted from 41,893 strides were more strongly correlated ($r = -0.87$, $p < 0.01$) with recovery time than standard step counts ($r = 0.25$, $p = 0.52$) and significantly differed between patients 2- and 17-weeks post-op ($p < 0.01$, effect size: 2.20-2.96), and controls ($p < 0.01$, effect size: 1.74-4.20). Results point toward future use of this open-source platform for capturing rehabilitation progress and, more broadly, for free-living gait analysis.

TI Ipriflavone attenuates the degeneration of cartilage by blocking the Indian hedgehog pathway
SO ARTHRITIS RESEARCH & THERAPY
LA English
DT Article
DE Ipriflavone; Osteoarthritis; Indian hedgehog; Chondrocyte hypertrophy
ID growth-plate; osteoblast differentiation; postmenopausal women; signaling pathway; osteoarthritis; recommendations; osteoporosis; cyclopamine; combination; prevention
AB BackgroundTo determine if ipriflavone, a novel and safe inhibitor of Indian hedgehog (Ihh) signaling, can attenuate cartilage degeneration by blocking the Ihh

pathway.MethodsHuman chondrocytes were used to evaluate Ihh signaling, cell proliferation, apoptosis, gene, and protein expression of chondrocytes by cell proliferation and apoptosis assays, real-time qPCR, and Western blotting at 48h after ipriflavone treatment. Human cartilage explants were further used to validate the cell culture results. The effects of ipriflavone on cartilage degeneration in vivo were assessed using the rat ACLT OA model. Two-month-old male SD rats were randomized into 3 groups (n=75): (1) sham, (2) ACLT alone, and (3) ACLT+ ipriflavone. Ipriflavone was administered intragastrically at 24h after ACLT for 6weeks. The extent of OA progression was evaluated by the OARSI score and immunohistochemistry at 12weeks after surgery. The Ihh signaling pathway and OA-related genes were quantified by real-time PCR.ResultsCell proliferation in the cells treated with ipriflavone was increased to 36.40%1.32% (5M) and 28.54%+/- 0.74% (10M) from 11.99%+/- 0.35% (DMSO) ($P<0.001$), and apoptosis was decreased to 12.64%+/- 3.7% (5M) and 15.18%+/- 3.13% (10M) from 25.76%+/- 5.1% (DMSO) ($P<0.05$). Ipriflavone blocked Runx-2 mainly through the Smo-Gli2 pathway. A similar result was found in the cartilage explant culture. Ihh signaling in vivo was inhibited in animals treated with ipriflavone. Safranin-O staining revealed a less cartilage damage with lower OARSI scores ($P<0.05$) in the ipriflavone-treated animals compared with untreated animals. The gene expression of Smo and Gli2 was inhibited significantly by ipriflavone ($P<0.05$). The OA-related gene and protein type X, MMP-13, and type II collagen-C fragment were reduced, while type II collagen and Agg were increased in the ipriflavone-treated animals ($P<0.05$).Conclusions Catabolic genes were disrupted by blocking the Ihh pathway. This finding suggests that disruption of Ihh signaling with ipriflavone provides chondral protection in rat posttraumatic OA.

TI The impact of musculoskeletal diseases on the presence of locomotive syndrome
SO MODERN RHEUMATOLOGY
LA English
DT Article
DE Hypertension; locomotive syndrome; low back pain; musculoskeletal disease;

osteoporosis
ID quality-of-life; back muscle strength; elderly-people; body-mass; osteoarthritis; osteoporosis; association; population; knee; dysfunction
AB Objectives: We assessed the impact of musculoskeletal diseases, depressive mental state, and hypertension on locomotive syndrome, a condition of reduced mobility requiring nursing care. Since locomotive syndrome is a major public health issue that needs attention, its relationship with functional inconvenience in performing daily activities was also investigated. Methods: We conducted a cross-sectional study using an Internet panel survey, comprising 747 persons aged 30-90 years. Demographics, personal medical history, and daily activity data were assessed. The 25-question Geriatric Locomotive Function Scale was used to diagnose locomotive syndrome. Stepwise linear regression analysis and logistic regression analysis were conducted to evaluate the association between locomotive syndrome, musculoskeletal diseases, and functional inconvenience. Results: Aging, osteoporosis, and low back pain significantly increased the risk of locomotive syndrome, followed by knee osteoarthritis and lumbar spinal stenosis. Locomotive syndrome was significantly related to depressive mental state and hypertension, and led to functional inconvenience in Seiza sitting, cleaning, shopping, and strolling. Conclusion: Locomotive syndrome was associated with functional inconvenience in performing common daily activities involving the lower extremities and spine. Osteoporosis and aging were significantly associated with locomotive syndrome. The risk of locomotive syndrome may be decreased by treating comorbid osteoporosis and instituting exercise and diet-related modifications.

TI Relationship between osteoporosis and osteoarthritis based on DNA methylation
SO INTERNATIONAL JOURNAL OF CLINICAL AND EXPERIMENTAL PATHOLOGY
LA English
DT Article
DE Osteoporosis; osteoarthritis; mitochondria; DNA methylation
ID gene-expression; bone; epigenetics; mechanisms; fractures
AB The aim of this study was to investigate the relationship between osteoporosis and osteoarthritis by analyzing the DNA methylation in osteoporosis and osteoarthritis. The cancellous bone specimens were collected from a total of 12 hospitalized patients and divided into the osteoporosis group (OA), the osteoarthritis group (OP), the osteoporosis combined with osteoarthritis group (OA & OP), and the normal control group (N). The cancellous bone specimens of each group were detected and the differences in gene expression profiles by the MeDIP-chip technique were compared. Compared with Group OA & OP, the methylation levels in Group OA and Group OP were statistically higher, $P < 0.05$. In the microarray analysis, a total of 1,222 sites occurred hypermethylation. The analysis targeting the differentially expressed genes between Group OA & OP and Group N revealed that group OA and group OP had 4 common genes: PPIL3, NIF3L1, SMTN, and CALHM2. The level of genomic methylation is lower in the

patients with osteoporosis and/or osteoarthritis. The common difference between osteoarthritis and osteoporosis is reflected in some specific promoters, which may participate in the processes of diseases through different pathways.

TI Effect of GGCX on the differentiation function of osteoporosis bone marrow mesenchymal stem cells through regulating TGFβ/smad signaling pathway
SO EUROPEAN REVIEW FOR MEDICAL AND PHARMACOLOGICAL SCIENCES
LA English
DT Article
DE Osteoporosis; GGCX; BMSC; TGF beta/smad signaling pathway; Differentiation
ID gla-rich protein; association
AB OBJECTIVE: Osteoporosis (OP) has a high incidence and can be found in multiple age groups. The bone marrow mesenchymal stem cells (BMSCs) have the potential for self-renewal and multi-directional differentiation, which are often used for investigating the differentiation function of osteoporosis bone marrow mesenchymal stem cells. gamma-glutamyl carboxylase (GGCX) is a carboxylase-related carboxylase and was observed to be abnormally expressed in osteoarthritis. However, the role and related mechanisms of GGCX in OP have not been fully elucidated. This work aimed to evaluate the effect of GGCX on the differentiation function of BMSCs. PATIENTS AND METHODS: Sprague-Dawley rats were randomly divided into the OP group prepared by ovariectomy and sham group. GGCX expression was tested by enzyme-linked immunosorbent assay (ELISA). BMSCs were isolated from OP rats and transfected with pcDNA-GG-CX plasmids. BMSC proliferation was detected by tetrazolium salt colorimetry (MTT) assay. The osteogenic and adipogenic differentiation of BMSCs was analyzed by alizarin red staining and oil red O staining. The ALP activity was determined by alkaline phosphatase (ALP) activity colorimetric assay. Real time-PCR was used to test the expressions of osteogenesis-related genes RUNX2 and OPN mRNA. Western blot was adopted to assess the TGF beta/smad signaling pathway activity. RESULTS: GGCX expression was significantly decreased in the serum of OP rats compared with the sham group ($p < 0.05$). The transfection of pcDNA-GGCX plasmid significantly promoted BMSC cell proliferation, increased calcified nodule formation, inhibited adipogenic differentiation, enhanced ALP activity, elevated RUNX2, and OPN mRNA expressions, and upregulated TGF beta 1, Smad2, and Smad7 expressions ($p < 0.05$). CONCLUSIONS: GGCX secretion is reduced in osteoporosis. GGCX can regulate osteoporosis via promoting the TGF beta/smad signaling pathway, facilitating BMSCs osteogenic differentiation, and inhibiting BMSCs adipogenic differentiation.

TI Physical activity and depression symptoms in women with chronic illness and the mediating role of health-related quality of life
SO JOURNAL OF AFFECTIVE DISORDERS
LA English
DT Article
DE Depression; Health behaviour; Exercise; Women's health; Quality of life; Chronic disease
ID psychological distress; older-adults; exercise; hardiness; care; association; prevalence; impact
AB Background: The aim of this study was to determine the impact of physical activity on depression symptom severity in women 45 years and older with a chronic illness diagnosis, and explore relations between physical activity and psychological and health-related characteristics predicting depression symptoms.

Methods: 1932 women diagnosed with one of five chronic illnesses: asthma, depression, diabetes, osteoarthritis, or osteoporosis participated in a sub-study of the 45 and Up Study-a cross-sectional study of people aged 45 years and older. The survey included items measuring demographics, depression symptoms, health-related quality of life (HRQoL), health-related hardiness, sleep quality, and health behaviours, such as physical activity. Results: A multiple regression model explained 43% of the variance in depression symptoms (R-2 = 0.43, F (18) = 61.72, p < .001); intensity of physical activity was a significant predictor of depression symptoms (p < .001), and HRQoL was found to explain the most variance (B = -10.00) in depression symptoms. Mediation analysis confirmed that HRQoL partially mediated the relation between physical activity and depression symptoms; however, the effect was very small. Limitations: Cross-sectional data and self-report measures limit the implications of the findings. Conclusion: Women with chronic illness engaging in more vigorous physical activity had less severe depression symptoms. Findings suggest that improving HRQoL is critical to the prevention and management of depression symptoms in women with chronic illness. Psychological and health-related factors that influence HRQoL, such as sleep quality and health-related hardiness, are important clinical considerations for health practitioners.

TI Regulatory mechanisms and clinical manifestations of musculoskeletal aging
SO JOURNAL OF ORTHOPAEDIC RESEARCH
LA English
DT Review

DE musculoskeletal aging; sarcopenia; osteoporosis; osteoarthritis; tendinopathy
ID human articular-cartilage; age-related-changes; different fiber types; dna-damage; bone mass; stem-cells; cellular senescence; skeletal-muscle; cross-linking; life-span
AB Aging is the strongest risk factor for degenerative bone and joint diseases. Clinical therapies for age-related musculoskeletal disorders face significant challenges as their pathogenic mechanisms remain largely unclear. This review article focuses on the recent advances in the understanding of regulatory mechanisms of musculoskeletal aging and their clinical relevance. We begin with the prevalence and socioeconomic impacts of major age-related musculoskeletal disorders such as sarcopenia, osteoporosis, osteoarthritis, and degenerative tendinopathy. The current understanding of responsible biological mechanisms involved in general aging is then summarized. Proposed molecular, cellular, and biomechanical mechanisms relevant to the clinical manifestations of aging in the musculoskeletal system are discussed in detail, with a focus on the disorders affecting muscle, bone, articular cartilage, and tendon. Although musculoskeletal aging processes share many common pathways with the aging of other body systems, unique molecular and cellular mechanisms may be involved in the aging processes of musculoskeletal tissues. Advancements in the understanding of regulatory mechanisms of musculoskeletal aging may promote the development of novel treatments for age-related musculoskeletal disorders. Finally, future research directions for major musculoskeletal tissues including functional interaction between the tissues and their clinical relevance to age-related musculoskeletal disorders are highlighted in the Future Prospects section. TI Recommendations for the Reporting of Harms in Manuscripts on Clinical Trials Assessing Osteoarthritis Drugs: A Consensus Statement from the European Society for Clinical and Economic Aspects of Osteoporosis, Osteoarthritis and Musculoskeletal Diseases (ESCEO)
SO DRUGS & AGING
LA English
DT Article
ID single intraarticular injection; topical diclofenac solution; randomized controlled-trial; adverse event assessment; vehicle tdt 064; double-blind; knee osteoarthritis; hyaluronic-acid; glucosamine sulfate; hand osteoarthritis
AB BackgroundThere is strong evidence of under-reporting of harms in manuscripts on randomized controlled trials (RCTs) compared with the volume of raw data retrieved from these trials. Many guidelines have been developed to tackle this, but they have failed to address some important issues that would allow for standardization and transparency. As a consequence, harms reporting in manuscripts remains suboptimal.ObjectiveThe European Society for Clinical and Economic Aspects of Osteoporosis, Osteoarthritis and Musculoskeletal Diseases (ESCEO) aimed to deliver accurate recommendations for better reporting of harms in clinical trials manuscripts on anti-osteoarthritis (OA) drugs. These could help to better inform clinicians on harms recorded in RCTs and further help researchers conducting meta-analyses.MethodsUsing the outcomes of several systematic reviews on the safety of anti-OA drugs, we summarized the ways in which harms have been reported in OA RCT manuscripts to date. Next, we drafted some recommendations and initiated a modified Delphi process that involved a panel of clinicians and clinical researchers to build an expert consensus on recommendations from the ESCEO for the reporting of harms in future manuscripts

on RCTs assessing anti-OA drugs.ResultsThese recommendations emphasize that all treatment-emergent adverse events (AEs) should always be taken into account for harms reporting, with no frequency threshold, and describe how specific AEs should be reported; they also provide a list of the most relevant organ systems to be considered according to each class of drug for reporting of harms within the results section of a manuscript. Irrespective of the drug, the ESCEO recommends that total, severe and serious AEs and withdrawals due to AEs should always be reported; guidance on the reporting of specific events pertaining to each category is provided. The ESCEO also recommends the reporting of information on drug effect on biological parameters, with specific guidance.ConclusionsThese recommendations may contribute to improve transparency in the field of safety of anti-OA medications. Pharmaceutical companies developing drugs for OA, and researchers conducting clinical trials, are encouraged to comply with them when reporting harms-related results in manuscripts on RCTs. The ESCEO also encourages journals to refer to the ESCEO recommendations in their instructions to authors for the publication of manuscripts on trials of anti-OA medications.

TI Increased rates of knee arthroplasty and cost of patients with meniscal tears treated with arthroscopic partial meniscectomy versus non-operative management
SO KNEE SURGERY SPORTS TRAUMATOLOGY ARTHROSCOPY
LA English
DT Article
DE Meniscal tear; Meniscectomy; Knee arthroscopy; Knee; Total knee replacement; Total knee arthroplasty
ID anterior cruciate ligament; osteoarthritis; surgery; injury; prevalence; outcm; 5-year; repair; trial; risk
AB PurposeThe purpose of this study was to determine the cost of arthroscopic partial meniscectomy (APM), one of the most common surgeries performed by orthopaedic surgeons, and the associated rate of progression to knee arthroplasty (KA) compared to patients treated non-operatively after diagnosis of meniscal tear.MethodsUtilizing data mining software (PearlDiver, Colorado Springs, CO), a national insurance database of approximately 23.5million orthopaedic patients was queried for patients diagnosed with a meniscal tear. Patients were classified by treatment: non-operative and arthroscopic partial meniscectomy and were followed after initial diagnosis for cost and progression to knee arthroplasty.ResultsThere were 176,407 subjects in the non-op group and 114,194 subjects in the arthroscopic partial meniscectomy group. Arthroscopic partial meniscectomy generated more cost than non-operative ($3842.57 versus $411.05, P<0.001). Arthroscopic partial meniscectomy demonstrated greater propensity to need future knee arthroplasty (11.4% at 676days) than those treated non-operatively (9.5% at 402 days) (P<0.001). Female patients demonstrated a higher rate of progression to knee arthroplasty in the arthroscopic partial meniscectomy and non-operative groups (P<0.001).ConclusionCompared to non-operative treatment for meniscal tears, arthroscopic partial meniscectomy is more expensive and does not appear to decrease the rate of progression to knee arthroplasty. Patients undergoing arthroscopic partial meniscectomy yielded on average a delay of only 9months (274days) before undergoing knee arthroplasty. Female patients experienced a significantly higher rate of progression to knee arthroplasty. The authors recognize the limitations of this type of study including its retrospective nature, reliance upon accurate coding and billing information, and the inability to determine whether symptoms including mechanical locking played a role in the decision to perform an APM.Level of evidenceIV.

DT Review
DE Metformin; Diabetes; AMPK; Bone disorders; Bone cancers
ID activated protein-kinase; type-2 diabetes-mellitus; x-ray absorptiometry; mineral density; skeletal-muscle; postmenopausal women; fracture risk; in-vivo; osteoblast differentiation; glucose-uptake
AB The prevalence of diabetes mellitus especially type 2 diabetes mellitus is increasing all over the world. In addition to cardiomyopathy and nephropathy, diabetics are at higher risk of mortality and morbidity due to greater risk of bone fractures and skeletal abnormalities. Patients with diabetes mellitus have lower bone quality in comparison to their non-diabetic counterparts mainly because of hyperglycemia, toxic effects of advanced glycosylation end-products (AGEs) on bone tissue, and impaired bone microvascular system. AGEs may also contribute to the development of osteoarthritis further to osteoporosis. Therefore, glycemic control in diabetic patients is vital for bone health. Metformin, a widely used antidiabetic drug, has been shown to improve bone quality and decrease the risk of fractures in patients with diabetes in addition to glycemic control and improving insulin sensitivity. AMP activated protein kinase (AMPK), the key molecule in metformin antidiabetic mechanism of action, is also effective in signaling pathways involved in bone physiology. This review, discusses the molecules linking diabetes and bone turnover, role of AMPK in bone metabolism, and the effect of metformin as an activator of AMPK on bone disorders and malignancies.

TI Perioperative pregabalin does not reduce opioid requirements in total knee arthroplasty
SO KNEE SURGERY SPORTS TRAUMATOLOGY ARTHROSCOPY
LA English
DT Article
DE Total knee arthroplasty; Pregabalin; Morphine; Preoperative; Analgesia; Pain score
ID postoperative pain; controlled-trial; oral pregabalin; analgesia; management; single; gabapentin; efficacy; morphine; hip
AB PurposeThe purpose of this prospective, randomized, double-blinded, placebo-controlled study was to determine if pregabalin, when given perioperatively in addition to patient-controlled analgesia morphine, paracetamol and etoricoxib, is effective in reducing morphine requirements and moderating pain scores after primary total knee arthroplasty. We hypothesize that there would be no difference in postoperative opioid requirements, postoperative pain scores, and functional scores with the use of perioperative pregabalin.MethodsEighty-seven patients who underwent primary total knee arthroplasty were randomised and allocated to two groups. One group received capsules containing pregabalin 75mg, and the other a placebo-one capsule before surgery and one capsule once per night up till postoperative day 2. Multimodal analgesia provided for all patients in this study included femoral nerve block, intravenous patient-controlled analgesia (morphine), paracetamol and etoricoxib. The primary outcome of patient's pain control was based on the measurement of cumulative morphine consumption during the first 72h postoperatively.ResultsPregabalin did not reduce the cumulative or effective morphine consumption at 48h and 72h post-operation. There were also no significant differences noted in pain scores at 48h and 72h after surgery, functional range of motion of the operated knee at 72h post-op, or outcomes recorded on

the Knee Society Score (KSS), Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) and 36-Item Short Form Survey (SF-36) questionnaires at 3 and 6months post-op. None of the patients demonstrated common adverse reactions to pregabalin.ConclusionThis study showed no reduction in postoperative opioid requirements, or improvement in early postoperative pain scores or functional outcomes at 6months, with perioperative use of pregabalin. Orthopaedic surgeons may consider this when selecting an analgesic regimen for their patients.Level of evidenceII.

TI Bulgarian rheumatology: science and practice in a cost-constrained environment
SO RHEUMATOLOGY INTERNATIONAL
LA English
DT Review
DE Bulgaria; Rheumatology; Vasculitis; Osteoarthritis; Rheumatoid arthritis; Spondylitis; Systemic lupus erythematosus; Scleroderma; Myositis; Biologics
ID systemic-lupus-erythematosus; society classification criteria; american-college; eular recommendations; ankylosing-spondylitis; double-blind; arthritis; management; disease; rheumatism
AB Our aim was to appraise publications from Bulgaria, to assess their global impact, and to describe features and challenges unique to the rheumatology practice in Bulgaria characterized by stringent cost constraints. The Scopus database was queried on 25th July 2018 and data on the number of published documents, their Hirsch-indices and citations number were extracted. Published Bulgarian guidelines for the management of rheumatic diseases and the presented data on Bulgarian Rheumatology Society were identified based on prior knowledge of the authors. From all the identified 1082 document the most extensively researched areas were rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), osteoporosis, and osteoarthritis (OA). For the last five years (from Jan 2013 to 25th July 2018) the number of publications was 293. We found that Bulgaria's international scientific collaboration in the field of rheumatology is focused on a handful of countries mainly from Europe. Although Bulgarian rheumatologists have access to costly biologic agents for treating their patients with rheumatic diseases, their funding may not be granted according to the current recommendations of European League against Rheumatism (EULAR) and national guidelines for the management of rheumatic diseases. Although the western world clearly dominates the production of scientific publications in rheumatology, Bulgarian rheumatology may present another perspective for diagnosis and management of patients with rheumatic diseases in a cost-stringent environment. Nevertheless, both rheumatology science and practice in Bulgaria still have a long way to go to take its deserved place among the other European countries.

TI Modified gait patterns due to cam FAI syndrome remain unchanged after surgery
SO GAIT & POSTURE

DT Article
DE Femoroacetabular impingement syndrome; Osteochondroplasty; Muscle forces; Hip contact forces; Kinetics; Kinematics; Gait parameters
ID hip muscle strength; femoroacetabular impingement; surgical dislocation; biomechanics; arthroscopy; kinematics; walking; joint; osteoarthritis; individuals
AB Background: In order to reduce the development of hip osteoarthritis related to cam-type femoroacetabular impingement syndrome (FAIS), corrective surgery has evolved to become a safe and effective treatment. Although corrective surgery produces high level of patient satisfaction, it is still unclear how it affects muscle and hip contact forces during level walking. Research question: The purpose was to compare the muscle force contributions and hip contact forces in patients before and after surgical correction for cam FAIS with healthy control (CTRL) individuals during level walking. Methods: Eleven male patients with symptomatic cam-type morphology, who underwent hip osteochondroplasty, had their level walking recorded pre- and at 2-year postoperatively. The patients were sex-, age-, BMI-matched to 11 CTRL individuals. Sagittal and frontal hip kinematics and kinetics were computed and, subsequently, muscle and hip contact forces were estimated using musculoskeletal modelling and static optimization. Results: Patient-reported outcomes improved postoperatively. The pre- and postoperative FAIS walked slower and with shorter steps than the CTRL. Postoperative biceps femoris (CTRL: 0.35 +/- 0.13 N/BW; pre-op: 0.28 +/- 0.11 N/BW; post-op: 0.20 +/- 0.07 N/BW) and semimembranosus forces (CTRL: 0.77 +/- 0.24 N/BW; pre-op: 0.66 +/- 0.24 N/BW; post-op: 0.41 +/- 0.14 N/BW) were lower at ipsilateral foot-strike. Postoperative rectus femoris force (CTRL: 1.73 +/- 0.35 N/BW; pre-op: 1.44 +/- 0.24 N/BW; post-op: 1.18 +/- 0.23 N/BW) was lower than the other two groups, and the pre- and postoperative FAIS had lower iliacus (CTRL: 1.17 +/- 0.18 N/ BW; pre-op: 0.93 +/- 0.16 N/BW; post-op: 0.94 +/- 0.21 N/BW) and psoas (CTRL: 1.55 +/- 0.24 N/BW; pre-op: 1.14 +/- 0.38 N/BW; post-op: 1.10 +/- 0.46 N/BW) muscle forces at contralateral foot-strike compared with the CTRL. Pre- and postoperative FAIS

demonstrated lower peak hip contact loading resultant than the CTRL. Significance: The altered gait parameters observed in the preoperative FAIS was not restored after surgery, and was still away from the CTRL. It is possible that the reduced dynamic muscle forces of the biceps femoris, semimembranosus and rectus femoris postoperatively were associated with the protected mechanism that involved the iliopsoas preoperatively. This is an indication that the gait adaptations affected by the FAIS do not restore to normal after surgical correction at the 2-years follow-up.

TI Risk Factors for Poor Functional Recovery, Mortality, Recurrent Fractures, and Falls Among Patients Participating in a Fracture Liaison Service Program
SO JOURNAL OF THE AMERICAN MEDICAL DIRECTORS ASSOCIATION

LA English
DT Article
DE Body mass index; chronic kidney disease; fall; fracture liaison service; osteoporosis
ID hip fracture; body-mass; burden; health; women; care
AB Objective: A fracture liaison service (FLS) for patients with fractures is a promising approach for improving outcomes, but barriers to the successful implementation of an FLS remain. The factors influencing the outcomes of patients already receiving FLS care are unclear. Design: A prospective multicenter cohort study. Settings and participants: Patients with incident hip and clinical vertebral fractures treated at 2 institutions between January 2014 and June 2016 were prospectively enrolled. Demographic profiles, comorbidities, prior fracture experiences, T scores, Fracture Risk Assessment Tool (FRAX) scores, and serum markers were examined. Measures: Self-reported functional status (at the 4th month), mortality, recurrent fractures, and falls (at the 2-year follow-up). Results: Of 712 patients screened for eligibility, 600 (84%) participants (age 78 +/- 10 years) were enrolled in the FLS program. At 4 months, 58%, 53%, and 60% of the participants reported improved mobility, self-care, and daily activities after FLS care, respectively. After 2 years, 85 (14%) died, 36 (6%) developed recurrent fractures, and 199 (33%) had 1 or more fall episodes. Multivariate logistic regression showed that neurologic disorders, heart disease, and diabetes were associated with a decreased probability of functional recovery. Cox regression showed that older age and chronic kidney disease (CKD) were predictive of increased mortality, whereas heart disease was correlated with an increased refracture risk. Older age and cancer or osteoarthritis were associated with a higher risk of falls. Importantly, a higher body mass index predicted a lower risk of mortality and a higher probability of improved self-care but a higher risk of fall at follow-up. Conclusions/Implications: We discovered that comorbidities including CKD, heart disease, cancer, and osteoarthritis could influence short-term functional changes, survival, and the risk of refractures or falls among patients participating in FLSs. These factors are expected to aid in prognosis estimation and management planning for those with fractures. (C) 2018 AMDA - The Society for Post-Acute and Long-Term Care Medicine.

TI Functional outcome of total hip arthroplasty after a previous hip arthroscopy: a retrospective comparative cohort study
SO HIP INTERNATIONAL
LA English
DT Article
DE Hip arthroscopy; total hip arthroplasty
ID knee arthroscopy; impingement; trends; age

AB Background: Despite patients demonstrating significant short-term clinical improvement from a hip arthroscopy (HA), a number of patients progress to significant osteoarthritis of the hip requiring total hip arthroplasty (THA). This study aims to evaluate if there is any difference in the functional outcome of patients undergoing THA after a previous hip arthroscopy compared to patients undergoing THA for primary osteoarthritis of the hip. Methods: Between 2010 and 2013, in a group of 414 patients who underwent hip arthroscopy, we identified 18 patients who underwent a subsequent uncemented THA. These formed the study group. During the same period, 625 patients underwent an uncemented THA performed for primary OA, of which 63 patients were matched to the study group for age, follow-up and implants used. These formed the control group. Pre-op and post-op Oxford Hip Scores (OHS) were recorded for all patients. Results: A mean follow-up of 26.5 and 26.3months was observed in the study and control groups respectively. The median (interquartile ranges) preoperative OHS were 14 (8.25, 17.0) and 18.5 (13.25, 24.75) in the 2 groups. Corresponding postoperative scores were 40 (31.25, 45) and 46 (43, 48). Median difference between the preoperative and postoperative OHS was 27 (19, 31) and 25 (18.25, 31). Adjusting for the pre-treatment scores, the postoperative scores in the study arm were significantly lower than for the control arm with an estimate (SE) of -0.464 (p = 0.012). Post-hoc power analysis showed that the study was sufficiently powered to detect a meaningful difference in scores. Conclusion: Total hip arthroplasty after hip arthroscopy leads to satisfactory functional outcomes. However, the functional outcome in this group is significantly worse than in a matched cohort of patients undergoing THA for osteoarthritis. There was no difference in the rate of complications between the 2 groups.

TI Effectiveness of home based intervention program in reducing mortality of hip fracture patients: A non-randomized controlled trial
SO ARCHIVES OF GERONTOLOGY AND GERIATRICS
LA English
DT Article
DE Intervention; Hip fracture; Postoperative; Mortality; Mobility; Comanaged care
ID osteoarthritis index womac; western-ontario-university; elderly-patients; nutritional-status; surgical fixation; surgery; predictors; population; exercise; women
AB Purpose: The study was done to investigate whether a postoperative intervention program is effective in reducing mortality and improving mobility in two comparative hip fracture patients over one year postoperatively. Methods: A non-randomized controlled trial study with an intervention group of hip fracture patients and historical control group with 12 months follow up. One hundred twenty four admitted hip fracture patients to the Trauma Unit of Assiut University Hospitals, aged 50 years and older were included from 1st July to 31st December 2014. They were divided into 64 and 60 patients as intervention and control groups respectively. Weight, height and bone mineral density were measured and baseline characteristics were taken. The intervention was a postoperative care program in the form of education sessions with an explanatory leaflet on discharge for nutrition and physical exercise program at home. Follow up phone calls were done at 3 months, 6 months and one year postoperatively by one assessor. Physical mobility was assessed by 24 items Western Ontario And McMaster Universities Osteoarthritis Index (WOMAC). Results: Mortality was significantly higher in the control group, WOMAC score was significantly better among intervention group through follow up. By multivariate Cox survival analysis, advancing age, no intervention, osteoporosis, postoperative complications, chest infections and heart attacks were significant predictors for mortality. Conclusion: A significant improvement in mobility and reduction of mortality was achieved by application of

a postoperative care program that could be incorporated into the hip fracture patients' care pathway.

TI Fall Ascertainment and Development of a Risk Prediction Model Using Electronic Medical Records
SO JOURNAL OF THE AMERICAN GERIATRICS SOCIETY
LA English
DT Article
DE adults; falls; risk; EMR
ID older-people; adults
AB OBJECTIVES To examine the use of electronic medical record (EMR) data to ascertain falls and develop a fall risk prediction model in an older population. DESIGN Retrospective longitudinal study using 10 years of EMR data (2004-2014). A series of 3-year cohorts included members continuously enrolled for a minimum

of 3 years, requiring 2 years pre-fall (no previous record of a fall) and a 1-year fall risk period. SETTING Kaiser Permanente Hawaii, an ambulatory setting. PARTICIPANTS A total of 57 678 adults, age 60 years and older. MEASUREMENTS Initial EMR searches were guided by current literature and geriatricians to understand coding sources of falls as our outcome. Falls were captured by two coding sources: International Classification of Diseases, Ninth Revision (ICD-9) codes (E880-889) and/or a fall listed as a "primary reason for visit." A comprehensive list of EMR predictors of falls were included into prediction models enabling statistical subset selection from many variables and modeling by logistic regression. RESULTS Although 72% of falls in the training data set were coded as "primary reason for visit," 22% of falls were coded as ICD-9 and 6% coded as both. About 80% were reported in face-to-face encounters (eg, emergency department). A total of 2164 individuals had a fall in the risk period. Using the 13 key predictors (age, comorbidities, female sex, other mental disorder, walking issues, Parkinson's disease, urinary incontinence, depression, polypharmacy, psychotropic and anticonvulsant medications, osteoarthritis, osteoporosis) identified through LASSO regression, the final model had a sensitivity of 67%, specificity of 69%, positive predictive value of 8%, negative predictive value of 98%, and area under the curve of .74. CONCLUSION This study demonstrated how the EMR can be used to ascertain falls and develop a fall risk prediction model with moderate sensitivity/specificity. Concurrent work with clinical providers to enhance fall documentation will improve the ability of the EMR to capture falls and consequently may improve the model to predict fall risk.

TI Study of the cartilage matrix production-promoting effect of chicken leg extract and identification of the active ingredient
SO NUTRITION RESEARCH AND PRACTICE
LA English
DT Article
DE Osteoarthritis; phenylalanyl-hydroxyproline; cartilage; chicken leg
ID articular-cartilage; osteoarthritis; digestion; efficient; peptides; pepsin
AB BACKGROUND/OBJECTIVES: Osteoarthritis (OA) is a major public health issue in Japan and other countries, and foods that prevent or treat OA are in strong demand. Proteins and peptides in chicken meat and bones are known for being rich in functional and nutritional ingredients for the improvement of osteoporosis. We speculated that chicken legs, a food consumed in many regions of the world, may also contain such ingredients. In this study, we aim to (i) evaluate the effect of chicken leg extract (CLE) on the promotion of cartilage matrix production and (ii) identify the active ingredient in CLE that contributes to this function. MATERIALS/METHODS: Artificial CLE digest was prepared, and the acid mucopolysaccharide production-promoting activity of the CLE digest was

evaluated by alcian blue staining of ATDC5 cells. CLE was orally administered to rabbits with burr holes in the knee joint of the femur, and the degree of regeneration of cartilage matrix was evaluated. Furthermore, we investigated orally administered CLE-derived peptides in human plasma using LC-MS. From measuring the acid mucopolysaccharide production-promotion activity of these peptides, a molecule considered to be an active ingredient in the CLE digest was identified. RESULTS: CLE digest promoted acid mucopolysaccharide production and facilitated regeneration of cartilage matrix in in vitro and in vivo experiments. Four peptides including phenylalanyl-hydroxyproline (Phe-Hyp) were detected as CLE-derived peptides in human plasma. The effect of CLE was inferred to be due to Phe-Hyp, which was confirmed to be present in the CLE digest. CONCLUSIONS: It was shown that CLE stimulated the production of articular cartilage matrix both in vitro and in vivo, and that CLE could be an effective food for preventing or treating OA. Furthermore, only Phe-Hyp was confirmed as the active compound in the CLE digest, suggesting that the activity of CLE was due to Phe-Hyp.

TI Clusterin silencing restores myoblasts viability and down modulates the inflammatory process in osteoporotic disease
SO JOURNAL OF TRANSLATIONAL MEDICINE
LA English
DT Article
DE Clusterin (CLU); Osteoporosis; Osteoarthritis; Sarcopenia; Muscle waist; Osteoporosis marker
ID skeletal-muscle; isoforms; protein; bone
AB Background: Targeting new molecular pathways leading to Osteoporosis (OP) and Osteoarthritis (OA) is a hot topic for drug discovery. Clusterin (CLU) is a glycoprotein involved in inflammation, proliferation, cell death, neoplastic disease, Alzheimer disease and aging. The present study focuses on the expression and the role of CLU in influencing the decrease of muscle mass and fiber senescence in OP-OA condition. Methods: Vastus lateralis muscle biopsies were collected from 20 women with OP undergoing surgery for fragility hip fracture and 20 women undergoing arthroplasty for hip osteoarthritis. Results: We found an overexpression of CLU in degenerated fibers in OP closely correlated with interleukin 6 (IL6) and histone H4 acetylation level. Conversely, in OA muscle tissues we observed a weak expression of CLU but no nuclear histone H4 acetylation. Ex vivo studies on isolated human myoblasts confirmed CLU overexpression in OP as compared to OA ($p<0.001$). CLU treatment of isolated OP and OA myoblasts showed: modulation of proliferation, morphological changes, increase of histone H4 acetylation and induction of myogenin (MYOG) activation in OP myoblast only. In OP condition, functional knockdown of CLU by siRNA restores proliferative myoblasts capability

and tissue damage repair, carried out by an evident upregulation of Transglutaminase 2 (TGM2). We also observed downmodulation of CX3CR1 expression with consequent impairing of the inflammatory infiltrate recruitment. Conclusions: Results obtained suggest a potential role of CLU in OP by influencing myoblasts terminal differentiation, epigenetic regulation of muscle cell differentiation and senescence. Moreover, CLU silencing points out its role in the modulation of tissue damage repair and inflammation, proposing it as a new diagnostic marker for muscle degeneration and a potential target for specific therapeutic intervention in OP related sarcopenia.

TI Clinical Role of Aspirin in Mood Disorders: A Systematic Review
SO BRAIN SCIENCES
LA English
DT Review
DE aspirin; anti-inflammatory; psychiatry; mood disorder; depression; bipolar;

systematic review
ID low-dose aspirin; primary prevention; depression; risk; minocycline; lithium; metaanalysis; dysfunction; microglia; secretion
AB Worldwide, depression and bipolar disorder affect a large and growing number of people. However, current pharmacotherapy options remain limited. Despite adequate treatment, many patients continue to have subsyndromal symptoms, which predict relapse in bipolar illness and often result in functional impairments. Aspirin, a common nonsteroidal anti-inflammatory drug (NSAID), has purported beneficial effects on mood symptoms, showing protective effects against depression in early cohort studies. This systematic review thus aimed to investigate the role of aspirin in mood disorders. Using the keywords (aspirin or acetylsalicy* or asa) and (mood or depress* or bipolar or mania or suicid*), a comprehensive search of PubMed, EMBASE, Medline, PsycINFO, Clinical Trials Register of the Cochrane Collaboration Depression, Anxiety and Neurosis Group (CCDANTR), Clinicaltrials.gov and Google Scholar databases found 13,952 papers published in English between 1 January 1988 and 1 May 2019. A total of six clinical studies were reviewed. There were two randomized, placebo-controlled, double-blind trials and populations drawn from two main cohort studies (i.e., the Geelong Osteoporosis Study and the Osteoarthritis Initiative study). Using a random-effects model, the pooled hazard ratio of the three cohort studies was 0.624 (95% confidence interval: 0.0503 to 1.198, p = 0.033), supporting a reduced risk of depression with aspirin exposure. Overall, the dropout rates were low, and aspirin appears to be well-tolerated with minimal risk of affective switch. In terms of methodological quality, most studies had a generally low risk of bias. Low-dose aspirin (80 to 100 mg/day) is safe, well-tolerated and potentially efficacious for improving depressive symptoms in both unipolar and bipolar depression. Due to its ability to modulate neuroinflammation and central nervous system processes, aspirin may also have valuable neuroprotective and pro-cognitive effects that deserve further exploration. Further randomized, controlled trials involving the adjunctive use of aspirin should be encouraged to confirm its therapeutic benefits.

TI Yearlong variability of oxidative potential of particulate matter in an urban Mediterranean environment
SO ATMOSPHERIC ENVIRONMENT
LA English
DT Article
DE Oxidative potential; Reactive oxygen species; DTT assay; Particulate matter; Toxicity; Urban aerosol
ID oxygen species activity; organic aerosol composition; ultrafine particles pm0.25; humic-like substances; water-soluble pm2.5; reactive oxygen; chemical-composition; los-angeles; dithiothreitol dtt; redox activity
AB The oxidative potential (OP) of fine and coarse fractions of ambient aerosols was studied in the urban environment of Athens, Greece. OP was quantified using a dithiothreitol (DTT) assay, applied to the water soluble fraction of aerosol that was extracted from 361 fine and 84 coarse mode of 24-h and 12-h filter samples over a one-year period. During the cold period, samples were collected on a 12-h basis, to assess the impact of night-time biomass burning emissions from domestic heating on OP. The chemical characteristics of aerosols were measured in parallel using an Aerosol Chemical Speciation Monitoring (ACSM) and a 7-wavelength Aethalometer. A source apportionment analysis on the ACSM data resulted in the identification of organic aerosol (OA) factors on a seasonal basis. A good correlation of OP with NO3-, NH4+, BC (Black Carbon), Organics and LV-OOA (low volatility oxygenated OA) was found during winter, revealing the importance of combustion and aging processes for OP. During the summertime, a good correlation between OP and SO4-2 and NH4+ indicates its association with

regional aerosol - thus the importance of oxidative aging that reduces its association with any characteristic source. Multiple regression analysis during winter revealed that highly oxygenated secondary aerosol (LV-OOA) and, to a lesser extent, fresh biomass burning (BBOA) and fossil fuel HOA) organic aerosol, are the prime contributors to the OP of fine aerosol, with extrinsic toxicities of 54 +/- 22 pmol min(-1) mu g(-1), 28 +/- 7 and 17 +/- 4 pmol min(-1) mu g(-1), respectively. In summer, OP cannot be at- tributed to any of the identified components and corresponds to a background aerosol value. In winter however, the regression model can reproduce satisfactorily the water soluble DTT activity of fine aerosol, providing a unique equation for the estimation of aerosol OP in an urban Mediterranean environment.

DT Review
DE -glutamyl carboxylase (GGCX); steroid and xenobiotic receptor (SXR); pregnane X receptor (PXR); osteoporosis; osteoarthritis; sarcopenia; osteocalcin; matrix Gla protein (MGP); Gla-rich protein (GRP)
ID gamma-carboxyglutamic acid; xenobiotic receptor sxr; matrix gla protein; single nucleotide polymorphism; pregnane x receptor; bone-formation; hip-fracture; undercarboxylated osteocalcin; circulating levels; androgen receptor
AB Vitamin K is a fat-soluble vitamin that was originally found as an essential factor for blood coagulation. With the discovery of its role as a co-factor for -glutamyl carboxylase (GGCX), its function for blood coagulation was understood as the activation of several blood coagulation factors by their -carboxylation. Over the last two decades, other modes of vitamin K actions have been discovered, such as the regulation of transcription by activating the steroid and xenobiotic receptor (SXR), physical association to 17-Hydroxysteroid dehydrogenase type 4 (17-HSD4), covalent modification of Bcl-2 antagonist killer 1 (Bak), and the modulation of protein kinase A (PKA) activity. In addition, several epidemiological studies have revealed that vitamin K status is associated with some aging-related diseases including osteoporosis, osteoarthritis, and sarcopenia. Clinical studies on single nucleotide polymorphisms of GGCX suggested an association between higher GGCX activity and bone protective effect, while recent findings using conditional knockout mice implied that a contribution in protective effect for bone loss by GGCX in osteoblastic lineage was unclear. GGCX in other cell lineages or in other tissues might play a protective role for osteoporosis. Meanwhile, animal experiments by our groups among others revealed that SXR, a putative receptor for vitamin K, could be important in the bone metabolism. In terms of the cartilage

protective effect of vitamin K, both GGCX- and SXR-dependent mechanisms have been suggested. In clinical studies on osteoarthritis, the -carboxylation of matrix Gla protein (MGP) and gla-rich protein (GRP) may have a protective role for the disease. It is also suggested that SXR signaling has protective role for cartilage by inducing family with sequence similarity 20a (Fam20a) expression in chondrocytes. In the case of sarcopenia, a high vitamin K status in plasma was associated with muscle strength, large muscle mass, and high physical performance in some observational studies. However, the basic studies explaining the effects of vitamin K on muscular tissue are limited. Further research on vitamin K will clarify new biological mechanisms which contribute to human longevity and health through the prevention and treatment of aging-related musculoskeletal disorders.

TI THE RELATIONSHIP BETWEEN ACUTE ARTERIAL OCCLUSIONS AND THE STAGE OF PERIPHERAL ARTERIAL DISEASE ACCORDING TO THE FONTAINE CLASSIFICATION
SO TURKISH JOURNAL OF GERIATRICS-TURK GERIATRI DERGISI
LA English
DT Article
DE Peripheral arterial disease; Ankle Brachial Index; Amputation
ID ankle-brachial index; cardiovascular-disease; arm index; mortality; risk; prevalence; epidemiology; predictor
AB Introduction: Peripheral vascular disease is defined as narrowing of blood vessels that restricts blood flow. Atherosclerosis is the most common etiology followed by vasculitis, dysplastic syndromes, degenerative diseases, thrombosis, and thromboembolism. The mortality rate at diagnosis is 4%-6%. Atherosclerotic peripheral vascular disease and leg amputation from such condition increase the mortality rate to 30%, and the 5-year survival rate is less than 30%. Thus, disease severity and extent of peripheral vascular disease must be evaluated and presented. Materials and Method: Between January 2005 and March 2018,98 patients underwent surgery for acute arterial occlusion owing to chronic peripheral arterial disease were evaluated according to the Fontaine Classification, demographic characteristics, concomitant disease, physical examination findings, type of surgery and amputation and mortality rates, and its causes were analyzed. Results: None of the patients (n=98) presented with Fontaine stage I disease. Because peripheral arterial disease is usually observed in the elderly population, elderly patients with several health problems at advanced age are more likely to undergo extremity amputation. It can be reduced by including the ankle brachial index examination in any outpatient clinic. Other stages of the disease were also evaluated in detail. Conclusion: ABI examination should be included in the systemic examination for patients aged>70 years. Currently, lumbar hernia, osteoporosis or osteoarthritis are also observed in such patients, and the clinical signs of peripheral arterial disease are masked. Due to these diseases, the diagnosis of peripheral arterial disease is delayed.

TI Effect of Mir-663 on the Differentiation of Bone Marrow Mesenchymal Stem Cells in Inflammatory Environment Through Regulating Oxidative Stress and Transforming Growth Factor β1
SO JOURNAL OF BIOMATERIALS AND TISSUE ENGINEERING
LA English
DT Article
DE Mir-663; Osteoarthritis; TGF-beta 1; Oxidative Stress; Inflammatory Factor
ID osteogenic differentiation; replacement
AB BMSCs are beneficial for the treatment of Osteoarthritis (OA). Mir-663 involves in various diseases. However, the role of Mir-663 in the differentiation of BMSCs in an inflammatory environment remains unclear. Rat BMSCs were isolated and divided into control group, and inflammation group which was treated with 1 mu g/ml lipopolysaccharide (LPS), Mir-663 group and Mir-663 siRNA groups which was respectively transfected with Mir-663 plasmid and Mir-663 siRNA into LPS-treated BMSCs followed by analysis of the survival rate of BMSC by MTT, Caspase 3 activity, ALP activity, expression of osteogenic genes Runx2 and OP by Real time PCR, ROS content and SOD activity, TGF-beta 1 level by Real time PCR and ELISA, TNF-alpha and IL-1 beta, secretion by ELISA. LPS treatment significantly increased Mir-663 expression, inhibited cell proliferation, increased Caspase 3 activity, and inhibited ALP activity. Meanwhile it also significantly decreased Runx2 and OP expression, increased ROS content, decreased SOD activity and TGF-beta 1 expression as well

as elevated TNF-alpha and IL-1 beta secretion compared to control (P < 0005); Mir-663 plasmid transfection can further promote the above changes (P < 0005); whereas, Mir-663 siRNA could reverse the above changes (P < 0005). Mir-663 expression was increased in BMSCs in inflammatory environment. Down-regulation of Mir-663 expression can regulate oxidative stress, up-regulate TGF-,1 level, inhibit the secretion of TNF-alpha and IL-1 beta, and promote the proliferation and osteogenic differentiation of BMSCs in inflammatory environment.

TI Recommendations for the conduct of economic evaluations in osteoporosis: outcomes of an experts' consensus meeting organized by the European Society for Clinical and Economic Aspects of Osteoporosis, Osteoarthritis and Musculoskeletal Diseases (ESCEO) and the US branch of the International Osteoporosis Foundation
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE Cost-effectiveness; Economic evaluation; Osteoporosis; Recommendations; Reference case
ID cost-effectiveness analyses; fracture risk reduction; quality-of-life; postmenopausal women; excess mortality; hip fracture; vertebral fractures; older women; health; impact

AB Economic evaluations are increasingly used to assess the value of health interventions, but variable quality and heterogeneity limit the use of these evaluations by decision-makers. These recommendations provide guidance for the design, conduct, and reporting of economic evaluations in osteoporosis to improve their transparency, comparability, and methodologic standards.IntroductionThis paper aims to provide recommendations for the conduct of economic evaluations in osteoporosis in order to improve their transparency, comparability, and methodologic standards.MethodsA working group was convened by the European Society for Clinical and Economic Aspects of Osteoporosis and Osteoarthritis to make recommendations for the design, conduct, and reporting of economic evaluations in osteoporosis, to define an osteoporosis-specific reference case to serve a minimum standard for all economic analyses in osteoporosis, to discuss methodologic challenges and initiate a call for research. A literature review, a face-to-face meeting in New York City (including 11 experts), and a review/approval by a larger group of experts worldwide (including 23 experts in total) were conducted.ResultsRecommendations on the type of economic evaluation, methods for economic evaluation, modeling aspects, base-case analysis and population, excess mortality, fracture costs and disutility, treatment characteristics, and model validation were provided. Recommendations for reporting economic evaluations in osteoporosis were also made and an osteoporosis-specific checklist was designed that includes items to report when performing an economic evaluation in osteoporosis. Further, 12 minimum criteria for economic evaluations in osteoporosis were identified and 12 methodologic challenges and need for further research were discussed.ConclusionWhile the working group acknowledges challenges and the need for further research, these recommendations are intended to supplement general and national guidelines for economic evaluations, improve transparency, quality, and comparability of economic evaluations in osteoporosis, and maintain methodologic standards to increase their use by decision-makers.

AB Background: Osteoporosis is common in total joint arthroplasty (TJA) patients and likely contributes to the increasing incidence of periprosthetic fracture. Despite this, the prevalence of osteoporosis in patients undergoing elective TJA is inadequately studied. We hypothesize that preoperative osteoporosis is underrecognized and undertreated in the TJA population. The purpose of this study is to report preoperative osteoporosis screening rates and prevalence prior to TJA and rates of pharmacologic osteoporosis treatment in the TJA population. Methods: This is a retrospective case series of 200 consecutive adults (106F, 94M) aged 48-92 years who underwent elective TJA (100 total hip, 100 total knee) at a single tertiary-care center. Charts were retrospectively reviewed to determine preoperative osteoporosis risk factors, prior dual-energy X-ray absorptiometry (DXA) testing, and prior osteoporosis pharmacotherapy. Fracture risk was estimated using the Fracture Risk Assessment Tool and the National Osteoporosis Foundation criteria for screening and treatment were applied to all patients. Results: One hundred nineteen of 200 patients (59.5%) met criteria for DXA testing. Of these 119, 21 (17.6%) had DXA testing in the 2 years prior to surgery, and 33% had osteoporosis by T-score. Forty-nine patients (24.5%) met National Osteoporosis Foundation criteria for pharmacologic osteoporosis treatment, and 11 of these 49 received a prescription for pharmacotherapy within 6 months before or after surgery. Conclusion: One quarter of TJA patients meet criteria to receive osteoporosis medications, but only 5% receive therapy preoperatively or postoperatively. This lack of preoperative osteoporosis screening and treatment may contribute to periprosthetic fracture risk. (c) 2019 Elsevier Inc. All rights reserved.

AB The circadian system in mammals is responsible for the temporal coordination

of multiple physiological and behavioural processes that are necessary for homeostasis. In the skeleton, it has long been known that metabolic functions of chondrocytes, osteoblasts and osteoclasts exhibit intrinsic circadian rhythms. In addition, results from animal models reveal a close connection between the disruption of circadian rhythms and skeletal disorders such as rheumatoid arthritis, osteoarthritis and osteoporosis. In this review, we summarise the latest insights into the genetic and biochemical mechanisms linking cartilage and bone physiology to the circadian clock system. We also discuss how this knowledge can be utilised to improve human health.

TI Adrenocortical hypofunction with simultaneous primary aldosteronism A case report
SO MEDICINE
LA English
DT Article
DE adenoma; adrenal; aldosteronism; cortical hypofunction; diabetes

ID adrenal-tumors; immunoassay; diagnosis; cortisol
AB Rationale: Cases of adrenocortical hyperfunction combined with primary aldosteronism have been reported in the literature, and the underlying mechanism involves the secretion of aldosterone and glucocorticoids by a tumor or an adenoma. However, adrenocortical hypofunction and coexisting primary aldosteronism have not been reported until now. Herein, we report a case of adrenocortical hypofunction combined with primary aldosteronism. Patient concerns: A 66-year-old Chinese woman with rheumatoid arthritis who had been diagnosed with secondary adrenal insufficiency and was taking prednisone acetate tablets for replacement treatment presented to our department. She also had type 2 diabetes mellitus, osteoporosis, bilateral knee osteoarthritis, and lumbar vertebral compression fracture. She had previously developed tuberculosis, which had been cured. Diagnosis: The cortisol and adrenocorticotropic hormone rhythm indicated cortisol dysfunction in the patient. A 64-slice computed tomography and magnetic resonance imaging both showed bilateral adrenal hyperplasia. A postural stimulation test indicated a high level of aldosteronism and a high aldosterone-to-renin ratio (ARR, supine position: aldosterone 1788.73pg/mL, ARR 146.62; upright position: aldosterone 2916.21pg/mL, ARR 92.29). The captopril test showed the aldosterone level decreased by 364.70pg/mL 1hour after administration of captopril (from 2153.28 to 1788.58pg/mL). The decline in aldosterone level was approximately 16.90% (i.e., <30%), and the ARR was still >40. Based on the above-mentioned findings, we diagnosed the patient with adrenocortical hypofunction with primary aldosteronism. Interventions: We administered spironolactone 20 mg twice daily and continued the glucocorticoid replacement therapy. Outcomes: One week after diagnosis, the patient had an aldosterone level of 2201.16pg/mL, plasma renin activity of 3.88ng/mL/h, and an ARR of 56.7 (upright position). Her blood pressure was maintained within the normal range. Lessons: Although adrenocortical hypofunction with primary aldosteronism is rare, cases of primary aldosteronism complicated with hypercortisolism are occasionally encountered. Hence, whenever possible, we recommend testing both aldosterone and cortisol levels in all patients with adrenal dysfunction.

TI Steroid-Enriched Fraction of Achyranthes bidentata Protects Amyloid β Peptide 1-40-Induced Cognitive Dysfunction and Neuroinflammation in Rats
SO MOLECULAR NEUROBIOLOGY
LA English
DT Article
DE Achyranthes bidentata; Ecdysterone; A beta 1-40; Oxidative stress; Neuroinflammation; ERK; NF-kappa B pathway; Hippocampus
ID cascade hypothesis; memory impairment; nitric-oxide; in-vitro; cells; apoptosis; disease; chondrocytes; inflammation; involvement
AB The roots of Achyranthes bidentata Blume (AB) is commonly used in the treatment of osteoporosis and dementia in traditional Chinese medicine. Pharmacological reports evidenced that AB possessed anti-osteoarthritis effects. However, there is little literature about the anti-dementia activities of AB. The present study was designed to prepare steroid-enriched fraction of AB (ABS) and investigate whether ABS can protect from cognitive dysfunction and neuroinflammation against A beta 1-40-induced Alzheimer's disease (AD) model in rats. ABS only contained 135.11 +/- 4.28mg of ecdysterone per gram. ABS (50mg/kg) reversed the dysfunction of exploratory activity and memory function on plus-maze and Morris water maze caused by A beta 1-40 in rats. ABS (50mg/kg) also decreased amyloid deposition, neurofibrillary tangle, neural damage, activated astrocyte, and microglial caused by A beta 1-40. Furthermore, ABS reversed the phenomenon of neural oxidative damage and neuroinflammation, including the higher levels of MDA and cytokines, and the lower activities of antioxidant enzymes and GSH levels caused by A beta 1-40 in rat cortex and hippocampus. Finally, ABS restored the activation of ERK pathway and decreased NF-kappa B phosphorylation and translocation altered by A beta 1-40. ABS alone (50mg/kg) promoted cognitive function, activated brain antioxidant defense system, and decreased brain TNF-alpha levels in sham group. Therefore, ABS has the cognition-promoting and antidementia potential. Steroids especial ecdysterone are major active components of AB. The action mechanism is due to decreasing oxidative stress and neuroinflammation through modulating ERK pathway, NF-kappa B phosphorylation, and translocation in A beta 1-40-induced AD rat model.

TI Activation of The Phosphatidylcholine to Lysophosphatidylcholine Pathway Is Associated with Osteoarthritis Knee Cartilage Volume Loss Over Time
SO SCIENTIFIC REPORTS
LA English
DT Article
ID synovial-fluid; human plasma; progression; phospholipase-a2; quantification; osteoporosis; replacement; degradation; thickness; symptoms
AB To identify serum biomarker(s) for predicting knee cartilage volume loss overtime, we studied 139 knee osteoarthritis (OA) patients from a previous 24-month clinical trial cohort. Targeted metabolomic profiling was performed on serum collected at baseline. The pairwise metabolite ratios as proxies for enzymatic reaction were calculated and used in the analysis. Cartilage volume loss between baseline and 24 months was assessed quantitatively by magnetic resonance imaging (MRI). Data revealed an association between the serum ratio of lysophosphatidylcholine 18:2 (lysoPC 18:2) to phosphatidylcholine 44:3 (PC44:3) and the cartilage volume loss in the lateral compartment (beta = -0.21 +/- 0.04, p =

8.53*10(-7)) and with joint degradation markers, COMP (r = 0.32, p =0.0002) and MMP1 (r = 0.26, p = 0.002). The significance remained after adjustment for age, sex, BMI, diabetes, hypertension, dyslipidemia, and the treatment taken in the original study. As the ratio indicated the over activation of the conversion pathway of PC to lysoPC catalyzed by phospholipase A(2) (PLA(2)), we assessed and found that a specific PLA(2), PLA(2)G5, was significantly increased in human OA cartilage and synovial membrane (85% and 19% respectively, both p < 0.04) compared to controls, and its overexpression correlated with IL-6 (r = 0.63, p = 0.0008). Our data suggest that the serum lysoPC 18:2 to PC44:3 ratio is highly associated with a greater risk of cartilage volume loss of the knee and warrants further investigation in an independent cohort.

TI Update on the role of pharmaceutical-grade chondroitin sulfate in the symptomatic management of knee osteoarthritis
SO AGING CLINICAL AND EXPERIMENTAL RESEARCH

LA English
DT Article
DE Osteoarthritis; Chondroitin; Pain; Function; Safety; Treatment
ID slow-acting drugs; double-blind; european-society; economic-aspects; placebo; recommendations; osteoporosis; hip; tolerability; progression
AB Osteoarthritis (OA) is the most prevalent musculoskeletal disease and a major cause of negative relevant outcomes, associated with an ever-increasing societal burden. Pharmaceutical-grade chondroitin sulfate (CS) was repeatedly reported to reduce pain and improve function in patients with knee OA. This treatment was also shown to be cost-effective, compared to placebo, up to 24months. However, controversies still persist regarding the usefulness of CS for patients with knee OA, mainly due to inconsistent reports from various clinical trials. In this literature review, we aimed to summarize the main most recent findings on the efficacy and safety of CS in OA. Based on the results of studies presenting a low risk of bias, the most recent meta-analysis shows that only the pharmaceutical-grade CS may be considered as an appropriate background treatment for the management of knee OA. Evidence from another recent meta-analysis, using data from full safety reports, confirms the good safety profile of CS in OA. This new evidence on efficacy and safety suggests that recommendations for the use of CS in patients with knee OA cannot be extrapolated to other low-grade preparations as generics, nutraceutical-grade or over-the-counter preparations.

TI Non-Viral Delivery System and Targeted Bone Disease Therapy
SO INTERNATIONAL JOURNAL OF MOLECULAR SCIENCES
LA English
DT Review
DE non-viral delivery system; cationic lipids; bone targeting moieties;

bisphosphonates; bone therapeutic agents
ID mediated gene delivery; drug-delivery; calcium-phosphate; cathepsin-k; in-vitro; osteoclast differentiation; plasmid dna; nanoparticles; resorption; bisphosphonate
AB Skeletal systems provide support, movement, and protection to the human body. It can be affected by several life suffering bone disorders such as osteoporosis, osteoarthritis, and bone cancers. It is not an easy job to treat bone disorders because of avascular cartilage regions. Treatment with non-specific drug delivery must utilize high doses of systemic administration, which may result in toxicities in non-skeletal tissues and low therapeutic efficacy. Therefore, in order to overcome such limitations, developments in targeted delivery systems are urgently needed. Although the idea of a general targeted delivery system using bone targeting moieties like bisphosphonates, tetracycline, and calcium phosphates emerged a few decades ago, identification of carrier systems like viral and non-viral vectors is a recent approach. Viral vectors have high transfection efficiency but are limited by inducing immunogenicity and oncogenicity. Although non-viral vectors possess low transfection efficiency they are comparatively safe. A number of non-viral vectors including cationic lipids, cationic polymers, and cationic peptides have been developed and used for targeted delivery of DNA, RNA, and drugs to bone tissues or cells with successful consequences. Here we mainly discuss such various non-viral delivery systems with respect to their mechanisms and applications in the specific targeting of bone tissues or cells. Moreover, we discuss possible therapeutic agents that can be delivered against various bone related disorders.

DT Article
DE Femoral neck fracture; Bone mineral density; Comorbidity; Osteoporosis
ID hip fracture; internal-fixation; risk-factors; young; age; hemiarthroplasty; arthroplasty; epidemiology; osteoporosis; metaanalysis
AB Background A displaced femoral neck fracture (FNF) in patients 55-70 years is a serious injury with a high risk of treatment failure and the optimal surgical treatment remains unclear. We aimed to describe characteristics of fracture patients compared to a sample from the normal population. Methods Fifty patients aged 55-70 years with a displaced FNF were gender- and age- matched with a control group of 150 persons without a hip fracture using computergenerated randomization and the Norwegian National Population Register. To reduce the risk

of spurious selection bias, the sample size of the control group was trebled compared to the fracture group. Dual-energy x-ray absorptiometry (DXA) was performed. Demographics and hip function (Harris Hip Score, Oxford Hip Score, and Hip Dysfunction and Osteoarthritis Outcome Score) were collected. Results There were more than 75% women in both groups. The mean age was 64.5 years in the fracture group and 65.1 in the control group. Results for DXA measured for lumbar spine, total hip and the femoral neck showed that patients with displaced FNF were significantly more osteoporotic. Fracture patients had significantly lower body mass index, higher Charlson comorbidity index (CCI), and higher ASA (American Society of Anesthesiologists) score than the control group. No clinically relevant differences in hip function were found. There were 48% smokers in the fracture group compared to 10% in the control group. The odds ratio for obtaining a displaced FNF was high if the patients suffered from osteoporosis, smoked or had several comorbidities. Conclusions This study showed that patients aged 55-70 years with a displaced femoral neck fracture had lower bone density and higher comorbidity compared with a gender- and age-matched population without femoral neck fractures. This suggests that this patient group is epidemiologically similar to older patients with femoral neck fractures.

TI Diagnosis and Management of Paget's Disease of Bone in Adults: A Clinical Guideline
SO JOURNAL OF BONE AND MINERAL RESEARCH
LA English
DT Article
DE PAGET'S DISEASE OF BONE; ANTIRESORPTIVES; RADIONUCLIDE BONE SCANS; ALP; BISPHOSPHONATES
ID giant-cell tumor; distemper virus transcripts; total hip-arthroplasty; measles-virus; double-blind; disodium etidronate; bisphosphonate treatment; intravenous pamidronate; symptomatic management; familial aggregation
AB An evidence-based clinical guideline for the diagnosis and management of Paget's disease of bone (PDB) was developed using GRADE methodology, by a Guideline Development Group (GDG) led by the Paget's Association (UK). A systematic review of diagnostic tests and pharmacological and nonpharmacological treatment options was conducted that sought to address several key questions of clinical relevance. Twelve recommendations and five conditional recommendations were made, but there was insufficient evidence to address eight of the questions posed. The following recommendations were identified as the most important: 1) Radionuclide bone scans, in addition to targeted radiographs, are recommended as a means of fully and accurately defining the extent of metabolically active disease in patients with PDB. 2) Serum total alkaline phosphatase (ALP) is recommended as a first-line biochemical screening test in combination with liver function tests in

screening for the presence of metabolically active PDB. 3) Bisphosphonates are recommended for the treatment of bone pain associated with PDB. Zoledronic acid is recommended as the bisphosphonate most likely to give a favorable pain response. 4) Treatment aimed at improving symptoms is recommended over a treat-to-target strategy aimed at normalizing total ALP in PDB. 5) Total hip or knee replacements are recommended for patients with PDB who develop osteoarthritis in whom medical treatment is inadequate. There is insufficient information to recommend one type of surgical approach over another. The guideline was endorsed by the European Calcified Tissues Society, the International Osteoporosis Foundation, the American Society of Bone and Mineral Research, the Bone Research Society (UK), and the British Geriatric Society. The GDG noted that there had been a lack of research on patient-focused clinical outcomes in PDB and identified several areas where further research was needed. (c) 2019 The Authors. TI Integrins in Osteocyte Biology and Mechanotransduction
SO CURRENT OSTEOPOROSIS REPORTS
LA English
DT Review
DE Osteocyte; Integrin; Mechanotransduction; Osteoporosis; Osteoarthritis; Bone metastasis
ID focal adhesion kinase; mechanical stimulation; signaling pathways; bone-cells; molecular-mechanisms; strain amplification; gene-expression; down-regulation; primary cilium; fluid-flow
AB Purpose of ReviewOsteocytes are the main mechanosensitive cells in bone. Integrin-based adhesions have been shown to facilitate mechanotransduction, and therefore play an important role in load-induced bone formation. This review outlines the role of integrins in osteocyte function (cell adhesion, signalling, and mechanotransduction) and possible role in disease.Recent FindingsBoth beta(1) and beta(3) integrins subunits have been shown to be required for osteocyte mechanotransduction. Antagonism of these integrin subunits in osteocytes resulted in impaired responses to fluid shear stress. Various disease states (osteoporosis, osteoarthritis, bone metastases) have been shown to result in altered integrin expression and function.SummaryOsteocyte integrins are required for normal cell function, with dysregulation of integrins seen in disease. Understanding the mechanism of faulty integrins in disease may aid in the creation of novel therapeutic approaches.

TI PLGA scaffold carrying icariin to inhibit the progression of osteoarthritis in rabbits
SO ROYAL SOCIETY OPEN SCIENCE
LA English
DT Article
DE electrospinning; icariin; osteoarthritis; cartilage degeneration; subchondral bone
ID subchondral bone; osteogenic differentiation; articular-cartilage; gene-expression; chondrocytes; cells; osteoporosis; osteopontin; degradation; collagen
AB Icariin, the main effective component extracted from epimedium, has been shown to stimulate osteogenic differentiation and bone formation and to increase synthesis of the cartilage extracellular matrix. However, there has been little study on the effects of icariin on osteoarthritis. In this study, we loaded icariin onto poly(lactic-co-glycolic acid) (PLGA) electrospinning. The aim of this study was to explore a composite scaffold and to inhibit the progression of osteoarthritis. Our main experimental results demonstrated that the PLGA/icariin composite spinning scaffold had higher hydrophilicity, and icariin was released slowly and steadily from the scaffold. According to the results of an MTT test, immunofluorescence staining, an alkaline phosphate activating assay and a real-time polymerase chain reaction (RT-PCR) assay, the PLGA/icariin composite scaffold had good biocompatibility. In models of osteoarthritis, the results of a RT-PCR assay indicated that the PLGA/icariin scaffold promoted the synthesis of the extracellular matrix. The results of X-ray microtomography and histological evaluation demonstrated that the PLGA/icariin scaffold maintained the functional morphology of articular cartilage and inhibited the resorption of subchondral bone trabeculae. These findings indicated that the PLGA and icariin composite scaffold has therapeutic potential for use in the treatment of osteoarthritis.

TI Defective WNT signaling may protect from articular cartilage deterioration - a quantitative MRI study on subjects with a heterozygous WNT1 mutation
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE WNT signaling; WNT1; Osteoporosis; Osteoarthritis; Radiology
ID t-2 relaxation-times; focal knee lesions; early osteoarthritis; adiabatic t-1-rho; regional-analysis; spatial-patterns; t2 measurements; bone; association; osteoporosis
AB Objective: WNT signaling is of key importance in chondrogenesis and defective WNT signaling may contribute to the pathogenesis of osteoarthritis and other cartilage diseases. Biochemical composition of articular cartilage in patients with aberrant WNT signaling has not been studied. Our objective was to assess the knee articular cartilage in WNT1 mutation-positive individuals using a 3.0T MRI unit to measure cartilage thickness, relaxation times, and texture features. Design: Cohort comprised mutation-positive (N = 13; age 17-76 years) and mutation-negative (N = 13; 16-77 years) subjects from two Finnish families with autosomal dominant WNT1 osteoporosis due to a heterozygous missense mutation c.652T>G (p.C218G) in WNT1. All subjects were imaged with a 3.0T MRI unit and assessed for cartilage thickness, T2 and T1 rho relaxation times, and T2 texture features contrast,

dissimilarity and homogeneity of T2 relaxation time maps in six regions of interest (ROIs) in the tibiofemoral cartilage. Results: All three texture features showed opposing trends with age between the groups in the medial tibiofemoral cartilage (P = 0.020-0.085 for the difference of the regression coefficients), the mutation-positive individuals showing signs of cartilage preservation. No significant differences were observed in the lateral tibiofemoral cartilage. Cartilage thickness and means of T2 relaxation time did not differ between groups. Means of T1r relaxation time were significantly different in one ROI but the regression analysis displayed no differences. Conclusions: Our results show less age-related cartilage deterioration in the WNT1 mutation-positive than the mutation-negative subjects. This suggests, that the WNT1 mutation may alter cartilage turnover and even have a potential cartilage-preserving effect. (C) 2019 Osteoarthritis Research Society International. TI RELATIONSHIP BETWEEN OSTEOARTHRITIS AND OSTEOPOROSIS IN HOMOLOGOUS JOINTS
SO ACTA MEDICA MEDITERRANEA

LA English
DT Article
DE Bone mineral density; Coxarthrosis; Osteoporosis
ID bone-mineral density; postmenopausal women; inverse relationship; knee osteoarthritis; fracture; hip
AB Introduction: Osteoarthritis and osteoporosis are the two most common musculoskeletal diseases. We investigated whether there is an inverse relationship between osteoarthritis and osteoporosis for the right and left hips. Material and methods: Sixty-six postmenopausal women were included in this study. The subjects were divided into two groups, the osteoarthritis and control groups (n = 33 each), according to whether they had hip osteoarthritis. In the osteoarthritis group, subjects were blindly graded using the Kellgren- Lawrence system and divided into a right hip osteoarthritis group (n = 29) and a left hip osteoarthritis group (n = 32) according to the affected hip joint. The bone mineral density of both hips was measured using dual-energy X-ray ahvorptiometry. Physical activity was assessed using the International Physical Activity Questionnaire. Results: A correlation between the presence of osteoarthritis and bone loss at the femoral neck was observed for the right hip (R = -0,302, p = 0.017), whereas no significant correlation was observed for the left hip. Osteoarthritis in the right hip was associated with older age and higher right femoral neck bone mineral density (R2 = 0368). The odds ratio for the radiographic presence of right hip osteoarthritis was 55678.5 per unit difference in bone mineral density of the right femoral neck. Conclusion: Although the right and left hips are homologous joints, the present study revealed an inverse relationship between OA and OP only for the right hip, indicating that the relationship between osteoarthritis and osteoporosis should be assessed using a joint-by-joint approach

TI Depressive disorders, anxiety disorders and subjective mental health in common musculoskeletal diseases: A review
SO MATURITAS
LA English
DT Review
DE Depressive disorder; Anxiety disorders; Mental health; Subjective well-being; Life satisfaction; Musculoskeletal diseases
ID bone-mineral density; reported life satisfaction; 15-year follow-up; quality-of-life; low-back; work disability; risk; metaanalysis; dissatisfaction; osteoarthritis
AB Globally, musculoskeletal diseases (MSDs) and mental disorders are the leading causes of disability, but their mutual relationships have been little studied. The objective of the current review is to summarize the evidence on the relationships between depressive and anxiety disorders, subjective mental health and common MSDs in adults aged 45 years and over. A review of studies published in English, identified using MEDLINE, was conducted. Search terms included spinal stenosis, intervertebral disc displacement, osteoarthritis, osteoporosis, depressive disorder, anxiety disorders, mental health, subjective well-being, subjective quality of life, life satisfaction and personal satisfaction. A total of 287 records were initially identified, and an additional 190 records were identified from their reference lists. Eight studies were considered eligible and were, thus, included in the current review. The

included studies reported that: 1) major depressive disorder is associated with chronic back pain; 2) anxiety disorders are associated with cervical or lumbar disc herniation; 3) mood and anxiety disorders are associated with lower bone mineral density in men; 4) life satisfaction and its improvement prevent bone loss in postmenopausal women; and 5) quality of life reduces progressively as the number of osteoporotic fractures increases. In conclusion, common MSDs are associated with mental disorders and subjective mental health in adults aged 45 years or more, but longitudinal research is needed.

TI Identification of Novel Loci Associated With Hip Shape: A Meta-Analysis of Genomewide Association Studies
SO JOURNAL OF BONE AND MINERAL RESEARCH
LA English
DT Article
DE HIP SHAPE; OSTEOARTHRITIS; HIP FRACTURE RISK; DXA; GWAS
ID susceptibility loci; parathyroid-hormone; noncoding elements; indian hedgehog; factor sox9; differentiation; osteoarthritis; risk; abnormality; prediction
AB We aimed to report the first genomewide association study (GWAS) meta-analysis of dual-energy X-ray absorptiometry (DXA)-derived hip shape, which is thought to be related to the risk of both hip osteoarthritis and hip fracture. Ten hip shape modes (HSMs) were derived by statistical shape modeling using SHAPE software, from hip DXA scans in the Avon Longitudinal Study of Parents and Children (ALSPAC; adult females), TwinsUK (mixed sex), Framingham Osteoporosis Study (FOS; mixed), Osteoporotic Fractures in Men study (MrOS), and Study of Osteoporotic Fractures (SOF; females) (total N = 15,934). Associations were adjusted for age, sex, and ancestry. Five genomewide significant ($p < 5 \times 10(-9)$, adjusted for 10 independent outcomes) single-nucleotide polymorphisms (SNPs) were associated with HSM1, and three SNPs with HSM2. One SNP, in high linkage disequilibrium with rs2158915 associated with HSM1, was associated with HSM5 at genomewide significance. In a look-up of previous GWASs, three of the identified SNPs were associated with hip osteoarthritis, one with hip fracture, and five with height. Seven SNPs were within 200 kb of genes involved in endochondral bone formation, namely SOX9, PTHrP, RUNX1, NKX3-2, FGFR4, DICER1, and HHIP. The SNP adjacent to DICER1 also showed osteoblast cis-regulatory activity of GSC, in which mutations have previously been reported to cause hip dysplasia. For three of the lead SNPs, SNPs in high LD ($r(2) > 0.5$) were identified, which intersected with open chromatin sites as detected by ATAC-seq performed on embryonic mouse proximal femora. In conclusion, we identified eight SNPs independently associated with hip shape, most of which were associated with height and/or mapped close to endochondral bone formation genes, consistent with a contribution of processes involved in limb growth to hip shape and pathological sequelae. These findings raise the possibility that genetic studies of hip shape might help in understanding potential pathways involved in hip osteoarthritis and hip fracture. (c) 2018 The Authors. TI Association between cam-type femoroacetabular impingement and osteitis pubis in non-athletic population on magnetic resonance imaging
SO JOURNAL OF ORTHOPAEDIC SURGERY AND RESEARCH
LA English
DT Article
DE Femoroacetabular impingement; Osteitis pubis; Magnetic resonance imaging
ID femoral-head; alpha angle; groin pain; hip; osteoarthritis; management; motion; hernia
AB Background Osteitis pubis (OP) is a common source of groin and extra-articular hip pain and is associated with intra-articular hip pathology. In this study, we aimed to determine the prevalence of osteitis pubis on magnetic resonance imaging (MRI) in non-athletic patients with cam-type femoroacetabular impingement (FAI). Methods This retrospective cross-sectional study included 178 subjects: 90 patients with cam-type FAI diagnosed by MRI and 88 subjects used as a control group. Additionally, their MRI data were analyzed for the characteristics of osteitis pubis, with severity graded from minimal to severe on a four-point scale. Results A total of 98 patients and 88 controls were studied. Seventy-two males (80%) and 18 females (20%) were the patient group, whereas 71 males (80.68%) and 17 females (19.32%) were the control group. The mean alpha angle of the patients with FAI was 65.8 +/- 3.3 degrees in the right side and 66.2 +/- 3.2 degrees in the left side, whereas in the control group, it was 47 +/- 5.6 degrees in the right side and 47.8 +/- 5.2 degrees in the left side. Alpha angle measurements were significantly higher in the patient group than the control group ($p < 0.001$). A statistically significant increase in the prevalence of osteitis pubis was found in patients with

cam-type FAI (45.56%) compared to control subjects (5.68%) ($p < 0.001$). Conclusions This study demonstrated that the frequency of osteitis pubis was increased in non-athletic patients with FAI syndrome. Further studies are required to determine whether these findings reflect the clinical symptoms in patients with hip pain.

TI The Effect of Exercise on the Prevention of Osteoporosis and Bone Angiogenesis

SO BIOMED RESEARCH INTERNATIONAL
LA English
DT Review
ID pathway
AB Physical activity or appropriate exercise prevents the development of osteoporosis. However, the exact mechanism remains unclear although it is well accepted that exercise or mechanical loading regulates the hormones, cytokines, signaling pathways, and noncoding RNAs in bone. Accumulating evidence has shown that bone is a highly vascularized tissue, and dysregulation of vasculature is associated with many bone diseases such as osteoporosis or osteoarthritis. In addition, exercise or mechanical loading regulates bone vascularization in bone microenvironment via the modulation of angiogenic mediators, which play a crucial role in maintaining skeletal health. This review discusses the effects of exercise and its underlying mechanisms for osteoporosis prevention, as well as an angiogenic and osteogenic coupling in response to exercise.

TI A Jack of All Trades: Impact of Glucocorticoids on Cellular Cross-Talk in Osteoimmunology
SO FRONTIERS IN IMMUNOLOGY
LA English
DT Review
DE glucocorticoids; glucocorticoid receptor; osteoporosis; arthritis; inflammation; fracture healing; conditional knockout mice
ID induced leucine-zipper; toll-like receptor; 11-beta-hydroxysteroid dehydrogenase type-1; synovial lining macrophages; suppress bone-formation; necrosis-factor-alpha; osteophyte formation; endogenous glucocorticoids; skeletal-muscle; mast-cells
AB Glucocorticoids (GCs) are known to have a strong impact on the immune system, metabolism, and bone homeostasis. While these functions have been long investigated separately in immunology, metabolism, or bone biology, the understanding of how GCs regulate the cellular cross-talk between innate immune cells, mesenchymal cells, and other stromal cells has been garnering attention rather recently. Here we review the recent findings of GC action in osteoporosis, inflammatory bone diseases (rheumatoid and osteoarthritis), and bone regeneration during fracture healing. We focus on studies of pre-clinical animal models that enable dissecting the role of GC actions in innate immune cells, stromal cells, and bone cells using conditional and function-selective mutant mice of the GC receptor (GR), or mice with impaired GC signaling. Importantly, GCs do not only directly affect cellular functions, but also influence the cross-talk between mesenchymal and immune cells, contributing to both beneficial and adverse effects of GCs. Given the importance of endogenous GCs as stress hormones and the wide prescription of pharmaceutical GCs, an improved understanding of GC action is decisive for tackling inflammatory bone diseases, osteoporosis, and aging.

TI Cryptotanshinone inhibits RANKL-induced osteoclastogenesis by regulating ERK and NF-κB signaling pathways
SO JOURNAL OF CELLULAR BIOCHEMISTRY
LA English
DT Article
DE Cryptotanshinone; extracellular signal-regulated kinase; NF-kappa B; osteoclast differentiation; osteoclastogenesis; osteoporosis
ID receptor activator; c-fos; osteoporosis; prevention; differentiation; protects
AB Osteoporosis (OS) is one of the most common healthy problems characterized by low bone mass. Osteoclast, the primary bone-resorbing cell, is responsible for destructive bone diseases including osteoporosis (OS). Cryptotanshinone (CTS), an active component extracted from the root of Salvia miltiorrhiza bunge, has been shown to prevent the destruction of cartilage and the thickening of subchondral bone in mice osteoarthritis models. However, its molecular mechanism in osteoclastogenesis needs to be determined. The aim of the current study was to explore the effect of CTS on osteoclastogenesis and further evaluate the underlying mechanism. Our results showed that CTS inhibited receptor activator of NF-kappa B ligand (RANKL)-induced the increase in tartrate-resistant acid phosphatase (TRAP) activity in bone marrow-derived macrophages (BMMs). In addition, the expressions of osteoclastogenesis-related marker proteins and nuclear factor of activated T-cells (NFAT) activation were suppressed by CTS treatment in BMMs. Furthermore, CTS attenuated RANKL-induced ERK phosphorylation and NF-kappa B

activation in BMMs. These findings indicated that CTS inhibited RANKL-induced osteoclastogenesis by inhibiting ERK phosphorylation and NF-kappa B activation in BMMs. Thus, CTS may function as an inhibitor of osteoclastogenesis and may be considered as an alternative medicine for the prevention and treatment of OS.

TI Nirogacestat suppresses RANKL-Induced osteoclast formation in vitro and attenuates LPS-Induced bone resorption in vivo
SO EXPERIMENTAL CELL RESEARCH
LA English
DT Article
DE Nirogacestat; Osteoclasts; RANKL; Bone resorption; Notch2
ID nf-kappa-b; induced osteolysis; notch2; osteoporosis; differentiation; activation; expression; prevention; mutations; roles
AB Bone resorption, initiated by osteoclasts (OCs), plays an essential role in bone homeostasis. The abnormalities of bone resorption may induce a series of diseases, including osteoarthritis, osteoporosis and aseptic peri-implant loosening. Nirogacestat (PF-03084014, PF), a novel gamma-secretase inhibitor, has been used in phase II clinical trial for treatment of desmoid tumor. However, whether it has the therapeutic effect on abnormal bone resorption remains to be evaluated. In this study, we investigated the role of PF in the regulation of receptor activator of nuclear factor-kB ligand (RANKL)-induced osteoclastogenesis in vitro, and the lipopolysaccharide (LPS)-induced bone resorption in vivo. It was found that PF could suppress the formation of osteoclasts from bone marrow macrophages (BMMs) without causing cytotoxicity, inhibit bone resorption and downregulate the mRNA level of osteoclast-specific markers, including calcitonin receptor (CTR), tartrate resistant acid phosphatase (TRAP), cathepsin K (CTSK), dendritic cell-specific transmembrane protein (Dc-stamp), Atp6v0d2 (V-ATPase d2) and nuclear factor of activated T-cells cytoplasmic 1 (NFATc1). Furthermore, Notch2 signaling, as well as RANKL-induced AKT signaling was significantly inhibited in BMMs. Consistent with in vitro observation, we found that PF greatly ameliorated LPS-induced bone resorption. Taken together, our study demonstrated that PF has a great potential to be used in management of osteolytic diseases.

TI Clinical Impact of the Fracture Risk Assessment Tool on the Treatment Decision for Osteoporosis in Patients with Knee Osteoarthritis: A Multicenter Comparative Study of the Fracture Risk Assessment Tool and World Health Organization Criteria
SO JOURNAL OF CLINICAL MEDICINE
LA English
DT Article
DE osteoporosis; fracture; fracture risk assessment tool; knee osteoarthritis
ID bone-mineral density; prevalence; women; hip; population; intervention; association; thresholds; burden; female
AB Background: To compare the frequency of high-risk osteoporotic fracture in patients with knee OA (OA) using the fracture risk assessment tool (FRAX) and the bone mineral density (BMD). Methods: We retrospectively assessed 282 Korean patients with knee OA who visited five medical centers and 1165 healthy controls (HCs) aged >= 50 years without knee OA. After matching for age, sex, and body mass index, 478 subjects (239 patients with knee OA and 239 HCs) were included. Results: Based on the BMD, the frequency of osteoporosis was 40.2% in patients with knee OA and 36.4% in HCs. The predicted mean FRAX major osteoporotic

fracture probabilities calculated with or without femur neck BMD differed significantly between the knee OA and HCs (6.9 +/- 3.8% versus 6.1 +/- 2.8%, p = 0.000 and 8 +/- 3.6% versus 6.8 +/- 2.3%, p < 0.001, respectively). The mean FRAX hip fracture probabilities calculated with or without femur neck BMD differed significantly in the knee OA and HCs (2.1 +/- 2.4% versus 1.7 +/- 1.8%, p = 0.006 and 3 +/- 2.3% versus 2.4 +/- 1.6%, p < 0.001, respectively). Conclusion: Our study suggests that FRAX may have a clinical impact on treatment decisions to reduce osteoporotic facture in patients with knee OA.

TI Magnetic resonance imaging T1 and T2 mapping provide complementary information on the bone mineral density regarding cancellous bone strength in the femoral head of postmenopausal women with osteoarthritis
SO CLINICAL BIOMECHANICS
LA English
DT Article
DE MRI T1 mapping; MRI T2 mapping; Cancellous bone; Bone strength; Bone marrow
ID marrow adipose-tissue; osteoporosis; mri; collagen; fractures; volume; spine; age
AB Background Since bone mass is not the only determinant of bone strength, there has been increasing interest in incorporating the bone quality into fracture

risk assessments. We aimed to examine whether the magnetic resonance imaging (MRI) T1 or T2 mapping value could provide information that is complementary to bone mineral density for more accurate prediction of cancellous bone strength. Methods: Four postmenopausal women with hip osteoarthritis underwent 3.0-T MRI to acquire the T1 and T2 values of the cancellous bone of the femoral head before total hip arthroplasty. After the surgery, the excised femoral head was portioned into multiple cubic cancellous bone specimens with side of 5 mm, and the specimens were then subjected to microcomputed tomography followed by biomechanical testing. Findings: The T1 value positively correlated with the yield stress (sigma(y)) and collapsed stress (sigma(c)). The T2 value did not correlate with the yield stress, but it correlated with the collapsed stress and strength reduction ratio (sigma(c),/sigma(y)), which reflects the progressive re-fracture risk. Partial correlation coefficient analyses, after adjusting for the bone mineral density, showed a statistically significant correlation between T1 and yield stress. The use of multiple coefficients of determination by least squares analysis emphasizes the superiority of combining the bone mineral density and the MRI mapping values in predicting the cancellous bone strength compared with the bone mineral density-based prediction alone. Interpretation: The MRI T1 and T2 values predict cancellous bone strength including the change in bone quality.

TI Toxicity of cadmium in musculoskeletal diseases
SO ENVIRONMENTAL TOXICOLOGY AND PHARMACOLOGY
LA English
DT Review
DE Cadmium; Osteoarthritis; Osteoporosis; Rheumatoid arthritis; Oxidative stress
ID scalp hair samples; environmental exposure; bone-resorption; population; level; osteomalacia; association; tissue; risk; zinc
AB Epidemiological studies have reported that exposure to toxic metals like cadmium (Cd) may promote the development of musculoskeletal diseases, such as osteoporosis, rheumatoid arthritis (RA), and osteoarthritis (OA), among others. The objective of this review is to summarize the molecular mechanisms of inflammation and oxidative stress activated by Cd at the bone level, particularly in osteoporosis, RA, and OA. Cadmium can increase bone resorption, affect the activity of osteoclasts and calcium (Ca) absorption, and impair kidney function, which favors the development of osteoporosis. In the case of RA, Cd interferes with the activity of antioxidant proteins, like superoxide dismutase (SOD) and catalase (CAT). It also promotes an inflammatory state, inducing the process of citrullination, which affects the proteins of immune response. On the other hand, accumulation of Cd in the tissues and blood of smokers has been related to the development of some musculoskeletal diseases. Therefore, knowing the negative impact of Cd toxicity at the articular level can help understand the damage mechanisms it produces, leading to the development of such diseases.

TI Comparative Analyses of Pharmaceuticals or Food Supplements Containing Chondroitin Sulfate: Are Their Bioactivities Equivalent?
SO ADVANCES IN THERAPY
LA English
DT Article
DE Chondroitin sulfate; Food supplements; Glucosamine; HPAE-PAD; Human primary chondrocytes; Human primary synoviocytes; Keratan sulfate; NF-kappa B mediated inflammation pathway; OA in vitro model; Rheumatology
ID residual keratan sulfate; task-force; knee osteoarthritis; standing-committee; european-society; economic-aspects; in-vitro; management; recommendations; osteoporosis
AB Introduction Oral supplementation of chondroitin sulfate (CS) and glucosamine (GlcN), symptomatic slow-acting molecules, is recommended by European Society for Clinical and Economic Aspects of Osteoporosis and Osteoarthritis and

Musculoskeletal Diseases (ESCEO) and other European Union (EU) guidelines for the restoration of the articular cartilage surface in patients affected by osteoarthritis (OA). They are commercialized as pharmaceutical grade products and as food supplements in combination with plant extracts hyaluronic acid, methylsulfonylmethane, and other components. Food supplements do not need to undergo the strict regulatory controls of pharmaceutical grade products; thus, composition and contaminants that could be present may not be evidenced before commercialization and these uncertainties may give rise to concerns about the bioactivity of these formulations. Methods In this paper 10 different food supplements (FS) from diverse European countries were analyzed in comparison with two pharmaceutical grade products (Ph) using updated analytical approaches and biochemical cell-based assays. The purity, the titer, and the origin of CS in Ph and FS samples were initially assessed in order to successively compare the biological function. Both food supplements and pharmaceutical formulations were tested in vitro, using the same final CS concentration, on primary chondrocytes and synoviocytes in terms of (i) cell viability, (ii) activation of the NF-kappa B-mediated inflammation pathway, (iii) cartilage oligomeric matrix protein (COMP-2), IL-6, and IL-8 production. Results All the FS presented a certain insoluble fraction; the CS and the GlcN contents were lower than the declared ones in 9/10 and 8/10 samples, respectively. All FS contained keratan sulfate (KS) at up to 50% of the total glycosaminoglycan amount declared on the label. Primary cells treated with the samples diluted to present the same CS concentration in the medium showed cytotoxicity in 7/10 FS while Ph preserved viability and reduced NF-kappa B, COMP-2, and secreted inflammatory cytokines. Conclusion Among all samples tested, the pharmaceutical grade products demonstrated effective modulation of biomarkers counteracting the inflammation status and improving viability and the physiological condition of OA human primary chondrocyte and synoviocyte cells. In contrast to that, most FS were cytotoxic at the tested concentrations, and only 3/10 of them showed similarities to Ph sample behavior in vitro. Funding This work was partially supported by PON01_1226 NUTRAFAST, MIUR Ministero dell'Universita e della Ricerca Scientifica. Bioteknet financed two short-term grants for graduate technicians. The journal's Rapid Service and Open Access fees were funded by IBSA CH.

TI POSS Hybrid Robust Biomass IPN Hydrogels with Temperature Responsiveness
SO POLYMERS
LA English
DT Article
DE octa-ammonium POSS; sodium alginate; hydrogels; temperature responsiveness
ID double-network hydrogels; biocompatibility evaluation; alginate; delivery; release; design
AB In order to improve the performance of traditional sodium alginate (SA) hydrogels cross-linked by Ca2+ ions to meet greater application demand, a strategy was designed to structure novel SA-based gels (named OP-PN gels) to achieve both stimulus responsiveness and improved mechanical strength. In this strategy, the SA chains are co-cross-linked by CaCl2 and cationic octa-ammonium polyhedral oligomeric silsesquioxane (Oa-POSS) particles as the first network, and an organically cross-linked poly(N-isopropyl acrylamide) (PNIPA) network is introduced into the gels as the second network. Several main results are obtained from the synthesis and characterization of the gels. For OP-PN gels, their properties depend on the content of both uniformly dispersed Oa-POSS and PNIPA network directly. The increased Oa-POSS and PNIPA network content significantly improves both the strength and resilience of gels. Relatively, the increased Oa-POSS is greatly beneficial to the modulus of gels, and the increased PNIPA network is more favorable to advancing the tensile deformation of gels. The gels with hydrophilic PNIPA network exhibit better swelling ability and remarkable temperature responsiveness, and their volume phase transition temperature can be adjusted by altering the content of Oa-POSS. The deswelling rate of gels increases gradually with the increase of POSS content due to the hydrophobic Si-O skeleton of POSS. Moreover, the enhanced drug loading and sustained release ability of the target drug bovine serum albumin displays great potential for this hybrid gel in the biomedical field.

AB The increasing incidence of osteoporotic bone fractures makes fracture risk prediction an important clinical challenge. Computational models can be utilised to facilitate such analyses. However, they critically depend on bone's underlying hierarchical material description. To understand bone's irreversible behaviour at the micro- and nanoscale, we developed an in situ testing protocol that allows us to directly relate the experimental data to the mechanical behaviour of individual mineralised collagen fibres and its main constitutive phases, the mineralised collagen fibrils and the mineral nanocrystals, by combining micropillar compression of single fibres with small angle X-ray scattering (SAXS) and X-ray diffraction (XRD).

Failure modes were assessed by SEM. Strain ratios in the elastic region at fibre, fibril and mineral levels were found to be approximately 22:5:2 with strain ratios at the point of compressive strength of 0.23 +/- 0.11 for fibril-to-fibre and 0.07 +/- 0.01 for mineral-to-fibre levels. Mineral-to-fibre levels showed highest strain ratios around the apparent yield point, fibril-to-fibre around apparent strength. The mineralised collagen fibrils showed a delayed mechanical response, contrary to the mineral phase, which points towards preceding deformations of mineral nanocrystals in the extrafibrillar matrix. No damage was measured at the level of the mineralised collagen fibre which indicates an incomplete separation of the mineral and collagen, and an extrafibrillar interface failure. The formation of kink bands and the gradual recruitment of fibrils upon compressive loading presumably led to localised strains. Our results from a well-controlled fibrillar architecture provide valuable input for micromechanical models and computational non-linear bone strength analyses that may provide further insights for personalised diagnosis and treatment as well as bio-inspired implants for patients with bone diseases. Statement of significance Musculoskeletal diseases such as osteoporosis, osteoarthritis or bone cancer significantly challenge health care systems and make fracture risk prediction and treatment optimisation important clinical goals. Computational methods such as finite element models have the potential to optimise analyses but highly depend on underlying material descriptions. We developed an in situ testing set-up to directly relate experimental data to the mechanical behaviour of bone's fundamental building block, the individual mineralised collagen fibre and its main constituents. Low multilevel strain ratios suggest high deformations in the extrafibrillar matrix and energy dissipation at the interfaces, the absence of damage indicates both an incomplete separation between mineral and collagen and an extrafibrillar interface failure. The formation of kink bands in the fibril-reinforced composite presumably led to localised strains. The deformation behaviour of a well-controlled fibrillar architecture provides valuable input for nonlinear bone strength analyses. (C) 2019 Acta Materialia Inc. Published by Elsevier Ltd. TI Efficacy of Chondroitin Sulfate in Patients with Knee Osteoarthritis: A Comprehensive Meta-Analysis Exploring Inconsistencies in Randomized, Placebo-Controlled Trials
SO ADVANCES IN THERAPY
LA English
DT Review
DE Chondroitin sulfate; Functional status; Meta-analysis; Osteoarthritis; Pain; Rheumatology
ID controlled clinical-trial; double-blind; european-society; economic-aspects; cartilage volume; task-force; osteoporosis; glucosamine; management; recommendations
AB IntroductionThere are some controversies about treatment modalities in

osteoarthritis (OA), including chondroitin sulfate (CS). The objective of this study was to determine whether CS is effective at alleviating pain and improving function in patients with knee OA and to identify the factors that explain inconsistencies in clinical trial results.MethodsWe conducted a systematic review of randomized, placebo-controlled trials, searching the databases Medline, Cochrane central register for controlled trials and Scopus. Random effects meta-analysis was then performed, using tau(2) and I-2 statistics to assess heterogeneity. The pain and Lequesne index (LI) scores were expressed as standardized mean differences (SMDs), with a 95% confidence interval (CI). Heterogeneity was explored by stratifying the analyses according to pre-specified study-level characteristics and assessing the sources of funnel plot asymmetry.ResultsThe inclusion criteria yielded 18 trials. Overall, CS significantly but inconsistently reduced pain (SMD: - 0.63; 95% CI: - 0.91, - 0.35; I-2=94%) and improved function (SMD: - 0.82; 95% CI: - 1.31, - 0.33; I-2=95%). When limiting the analysis to studies with a low risk of bias, the pharmaceutical grade CS of IBSA origin showed a greater reduction in pain (SMD: - 0.25; 95% CI: - 0.34, - 0.16; I-2=75%) and function (SMD: - 0.33; 95% CI: - 0.47, - 0.20; I-2=53%, p=0.07) compared with the other preparations (SMDPain: - 0.08; 95% CI: - 0.19, + 0.02; I-2=20%; SMDFunction: - 0.18; 95% CI: - 0.36, +0.01; I-2=0%). Assessing funnel plot asymmetry in the studies with a low risk of bias, we found strong correlations between the treatment effects and study size (pain: r(S)=0.93; LI: r(S)=0.86; p<0.05). Ultimately, there was no residual heterogeneity in the CS effects when the smallest studies were removed from the analyses.ConclusionThis new meta-analysis suggests that CS provides a moderate benefit for pain and has a large effect on function in knee OA, however with large inconsistency. The risks of bias, brand and study size were the factors explaining heterogeneity among the clinical trial results.

DT Article
DE Chondroitin sulfate; Food supplement; Glucosamine; Keratan sulfate; HPAE-PAD; NF-kB mediated inflammation pathway
ID keratan sulfate; economic-aspects; task-force; osteoarthritis; formulations; osteoporosis; hyaluronan; management; society; knee
AB Chondroitin sulfate and glucosamine, commercialized as anti-osteoarthritis food supplements, do not undergo the strict quality controls of pharmaceuticals. In this paper a systematic multi-analytical approach was designed to analyse 25 food supplements from 8 European countries compared to 2 pharmaceuticals by using high performance anion-exchange chromatography with pulsed amperometric detection, size exclusion chromatography with triple detector array, capillary electrophoresis, mono and bi-dimensional NMR. Furthermore the biological activity was assessed on in vitro human synoviocyte and chondrocyte primary cell models. Most of the samples (over 19 out of 25) showed lower condroitin sulfate and glucosamine contents than the declared ones (up to -60.3%) while all of them showed a KS contamination (up to 47.1%). Mixed animal origin chondroitin sulfate and multiple molecular weight species were determined in more than 32% of the samples. Only 1 on 5 biologically screened samples had an effective action in vitro almost comparable to the pharmaceuticals.

TI Asperosaponin VI protects against bone destructions in collagen induced arthritis by inhibiting osteoclastogenesis
SO PHYTOMEDICINE
LA English
DT Article
DE Asperosaponin VI; Osteoclasts; CIA; Bone erosion; Signaling pathway
ID adhesion kinase; differentiation; resorption; mice; osteoarthritis; mechanisms; nfat
AB Background: Bone destructive diseases like rheumatoid arthritis (RA), osteoporosis and bone metastatic tumors are mainly mediated by over-activated osteoclasts. Asperosaponin VI (AVI), isolated from the rhizome of Dipsacus asper, belongs to triterpenoid saponins. It has multiple physiological activities but its effects on RA, especially on osteoclast differentiation and activation are still unclear. Purpose: Explore the protective role of AVI on collagen induced arthritis (CIA) in vivo and RANKL induced osteoclastogenesis in vitro. Methods: The effects of AVI on cell viability and RANKL-induced osteoclastogenesis, actin ring formation, bone resorption activity as well as on osteoclast specific gene and protein expression were tested using bone marrow derived monocytes (BMMs). Paws from CIA mice were used for micro-CT, HE and TRAP staining, real-time PCR and western blot. Sera were used for cytokine analysis by ELISA. The signaling pathways were detected using western blot, real-time PCR and immunofluorescence assay. Results: AVI significantly inhibited RANKL-induced osteoclast formation and bone resorption activity by suppressing the formation of actin ring. It also inhibited the expression of various osteoclatogenesis marker genes and signaling pathways. AVI protected arthritis in vivo by suppressing inflammation and bone loss. Conclusion: AVI exerts its anti-osteoclastogenic activity both in vitro and in vivo by inhibiting RANKL-induced osteoclast differentiation and function. Thus, our studies demonstrate a potential therapeutic role for AVI in preventing or inhibiting RANKL-mediated osteolytic bone diseases.

TI Prevalence of High-Burden Medical Conditions Among Young and Middle-Aged

Adults With Pediatric-Onset Medical Conditions: Findings From US Private and Public Administrative Claims Data
SO INTERNATIONAL JOURNAL OF HEALTH POLICY AND MANAGEMENT
LA English
DT Article
DE Clinical Epidemiology; Pediatric-Onset Medical Conditions; Noncommunicable Diseases; United States
ID life-years dalys; global burden; systematic analysis; disease; disability; multimorbidity; injury
AB Adults with pediatric-onset medical conditions (POMCs) are susceptible to early development of high-burden medical conditions. However, research pertaining to this topic is lacking, which is vital information that could assist in health benefit planning and administration. The purpose of this study was to determine the prevalence of high-burden medical conditions among privately and publicly insured adults with POMCs, as compared to adults without POMCs, from the US. Data from 2016 were extracted from Optum Clinformatics (R) Data Mart (private insurance) and a random 20% sample from Medicare fee-for-service (public insurance). International Classification of Diseases, Tenth Revision, Clinical Modification (ICD-10-CM) diagnosis codes were used to identify 18-64-year-old beneficiaries with POMCs, as well as several high-burden medical conditions, including pain, fracture, mood affective disorders, anxiety disorders, ischemic heart diseases, cerebrovascular diseases, hypertensive and other cardiovascular diseases, type 2 diabetes, osteoporosis, osteoarthritis, chronic obstructive pulmonary diseases, liver diseases, and cancer. Privately and publicly insured adults with POMCs had higher prevalence of all medical conditions compared to adults without POMCs. Publicly insured adults with POMCs had higher prevalence of all medical conditions compared to privately insured adults with POMCs, except for the lower prevalence of pain and cancer. When stratified by the category of POMCs (eg, musculoskeletal, circulatory), privately and publicly insured groups tended to have higher prevalence of most (private) or all (public) medical conditions compared to adults without POMCs. Adults with POMCs have higher prevalence of several high-burden medical conditions compared to adults without POMCs. This health disparity was present regardless of insurance coverage, but was generally more pronounced for public vs. private insured adults with POMCs.

TI Comparison of the therapeutic effect between the simultaneous and staged unicompartmental knee arthroplasty (UKA) for bilateral knee medial compartment arthritis
SO BMC MUSCULOSKELETAL DISORDERS
LA English
DT Article
DE Unicompartmental knee arthroplasty; Simultaneous; Staged; osteoarthritis; Postoperative complications
ID clinical-outcm; replacement; complications
AB BackgroundTo compare the efficacy and safety of simultaneous vs staged unicompartmental knee arthroplasty (UKA) for bilateral unicompartmental osteoarthritis of the knee.MethodsWe performed a retrospective analysis of prospectively collected data on 93 patients with bilateral knee medial compartment arthritis underwent simultaneous UKA (Group A, 39) or staged UKA (Group B, 54 cases) from January 2008 to December 2015. Group A: 6 males and 33 females aged 64.97.7years; Group B: 5 males and 49 females aged 64.26.4years. There were no statistically significant differences in pre-operative age, sex ratio, or body weight index between the groups (P>0.05). Groups were compared in terms of total anesthesia time, volume of drainage, blood transfusion rate, hemoglobin level on post-operative day 3, total post-operative inpatient days, treatment expenses, post-operative therapeutic effect (KSS scores), and complications.Results All patients had follow-up visits post-operatively. The follow-up visit interval was 32-133months and 41.9months on average. Total anesthesia time, postoperative length of hospital stay, and hospitalization expenses in Group A were significantly

less than those of Group B (P<0.05). Hemoglobin levels in Group A were significantly lower than those of Group B at post-op day 3 (P<0.05). However, no significant differences in volume of drainage, the rate of transfusion, complications, and KSS scores were detected between Groups A and B (P>0.05).Conclusions Both simultaneous and staged UKA achieved the desired therapeutic effect in treatment of bilateral knee medial compartment arthritis. However, simultaneous UKA reduced the cost and the postoperative length of hospital stay without increasing post-operative complications.

TI DXA evaluation of femoral bone mineral density and cortical width in patients with prior total knee arthroplasty
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE Bone mineral density (BMD); Cortical width; Dual energy x-ray absorptiometry (DXA); Total knee arthroplasty (TKA)
ID x-ray absorptiometry; revision total hip; periprosthetic fractures; risk-factors; follow-up; prevalence; epidemiology; osteoporosis; femur; osteoarthritis
AB A Summary Periprosthetic fractures after total knee arthroplasty (TKA) have devastating consequences. Osteoporosis increases periprosthetic fracture risk, but distal femur bone mineral density (BMD) is not measured post-TKA. This study measured distal femur BMD and cortical width; both were lower in the TKA compared to thenon-operated leg. BMD measurement reproducibility was good. Standardized DXA regions of interest are proposed. Introduction Periprosthetic fractures following total knee arthroplasty (TKA) are not rare. We hypothesized that TKA is associated with low BMD, potentially increasing periprosthetic fracture risk. However, distal femur dual energy x-ray (DXA) measurement is virtually never performed after TKA due to lack of standardized approaches. Thus, this study's aims were to develop standard DXA femur regions of interest (ROIs), assess cortical width, and determine measurement reproducibility in TKA patients. Methods Thirty

adults (15 M/15 F) age 59-80 years with unilateral, primary TKA within 2-5 years had femoral DXA scans performed in duplicate using a Lunar iDXA densitometer. In prior work, we established that femur BMD was lowest in the distal metaphysis and highest in mid-shaft. Thus, BMD and cortical width were measured at 15%, 25%, and 60% of the femur length measured from the distal notch. Femur BMD and cortical width were compared between limbs (TKA vs. non-operated side) by paired t test. Results BMD was 3.2-9.9% lower ($p < 0.001$) in the operated femur at all custom ROIs; substantial between individual differences existed with some up to 30% lower. Cortical width was lower ($p < 0.05$) at the 25% ROI on the TKA side. BMD reproducibility was excellent; CV 0.85-1.33%. Conclusions Distal femur BMD can be reproducibly measured using DXA and is similar to 10% lower on the TKA leg. Similarly, medial and lateral cortices are thinner at the 25% ROI. These bone changes likely increase periprosthetic fracture risk. Further work to define and mitigate periprosthetic fracture risk after TKA is needed.

TI Interventional therapeutic procedures to treat degenerative and inflammatory musculoskeletal conditions: state of the art
SO RADIOLOGIA MEDICA
LA English
DT Article
DE Interventional radiology; Ultrasound; Musculoskeletal system; Tendinopathy; Osteoarthritis
ID guided percutaneous irrigation; rotator cuff; calcific tendinitis; achilles tendinopathy; magnetic-resonance; septic bursitis; ultrasound; injection; vertebroplasty; osteoporosis
AB Imaging-guided interventional procedures have become increasingly popular in the treatment of several pathologic conditions in the musculoskeletal system. Besides oncological treatments, musculoskeletal procedures can be performed to treat different degenerative or inflammatory conditions. This paper is aimed to review clinical indications and technical aspects of these kinds of procedures. In particular, we revise the general aspects common to most procedures and the different imaging-guided interventions which can be performed around joints, soft tissues, and spine.

TI Trabecular structural changes in the mandibular condyle caused by degenerative osteoarthritis: a comparative study by cone-beam computed tomography imaging
SO ORAL RADIOLOGY
LA English
DT Article
DE Cancellous bone; Fractals; Mandibular condyle; Osteoarthritis
ID bone-mineral density; temporomandibular-joint; disorders; pattern; pain; osteonecrosis; osteoporosis
AB ObjectivesTemporomandibular osteoarthritis causes pain and loss of function. In advanced cases, it may also result in destruction of joint cartilage surfaces and bone structure.MethodsThis study was performed to examine the potential changes in the condylar trabecular bone structure in patients with temporomandibular osteoarthritis. Condylar trabecular structures were compared

between 35 healthy patients and 35 patients with temporomandibular osteoarthritis by a box-counting method using fractal dimensional analysis on cone-beam computed tomography images.ResultsThe average fractal dimensions of patients with temporomandibular osteoarthritis and healthy patients were 1.18 and 1.23, respectively. This difference was statistically significant (p0.05).ConclusionsOur results add to the existing preliminary knowledge regarding the osteoporotic changes that occur in the trabecular structure under the subchondral bone, which is normally not seen on radiographic images, as well as the destruction and remodeling that occur on the condyle surface, which is visible on radiographic images.

TI Current Stage of Marine Ceramic Grafts for 3D Bone Tissue Regeneration
SO MARINE DRUGS
LA English
DT Review
DE marine ceramic grafts; calcium phosphate; bone tissue regeneration; osteoinductive properties; structural strength; dissolution rate
ID antler cancellous bone; physicochemical characterization; osteoconductive effectiveness; substitutes; nacre; autograft; defects; matrix; reconstruction; sterilization
AB Bioceramic scaffolds are crucial in tissue engineering for bone regeneration. They usually provide hierarchical porosity, bioactivity, and mechanical support supplying osteoconductive properties and allowing for 3D cell culture. In the case of age-related diseases such as osteoarthritis and osteoporosis, or other bone alterations as alveolar bone resorption or spinal fractures, functional tissue recovery usually requires the use of grafts. These bone grafts or bone void fillers are usually based on porous calcium phosphate grains which, once disposed into the bone defect, act as scaffolds by incorporating, to their own porosity, the intergranular one. Despite their routine use in traumatology and dental applications, specific graft requirements such as osteoinductivity or balanced dissolution rate are still not completely fulfilled. Marine origin bioceramics research opens the possibility to find new sources of bone grafts given the wide diversity of marine materials still largely unexplored. The interest in this field has also been urged by the limitations of synthetic or mammalian-derived grafts already in use and broadly investigated. The present review covers the current stage of major marine origin bioceramic grafts for bone tissue regeneration and their promising properties. Both products already available on the market and those in preclinical phases are included. To understand their clear contribution to the field, the main clinical requirements and

the current available biological-derived ceramic grafts with their advantages and limitations have been collected.

TI Differences in prevalence and associated factors between mild and severe vertebral fractures in Japanese men and women: the third survey of the ROAD study
SO JOURNAL OF BONE AND MINERAL METABOLISM
LA English
DT Article
DE Vertebral fracture; Prevalence; Low back pain; Walking ability; ROAD study
ID quality-of-life; risk-factors; hong-kong; mortality; osteoporosis; deformity; consequences; level; mros
AB Vertebral fracture (VF) is a common osteoporotic fracture, while its epidemiology varies according to regions and ethnicities, little is known about it in Japan. Using whole-spine radiographs from a population-based cohort study, the Research on Osteoarthritis/Osteoporosis Against Disability study 3rd survey

performed in 2012-2013, we estimated the sex- and age-specific prevalence of VF in the Japanese. Genant's semiquantitative method (SQ) was used to define VF; SQ >= 1 as VF, SQ = 1 as mild VF, SQ >= 2 as severe VF. We also revealed accurate site-specific prevalence, and associated factors with mild and severe VF. The participants were 506 men [mean age 66.3 years, standard deviation (SD):13.0] and 1038 women (mean age 65.3 years, SD: 12.6). The prevalence of VF in participants aged under 40, in their 40s, 50s, 60s, 70s, and >= 80 years was 17.4, 7.9, 18.5, 25.6, 26.3, and 41.5%, respectively, in men, and 2.9%, 2.4%, 7,3, 10.3, 27.1, and 53.0%, respectively, in women. Men had a significantly higher prevalence of mild VF (21.2%) than women (10.0%, $p < 0.001$); whereas, severe VF was significantly more prevalent in women (9.1%) than in men (4.7%, $p = 0.003$). VF was distributed with 2 peaks regarding site; one large peak at the thoracolumbar region, and another at the middle thoracic lesion. Low back pain and decreased walking ability were independently associated with severe VF, but not with mild VF, after adjustment for participant characteristics. Decreased walking ability was associated with multiple VFs in women, but not in men.

TI Biochemical markers in osteoarthritis with lessons learned from osteoporosis
SO CLINICAL AND EXPERIMENTAL RHEUMATOLOGY
LA English
DT Article
DE osteoarthritis; biomarkers; osteoporosis
ID bone-mineral density; oral salmon-calcitonin; healthy postmenopausal women; vertebral fracture risk; ii collagen; synovial-fluid; matrix-metalloproteinase; cartilage degradation; knee osteoarthritis; alendronate treatment
AB Osteoarthritis (OA) is a disease of the whole joint, including synovium, bone and cartilage. OA is a slow degenerative and very heterogeneous disease, with both varying levels of disease activity and progression. Biomarkers are urgently needed to assist drug developers in selecting and developing the projects with the highest chance of success. Biomarkers for enrichment of clinical studies, early efficacy as well as other diagnostic tools are needed. Osteoporosis and OA have many similarities. In osteoporosis an armamentarium of treatments are now available with high clinical efficacy and well-described effects on biomarkers. Possibly, lessons learned from the osteoporosis field in the use of biomarkers may be applied in the OA field, from both technical and scientific perspectives. To help guide the way, the FDA has recently published the BEST guidelines, to facilitate obtaining a common vocabulary to assist biomarker researchers. In the current review, we will review the biomarkers of OA, with emphasis on bone, cartilage and synovial biomarkers, and draw clear perspectives to the use of biomarkers for drug development and clinical practice in the osteoporosis field.

TI Diffuse idiopathic skeletal hyperostosis is associated with lumbar spinal stenosis requiring surgery
SO JOURNAL OF BONE AND MINERAL METABOLISM
LA English
DT Article
DE Diffuse idiopathic skeletal hyperostosis; Lumbar spinal stenosis; General inhabitants; Prevalence; Standing whole-spine radiographs
ID diagnostic support tool; population; prevalence; hypertrophy; disorders; ligament; cohort; adult; pain; dish
AB Factors related to the onset and progression of lumbar spinal stenosis (LSS) have not yet been identified. Diffuse idiopathic skeletal hyperostosis (DISH)

increases mechanical loading on the non-fused lumbar levels and may therefore lead to LSS. This cross-sectional study aimed to identify associations between LSS and DISH. This study included 2363 consecutive patients undergoing surgery for LSS and 787 general inhabitants without symptoms of LSS as participants of the population-based cohort study, Research on Osteoarthritis/Osteoporosis Against Disability. Standing whole-spine radiographs were used to diagnose DISH based on the criteria proposed by Resnick and Niwayama. The prevalence of DISH showed a significant step-wise increase among asymptomatic inhabitants without radiographic LSS, asymptomatic inhabitants with radiographic LSS, and patients with LSS requiring surgery (14.4, 21.1, and 31.7%, respectively; $p<0.001$). The distribution of DISH was similar between the groups, but the lower thoracic and upper-middle lumbar spine regions were more frequently involved in patients with LSS requiring surgery. Multivariate analysis indicated that DISH was an independent associated factor for LSS requiring surgery (adjusted odds ratio 1.65; 95% confidence interval 1.32-2.07) after adjustment for age, sex, body mass index, and diabetes mellitus. Among patients with LSS requiring surgery, a higher occurrence of stenosis at the upper lumbar levels and multi-level stenosis were observed in patients with DISH requiring surgery than in patients without DISH. In conclusion, DISH is independently associated with LSS requiring surgery. The decrease in the lower mobile segments by DISH may increase the onset or severity of LSS.

TI Characteristics of yoga and meditation users among older Australian women - results from the 45 and up study
SO COMPLEMENTARY THERAPIES IN CLINICAL PRACTICE
LA English
DT Article
DE Chronic illness; Complementary medicine; Meditation; Women's health; Yoga
ID physical-activity; adults; metaanalysis; predictors; depression; outcm; scale; pain
AB Background and purpose: Yoga and meditation are predominantly utilised by healthy well-educated young women, but little is known about utilisation by older chronically ill women. Therefore, the purpose of this study was to investigate the characteristics of yoga and meditation use among middle-to-higher aged Australian women with chronic conditions. Materials and methods: This is a sub-study of the 45 and Up Study including 1925 Australian women aged 53-95 years diagnosed with chronic conditions (asthma, depression, diabetes, osteoarthritis, and osteoporosis). Information on yoga and meditation use frequencies (categories: 'no yoga', 'at least once daily', 'at least once weekly', and 'at least once monthly'), self-perceived effectiveness and communication with

health care providers were assessed via self-report. Logistic regression analyses were conducted to identify independent predictors of yoga and meditation use, using SPSS 24.0. Results: Overall 6.8% and 10.7% of women reported the use of yoga and meditation respectively. Meditation was rarely practiced supervised (11.7%), compared to significant higher rates in yoga (53.2%). Predictors for yoga and meditation use were marital status (married/in relationship > not married/in relationship), higher health related hardiness, and higher education, whereas obesity, and diabetes decreased likelihood of use. While the majority found yoga and meditation helpful for their condition, the use was rarely monitored by or discussed with health care practitioners. Conclusion: This study finds that yoga and meditation are used by middle-to-higher aged Australian women with chronic illnesses. The lack of communication with health care providers is concerning and might hinder co-ordinated and effective health care around chronic illness. Further research is necessary to help understand possible concurrent health care use and thereby help inform safe, effective and coordinate health seeking amongst those with chronic illness.

TI Glutamine Metabolism Is Essential for Stemness of Bone Marrow Mesenchymal Stem Cells and Bone Homeostasis
SO STEM CELLS INTERNATIONAL
LA English
DT Review
ID amino-acid; parenteral-nutrition; osteogenic differentiation; alpha-ketoglutarate; oral glutamine; stromal cells; osteoclast differentiation; intestinal adaptation; extracellular-matrix; articular-cartilage
AB Skeleton has emerged as an endocrine organ which is both capable of regulating energy metabolism and being a target for it. Glutamine is the most bountiful and flexible amino acid in the body which provides adenosine 5 '-triphosphate (ATP) demands for cells. Emerging evidences support that glutamine which acts as the second metabolic regulator after glucose exerts crucial roles in bone homeostasis at cellular level, including the lineage allocation and proliferation of bone mesenchymal stem cells (BMSCs), the matrix mineralization of osteoblasts, and the biosynthesis in chondrocytes. The integrated mechanism consisting of WNT, mammalian target of rapamycin (mTOR), and reactive oxygen species (ROS) signaling pathway in a glutamine-dependent pattern is responsible to regulate the complex intrinsic biological process, despite more extensive

molecules are deserved to be elucidated in glutamine metabolism further. Indeed, dysfunctional glutamine metabolism enhances the development of degenerative bone diseases, such as osteoporosis and osteoarthritis, and glutamine or glutamine progenitor supplementation can partially restore bone defects which may promote treatment of bone diseases, although the mechanisms are not quite clear. In this review, we will summarize and update the latest research findings and clinical trials on the crucial regulatory roles of glutamine metabolism in BMSCs and BMSC-derived bone cells, also followed with the osteoclasts which are important in bone resorption.

TI HIF-1α facilitates osteocyte-mediated osteoclastogenesis by activating JAK2/STAT3 pathway in vitro
SO JOURNAL OF CELLULAR PHYSIOLOGY

DE hypoxia-inducible factor-1 alpha; JAK2; STAT3 pathway; osteoclastogenesis; osteocyte; receptor activator of nuclear factor-kappa B
ID rankl expression; hypoxia; cells; differentiation; il-6; osteoblasts; hif1-alpha; binding; protein; oxygen
AB Osteocytes, entrapped within the mineralized bone matrix, has been found to have numerous functions such as acting as an orchestrator of bone remodeling through regulation of both osteoclast and osteoblast activity and also functioning as an endocrine cell. Due to a specialized morphology and surrounding structure, osteocytes are more tolerant to hypoxia during osteoporosis, fracture, osteoarthritis, and orthodontic-orthognathic combination therapy. Hypoxia-inducible factor-1 alpha (HIF-1 alpha) is one of the master regulators of hypoxia reactions, playing an important role in bone modeling, remodeling, and homeostasis. This study aimed to investigate the pivotal functional role of HIF-1 alpha in osteocytes initiating of bone remodeling under hypoxia. In the present study, the osteoclasts formation induced by RAW264.7 was significantly promoted in conditioned media (CM) from osteocytic MLO-Y4 exposed to hypoxia in vitro. Therefore, hypoxic MLO-Y4 cells simulated by 100 mu mol/L CoCl2 or 2% O-2 stably expressed HIF-1 alpha proteins and upregulated the expression of receptor activator of nuclear factor-kappa B ligand (RANKL) at both the messenger RNA (mRNA) and protein level. Furthermore, with the Knockdown of HIF-1 alpha, the expression of RANKL mRNA and protein decreased after transient transfection. In addition, the phosphorylation of Janus kinase 2 (JAK2) and signal transducer and activator of transcription (STAT3) was also correlated with HIF-1 alpha and RANKL levels under hypoxia. Then AG490, a JAK2 inhibitor, inhibited p-JAK2, p-STAT3 and RANKL expression. It was possible that AG490 disturbed the contact of HIF-1 alpha and RANKL by JAK2/STAT3 pathway, influencing osteoclastogenesis. Our findings suggested that HIF-1 alpha promoted the expression of RANKL by activating JAK2/STAT3 pathway in MLO-Y4 cells, and enhanced osteocyte-mediated osteoclastic differentiation in vitro.

TI Free fatty acid receptor 4-β-arrestin 2 pathway mediates the effects of different classes of unsaturated fatty acids in osteoclasts and osteoblasts
SO BIOCHIMICA ET BIOPHYSICA ACTA-MOLECULAR AND CELL BIOLOGY OF LIPIDS
LA English
DT Article
DE beta-Arrestin 2; Free fatty acid receptor 4; Osteoblast; Osteoclast; Unsaturated fatty acids
ID bone-formation; osteoporosis; gpr120; cells; japan
AB Bone is a dynamic tissue that is constantly remodelled by bone resorbing osteoclasts and bone forming osteoblasts, respectively. A breakdown in the remodelling process underlies several bone diseases such as osteoporosis. Unsaturated fatty acids (UFAs) have been shown to have beneficial effects on bone health. However, the mechanism of action of UFAs in bone remains unclear. Free fatty acid receptor 4 (FFAR4) is expressed in bone cells and preferentially binds omega-3 and omega-7 UFAs. Therefore, we sought to determine if FFAR4 influenced the action of different classes of UFAs in bone cells. FFAR4 and potential signalling pathways, beta-arrestin 2 (beta arr2) and G(uq) were silenced in RAW264.7 murine macrophages (pre-osteo-clasts) and MC3T3-E1 murine pre-osteoblasts. Cell differentiation, activation of signalling pathways and expression of regulatory genes were evaluated. The omega-3 UFAs, docosahexaenoic acid (DHA) and eicosapentaenoic acid (EPA), and the omega-7 UFA, palmitoleic acid (PLA), were shown to require the FFAR4/beta arr2 signalling

pathway to inhibit osteoclast differentiation in RAW264.7 murine macrophages. The omega-6 UFA, arachidonic acid, and the omega-9 UFA, oleic acid (OA), were shown to inhibit osteoclast formation but did not use FFAR4. DHA, EPA, PLA and OA enhanced osteoblast signalling through the FFAR4/beta arr2 signalling axis. This study reveals that FFAR4/beta arr2 signalling may mediate the bone protective effects of different classes of UFAs in osteoclasts and osteoblasts.

AB New technologies can do more than just digitize health information; they can support multimedia platforms for patient education and health decision support. Technology can simplify the way health decisions are made by offering quick access to a vast amount of information that can be tailored to specific populations. Digital tools can increase knowledge and assist consumers in comparing health care alternatives. They are well received by patients because of the myriad features that render them visually appealing and entertaining, including audiovisual and interactive elements. To be effective, however, digital tools must be evidence based and developed following quality standards.

TI Equivalent hip stem fixation by Hi-Fatigue G and Palacos R plus G bone cement: a randomized radiostereometric controlled trial of 52 patients with 2 years' follow-up
SO ACTA ORTHOPAEDICA
LA English
DT Article
ID low-viscosity cement; exeter femoral stem; oxford hip; rsa; arthroplasty; migration; replacement; micromotion; model
AB Background and purpose Long-term fixation of cemented femoral stems relies on several factors including cement adhesion and fatigue. Hi-Fatigue is a newer third-generation bone cement with low-viscosity properties at room temperature, good mechanical strength, and stable bone-cement interface in a laboratory testing environment. Palacos bone cement has excellent 10-year survival and is considered gold standard. We compared stem subsidence after fixation with Hi-Fatigue and Palacos bone cements using radiostereometry.Patients and methods In a patient-blinded randomized controlled trial, 52 patients (30 women) at mean age 76 years (71-87) with osteoarthrosis and no osteoporosis received Hi-Fatigue G or Palacos R+G cement fixation of collarless, polished, double-tapered stems (CPT). Tantalum beads were inserted in the periprosthetic bone. Supine stereoradiographs were obtained postoperatively, 3 months, 6 months, 1 year, and 2 years after surgery. Oxford Hip Score (OHS) and VAS pain were recorded preoperatively and 1 and 2 years after surgery. Cement working times and properties were registered.Results At 2 years, mean stem subsidence of 1.12mm (95% CI 0.96-1.29) for Hi-Fatigue and 1.19mm (CI 1.03-1.34) for Palacos was similar. Likewise, stem version was comparable between cement groups. Mean OHS and VAS pain were similar between cement groups.Cement working times were similar between cement groups, but the mean curing time was longer for Hi-Fatigue (13.7min) than for Palacos (11.6min).Interpretation We found similar and generally low migration of CPT femoral stems inserted with Hi-Fatigue and Palacos bone cement until 2 years' follow-up, which indicates a good long-term survival of polished taper femoral stems inserted with both cement types.

TI Human Enriched Serum Following Hydrolysed Collagen Absorption Modulates Bone Cell Activity: from Bedside to Bench and Vice Versa
SO NUTRIENTS
LA English
DT Article
DE metabolites; bone; hydrolysed collagen; nutrition; osteoporosis; absorption; collagen peptides
ID postmenopausal women; gene-expression; double-blind; hydroxyproline; peptides; calcium; differentiation; osteoarthritis; tripeptides; metabolism
AB Collagen proteins are crucial components of the bone matrix. Since collagen-derived products are widely used in the food and supplement industry, one may raise the question whether collagen-enriched diets can provide benefits for the skeleton. In this study, we designed an innovative approach to investigate this question taking into account the metabolites that are formed by the digestive tract and appear in the circulation after ingestion of hydrolysed collagen. Blood samples collected in clinical and pre-clinical trials following ingestion and absorption of hydrolysed collagen were processed and applied on bone-related primary cell cultures. This original ex vivo methodology revealed that hydrolysed collagen-enriched serum had a direct impact on the behaviour of cells from both human and mouse origin that was not observed with controls (bovine serum albumin or hydrolysed casein-enriched serum). These ex vivo findings were fully in line with in vivo results obtained from a mouse model of post-menopausal osteoporosis. A significant reduction of bone loss was observed in mice supplemented with hydrolysed collagen compared to a control protein. Both the modulation of osteoblast and osteoclast activity observed upon incubation with human or mouse serum ex vivo and the attenuation of bone loss in vivo, clearly indicates that the benefits of hydrolysed collagen for osteoporosis prevention go beyond the effect of a simple protein supplementation.

TI Generating evidence and understanding the treatment of osteoarthritis in Brazil: a study through Delphi methodology
SO CLINICS
LA English
DT Article
DE Osteoarthritis; Osteoarthrosis; Surgical Treatment; Drug Therapy; Glucosamine; Chondroitin
ID knee osteoarthritis; rheumatic conditions; european-society; economic-aspects; management; prevalence; arthritis; recommendations; osteoporosis; algorithm
AB OBJECTIVES: This study aimed to provide evidence for understanding how to

treat osteoarthritis (OA) in our country. Therefore, it was necessary to match information and investigations related to the treatment of the disease from the three main types of specialists involved: physiatrists, orthopedists and rheumatologists. METHODS: The authors acted as a scientific advisory committee. From the initial discussions, a structured questionnaire was developed for use with a group of specialists on OA using the Delphi technique. The questionnaire was sent to 21 experts appointed by the authors, and the results obtained were critically analyzed and validated. RESULTS: The prevalence of OA was 33% in Brazil, corresponding to one-third of the individuals in the reference population, which included individuals over 25 years of age. Another significant finding was that most patients did not receive any form of treatment in the early stages of OA. CONCLUSION: The committee pointed to the need for early intervention and that the available medicinal resources can fulfil this important role, as is the case with SYSADOA treatments. Glucosamine-based medicinal products with or without chondroitin could also fulfill this need for early treatment. The other generated evidence and included investigations were then grouped together and are the subject of this publication.

TI Price dispersion of generic medications
SO PLOS ONE
LA English
DT Article
AB Generic pharmaceuticals should have very little price dispersion. Economics' Law of One Price suggests that identical goods, in the absence of trade frictions and under conditions of free competition and price flexibility, should sell for the same price, and the FDA ensures that generics are identical. In this study, we examine whether generic pharmaceuticals indeed have the low price dispersion that theory predicts, and if not, whether the dispersion seen for pharmaceuticals used to treat neuropsychiatric conditions is substantially higher than that of other drugs. Such a difference may offer an explanation for the price dispersion seen: namely, a strategy that takes advantage of buyers' cognitive constraints and impaired ability to comparison shop. We thus assembled a list of generic pharmaceuticals and their prices using www.GoodRx.com, based on a convenience sample of the 5 most popular drugs for 10 common medical conditions listed there. Three neuropsychiatric diagnoses were used: Alzheimer's disease, depression and schizophrenia. Seven other diagnoses served as controls: asthma; diabetes mellitus-type II; high cholesterol; hypertension; osteoarthritis; osteoporosis; and urinary tract infection. For each drug, we identified the highest and lowest prices and calculated the mean, median and coefficient of variation (CV). We further calculated the ratios of the highest price to the median price and of the highest to lowest price. We found that the mean price CV was 43%. For neuropsychiatric drugs and controls, it was 61% and 35%, respectively. The mean high-to-median ratio was3.7 for neuropsychiatric drugs and 1.9 for controls. The mean high-to-low ratio was 5.9 for neuropsychiatric drugs and 2.8 for controls. In short, generic

medications have high price dispersion, despite public availability of prices. Although our study did not examine why this price dispersion is present, the especially large high-to-low price ratio for neuropsychiatric medications suggests a strategy that exploits vulnerable patients.

TI The Regulation of Bone Metabolism and Disorders by Wnt Signaling
SO INTERNATIONAL JOURNAL OF MOLECULAR SCIENCES
LA English
DT Review
DE osteoclast; osteoblast; osteocyte; Wnt; sclerostin; osteoporosis; romosozumab; osteoarthritis; rheumatoid arthritis; skeletal-related events
ID mesenchymal stem-cells; mammary oncogene int-1; sclerostin expression; rheumatoid-arthritis; cortical-bone; postmenopausal women; inhibitory factor-1; osteocyte control; dna methylation; mineral density
AB Wnt, a secreted glycoprotein, has an approximate molecular weight of 40 kDa, and it is a cytokine involved in various biological phenomena including ontogeny, morphogenesis, carcinogenesis, and maintenance of stem cells. The Wnt signaling pathway can be classified into two main pathways: canonical and non-canonical. Of these, the canonical Wnt signaling pathway promotes osteogenesis. Sclerostin produced by osteocytes is an inhibitor of this pathway, thereby inhibiting osteogenesis. Recently, osteoporosis treatment using an anti-sclerostin therapy has been introduced. In this review, the basics of Wnt signaling, its role in bone metabolism and its involvement in skeletal disorders have been covered. Furthermore, the clinical significance and future scopes of Wnt signaling in osteoporosis, osteoarthritis, rheumatoid arthritis and neoplasia are discussed.

TI Role of MicroRNA-141 in the Aging Musculoskeletal System: A Current Overview
SO MECHANISMS OF AGEING AND DEVELOPMENT
LA English
DT Article
DE MicroRNA-141; MiR-200 family; aging; musculoskeletal
ID oxidative stress; cell proliferation; osteogenic differentiation; regulatory roles; bone; expression; sarcopenia; regeneration; osteoporosis; transporter
AB MicroRNA's are small non-coding RNAs that regulate the expression of genes by targeting the 3' UTR's of mRNA. Studies reveal that miRNAs play a pivotal role in normal musculoskeletal function such as mesenchymal stem cell differentiation, survivability and apoptosis, osteogenesis, and chondrogenesis. Changes in normal miRNA expression have been linked to a number of pathological disease processes. Additionally, with aging, it is noted that there is dysregulation in the normal function of stem cell differentiation, bone formation/degradation, chondrocyte function, and muscle degeneration. Due to the change in expression of miRNA in degenerative musculoskeletal pathology, it is believed that these molecules may be at least partially responsible for cellular dysfunction. A number of miRNAs have already been identified to play a role in osteoarthritis, osteoporosis and sarcopenia. One miRNA that has become of interest recently is miRNA 141. The purpose of this article is to review the current literature available on miRNA 141 and how it could play a role in osteoporosis, osteoarthritis and musculoskeletal pathology overall.

TI Psychometrical properties of the Turkish translation of the New Knee Society Scoring System
SO ACTA ORTHOPAEDICA ET TRAUMATOLOGICA TURCICA
LA English
DT Article
DE Knee scoring; Reliability; Validity; Knee; Cultural adaptation; Total knee arthroplasty
ID cross-cultural adaptation; osteoarthritis; prevalence; validation; version; arthroplasty; reliability
AB Objective: To translate the New Knee Society Scoring System (KSS) into Turkish and to evaluate the psychometric properties of the translated questionnaire. Methods: This study was conducted on 66 knees of 43 pre-op patients who were scheduled for total knee arthroplasty (TKA) and 50 knees of 26 knee arthroplasty patients at least 6 months postoperatively. KSS was translated and culturally

adapted according to the guidelines of Guillemin and Beaton. Demographic and clinical characteristics of the patients were recorded. Patients completed WOMAC, KOOS and SF-36 surveys along with the Turkish version of the new KSS. After the initial evaluation, patients were asked to refill the new KSS 1 week later. Internal consistency and reliability were tested using Cronbach's alpha coefficient and intraclass correlation coefficient (ICC). Validity was assessed by calculating the Spearman's correlation coefficient between the new KSS and WOMAC, KOOS and SF-36 scores. Results: The mean ages of the pre and post-operative groups were 67.16 +/- 7.85 years and 71.65 +/- 6.95 years respectively. The Cronbach's alpha coefficients of the new KSS calculated for symptoms (0.814), patient satisfaction (0.947), patient expectations (pre-op =1.000, post-op =0.997) and functional activities (0.864) were high. The ICC scores ranged between 0.790 and 0.951. The pain subscore of the new KSS and the pain subscores of the WOMAC ($r = -0.720$; $p < 0.01$), KOOS ($r = 0.550$; $p < 0.01$) and SF-36 ($r = -0.434$; $p < 0.01$) were highly correlated. Emotional role functioning (RH), mental health (MH) and social role functioning (SF) subscores of SF-36 showed no correlation with the all subscores of the new KSS ($p > 0.05$). No floor or ceiling effects in the new KSS scores were detected. Conclusion: It is concluded that the new KSS is a valid and reliable questionnaire which can be used in evaluating the pre and post-operative Turkish speaking TKA patients. (C) 2019 Turkish Association of Orthopaedics and Traumatology. Publishing services by Elsevier B.V.

TI Pain catastrophising worsens RAPID3 in all rheumatologic conditions
SO CLINICAL AND EXPERIMENTAL RHEUMATOLOGY
LA English
DT Article
DE RAPID3; pain catastrophising; rheumatoid arthritis; spondyloarthritis; osteoarthritis; back pain; tendinitis; fibromyalgia; pain; HAQ; osteoporosis
ID index data 3; patient-reported outcm; disease-activity index; assessment questionnaire mdhaq; routine assessment; ankylosing-spondylitis; response criteria;

self-assessment; clinical-trial; activity score
AB Objective To assess RAPID3 in various rheumatologic conditions, and the impact of pain catastrophising on RAPID3. Methods A set of questionnaires, including RAPID3 (0-30) and pain catastrophising score (0-52), was given to all outpatients seen in a one-month period: 518 patients fulfilled the questionnaires, including 127 RA (42% taking biologics), and 135 SpA (58% taking biologics). Results Mean pain catastrophising was 18.5 +/- 12.5, and 19% of patients could be classified as catastrophisers (> 30). Higher RAPID3 scores were observed in the 33 osteoarthritis of lower limbs (16.44 +/- 5.20), 10 fibromyalgia (15.52 +/- 5.53), 47 back-pain (14.88 +/- 5.17), 17 osteoarthritis of upper limbs (13.61 +/- 7.42), and 38 tendinopathies (12.85 +/- 4.38). Lower RAPID3 were observed in the 135 SpA (12.79 +/- 6.03), 127 RA (12.18 +/- 6.30), 27 miscellaneous disorders (9.83 +/- 6.28), 7 entrapment neuropathies (9.81 +/- 4.51), 19 systemic connective tissue disorders (8.26 +/- 7.04) and 58 osteoporosis (7.85 +/- 6.95). Much higher RAPID3 scores were observed in the 19% with high pain catastrophising scores, whatever the conditions, and lower scores in the 15% with disablement benefits. RAPID3 was not associated with age or disease duration, but strongly correlated with daily fatigue, poor sleep, and length of daily pain. Conclusion Thanks to progress made in RA and SpA treatment, higher RAPID3 scores were mostly observed in other rheumatic conditions, but co-morbidities and pain catastrophising might contribute to floor effects when assessing rheumatic disorders with RAPID3, hindering the recognition of low disease activity in some RA of SpA patients.

TI Long-term mortality in older adults with chronic pain: a nationwide population-based study in Taiwan
SO EUROPEAN GERIATRIC MEDICINE
LA English
DT Article
DE Chronic pain; Long-term; Mortality; Older
ID quality-of-life; low-back-pain; geriatric-patients; risk; prevalence; association; management
AB Purpose This study was conducted to clarify the long-term mortality in the older population with chronic pain (CP), which is still unclear. Methods We identified 17,568 older participants (aged >= 65 years) with CP and an identical number of

comparison cohort without CP matched 1:1 by age and sex between 1996 and 2000 from the Taiwan National Health Insurance Research Database. Causes of CP, underlying comorbidities, living areas, and mortality were collected for analyses. The long-term mortality and the causes of mortality were compared between the two cohorts through follow-up since 2000 until 2015. Results The mean age (+/- standard deviation) was 73.5 +/- 5.7 years, and female participants comprised 55.1% in both cohorts. The most common causes of CP were osteoarthritis (24.2%), spinal disorders (22.4%), peripheral vascular diseases (14.0%), and osteoporosis (9.5%). Older participants with CP had an increased rate of long-term mortality compared to that among their counterparts without CP after adjusting for the underlying comorbidities and the causes of CP (adjusted hazard ratio [AHR]: 1.18; 95% confidence interval [CI] 1.14-1.21). The increased mortality rate was observed even after the follow-up of 6 years (AHR 1.15; 95% CI 1.10-1.20). No significant difference was observed in the causes of mortality between the two cohorts. The most common cause of mortality was malignancy, followed by cardiovascular and cerebrovascular diseases. Conclusions Chronic pain was associated with an increased rate of long-term mortality in the older population. Early detection and intervention for treating CP are suggested for this population.

TI Nomenclature of Subchondral Nonneoplastic Bone Lesions
SO AMERICAN JOURNAL OF ROENTGENOLOGY
LA English

DT Review
DE nomenclature; nonneoplastic; osteochondral; subchondral bone; white paper
ID edema-like lesions; resonance-imaging score; marrow edema; insufficiency fractures; femoral-head; osteochondritis-dissecans; spontaneous osteonecrosis; transient osteoporosis; rheumatoid-arthritis; destructive osteoarthritis
AB OBJECTIVE. The purpose of this article is to summarize the nomenclature of nonneoplastic conditions affecting subchondral bone through a review of the medical literature and expert opinion of the Society of Skeletal Radiology Subchondral Bone Nomenclature Committee. CONCLUSION. This consensus statement summarizes current understanding of the pathophysiologic characteristics and imaging findings of subchondral nonneoplastic bone lesions and proposes nomenclature to improve effective communication across clinical specialties and help avoid diagnostic errors that could affect patient care.

TI DXA Measured Distal Femur Bone Mineral Density in Patients After Total Knee Arthroplasty: Method Development and Reproducibility
SO JOURNAL OF CLINICAL DENSITOMETRY
LA English
DT Article
DE DXA; total knee arthroplasty; bone mineral density
ID x-ray absorptiometry; revision total hip; periprosthetic bone; femoral fractures; risk-factors; follow-up; epidemiology; prevalence; osteoarthritis; osteoporosis
AB Introduction: Total knee arthroplasty (TKA) is increasingly being performed. Distal femur periprosthetic fracture is a potentially catastrophic complication following TKA and existing data document substantial distal femur bone mineral density (BMD) loss following TKA. However, distal femur BMD is virtually never measured clinically as no consensus approach exists. This pilot study's purpose was to define regional BMD variation throughout the femur, suggest standard dual-energy X-ray absorptiometry (DXA) regions of interest (ROIs) and evaluate BMD reproducibility at these ROIs. Methods: Thirty volunteers 2-5 yr post TKA had both entire femurs imaged twice using a Lunar iDXA with subject repositioning between scans; the atypical femur fracture feature of enCORE software was utilized. To define femoral BMD distribution, custom 1 cm ROIs were stacked one atop the other starting at the intercondylar notch and continuing to the base of the lesser trochanter. Femur length was measured with the ruler tool to calculate distance at 5% increments. ROIs encompassing each 5% increment were utilized to measure BMD at each location. Descriptive statistics were used to determine mean BMD at each ROI and reproducibility at the 15%, 25%, 45%, 60%, and 80% ROIs. Results: The 5 and 10% ROIs included prosthetic and/or patella, causing high BMD values. Distal femur BMD was lowest at the 15% ROI and was higher ($p < 0.05$) at each more proximal ROI to 45%, then plateaued from 45% to 75%. BMD reproducibility at these regions was excellent; coefficient of variation (CV) from similar to 1% to 3.5%. As periprosthetic fractures generally occur in the distal femur, we propose measuring femur BMD using ROIs placed at 15% and 25%. A 60% region could also be used as a highly cortical site. Conclusion: Existing DXA capabilities allow distal femur BMD measurement with good reproducibility. Further research using standardized ROIs to assess distal femur BMD loss after TKA, and interventions to

mitigate this loss, is indicated.

TI miR-26b modulates OA induced BMSC osteogenesis through regulating GSKβ/β-catenin pathway
SO EXPERIMENTAL AND MOLECULAR PATHOLOGY
LA English
DT Article
DE BMSC; miR-26b; GSK3-beta; Osteogenesis; OA; DEX
ID mesenchymal stem-cells; osteoblast differentiation; induced osteoporosis; bone-formation; osteoactivin; dexamethasone; expression; rescues; mirnas
AB Backgrounds: Osteoactivin (OA) is a key regulator promoting bone marrow stromal cells osteogenesis progress, while Dexamethasone (Dex) could inhibit OA induced osteogenesis and lead to osteoporosis. miR-26b increased during BMSC osteogenesis but whether it participates in this progress is enigma. Osteogenesis is under regulation of canonical Wnt signaling pathway which could serve as potential target for miR-26b. It bears therapeutic potential if miR-26b could regulate osteogenesis and antagonize Dex induced Osteoporosis (OP). Methods: BMSC were isolated from bone marrow of rats and induced for osteogenesis by OA administration. We detected miR-26b mRNA level together with osteogenesis related genes or Wnt signal pathway related genes by qRT-PCR. BMSC cells with miR-26b inhibitor or mimics revealed the effect of miR-26b on osteogenesis. The osteogenesis efficiency was detected by Alizarin Red staining and ALP activity. Protein level of canonical Wnt signal pathway and other proteins were detected by Western blot. The interaction between miR-26b and GSK3 beta was detected by dual luciferase reporter assay. Results: We found that miR-26b was increased during OA induced BMSC osteogenesis. Inhibiting miR-26b could lead to osteogenesis inhibition while miR-26b mimics could promote this progress. The key regulator of Wnt signal pathway GSK3 beta is down-regulated when miR-26b was overexpressed, resulting in beta-catenin activation. Since Dex could promote GSK3 beta expression and inhibit Wnt signal, miR-26b could also alleviate Dex

induced osteogenesis inhibition. Conclusion: Our findings indicate that miR-26b promoted BMSC osteogenesis by directly targeting GSK3 beta and activating canonical Wnt signal pathway, suggesting miR-26b might be serve as potential therapeutic candidate of osteoporosis.

TI Musculoskeletal Factors and Geriatric Syndromes Related to the Absence of Musculoskeletal Degenerative Disease in Elderly People Aged over 70 Years
SO BIOMED RESEARCH INTERNATIONAL
LA English
DT Article
ID quality-of-life; locomotive syndrome; spinal alignment; body-mass; knee; health; osteoarthritis; osteoporosis; association; validation
AB Purpose. To investigate factors with a significant relationship with the absence of musculoskeletal disease (MSD: osteoporosis, knee osteoarthritis (K-OA), and lumbar spondylosis (L-OA)) in elderly people >= 70 years old. Methods. The subjects were 279 people (134 males, 145 females, mean age: 75.2 years) who attended an annual health checkup and were prospectively included in the study.

Osteoporosis was defined as %YAM <= 70%, K-OA as Kellgren-Lawrence grade >= 2, and L-OA as osteophytes of Nathan class >= 3. Subjects were divided into those with (group D) and without (group N) any MSD. Clinical variables including locomotive syndrome (LS), frailty, sarcopenia, and QOL (SF-36) were compared between the groups. Results. There was no significant difference in age or gender between group N (n=54) and group D (n=225). Lower BMI and pain, including neuropathic pain; greater back muscle strength, physical ability, and balance with eyes closed; larger lumbar lordosis, sacral inclination, and lumbar ROM; and smaller spinal inclination were found in group N. The rates of LS and sarcopenia were significantly lower and QOL was significantly higher in group N. Conclusions. This study firstly revealed the significant musculoskeletal factors and geriatric syndromes related to an absence of MSD, which may form the basis of interventions to improve QOL in elderly people >= 70 years old.

TI Consequences of bariatric surgery on outcomes in rheumatic diseases
SO ARTHRITIS RESEARCH & THERAPY
LA English
DT Review
DE Obesity; Bariatric surgery; Rheumatoid arthritis; Osteoarthritis; Gout; Psoriatic

arthritis; Fibromyalgia; Low back pain; Osteoporosis
ID morbidly obese-patients; quality-of-life; low-back-pain; psoriatic-arthritis; musculoskeletal pain; clinical-features; weight-reduction; risk-factors; bypass; osteoarthritis
AB Obesity is associated with numerous comorbidities including some rheumatic conditions. Through adipose-derived inflammation, obesity has been shown to induce increased initiation, progression, and worse responses on outcomes of rheumatic diseases. Bariatric surgery is being increasingly used thanks to its positive effects on major comorbidities such as type 2 diabetes mellitus and hypertension. Consequently, surgically induced weight and adipose tissue losses might play a role in the course of rheumatic conditions. The present narrative literature review aims to provide rheumatologists with an update on both the positive and negative effects of bariatric surgery on the rheumatic outcomes reported in the literature. Current evidence seems to show improved outcomes in obese populations with rheumatic disorders after bariatric surgery. However, rigorous prospective controlled studies with long follow-up are needed. Bariatric procedures have deleterious effects on bone and are associated with an increased risk of fractures.

TI Gut microbiota and osteoarthritis management: An expert consensus of the European society for clinical and economic aspects of osteoporosis, osteoarthritis and musculoskeletal diseases (ESCEO)
SO AGEING RESEARCH REVIEWS
LA English
DT Article
DE Osteoarthritis; Gut microbiota; Dysbiosis; Inflammaging; Obesity; Modern diet

ID body-mass index; low-grade inflammation; knee osteoarthritis; chondroitin sulfate; metabolic osteoarthritis; hand osteoarthritis; obese-patients; dietary fiber; cartilage; association
AB The prevalence of osteoarthritis (OA) increases not only because of longer life expectancy but also because of the modern lifestyle, in particular physical inactivity and diets low in fiber and rich in sugar and saturated fats, which promote chronic low-grade inflammation and obesity. Adverse alterations of the gut microbiota (GMB) composition, called microbial dysbiosis, may favor metabolic syndrome and inflammaging, two important components of OA onset and evolution. Considering the burden of OA and the need to define preventive and therapeutic interventions targeting the modifiable components of OA, an expert working group was convened by the European Society for Clinical and Economic Aspects of Osteoporosis, Osteoarthritis and Musculoskeletal Diseases (ESCEO) to review the potential contribution of GMB to OA. Such a contribution is supported by observational or dietary intervention studies in animal models of OA and in humans. In addition, several well-recognized risk factors of OA interact with GMB. Lastly, GMB is a critical determinant of drug metabolism and bioavailability and may influence the response to OA medications. Further research targeting GMB or its metabolites is needed to move the field of OA from symptomatic management to individualized interventions targeting its pathogenesis.

TI Association of blood n-3 fatty acid with bone mass and bone marrow TRAP-5b in the elderly with and without hip fracture
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE Bone mass; Bone resorption; n-3 fatty acid; Osteoporotic fracture

ID adipose-tissue; osteoporotic fracture; mineral density; older-adults; risk; consumption; omega-3-fatty-acids; biomarkers; humans; plasma
AB The SummaryThe plasma n-3 fatty acid level was 26.2% lower in patients with osteoporotic hip fracture than in those with osteoarthritis. In all patients, n-3 fatty acid was positively associated with bone mineral density and inversely associated with tartrate-resistant acid phosphatase-5b level in bone marrow aspirates, reflecting the bone microenvironment.IntroductionDespite the potential beneficial role of n-3 fatty acid (FA) on bone metabolism, the specific mechanisms underlying these effects in humans remain unclear. Here, we assessed whether the plasma n-3 level, as an objective indicator of its status, is associated with osteoporosis-related phenotypes and bone-related markers in human bone marrow (BM) samples.MethodsThis was a case-control and cross-sectional study conducted in a clinical unit. n-3 FA in the blood and bone biochemical markers in the BM aspirates were measured by gas chromatography/mass spectrometry and immunoassay, respectively. BM fluids were collected from 72 patients who underwent hip surgery because of either osteoporotic hip fracture (HF; n=28) or osteoarthritis (n=44).ResultsAfter adjusting for confounders, patients with HF had 26.2% lower plasma n-3 levels than those with osteoarthritis (P=0.006), and each standard deviation increment in plasma n-3 was associated with a multivariate-adjusted odds ratio of 0.40 for osteoporotic HF (P=0.010). In multivariate analyses including all patients, a higher plasma n-3 level was associated with higher bone mass at the lumbar spine (=0.615, P=0.002) and total femur (=0.244, P=0.045). Interestingly, the plasma n-3 level was inversely associated with the tartrate-resistant acid phosphatase-5b level (=-0.633, P=0.023), but not with the bone-specific alkaline phosphatase level, in BM aspirates.ConclusionsThese findings provide clinical evidence that n-3 FA is a potential inhibitor of osteoclastogenesis that favors human bone health.

TI Management of early-onset hip osteoarthritis in an adolescent patient with osteopetrosis tarda: a case report
SO JOURNAL OF PEDIATRIC ORTHOPAEDICS-PART B
LA English
DT Article
DE adolescent; hip; osteoarthritis; osteopetrosis
ID arthroplasty
AB Osteopetrosis (OP) is a group of rare sclerosing bone dysplasia characterized by increased bone density. The benign autosomal dominant form is the most common type. It typically carries a full life expectancy, despite increased propensity for fractures and other musculoskeletal problems, particularly hip osteoarthritis. In the current literature, the youngest OP patient having hip osteoarthritis is 16 years of

age and treated with total hip arthroplasty. Within the present study, a 16-year-old female patient with early-onset hip osteoarthritis treated with hip joint debridement and femoral head reshaping is presented. The pain relieved and hip joint movements recovered to almost normal range. At the final follow-up at 2 years after the surgery, the patient was still free of pain and ambulating without restriction. Hip joint debridement and femoral shaping may be beneficial in hip osteoarthritis secondary to OP in adolescents, and may delay hip arthroplasty in a young age.

TI FREQUENCY OF DEPRESSION AND ANXIETY SYMPTOMS IN MEXICAN PATIENTS WITH RHEUMATIC DISEASES DETERMINED BY SELF-ADMINISTERED QUESTIONNAIRES ADAPTED TO THE SPANISH LANGUAGE
SO REVISTA DE INVESTIGACION CLINICA-CLINICAL AND TRANSLATIONAL INVESTIGATION
LA English
DT Article
DE Depression; Anxiety; Mental health questionnaires; Rheumatic diseases
ID arthritis; validity; version; cohort
AB Background: The frequency of depression and anxiety symptoms in Spanish-speaking patients suffering from rheumatic conditions is unknown when using self-administered detection tools. Methods: A single-center, cross-sectional survey including 413 patients (341 women) with well-defined rheumatic diseases was conducted. The patient health questionnaire-9 (PHQ-9) and generalized anxiety disorder (GAD)-7 questionnaires were used to detect depression and anxiety symptoms, respectively. Results: A total of 193 patients (46.7%) reported depression symptoms, and increased PHQ-9 scores were more frequently observed in women than in men (23% vs. 13%; p = 0.038), particularly in association with osteoarthritis, fibromyalgia, Sjogren's syndrome, and osteoporosis. From 88 patients (21.3%) with PHQ-9 scores 10 points (moderate-to-severe depression

symptoms), 27 (30.6%) were previously diagnosed to have depression and only four were under antidepressant treatment. Anxiety symptoms were observed in 168 patients (40.6%) and classified as moderate-to-severe by elevated GAD-7 scores in 68 subjects (16.4%). Of them, 12 (17.6%) were previously diagnosed with GAD, but only 4 (5.8%) were under therapy. Conclusions: An unexpected and unusually high frequency of undiagnosed depression and anxiety symptoms was found in rheumatic patients. Self-administered screening tools adapted to the Spanish language are useful and may help clinicians to suspect these conditions.

TI Determinants, consequences and potential solutions to poor adherence to anti-osteoporosis treatment: results of an expert group meeting organized by the European Society for Clinical and Economic Aspects of Osteoporosis, Osteoarthritis and Musculoskeletal Diseases (ESCEO) and the International Osteoporosis Foundation (IOF)
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE Adherence; Determinants; Osteoporosis; Persistence; Solutions
ID shared decision-making; medication adherence; fracture risk; postmenopausal women; persistence; care; patient; interventions; bisphosphonates; nonadherence
AB A Summary Many patients at increased risk of fractures do not take their medication appropriately, resulting in a substantial decrease in the benefits of drug therapy. Improving medication adherence is urgently needed but remains laborious, given the numerous and multidimensional reasons for non-adherence, suggesting the need for measurement-guided, multifactorial and individualized solutions. Introduction Poor adherence to medications is a major challenge in the treatment of osteoporosis. This paper aimed to provide an overview of the consequences, determinants and potential solutions to poor adherence and persistence to osteoporosis medication. Methods A working group was organized by the European Society on Clinical and Economic Aspects of Osteoporosis, Osteoarthritis and Musculoskeletal diseases (ESCEO) to review consequences, determinants and potential solutions to adherence and to make recommendations for practice and further research. A systematic literature review and a face-to-face experts meeting were undertaken. Results Medication non-adherence is associated with increased risk of fractures, leading to a substantial decrease in the clinical and economic benefits of drug therapy. Reasons for non-adherence are numerous and multidimensional for each patient, depending on the interplay of multiple factors, suggesting the need for multifactorial and individualized solutions. Few interventions have been shown to improve adherence or persistence to osteoporosis treatment. Promising actions include patient education with counselling, adherence monitoring with feedback and dose simplification including flexible dosing regimen. Recommendations for practice and further research were also provided. To adequately manage adherence, it is important to (1) understand the problem (initiation, implementation and/or persistence), (2) to measure adherence and (3) to identify the reason of non-adherence and fix it. Conclusion These recommendations are intended for clinicians to manage adherence of their patients and to researchers and policy makers to design, facilitate and appropriately use adherence interventions.

ID qsar models; derivatives; discovery; validation; 3d-qsar; optimization; exploration; solubility; principles; define
AB Cathepsin K (CK) is the only cathepsin showing high expression in osteoclasts. CK is considered to be a drug target in treatment of osteoporosis, rheumatoid arthritis and osteoarthritis. Comprehensive application of quantitative structure-activity relationships (QSAR), molecular docking and absorption, distribution, metabolism, excretion and toxicity (ADMET) prediction was conducted for designing and screening for potential CK inhibitors based on 2-cyano-pyrimidine analogs. For the two-dimensional (2D)-QSAR study, a statistical model of PLS_FCFP was chosen for its best evaluated regression statistic values (r(2) = 0.759, q(2) = 0.637 and r(pred)(2) = 0.699). An equation that implied positive or negative contributions for several molecular descriptors was acquired. For the 3D-QSAR study, based on two methods of generation of molecular poses, three fingerprint-based cluster partitions, and two common substructures, 336 candidate CoMFA and CoMSIA models were generated for evaluation of statistic values. Among them, database Minimize_MDL_subs01 provided superior evaluated models: CoMFA model #41 (r(2) = 0.994, q(2) = 0.746 and r(pred)(2) = 0.8693) and CoMSIA model #42 (r(2) = 0.983, q(2) = 0.753 and r(pred)(2) = 0.8676). Informative clues for molecular design were derived from the created QSAR models and, based on them, an in-house library containing 190 purposefully designed unknown compounds was built for screening for potential CK inhibitors. Based on a combination of activity prediction and calculation of binding affinity, unknown

compound X139 emerged. Detailed molecular docking studies assisted in unveiling of the interactions between unknown compounds and the target protein. The strong pi-pi conjugation and preferably formed hydrogen bonds provided evidence that compound X139 had higher predicted activity. The subsequent study of ADMET prediction suggested acceptable drug-like properties for compound X139. (C) 2019 Elsevier B.V. All rights reserved.

TI Seno-suppressive molecules as new therapeutic perspectives in rheumatic diseases
SO BIOCHEMICAL PHARMACOLOGY
LA English
DT Review
DE Senescence; Therapies; Osteoarthritis; Osteoporosis; Rheumatology
ID senescent cells; cellular senescence; mitochondrial dysfunction; articular-cartilage; chondrocyte senescence; secretory phenotype; subchondral bone; telomeric loss; autophagy; osteoarthritis
AB Over the past years, through in vitro studies and unique animal models, biologists and clinicians have demonstrated that cellular senescence is at the root of numerous age-related chronic diseases including osteoarthritis and osteoporosis. This non-proliferative cellular syndrome can modify other surrounding tissue-resident cells through the establishment of a deleterious

catabolic and inflammatory microenvironment. Targeting these deleterious cells through local or systemic seno-therapeutic agent delivery in pre-clinical models improves dramatically clinical signs and extends health span. In this review, we will summarize the current knowledge on cellular senescence, list the different strategies for identifying seno-suppressive therapeutic agents and their translations to rheumatic diseases.

TI CORRELATION OF PRE-OPERATIVE PLANNING TO SURGICAL CORRECTION OF OPENING WEDGE HTO: A RADIOGRAPHIC STUDY UTILIZING A MANUAL MEASUREMENT METHOD
SO JOURNAL OF BIOLOGICAL REGULATORS AND HOMEOSTATIC AGENTS
LA English
DT Article
DE high tibial osteotomy; genu varum; mechanical axis correction; opening wedge
ID high tibial osteotomy; varus deformity; fixation; osteoarthritis; complications; stability; plate; knee
AB High tibial osteotomy (HTO) utilizing a medial opening wedge has become a common and effective surgical technique for treatment of isolated medial compartment knee osteoarthritis secondary to varus malalignment. To reduce the risk of under- or overcorrection, accurate preoperative planning is important. This is a radiographic study to evaluate the reliability of preoperative measurement on full-length weight-bearing X-rays (FLWBXr) compared to post-operative X-rays

after healing. In addition, we calculated if the intraoperative opening wedge performed was consistent with the preoperative calculation and the postoperative correction. Three independent observers measured preoperative and postoperative FLWBXr at three different times. The angle of varus deformity; the angle to correct and the wedge needed to achieve desired alignment: the angle achieved postoperatively, and the postoperative mechanical axis deviation were measured. Intra- and inter-rater reliability showed high values for all the investigated parameters. The discrepancy between the calculated wedge and the wedge actually used in surgery ranged from 1 mm of over-correction to 3 mm of undercorrection, averaging -1.3 mm. The mechanical axis crossed the tibial plateau an average of 53% +/- 12.7. Clustering the data by the plate type statistically significant differences were found for preoperative varus alignment, advocated correction, intraoperative correction and post-op alignment. The Dugdale method can be considered highly reliable. Possible factors affecting the final correction are: surgeon's desire not to overcorrect in young patients and minimal osteoarthritis; measurement errors; variability in the method the FLWBXr is performed. In addition, the under correction could be the result of some collapse with time or the correction could be affected by the fixation system. Further investigation should include complete post-operative evaluation of outcomes and assess the role of these potential factors and their relationship to correction. Level of Evidence: Level III, Retrospective study.

TI Living in immigrant communities does not impact total knee arthroplasty outcomes: experience from a high-volume center in the United States

SO BMC MUSCULOSKELETAL DISORDERS
LA English
DT Article
ID total joint arthroplasty; total hip; disparity; replacement; health; neighborhoods; projections; limitations; arthritis; born
AB BackgroundCommunity characteristics such as poverty affect total knee arthroplasty (TKA) outcomes. However, it is unknown whether other community factors such as immigrant proportion (IP) also affect outcomes. Our objective was to determine the association of neighborhood IP on preoperative (pre-op) and 2-year postoperative (post-op) Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) pain and function after elective TKA.MethodsPatients in a high volume institutional TKA registry between May 2007 and February 2011 were retrospectively analyzed. Demographics, pre-op and 2-year post-op WOMAC pain and function scores, and geocodable addresses were obtained. Patient-level variables were linked to US Census Bureau census tract data. The effect of patient and neighborhood-level factors on WOMAC scores were analyzed using linear mixed effects models.Results3898 TKA patients were analyzed. Pre-op and 2-year post-op WOMAC pain and function scores were between 2.75-4.88 WOMAC points worse in neighborhoods with a high IP (40%) compared to low IP (<10%). In multivariable analyses, these differences were not statistically significant. Women had worse pre-op and 2-year post-op WOMAC scores (all p0.04), but this difference was not influenced by neighborhood IP (all p(interaction) NS).ConclusionsPatients living in high (40%) IP neighborhoods do not have worse pre-op or 2-year post-op pain and function outcomes after TKA compared to those living in low (<10%) IP neighborhoods. Although sex differences favoring males are notable, these differences are not associated with IP. High neighborhood IP do not appear to affect outcomes after TKA.

TI Is the bone tissue of the femoral neck demineralised in patients with hip fracture?
SO INJURY-INTERNATIONAL JOURNAL OF THE CARE OF THE INJURED
LA English

DT Article
DE Mineralisation; Osteoporosis; Bone metabolism; Hip fracture; Surgical treatment; Hip osteoarthritis; Microstructural trabecular bone
ID eye cataract-surgery; x-ray-microanalysis; older-people; falls; prevention; injury; osteoporosis; risk; malnutrition; supplements
AB The aim of this study is to establish the falsifiability of the "osteoporotic hypothesis" for hip fracture, according to which the bone density and mineral composition of bone tissue in patients with hip fracture is poorer than when no such fracture is present, and that this circumstance is relevant to the occurrence of a fracture. The study population consisted of forty patients treated with arthroplasty. Twenty patients with femoral neck fracture and another twenty with hip osteoarthritis received the same diagnostic protocol and the same antibiotic, anaesthetic, surgical and antithrombotic prophylaxis. Levels of calcium (Ca), phosphorus (P) and vitamin D in blood, amongst other values, were determined, and five samples of bone tissue from the proximal femoral metaphysis were obtained and characterised by optical microscopy and microanalytical analysis. No statistically significant differences were observed between the two groups with respect to the trabecular number, area or thickness, or inter-trabecular distance. However, there were differences in the length of the trabeculae, which was greater in the patients with hip osteoarthritis ($p = 0.002$), but not when the groups were compared by gender. When compared by age, a greater inter-trabecular distance was observed in the patients aged over 75 years ($p = 0.036$) but there were no differences in the remaining parameters. Serum levels of Ca ($p = 0.03$), P ($p < 0.01$) and vitamin D ($p < 0.01$) were lower in the fracture group. In the quantitative microanalytical analysis, no significant differences were observed in bone levels of Ca or P or in the Ca/P index, nor was there any correlation between serum and levels of bone Ca or P (Ca-0.197:$p = 0.314$;P-0.274:$p = 0.158$).Multiple linear regression revealed no correlation between the diagnoses, vitamin D and bone levels of Ca or P. Despite the reduced serum levels of Ca and P in the patients with hip fracture, no correlation was observed with bone levels of Ca and P,which were similar in both groups. There were differences in the organic bone structure, in terms of length and inter-trabecular distance. For patients with osteoporosis, treatment should be aimed at increasing the synthesis of bone trabeculae to reinforce their structure. Nevertheless, no such treatment can prevent falls, and therefore no reduction in hip fractures amongst this population can be assured. (C) 2020 Elsevier Ltd. All rights reserved.

TI The Role of Mast Cells in Bone Metabolism and Bone Disorders
SO FRONTIERS IN IMMUNOLOGY
LA English
DT Review
DE mast cells; inflammation; bone disorders; osteoporosis; fracture healing
ID growth-factor-beta; necrosis-factor-alpha; human osteoclast formation; antigen-induced arthritis; colony-stimulating factor; kappa-b ligand; rheumatoid-arthritis; systemic mastocytosis; neutrophil recruitment; substance-p
AB Mast cells (MCs) are important sensor and effector cells of the immune system that are involved in many physiological and pathological conditions. Increasing evidence suggests that they also play an important role in bone metabolism and bone disorders. MCs are located in the bone marrow and secrete a wide spectrum of mediators, which can be rapidly released upon activation of mature MCs following their differentiation in mucosal or connective tissues. Many of these mediators can exert osteocatabolic effects by promoting osteoclast formation [e.g., histamine, tumor necrosis factor (TNF), interleukin-6 (IL-6)] and/or by inhibiting osteoblast activity (e.g., IL-1, TNF). By contrast, MCs could potentially act in an osteoprotective manner by stimulating osteoblasts (e.g., transforming growth factor-beta) or reducing osteoclastogenesis (e.g., IL-12, interferon-gamma). Experimental studies investigating MC functions in physiological bone turnover using MC-deficient mouse lines give contradictory results, reporting delayed or

increased bone turnover or no influence depending on the mouse model used. By contrast, the involvement of MCs in various pathological conditions affecting bone is evident. MCs may contribute to the pathogenesis of primary and secondary osteoporosis as well as inflammatory disorders, including rheumatoid arthritis and osteoarthritis, because increased numbers of MCs were found in patients suffering from these diseases. The clinical observations could be largely confirmed in experimental studies using MC-deficient mouse models, which also provide mechanistic insights. MCs also regulate bone healing after fracture by influencing the inflammatory response toward the fracture, vascularization, bone formation, and callus remodeling by osteoclasts. This review summarizes the current view and understanding of the role of MCs on bone in both physiological and pathological conditions.

ID causes spondylocostal dysostosis; alagille-syndrome; chondrocyte differentiation; osteoclast precursors; intracellular domain; articular-cartilage; missense mutations; synovial joint; mouse model; bone
AB Skeletal development is a complex process which requires the tight regulation of gene activation and suppression in response to local signaling pathways. Among these pathways, Notch signaling is implicated in governing cell fate determination, proliferation, differentiation and apoptosis of skeletal cells-osteoblasts, osteoclasts, osteocytes and chondrocytes. Moreover, human genetic mutations in Notch components emphasize the critical roles of Notch signaling in skeletal development and homeostasis. In this review, we focus on the physiological roles of Notch signaling in skeletogenesis, postnatal bone and cartilage homeostasis and fracture repair. We also discuss the pathological gain- and loss-of-function of Notch signaling in bone and cartilage, resulting in osteosarcoma and age-related degenerative diseases, such as osteoporosis and osteoarthritis. Understanding the physiological and pathological function of Notch signaling in skeletal tissues using animal models and human genetics will provide new insights into disease pathogenesis and offer novel approaches for the treatment of bone/cartilage diseases.

DE metabolomics; arthritis; inflammatory arthropathy; small molecule metabolite synovial fluid; arthritis biomarker
ID human synovial-fluid; rheumatoid-arthritis; knee osteoarthritis; h-1-nmr spectroscopy; metabolites; reveals; signature; subtypes
AB Osteoarthritis and inflammatory arthropathies are a cause of significant morbidity globally. New research elucidating the metabolic derangements associated with a variety of bone and joint disorders implicates various local and systemic metabolites, which further elucidate the underlying molecular mechanisms associated with these destructive disease processes. In osteoarthritis, atty acid metabolism has been implicated in disease development, both locally and systemically. Several series of rheumatoid arthritis patients have demonstrated overlapping trends related to histidine and glyceric acid, while other series showed similar results of increased cholesterol and glutamic acid. Studies comparing osteoarthritis and rheumatoid arthritis reported elevated gluconic acid and glycolytic- and tricarboxylic acid-related substrates in patients with osteoarthritis, while lysosphingolipids and cardiolipins were elevated only in patients with rheumatoid arthritis. Other bone and joint disorders, including osteonecrosis, intervertebral disc degeneration, and osteoporosis, also showed significant alterations in metabolic processes. The identification of the molecular mechanisms of osteoarthritis and inflammatory arthropathies via metabolomics-based workflows may allow for the development of new therapeutic targets to improve the quality of life in these patient populations.

ID bone-mineral density; vitamin-d deficiency; practice guidelines; north-africa; middle-east; saudi; fractures; population
AB The Summary A consensus platform is provided by the experts of the Gulf Cooperation Council (GCC) countries' respective osteoporosis societies, on which specific guidelines can be developed further for regional use on the assessment and treatment of postmenopausal women at risk from fractures due to osteoporosis. Introduction Guidance is provided in a Gulf Cooperation Council (GCC) country setting on the assessment and treatment of postmenopausal women at risk from fractures due to osteoporosis, which is an adaptation of the European guidance by Kanis et al., jointly published by the International Osteoporosis Foundation and the European Society for Clinical and Economic Aspects of Osteoporosis and Osteoarthritis (ESCEO). The respective osteoporosis societies of the Gulf Cooperation Council (GCC) countries assembled for a unifying consensus

on the diagnosis and management of osteoporosis in postmenopausal women for the region. Methods The Chair for Biomarkers of Chronic Diseases (CBCD) in King Saud University (KSU), Riyadh, Kingdom of Saudi Arabia (KSA), in cooperation with the Saudi Osteoporosis Society (SOS), hosted regional experts and respective leaders from different GCC osteoporosis societies, together with an adviser from the ESCEO. An assembly of experts representing the different osteoporosis societies from Saudi Arabia, the UAE, Bahrain, Oman, and Kuwait gathered on February 15-16, 2019 in Riyadh, KSA for the formulation of a general osteoporosis consensus for the region. Results The following areas were covered: diagnosis of osteoporosis and assessment of fracture risk; general and pharmacological management of osteoporosis; and hip fractures, vitamin D, recommendation on which FRAX tool to follow, and the importance of country-specific FRAX (R) and fracture liaison services for secondary fracture prevention. Conclusions A platform is provided on which specific guidelines can be developed for regional use in GCC.

TI DNA methylation of noncoding RNAs: new insights into osteogenesis and common bone diseases
SO STEM CELL RESEARCH & THERAPY
LA English
DT Review
DE DNA methylation; Noncoding RNAs; Osteogenesis; Bone
ID mesenchymal stem-cells; signaling pathway; osteosarcoma; differentiation; protein; proliferation; demethylation; osteoarthritis; regeneration; pathogenesis
AB Bone diseases such as osteoarthritis, osteoporosis, and bone tumor present a severe public health problem. Osteogenic differentiation is a complex process associated with the differentiation of different cells, which could regulate transcription factors, cytokines, many signaling pathways, noncoding RNAs (ncRNAs), and epigenetic modulation. DNA methylation is a kind of stable epigenetic alterations in CpG islands without DNA sequence changes and is involved in cancer and other diseases, including bone development and homeostasis. ncRNAs can perform their crucial biological functions at the RNA level, and many findings have demonstrated essential functions of ncRNAs in osteogenic differentiation. In this review, we highlight current researches in DNA methylation of two relevant ncRNAs, including microRNAs and long noncoding RNAs, in the initiation and progression of osteogenesis and bone diseases.

TI Serum concentrations of pesticides including organophosphates, pyrethroids and neonicotinoids in a population with osteoarthritis in Saudi Arabia
SO SCIENCE OF THE TOTAL ENVIRONMENT
LA English
DT Article
DE Organophosphate; Pyrethroid; Neonicotinoid; Metabolite; Biomonitoring
ID urinary concentrations; exposure assessment; dietary exposure; metabolites; insecticides; children; epidemiology; herbicides; health
AB Human exposure to pesticides is widespread and has received much attention in recent years because of its link to adverse health outcomes. Measurement of urinary concentrations of pesticides and their metabolites is often used in the assessment of body burdens of these chemicals. However, pesticides and their metabolites can be present in blood circulatory system, although little is known on serum levels of pesticides. In this study, we aimed to examine the occurrence and profile of four organophosphate (OP), five pyrethroid (PYR) insecticides, two phenoxy acid (PA) herbicides, 14 neonicotinoid (neonic) insecticides and six dialkylphosphate metabolites in serum from 25 individuals diagnosed with osteoarthritis in Jeddah, Saudi Arabia. 2-Isopropyl-4-methyl-6-hydroxypyrimidine (IMPY), 3,5,6-trichloro-2-pyridinol (TCPY), 2,4-dichlorophenoxyacetic acid, 2,4,5-trichlorophenoxyacetic acid, 3-phenoxybenzoic acid, N-desmethyl acetamiprid, dimethylphosphate (DMP) and dimethylthiophosphate (DMTP) were detected in >= 80% of the serum samples analyzed. Metabolites of OPs, DMTP (median concentration: 2.14 ng/mL), DMP (1.04 ng/mL) and TCPY (0.84 ng/mL), collectively accounted for 67-83% of the total serum pesticide concentrations. Serum concentrations of pesticides were similar to or lower than those reported in urine. Our preliminary evidence suggests that serum can be used as a matrix for the assessment of exposure to OPs, PYRs, PAs and neonics. (C) 2020 Elsevier B.V. All rights reserved.

TI Influence of Extracellular Vesicles Isolated From Osteoblasts of Patients With Cox-Arthrosis and/or Osteoporosis on Metabolism and Osteogenic Differentiation of BMSCs
SO FRONTIERS IN BIOENGINEERING AND BIOTECHNOLOGY
LA English
DT Article
DE extracellular vesicles; mesenchymal stem cells; osteoblasts; osteoarthritis; osteoporosis; EVs; osteogenic differentiation
ID mesenchymal stem-cells; estrogen deficiency; exosm; osteoarthritis; proliferation; epidemiology; apoptosis; culture; repair; rna
AB Background: Studies with extracellular vesicles (EVs), including exosomes, isolated from mesenchymal stem cells (MSC) indicate benefits for the treatment of musculoskeletal pathologies as osteoarthritis (OA) and osteoporosis (OP). However, little is known about intercellular effects of EVs derived from pathologically altered cells that might influence the outcome by counteracting effects from "healthy" MSC derived EVs. We hypothesize, that EVs isolated from osteoblasts of patients with hip OA (coxarthrosis/CA), osteoporosis (OP), or a combination of both (CA/OP) might negatively affect metabolism and osteogenic differentiation of bone-marrow derived (B)MSCs. Methods: Osteoblasts, isolated from bone explants of CA, OP, and CA/OP patients, were compared regarding growth, viability, and osteogenic differentiation capacity. Structural features of bone explants were analyzed via mu CT. EVs were isolated from supernatant of naive BMSCs and CA, OP, and CA/OP osteoblasts (osteogenic culture for 35 days). BMSC cultures were stimulated with EVs and subsequently, cell metabolism, osteogenic marker gene expression, and osteogenic differentiation were analyzed. Results: Trabecular bone structure was

different between the three groups with lowest number and highest separation in the CA/OP group. Viability and Alizarin red staining increased over culture time in CA/OP osteoblasts whereas growth of osteoblasts was comparable. Alizarin red staining was by trend higher in CA compared to OP osteoblasts after 35 days and ALP activity was higher after 28 and 35 days. Stimulation of BMSC cultures with CA, OP, and CA/OP EVs did not affect proliferation but increased caspase 3/7-activity compared to unstimulated BMSCs. BMSC viability was reduced after stimulation with CA and CA/OP EVs compared to unstimulated BMSCs or stimulation with OP EVs. ALP gene expression and activity were reduced in BMSCs after stimulation with CA, OP, and CA/OP EVs. Stimulation of BMSCs with CA EVs reduced Alizarin Red staining by trend. Conclusion: Stimulation of BMSCs with EVs isolated from CA, OP, and CA/OP osteoblasts had mostly catabolic effects on cell metabolism and osteogenic differentiation irrespective of donor pathology and reflect the impact of tissue microenvironment on cell metabolism. These catabolic effects are important for understanding differences in effects of EVs on target tissues/cells when harnessing them as therapeutic drugs.

TI Chronic pain and use of analgesics in the elderly: a nationwide population-based study
SO ARCHIVES OF MEDICAL SCIENCE
LA English

DT Article
DE acetaminophen; chronic pain; elderly; geriatric; non-steroidal anti-inflammatory drugs
ID term mortality risk; geriatric-patients; spinal-disorders; management; osteoarthritis; prevalence; arthritis; taiwan; age
AB Introduction: Chronic pain may cause many comorbidities in the elderly; however, nationwide data about this issue remain insufficient. We conducted this study to address the data gap. Material and methods: We identified geriatric participants (>= 65 years) with chronic pain between 2000 and 2013 from the Taiwan National Health Insurance Research Database. The causes of chronic pain and use of analgesics between two sexes and among three age subgroups were compared. Results: A total of 21,018 participants were identified with the mean age (standard deviation) of 72.7 years (5.6) and the female percentage of 50.8%. The prevalence of chronic pain in the elderly was 21.5%, and it was higher in the females than males. The proportions of each age subgroup were 65-74 (66.8%), 75-84 (29.4%), and >= 85 years (3.8%). Common causes of chronic pain were osteoarthritis (21.9%), spinal disorders (19.0%), peripheral vascular diseases (12.4%), and osteoporosis (11.4%). Non-steroidal anti-inflammatory drugs were the most common medication, followed by acetaminophen and opioids. The most commonly used opioid was morphine. The use of opioids increased with age. Conclusions: This study delineated the causes of chronic pain and use of analgesics in a geriatric population, which may help further studies about this issue in the future.

TI Bisphosphonate Use Is Protective of Radiographic Knee Osteoarthritis Progression Among those With Low Disease Severity and Being Non-Overweight: Data From the Osteoarthritis Initiative
SO JOURNAL OF BONE AND MINERAL RESEARCH
LA English
DT Article
DE ANTIRESORPTIVES; BONE HISTOMORPHOMETRY; FRACTURE RISK ASSESSMENT; OSTEOARTHRITIS; OSTEOPOROSIS
ID bone-marrow lesions; subchondral bone; intraarticular clodronate; hip osteoarthritis; osteoporosis; fracture; association; adherence; symptoms; turnover
AB Antiresorptive medications have been explored for treating knee osteoarthritis (OA); however, little data exist on the effects of today's more potent nitrogen-containing oral bisphosphonates on radiographic disease-progression in patients with varying disease-severity, especially those who are not overweight. The primary objective of this cohort study was to determine if the use of bisphosphonates is protective against 2-year radiographic-progression of knee OA in Osteoarthritis Initiative (OAI) participants, stratified by baseline radiographic disease status. Secondary objectives were to examine effects in non-overweight participants (body mass index [BMI] < 25 kg/m(2)) and cumulative bisphosphonate exposure effects. We identified female OAI participants aged >= 50 years and excluded those missing baseline radiograph readings, bisphosphonate use information, or all clinical questionnaire information at baseline. Participants reporting bisphosphonate use (69% alendronate) were propensity-matched 1:1 to non-bisphosphonate users and followed until first radiographic knee OA progression (1-unit increase in Kellgren and Lawrence [KL] grade) or data were censored (first missed visit or end of 2-year follow-up). Discrete-time logistic regression models estimated hazard ratios (HRs) between bisphosphonate users versus nonusers, with an interaction term for baseline KL grade (KL <2 or KL >= 2). We identified 1977 eligible women (n= 346 bisphosphonate users). Propensity-matched results indicated that bisphosphonate users with KL grade <2 were protected against progression (HR(KL<2)0.53; 95% CI, 0.35 to 0.79), while bisphosphonate use was not associated with radiographic progression in those with KL grade >= 2 (HR(KL >= 2)1.06; 95% CI, 0.83 to 1.35). When restricting analyses to those with BMI <25 kg/m(2), effects were strengthened (HR(KL<2)0.49 [95% CI, 0.26 to 0.92]; HR(KL >= 2)0.69 [95% CI, 0.33 to 1.26]). Duration of bisphosphonate use had no effect on progression, though sample size was limited. Bisphosphonate therapy may be protective against radiographic knee OA progression in early-stage patients, particularly those who are non-overweight, but less so for those with more advanced disease or more weight-bearing joint stress.

TI Association of the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) with Muscle Strength in Community-Dwelling Elderly with Knee Osteoarthritis
SO INTERNATIONAL JOURNAL OF ENVIRONMENTAL RESEARCH AND PUBLIC HEALTH
LA English
DT Article
DE muscle strength; WOMAC; osteoarthritis
ID body-composition; physical-activity; risk-factor; weakness; pain; incident; healthy; women; life
AB Purpose: The purpose of this study was to evaluate the correlation between muscle strength and knee symptoms (pain, stiffness, and functional limitation) regardless of the presence of radiologic knee osteoarthritis (RKOA) in community-dwelling elderly. Patients and methods: This cross-sectional study used data from the Namgaram-2 cohort. The Namgaram-2 cohort consisted of participants living in three rural communities. Such participants were included for studies on activity limitation due to age-related musculoskeletal disorders including knee osteoarthritis, osteoporosis, and sarcopenia. The Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC), a health assessment tool for patients with arthritis in lower extremities, was used to assess health-related quality of life (HRQOL). Muscle strengths were measured by knee strength (by using the isokinetic dynamometer) and hand grip strength. Results: The WOMAC pain of Kallgren-Lawrence (K/L) grade < 2 was correlated with age, grip strength, nutrition status, and knee extension 180 peak torque. The WOMAC pain of K/L grade <greater than or equal to> 2 was correlated with age, nutrition status, and knee extension 60 peak torque. The WOMAC stiffness of K/L grade < 2 was correlated with having a spouse, nutrition status, and knee extension 60 peak torque. The WOMAC stiffness of K/L grade <greater than or equal to> 2 was correlated with knee extension 60 peak torque. The WOMAC function of K/L grade < 2 was correlated with age, grip strength, osteoporosis, nutrition status, and knee extension 180 peak torque. The WOMAC function of K/L grade <greater than or equal to> 2 was correlated with age, nutrition status, and knee extension 60 peak torque. Conclusion: Muscle strength as measured by grip strength and knee extension was statistically significantly correlated with the WOMAC scores in patients with knee symptoms regardless of whether radiologic signs of knee osteoarthritis were observed.

TI Longitudinal changes in bone mineral density and trabecular bone score in Korean adults: a community-based prospective study
SO ARCHIVES OF OSTEOPOROSIS
LA English
DT Article
DE Osteoporosis; Natural history; Bone mineral density; Aging
ID lumbar spine; risk-factors; elderly-men; osteoporosis; age; association; women; tbs; osteoarthritis; population
AB The bone mineral densities (BMDs) of the femoral neck and total hip, and the lumbar spine trabecular bone score (TBS), tended to decrease with age in both men and women, whereas the lumbar spine BMD tended to increase. Lumbar spine BMD is thus inappropriate for evaluating longitudinal changes in bone loss; the lumbar spine TBS is an alternative measure. Purpose Aging is associated with a decrease in bone mass and quality. This community-based prospective cohort study investigated longitudinal changes in bone phenotype in Korean adults. Methods We analyzed data from a prospective community-based cohort study, the Korean Genome and Epidemiology Study. Postmenopausal women and men who underwent dual-energy X-ray absorptiometry at least twice from 2007 to 2014 were included. Longitudinal changes in bone mineral density (BMD) and trabecular bone score (TBS) over 6 years were analyzed by sex, age, and body mass index. Results A total of 1895 subjects were enrolled (men 965; postmenopausal women 929). The femoral neck (FN) BMD, total hip (TH) BMD, and lumbar spine (LS) TBS decreased significantly over time, but the LS BMD increased significantly. In men, the average annual changes were 0.3% in LS BMD ($p < 0.001$), - 0.33% in FN BMD ($p < 0.001$), - 0.26% in TH BMD ($p = 0.001$), and - 0.27% in LS TBS ($p < 0.001$). In women, the average annual changes were 0.27% in LS BMD ($p < 0.001$), - 0.67% in FN BMD ($p < 0.001$), - 0.66% in TH BMD ($p < 0.001$), and - 0.27% in LS TBS ($p < 0.001$). The longitudinal decrease in TH BMD over time was significantly greater in women (versus men) and those who were older (versus younger). Conclusion The

FN and TH BMDs decreased with aging. But, the LS BMD was inappropriate to evaluate longitudinal changes of bone loss. The LS TBS could be alterative.

TI Arthroscopic ankle fusion only has a limited advantage over the open operation if osseous operation type is the same: a retrospective comparative study
SO JOURNAL OF ORTHOPAEDIC SURGERY AND RESEARCH
LA English
DT Article
DE Arthroscopic ankle fusion; Open ankle fusion; Selection bias; Follow-up; Questionnaire survey
ID avascular necrosis; arthrodesis; expectations; arthritis; osteoarthritis; replacement; fixation; outcm; hindfoot; risk
AB Background A great deal of research suggests that arthroscopic ankle fusion (AAF) has advantages over open ankle fusion (OAF), but these outcomes would be imprecise because of a selection bias. The purpose of this study is to verify which is better for ankle fusion, AAF or OAF. We regrouped the OAF group into two subgroups according to whether the osseous operation type is the same as AAF group. The goal is to minimize the impact of disease severity, thereby reducing selection bias to some extent. Methods We retrospectively analyzed the data of ankle fusion in our hospital between July 2015 and October 2018. Forty-three patients were enrolled and divided into AAF group (n = 17) and OAF group (n = 26). In order to eliminate selection bias, we divided OAF group into complex osseous operation subgroup (COO subgroup) (n = 15) and simple osseous operation subgroup (SOO subgroup) (n = 11). The osseous operation type of SOO subgroup is the same as AAF group. Then, we compared the differences between these groups. All patients were followed up at least 1 year after operation. We analyzed data, including etiology composition, surgical time, intra-op blood loss, reduction of albumin, total hospital stays, union time, fusion situation, complications, radiological examination, functional score, and questionnaire survey. Then we performed statistical analyses. Results We found that the etiological components of AAF group and OAF group were different; the etiological components of AAF group and SOO subgroup were similar. We found that AAF

group has advantages over OAF group and COO subgroup in general. However, except in terms of surgical trauma, hospital stays, and short-term complications occurred, the AAF group has not obvious advantages over SOO subgroup, including intra-op blood loss, fusion condition, postoperative function score, and postoperative patient satisfaction; and AAF group need more surgical time than the SOO subgroup. Conclusions The arthroscopic ankle fusion can bring a good curative effect; however, if the osseous operation type is the same, the arthroscopic ankle fusion only has a limited advantage over the traditional open operation in perioperative soft tissue protection and enhanced recovery after surgery.

TI Long Noncoding RNAs as Bone Marrow Stem Cell Regulators in Osteoporosis
SO DNA AND CELL BIOLOGY
LA English
DT Article
DE mesenchymal stem cells; epigenetics; noncoding RNA; gene expression; osteoporosis
ID expression; tophat; gene
AB Long noncoding RNAs (lncRNAs) contribute toward regulating gene expression and cell differentiation and may be involved in the pathogenesis of several diseases. The objective of this study was to determine the expression patterns of lncRNAs in bone marrow mesenchymal stem cells (BMSCs) derived from patients with osteoporotic fractures and their relevance to osteogenic function. The BMSCs were isolated from the femoral head of patients with hip fractures (FRX) and controls with osteoarthritis (OA). We found 74 differentially expressed genes between FRX and OA, of which 33 were of the lncRNA type. Among them, 52 genes (20 lncRNAs) were replicated in another independent dataset. The differentially expressed lncRNAs were over-represented among those correlated with differentially expressed protein-coding genes. In addition, the comparison of pre- and post-differentiated paired samples revealed 163 differentially expressed genes, of which 99 were of the lncRNA type. Among them, the overexpression ofLINC00341induced an upregulation of typical osteoblastic genes. In conclusion, the analysis of lncRNA expression in BMSCs shows specific patterns in patients with osteoporotic fractures, as well as changes associated with osteogenic differentiation. The regulation of bone genes through lncRNAs might bring new opportunities for designing bone anabolic therapies in systemic and localized bone disorders.

TI Association of Tramadol Use With Risk of Hip Fracture
SO JOURNAL OF BONE AND MINERAL RESEARCH
LA English
DT Article
DE COHORT; FRACTURE; TRAMADOL
ID initiated opioid treatment; fall-related injury; trends; osteoporosis; management; recommendations; osteoarthritis; prescription; pharmacology; cohort
AB Several professional organizations have recommended tramadol as one of the first-line or second-line therapies for patients with chronic noncancer pain and its prescription has been increasing rapidly worldwide; however, the safety profile of tramadol, such as risk of fracture, remains unclear. This study aimed to examine the association of tramadol with risk of hip fracture. Among individuals age 50 years or older without a history of hip fracture, cancer, or opioid use disorder in The Health Improvement Network (THIN) database in the United Kingdom general practice (2000-2017), five sequential propensity score-matched cohort studies were assembled, ie, participants who initiated tramadol or those who initiated one of the following medications: codeine (n = 146,956) (another commonly used weak opioid), naproxen (n = 115,109) or ibuprofen (n = 107,438) (commonly used nonselective nonsteroidal anti-inflammatory drugs [NSAIDs]), celecoxib (n = 43,130), or etoricoxib (n = 27,689) (cyclooxygenase-2 inhibitors). The outcome was incident hip fracture over 1 year. After propensity-score matching, the included participants had a mean age of 65.7 years and 56.9% were women. During the 1-year follow-up, 518 hip fracture (3.7/1000 person-years) occurred in the tramadol cohort and 401 (2.9/1000 person-years) occurred in the codeine cohort. Compared with codeine, hazard ratio (HR) of hip fracture for tramadol was 1.28 (95% confidence interval [CI] 1.13 to 1.46). Risk of hip fracture was also higher in the tramadol cohort than in the naproxen (2.9/1000 person-years for tramadol, 1.7/1000 person-years for naproxen; HR = 1.69, 95% CI 1.41 to 2.03), ibuprofen (3.4/1000 person-years for tramadol, 2.0/1000 person-years for ibuprofen; HR = 1.65, 95% CI 1.39 to 1.96), celecoxib (3.4/1000 person-years for tramadol, 1.8/1000 person-years for celecoxib; HR = 1.85, 95% CI 1.40 to 2.44), or etoricoxib (2.9/1000 person-years for tramadol, 1.5/1000 person-years for etoricoxib; HR = 1.96, 95% CI 1.34 to 2.87) cohort. In this population-based cohort study, the initiation of tramadol was associated with a higher risk of hip fracture than initiation of codeine and commonly used NSAIDs, suggesting a need to revisit several guidelines on tramadol use in clinical practice. TI Cycloastragenol prevents age-related bone loss: Evidence in D-galactose-treated and aged rats
SO BIOMEDICINE & PHARMACOTHERAPY
LA English
DT Article
DE Cycloastragenol; Aging; Osteoporosis; Osteoactivin
ID formation in-vivo; osteoblast differentiation; enhances bone; osteoporosis; metabolism; activation; resorption; toxicity; mutation; disease
AB Background and aims: Aging-induced bone loss is a multifactorial, age-related, and progressive phenomenon among the general population and may further progress to osteoporosis and increase the risk of fractures. Cycloastragenol (CAG), currently the only compound reported that activates human telomerase, is thought to be able to alleviate or delay the symptoms of aging and chronic diseases. Previous research has suggested that CAG may have the potential to alleviate age-related bone loss. However, to date, no research has specifically focused on this aspect. In this study, we aimed to investigate whether CAG could prevent senile osteoporosis, and further reveal its underlying mechanism. Methods: CAG treatment was administrated into two bone loss rat models (D-galactose administration and aging) for 20 weeks and 33 weeks, respectively. Serum biomarkers analyses, bone biomechanical tests, microcomputed tomography assessment, and bone histomorphometry analyses were performed on the bone samples collected at the endpoint, to determine whether CAG could prevent or alleviate age-related bone loss. Proteomic analysis was performed to reveal the

changes in protein profiles of the bones, and western blot was used to further verify the identity of the key proteins. The viability, osteoblastic differentiation, and mineralization of MC3T3-E1 cells were also evaluated after CAG treatment in vitro. Results: The results suggest that CAG treatment improves bone formation, reduces osteoclast number, alleviates the degradation of bone microstructure, and enhances bone biomechanical properties in both n-galactose- and aging-induced bone loss models. CAG treatment promotes viability, osteoblastic differentiation, and mineralization in MC3T3-E1 cells. Proteomic and western blot analyses revealed that CAG treatment increases osteoactivin (OA) expression to alleviate bone loss. Conclusion: The results revealed that CAG alleviates age-related bone loss and improves bone microstructure and biomechanical properties. This may due to CAG-induced increase in OA expression. In addition, the results support preclinical investigations of CAG as a potential therapeutic medicine for the treatment of senile osteoporosis.

TI Sema4D Aggravated LPS-Induced Injury via Activation of the MAPK Signaling Pathway in ATDC5 Chondrocytes

SO BIOMED RESEARCH INTERNATIONAL
LA English
DT Article
ID nf-kappa-b; semaphorin 4d; mouse model; osteoarthritis; expression; cell; pathogenesis; inflammation; suppression; roles
AB Osteoarthritis (OA) is the most common chronic degenerative joint disease, and it remains the main cause of chronic disability in elderly individuals. Sema4D (semaphorin 4D) is involved in the immune system and related to bone injury, osteoporosis, osteoblast differentiation, and rheumatoid arthritis. However, the role of Sema4D in OA remains unclear. Hence, the LPS-stimulated chondrocyte cell injury model was constructed in this study to investigate the role of Sema4D in OA development. The results showed that Sema4D was increased in LPS-treated ATDC5 cells, and the knockdown of Sema4D suppressed the decline of cell viability, the increase of cell apoptosis, and the increase of IL-6, IL-1 beta, and TNF-alpha secretion in ATDC5 cells induced by LPS. Meanwhile, Sema4D overexpression aggravated the cell injury triggered by LPS, and inhibiting Plexin B1 partly abolished the effect of Sema4D overexpression on LPS-induced chondrocyte injury. Furthermore, silencing of Sema4D blocked the activation of the MAPK pathway in LPS-stimulated ATDC5 cells. Enhanced Sema4D promoted the activation of the MAPK pathway in LPS-stimulated ATDC5 cells. What is more, inhibiting the MAPK signaling pathway abolished the promoting effect of Sema4D overexpression on LPS-induced chondrocyte injury. Therefore, our study suggested that the knockdown of Sema4D protects ATDC5 cells against LPS-induced injury through inactivation of the MAPK signaling pathway via interacting with Plexin B1.

TI Differences in subchondral trabecular bone microstructure and finite element analysis-based biomechanical properties between osteoporosis and osteoarthritis
SO JOURNAL OF ORTHOPAEDIC TRANSLATION
LA English
DT Article
DE Finite element analysis; Individual trabecular segmentation; Mechanical property; Osteoarthritis; Osteoporosis
ID (its)-based morphological analysis; hip osteoarthritis; cancellous bone; femoral-head; cartilage histopathology; postmenopausal women; biochemical markers; articular-cartilage; elastic-modulus; microarchitecture
AB Background/Objective: The microstructure of the subchondral trabecular bone, including the composition and distribution of plates and rods, has an important influence on the disease progression and mechanical properties of osteoarthritis (OA) and osteoporosis (OP). We aimed to determine whether differences in plates and rods influence the variations in the quantities and qualifies of the subchondral trabecular bone between OA and OP. Materials and methods: Thirty-eight femoral head samples [OA, n = 13; OP, n = 17; normal control (NC), n = 8] were collected from male patients undergoing total hip arthroplasty. They were scanned using microcomputed tomography, and subchondral trabecular structures were analysed using individual trabecular segmentation. Micro-finite element analysis (mu FEA) was applied to assess the mechanical property of the trabecular bone. Cartilage changes were evaluated by using histological assessment. Analysis of variance was used to compare intergroup differences in structural and mechanical properties and cartilage degradation. Pearson analysis was used to evaluate the relationship between the trabecula microstructure and biomechanical properties. Results: Compared with the OP and NC group, there was serious cartilage damage in the OA group. With respect to the microstructure results, the OA group had the highest plate and rod trabecular microstructures including number and junction density among the three groups. For the mechanical properties detected via mu FEA, the OA group had higher stiffness and failure load than did the OP group. Pearson analysis revealed that compared with OP, OA had a higher number of microstructure parameters (e.g., rod bone volume fraction and rod trabecular number) that were positively correlated with its mechanical property. Conclusions: Compared with OP, the OA subchondral bone has both increased plate and rod microarchitecture and has more microstructures positively related with its mechanical property. These differences may help explain the variation in mechanical properties between these bone diseases. The translational potential of this article: Our findings suggested that changes in the plates and rods of the subchondral trabecular bone play a critical role in OA and OP progression and that the improvement of the subchondral trabecular bone may be a promising treatment approach.

TI Dielectric characterization of diseased human trabecular bones at microwave frequency
SO MEDICAL ENGINEERING & PHYSICS
LA English
DT Article
DE Dielectric properties; Bone volume fraction; Osteoporosis; Osteoarthritis; Open-ended coaxial probe

ID mechanical-property; interrelationships; osteoporosis; density; tissue; systems
AB The objective of this study is to determine whether in vitro dielectric properties of human trabecular bones, can distinguish between osteoporotic and osteoarthritis patients' bone samples. Specifically this study enlightens intra-patient variation of trabecular bone microarchitecture and dielectric properties, inter-disease comparison of bone dielectric properties, and finally establishes the correlation to traditional bone histomorphometry parameter (bone volume fraction) for diseased bone tissue. Bone cores were obtained from osteoporotic and osteoarthritis patients (n = 12). These were scanned using microCT to examine bone volume fraction. An open-ended coaxial probe measurement technique was employed to measure dielectric properties over the 0.5 - 8.5 GHz frequency range. The dielectric properties of osteoarthritis patients are significantly higher than osteoporotic patients; with an increase of 41% and 45% for relative permittivity and conductivity respectively. The dielectric properties within each patient vary significantly, variation in relative permittivity and conductivity was found to be greater than 25% and 1.4% respectively. A weak correlation (r = 0.5) is observed between relative permittivity and bone volume fraction. Osteoporotic and osteoarthritis bones can be differentiated based on difference of dielectric properties. Although these do not correlate strongly to bone volume fraction, it should be noted that bone volume fraction is a poor predictor of fracture risk. The dielectric properties of bones are found to be influenced by mineralization levels of bones. Therefore, dielectric properties of bones may have potential as a diagnostic measure of osteoporosis. TI Peri-prosthetic bone mineral density after simultaneous bilateral total knee arthroplasty under oral bisphosphonate therapy - A comparison between mobile- and fixed-bearing prostheses
SO KNEE
LA English
DT Article
DE Bone mineral density; Total knee arthroplasty; Bisphosphonate; Fixed-bearing; Mobile-bearing
ID prevents periprosthetic loss; follow-up; porous tantalum; japanese patients; trabecular bone; proximal tibia; alendronate; osteoporosis; replacement; component
AB Background: Peri-prosthetic bone mineral density (BMD) decreases after total knee arthroplasty (TKA). We aimed to specifically compare peri-prosthetic BMD changes between mobile- and fixed-bearing prostheses in patients undergoing oral bisphosphonate therapy, hypothesizing that mobile-bearing components would have a favorable effect on postoperative peri-prosthetic BMD. Methods: This prospective cohort study investigated 30 patients who underwent simultaneous bilateral TKA for primary knee osteoarthritis between December 2007 and September 2012. All patients underwent mobile-bearing TKA in one knee and

fixed-bearing TKA in the other and received oral alendronate therapy at a dosage of 35 mg/week. Peri-prosthetic and lumbar spine BMDs were measured using dual X-ray absorptiometry scans, with ped-prosthetic BMD changes being compared between the two prostheses in each patient at six months and one, two, three, and five years post-operation. Results: Clinical results did not significantly differ between two prostheses. Relative change of lumbar spine BMD was significantly greater at five years post-operation than at one year post-operation (p=0.01), and was significantly correlated at five years post-operation with peri-prosthetic BMD in the central femur (r=0.39, p=0.002), posterior femur (r = 0.39, p=0.002), and medial tibia (r = 0.42, p=0.007). Conclusions: There was no difference in peri-prosthetic BMD changes between two prostheses in patients undergoing oral bisphosphonate therapy. Our results suggest that the influence of oral bisphosphonate therapy might offset the influence of prosthetic design. Thus, oral bisphosphonate therapy may be more effective than prosthetic design selection in preventing post-TKA peri-prosthetic BMD loss. (C) 2020 Elsevier B.V. All rights reserved.

TI Differences between muscle from osteoporotic and osteoarthritic subjects: in vitro study by diffusion-tensor MRI and histological findings
SO AGING CLINICAL AND EXPERIMENTAL RESEARCH
LA English
DT Article
DE Osteoporosis; Osteoarthritis; Skeletal muscle; IMCL; DTI
ID marrow fat-content; skeletal-muscle; cancellous bone; sarcopenia; atrophy; women; diagnosis; risk; pain; size
AB Background Osteoarthritis and osteoporosis are strongly coupled with

alterations of muscles quality and fats metabolism. However, there are no studies for investigating possible differences between osteoporotic and osteoarthritic muscles. Understanding muscle-bone and muscle-cartilage interactions would be of high clinical value. Aim Investigate potential microstructural and physiological differences between osteoporotic and osteoarthritic muscles by diffusion Nuclear Magnetic Resonance (NMR) imaging (diffusion MRI) and histological findings. Methods Vastus-lateralis muscles excised from osteoporotic (n = 26, T Score < - 2.5, Kellgren-Lawrence <= 2) and osteoarthritic (n = 26, T Score > - 2.5, Kellgren--Lawrence 3 and 4) age-matched women were investigated by NMR relaxometry, diffusion-tensor imaging (DTI) at 9.4 T, and histological techniques. Intramyocellular (IMCL) and extramyocellular (EMCL) lipid were quantified. The percentage and mean diameters of fibers I and II were evaluated. Relationship between mean diffusivity (MD), fractional anisotropy (FA), the DTI eigenvalues (lambda(1), lambda(2), lambda(3)), histological findings in muscles and clinical data (Kellgren-Lawrence and T score, age, menopausal age, body mass index) were studied. Pairwise comparisons between groups were made using one-way analysis of variance and correlation between variables was assessed with linear correlation analysis (Pearson's r coefficient). Results Osteoporotic muscles showed higher MD, lambda(1,)lambda(2), lambda(3) compared to osteoarthritis ones. This is explainable with a significant higher density of IMCL droplets found inside the osteoarthritic muscles and a large amount of fibrotic tissue and IMCL infiltration between fibers, i.e. in endomysium and perimysium that lead to a more hindered diffusion. Furthermore, histological analysis suggests mitochondrial degeneration as the origin of the greatest amount of IMCL droplets in osteoarthritic muscles. Conclusion This work highlights differences between muscles of osteoporotic and osteoarthritic subjects that can be quantified by NMR DTI investigations.

TI The role of sphingosine 1-phosphate metabolism in bone and joint pathologies and ectopic calcification
SO BONE
LA English
DT Review
DE Sphingosine 1-phosphate; Sphingosine kinases; Arthritis; Spondyloarthritis; Osteoporosis
ID advanced atherosclerotic lesions; molecular-cloning; functional-characterization; media calcification; oral fingolimod; cancer cells; sphingosine-1-phosphate; kinase; fty720; receptor
AB Sphingolipids display important functions in various pathologies such as cancer, obesity, diabetes, cardiovascular or neurodegenerative diseases. Sphingosine, sphingosine 1-phosphate (SIP), and ceramide are the central molecules of sphingolipid metabolism. Sphingosine kinases 1 and 2 (SKi and SK2) catalyze the conversion of the sphingolipid metabolite sphingosine into S1P. The balance between the levels of SIP and its metabolic precursors ceramide and sphingosine has been considered as a switch that could determine whether a cell proliferates or

dies. This balance, also called "sphingolipid rheostat", is mainly under the control of SKs. Several studies have recently pointed out the contribution of SK/S1P metabolic pathway in skeletal development, mineralization and bone homeostasis. Indeed, SK/S1P metabolism participates in different diseases including rheumatoid arthritis, spondyloarthritis, osteoarthritis, osteoporosis, cancer-derived bone metastasis or calcification disorders as vascular calcification. In this review, we will summarize the most important data regarding the implication of SK/S1P axis in bone and joint diseases and ectopic calcification, and discuss the therapeutic potential of targeting SK/S1P metabolism for the treatment of these pathologies.

TI Risk factors for secondary displacement in conservatively treated proximal humeral fractures INTRODUCING TWO NEW RADIOLOGICAL PREDICTORS
SO BONE & JOINT JOURNAL
LA English
DT Article
ID local bone quality; nonoperative treatment; internal-fixation; elderly-patients; open reduction; surgery; classification; epidemiology; arthroplasty
AB Aims Conservative treatment of moderately displaced proximal humeral head fractures yields good clinical results, but secondary fragment displacement may occur. Identification of those fractures at risk of displacement may influence initial decision-making. Methods A total of 163 shoulders in 162 patients with conservatively treated isolated proximal humeral fractures were included. The fractures occurred between January 2015 and May 2018. The mean age of the patients was 69 years (26 to 100) and the mean follow-up was 144 days (42 to 779). The fractures were classified according to Neer. Scores for osteoporosis (Tingart, Deltoid Tuberosity Index (DTI)) and osteoarthritis (OA) of the glenohumeral joint were assessed. Translation of the head on follow-up radiographs of more than 10 mm was defined as displacement. Eccentric head index (EHI) describes the offset of the humeral head centre in relation to the diaphyseal axis. The ratio was estimated on anteroposterior (AP) and Neer views. Medial hinge was considered intact if the medial cortex proximal and distal to the fracture was in line on AP view. Results Secondary fracture displacement occurred in 41 patients (25.2%). Clinical risk factors were alcohol abuse (odds ratio (OR) 6.8; 95% confidence interval (CI) 1.3 to 36; p = 0.025) and previously diagnosed osteoporosis (OR 4.6; 95% CI 0.6 to 34; p = 0.136). Age (OR 1.1; 95% CI 1.0 to 1.1; p = 0.003) and sex (OR 0.9; 95% CI 0.3 to 2.8; p = 0.867) were not independent factors. Radiological risk factors were OA grade 3 (OR 16.4; 95% CI 0.25 to 37.6; p = 0.107) and osteoporosis with the DTI (OR 10; 95% CI 0.8 to 250; p = 0.031) being more predictive than the Tingart score (OR 2.3; 95% CI 0.8 to 4.7; p = 0.041). A high EHI (AP/Neer > 0.4, OR 18.9; 95% CI 2.1 to 30.9/3.0; 95% CI 1.1 to 8.0; p = 0.002/p = 0.033) and a disrupted medial hinge (OR 3.7; 95% CI 1.1 to 12.6; p = 0.039) increased the risk of secondary displacement significantly. Neer classification had no influence. Conclusion During conservative treatment, a quarter of patients showed secondary fracture displacement of at least 10 mm. Patients with alcohol abuse, severe OA, and osteoporosis are at risk. Newly defined EHI and disrupted medial hinge are relevant predictors for secondary displacement.

TI A new ligament-compatible patient-specific 3D-printed implant and instrumentation for total ankle arthroplasty: from biomechanical studies to clinical cases
SO JOURNAL OF ORTHOPAEDICS AND TRAUMATOLOGY
LA English
DT Article
DE Custom-made implant; 3D-printing; Total ankle arthroplasty; Total ankle replacement; PSI; Surgical treatment
ID posttraumatic osteoarthritis; replacement; design; accuracy; rates
AB Background Computer navigation and patient-specific instrumentation for total ankle arthroplasty have still to demonstrate their theoretical ability to improve implant positioning and functional outcomes. The purpose of this paper is to present a new and complete total ankle arthroplasty customization process for severe posttraumatic ankle joint arthritis, consisting of patient-specific 3D-printed implant and instrumentation, starting from a ligament-compatible design. Case presentation The new customization process was proposed in a 57-year-old male patient and involved image analysis, joint modeling, prosthesis design, patient-specific implant and instrumentation development, relevant prototyping, manufacturing, and implantation. Images obtained from a CT scan were processed for a 3D model of the ankle, and the BOX ankle prosthesis (MatOrtho, UK) geometries were customized to best fit the model. Virtual in silico, i.e., at the computer, implantation was performed to optimize positioning of these components. Corresponding patient-specific cutting guides for bone preparation were designed. The obtained models were printed in ABS by additive manufacturing for a final check. Once the planning procedure was approved, the models were sent to final state-of-the-art additive manufacturing (the metal components using cobalt-chromium-molybdenum powders, and the guides using polyamide). The custom-made prosthesis was then implanted using the cutting guides. The design, manufacturing, and implantation procedures were completed successfully and consistently, and final dimensions and location for the implant corresponded with the preoperative plan. Immediate post-op X-rays showed good

implant positioning and alignment. After 4 months, clinical scores and functional abilities were excellent. Gait analysis showed satisfactory joint moment at the ankle complex and muscle activation timing within normality. Conclusions The complete customization process for total ankle arthroplasty provided accurate and reliable implant positioning, with satisfactory short-term clinical outcomes. However, further studies are needed to confirm the potential benefits of this complete customization process.

TI Incidence rate and risk factors for radiographic hip osteoarthritis in Japanese men and women: a 10-year follow-up of the ROAD study
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE Osteoarthritis; Incidence; Progression; Acetabular dysplasia; Cohort study
ID knee osteoarthritis; dysplasia; associations; progression; disability; morphology; joint; hand; pain
AB Objective: To investigate the incidence and progression rate of radiographic hip osteoarthritis (OA) and its risk factors in Japanese men and women using a large-scale population of a nationwide cohort study, Research on Osteoarthritis/osteoporosis Against Disability (ROAD). Methods: From the baseline survey of the ROAD study, 2,975 participants (1,043 men and 1,932 women) aged 23-94 years (mean, 70.2 years) living in urban, mountainous, and coastal communities were followed up with hip radiography at 3, 7, and 10 years (mean follow-up, 7.1 years). Radiographs were scored using the Kellgren/Lawrence (K/L) grading system, and radiographic hip OA was defined as K/L >= 2. The incidence and progression rate of hip OA were examined. Acetabular dysplasia was defined as a central-edge angle <20 degrees. Cox's proportional hazard model was used to assess risk factors for incident and progressive radiographic hip OA. Results: The incidence rate of radiographic hip OA was 5.6/1,000 person-years and 8.4/1,000 person-years in men and women, respectively. The progression rate of hip OA was 2.2/1,000 person-years and 6.0/1,000 person-years in men and women, respectively. The significant risk factors for incident hip OA were age, obesity, and acetabular dysplasia at baseline (hazard risk [HR] 1.05, 95% confidence interval [CI] 1.03-1.08; 1.78, 1.10-2.75; 2.06, 1.30-3.17, respectively). The significant risk factors for progressive hip OA were baseline hip pain and acetabular dysplasia (HR 5.68,

95%CI 1.07-22.61; 14.78, 3.66-56.06, respectively). Conclusion: Continued longitudinal surveys of the ROAD study will contribute to knowledge about and potential prevention of incident and progressive hip OA. TI Glucosamine sulphate: an umbrella review of health outcomes
SO THERAPEUTIC ADVANCES IN MUSCULOSKELETAL DISEASE
LA English
DT Review
DE glucosamine sulphate; osteoarthritis; umbrella review
ID knee osteoarthritis; systematic reviews; european-society; economic-aspects; chondroitin sulfate; double-blind; progression; osteoporosis; management; efficacy
AB Background and Aims: Glucosamine sulphate (GS) can be used as background therapy in people affected by knee osteoarthritis (OA). Knowledge regarding the efficacy and safety of GS is of importance since its use worldwide is increasing. Therefore, the present study aimed to map and grade the diverse health outcomes associated with GS using an umbrella review approach. Methods: Medline, Cinahl and Embase databases were searched until 1 April 2020. An umbrella review of systematic reviews and meta-analyses of randomized controlled trials (RCTs) was carried out. The evidence from the RCTs was graded using the Grading of Recommendations Assessment, Development and Evaluation (GRADE) tool. Results: From 140 articles returned, 11 systematic reviews, for a total of 21 outcomes (37 RCTs; 3949 participants; almost all using 1500 mg/day), were included. No systematic reviews/meta-analyses of observational studies were included. Regarding the findings of the meta-analyses, 9/17 outcomes were statistically significant, indicating that GS is more effective than placebo. A high certainty of evidence, as assessed by GRADE, supported the use of GS (versus placebo) in improving the Lequesne Index, joint space width change, joint space width change after 3 years of follow up, joint space narrowing and OA progression. No difference in terms of adverse effects was found between GS and placebo. In systematic reviews, GS was associated with a better glucose profile and a better physical function performance than placebo. Conclusion: GS, when used as a prescription drug (i.e. crystalline glucosamine sulphate) at 1500 mg daily dosage, can positively affect the cartilage structure, reduce pain, improve function and glucose metabolism in people with knee OA, without having a greater incidence of adverse effects than placebo.

ID strain amplification; osteocyte processes; in-situ; contrast; resolution; resins; model; decalcification; reconstruction; environment
AB There is an unmet need for a high-resolution three-dimensional (3D) technique

to simultaneously image osteocytes and the matrix in which these cells reside. In serial block-face scanning electron microscopy (SBF SEM), an ultramicrotome mounted within the vacuum chamber of a microscope repeatedly sections a resin-embedded block of tissue. Backscattered electron scans of the block face provide a stack of high-resolution two-dimensional images, which can be used to visualise and quantify cells and organelles in 3D. High-resolution 3D images of biological tissues from SBF SEM have been exploited considerably to date in the neuroscience field. However, non-brain samples, in particular hard biological tissues, have appeared more challenging to image by SBF SEM due to the difficulties of sectioning and rendering the samples conductive. We have developed and propose protocols for bone tissue preparation using SBF SEM, for imaging simultaneously soft and hard bone tissue components in 3D. We review the state of the art in high-resolution imaging of osteocytes, provide a historical perspective of SBF SEM, and we present first SBF SEM proof-of-concept studies for murine and human tissue. The application of SBF SEM to hard tissues will facilitate qualitative and quantitative 3D studies of tissue microstructure and ultrastructure in bone development, ageing and pathologies such as osteoporosis and osteoarthritis.

TI The Role of Substance P in the Regulation of Bone and Cartilage Metabolic Activity
SO FRONTIERS IN ENDOCRINOLOGY
LA English
DT Review
DE substance P; Nk-R1 (neurokinin-receptor 1); osteoblasts; osteoclasts; osteoporosis; fracture healing; osteoarthritis
ID gene-related peptide; factor-kappa-b; rheumatoid-arthritis; sensory neurons; synovial-fluid; expression; pain; osteoarthritis; cells; differentiation
AB Substance P (SP) is a neuropeptide that is released from sensory nerve endings and is widely present in nerve fibers. It acts on bones and related tissues by binding to receptors, thereby regulating bone metabolism, cartilage metabolism, and fracture healing. SP has attracted widespread attention as a signaling substance that can be recognized by both the immune system and the nervous system. Previous studies have shown that bone and chondrocytes can synthesize and secrete sensory neuropeptides and express their receptors, and can promote proliferation, differentiation, apoptosis, matrix synthesis, and the degradation of target cells through autocrine/paracrine modes. In this paper, we review the research progress made in this field in recent years in order to provide a reference for further understanding the regulatory mechanism of bone and cartilage physiology and pathological metabolism.

TI Can knee flexion contracture affect cervical alignment and neck tension? A prospective self-controlled pilot study
SO SPINE JOURNAL
LA English

DT Article
DE Cervical alignment; Compensation mechanism; Flexion-relaxation ratio; Horizontal gaze; Knee flexion contracture; Neck tension; Shear wave elastography; Surface electromyography
ID sagittal spinal alignment; low-back-pain; asymptomatic adults; radiographic data; osseous anatomy; range; motion; osteoarthritis; values
AB BACKGROUND CONTEXT: The coordination of the alignment between the lower extremities and cervical spine helps to achieve balance and horizontal gaze during standing and walking. Malalignment in any segment can disturb the global balance, causing compensation in another segment. Knee flexion contracture (KFC) can cause spine inclination with increased C7 tilt or C7 SVA (sagittal vertical axis). Cervical alignment and the posterior muscles are essential for maintaining the horizontal gaze which is closely related to neck tension (NT). PURPOSE: This study aimed to determine whether KFC can affect cervical alignment and its potential effects on the posterior muscles and NT. DESIGN: A prospective pilot study was carried out in preoperative (pre-op) and postoperative (post-op) phases. PATIENT SAMPLE: This study included 22 consecutive patients with KFC and 12 control subjects in our department who agreed to participate from between August 1, 2018 and February 28, 2019 in our department. OUTCOME MEASURES: Visual analog scale (VAS) and neck disability index (NDI) were used. The sagittal alignment parameters and cervical range of motion (ROM) were measured on radiographic images, and included the C0-C2 lordosis (C0-2L), C2-C7 lordosis (C2-7L), C2 SVA, C7 SVA, T1 slope, thoracic kyphosis, lumbar lordosis (LL), pelvic tilt, sacral slope, and knee flexion angle (KA). Surface electromyography-based flexion-relaxation ratio (FRR) and ultrasound-based shear wave elastography (SWE) were performed. METHODS: The control group was matched for age, sex, and body mass index with the KFC group. Patients in the KFC group underwent arthroscopic surgery to correct knee alignment. Comparisons between pre-op and post-op phases were performed using paired sample t tests, comparisons between KFC and control groups were performed using independent samples t tests. The correlation analysis between the parameters was performed using Spearman analysis. Funding for this study was provided by the National Natural Science Foundation of China (60,000 USD), Beijing Municipal Administration of Hospitals Incubating Program (50,000 USD), and Beijing Municipal Administration of Hospitals Clinical Medicine Development of Special Funding Support (20,000 USD). There were no conflicts of interest associated with this study. RESULTS: The average follow-up time for this pilot study was 11.4 +/- 1.5 days. Pre-op, the KFC group had higher KA, T1S, C7 SVA, C2 SVA, C0-2L, SWE, VAS, and NDI compared with the control group, but all of these parameters were decreased significantly post-op. The LL, FRR of splenius capitis (FRRsc), and ROM of the KFC group pre-op were lower than the control group, and all of these were increased significantly post-op. There were no differences in pelvic tilt, sacral slope, C2-7 L, or TK between the KFC and control groups, or in FRR of splenius capitis (FRRutr) between pre-op and post-op phases. KA had strong correlations with LL (r=-0.83), which correlated well with C7 SVA

(r=-0.75). C7 SVA correlated strongly with C2 SVA (r=0.79), which also correlated strongly with C0-2 L (r=0.76). C0-2 L correlated well with FRRsc (r=-0.65) and SWEsc (r=0.72), and both of them correlated well with VAS (r=-0.54, r=0.71) and NDI (r=-0.57, r=0.76). ROM correlated well with FRRsc (r=0.71), SWEsc (r=-0.74), VAS (r=-0.66), and NDI (r=-0.66). CONCLUSIONS: KFC may cause spine inclination and craniocervical malalignment, leading to NT and ROM reduction. The results of this pilot study may be helpful in guiding further studies concerning KFC and NT.

TI Composition and characteristics of trabecular bone in osteoporosis and osteoarthritis
SO BONE
LA English
DT Article
DE Micro-computed tomography; Nuclear magnetic resonance; Femoral head bone fractures; Osteoporosis; Hydroxyapatite; Crystal; Structure
ID synthetic calcium phosphates; age-related-changes; mineral density;

femoral-neck; mechanical-property; cross-polarization; collagen; hip; microarchitecture; fractures
AB Background: Bone strength depends on multiple factors such as bone density, architecture and composition turnover. However, the role these factors play in osteoporotic fractures is not well understood. Purpose: The aim of this study was to analyze trabecular bone architecture, and its crystal and organic composition in humans, by comparing samples taken from patients who had a hip fracture (HF) and individuals with hip osteoarthritis (HOA). Methods: The study included 31 HF patients and 42 cases of HOA who underwent joint replacement surgery between 1/1/2013 and 31/12/2013. Trabecular bone samples were collected from the femoral heads and analyzed using a dual-energy X-ray absorptiometry, micro-CT, and solid-state high-resolution magic-angle-spinning nuclear magnetic resonance (MAS-NMR) spectroscopy. Results: No differences in proton or phosphorus concentration were found between the two groups using H-1 single pulse, P-31 single pulse, P-31 single pulse with proton decoupling NMR spectroscopy, in hydroxyapatite (HA) c-axis or a-axis crystal length. Bone volume fraction (BV/TV), trabecular number (Tb.N), and bone mineral density (BMD) were higher in the HO group than in the HF group [28.6% +/- 10.5 vs 20.3% +/- 6.6 (p = 0.026); 2.58 mm(-1) +/- 1.57 vs 1.5 mm(-1) +/- 0.79 (p = 0.005); and 0.39 g/cm(2) +/- 0.10 vs. 0.28 g/cm(2) +/- 0.05 (p = 0.002), respectively]. The trabecular separation (Tp.Sp) was lower in the HO group 0.42 mm +/- 0.23 compared with the HF group 0.58 mm +/- 0.27 (p = 0.036). In the HO group, BMD was correlated with BV/TV (r = 0.704, p < 0.001), BMC (r = 0.853, p < 0.001), Tb.N (r = 0.653, p < 0.001), Tb.Sp (- 0.561, p < 0.001) and 1 H concentration (- 0.580, p < 0.001) in the HO group. BMD was not correlated with BV/TV, Tb.Sp, Tb.Th, Tb.N, Tb.PF, H-1 concentration or HA crystal size in the HF group. Conclusions: Patients with HO who did not sustain previous hip fractures had a higher femoral head BMD, BV/TV, and Tb.N than HF patients. In HO patients, BMD was positively correlated with the BV/TV and Tb.N and negatively correlated with the femoral head organic content and trabecular separation. Interestingly, these correlations were not found in HF patients with relatively lower bone densities. Therefore, osteoporotic patients with similar low bone densities could have significant microstructural differences. No differences were found between the two groups at a HA crystal level.

TI Cell Proliferation Stimulation Ability and Osteogenic Activity of Low Molecular Weight Peptides Derived from Bovine Gelatin Hydrolysates
SO JOURNAL OF AGRICULTURAL AND FOOD CHEMISTRY
LA English
DT Article
DE bioactive peptides; bovine gelatin hydrolysates; cell proliferation stimulation; osteogenic activity; tandem mass spectrometry
ID osteoblast proliferation; alkaline-phosphatase; collagen peptides; bone-development; mc3t3-e1 cells; expression; identification; antioxidant; mechanism; skin
AB It has been recognized that collagen peptides of MW 878 Da (CP1) promote osteoblast proliferation and mineralization. The objective of this study is to identify the peptides responsible for proliferation of osteoblast growth, enhancement of ALP (alkaline phosphatase) activity in osteoblasts and promotion of osteoblast

mineralization. To this end, the CP1 were fractioned by a series of chromatography procedures, and 51 peptides from the fraction possessing the most powerful cell proliferation ability were identified by LC-MS-MS. The peptides, GPAGPSGPAGK and GPPGSPGPR, were validated on a simultaneous basis as possessing enhanced bioactivity-inducing properties. In particular, the ALP activity of the cells treated with these two peptides was almost twice that of the control cells. Hydrogen bonds were formed, and the hydrophobic interactions with the EGFR (epidermal growth factor receptor) might be responsible for the osteoblast proliferation activity. On this basis, the two peptides might be potential lead compounds against osteoporosis and osteoarthritis.

TI Destroy to Rebuild: The Connection Between Bone Tissue Remodeling and Matrix Metalloproteinases
SO FRONTIERS IN PHYSIOLOGY
LA English
DT Review
DE bone; remodeling; metabolism; matrix metalloproteinase; deficiency; underactivity
ID growth-factor-beta; mesenchymal stem-cells; activated protein-c; human osteoarthritic cartilage; sensitive calcium influx; extracellular-matrix; gene-expression; multicentric osteolysis; osteoclast differentiation; in-vitro
AB Bone is a dynamic organ that undergoes constant remodeling, an energetically costly process by which old bone is replaced and localized bone defects are repaired to renew the skeleton over time, thereby maintaining skeletal health. This review provides a general overview of bone's main players (bone lining cells, osteocytes, osteoclasts, reversal cells, and osteoblasts) that participate in bone remodeling. Placing emphasis on the family of extracellular matrix metalloproteinases (MMPs), we describe how: (i) Convergence of multiple protease families (including MMPs and cysteine proteinases) ensures complexity and robustness of the bone remodeling process, (ii) Enzymatic activity of MMPs affects bone physiology at the molecular and cellular levels and (iii) Either overexpression or deficiency/insufficiency of individual MMPs impairs healthy bone remodeling and systemic metabolism. Today, it is generally accepted that proteolytic activity is required for the degradation of bone tissue in osteoarthritis and osteoporosis. However, it is increasingly evident that inactivating mutations in MMP genes can also lead to bone pathology including osteolysis and metabolic abnormalities such as delayed growth. We argue that there remains a need to rethink the role played by proteases in bone physiology and pathology.

TI Return to Sport After Hip Arthroscopy for Femoroacetabular Impingement Syndrome in NCAA Division I Athletes: Experience at a Single Institution
SO ORTHOPAEDIC JOURNAL OF SPORTS MEDICINE
LA English
DT Article
DE femoroacetabular impingement syndrome; surgery; collegiate; sport type; return to sport; endurance
ID radiographic findings; prevalence; outcm
AB Background: The rate of return to sport after surgical treatment of femoroacetabular impingement (FAI) syndrome (FAIS) has been studied in high-level athletes. However, few studies examining this rate have focused exclusively on National Collegiate Athletic Association (NCAA) Division I athletes. Purpose: To evaluate the return-to-sport rate after hip arthroscopy for FAIS and to examine the influence of sport type on the clinical presentation of FAIS in collegiate athletes. Study Design: Case series; Level of evidence, 4. Methods: Included in this study were NCAA Division I student-athletes who underwent hip arthroscopy for FAIS at our institution between 2010 and 2017. Exclusion criteria were history of previous hip pathology, pediatric hip disease, radiographic evidence of osteoarthritis (Tonnis grade >0), prior lower extremity procedure, history of chronic pain, osteoporosis, or history of systemic inflammatory disease. Athletes were categorized into 6 subgroups based on the type of sport (cutting, contact, endurance, impingement, asymmetric/overhead, and flexibility) by using a previously reported classification system. Patient characteristics and preoperative, intraoperative, and return-to-sport variables were compared among sport types. Results: A total of 49 hip arthroscopies for FAIS were performed in 39 collegiate athletes (10 females, 29 males; mean age, 19.5 +/- 1.3 years). A total of 1 (2.6%) cutting athlete, 15 (38.5%) contact athletes, 8 (20.5%) impingement athletes, 6 (15.4%) asymmetric/overhead athletes, and 9 (23.1%) endurance athletes were included in the study. There were no differences among sports groups with respect to the FAI type. Endurance athletes had lower rates of femoral osteochondroplasty (45.5%) and labral debridement (0.0%) (P < .0001). Contact sport athletes had higher rates of labral debridement (50.0%; P < .0001). Patients were evaluated for

return to sport at an average of 1.96 +/- 0.94 years. Overall, the return-to-sport rate was 89.7%. There were no differences in return-to-sport rates based on the sport type except for endurance athletes, who returned at a lower rate (66.6%; P < .001). No differences in return-to-sport rate (P = .411), duration after return (P = .265), or highest attempted level of sport resumed (P = .625) were found between patients who underwent labral repair versus debridement. Conclusion: Collegiate-level athletes who underwent hip arthroscopy for FAIS returned to sport at high and predictable rates, with endurance athletes possibly returning to sport at lower rates than all other sport types. Surgical procedures may be influenced by sport type, but the rate of return to sport between athletes who underwent labral debridement versus labral repair was similar.

TI Prolonged 25-OH Vitamin D Deficiency Does Not Impair Bone Mineral Density in Adult Patients With Vitamin D 25-Hydroxylase Deficiency (CYP2R1)
SO CALCIFIED TISSUE INTERNATIONAL
LA English
DT Article
DE Rickets; Vitamin D; Bone mass density; Adults
ID d-dependent rickets; 25-hydroxyvitamin d; fractures; risk
AB Vitamin D-dependent rickets type 1B (VDDR1B) is an autosomal semidominant genetic disorder caused by a deficiency in CYP2R1, which encodes vitamin D 25-hydroxylase, an enzyme that plays a crucial role in the conversion of vitamin D to 25-dihydroxyvitamin D-3. VDDR1B is a severe form of rickets that occurs during infancy and which is responsive to 25-OH vitamin D supplementation. We studied three adult patients from a multi-consanguineous family with VDDR1B. They have been diagnosed with pseudo-nutritional rickets and treated during their adolescence with 25-OH vitamin D. These patients stopped their treatments at the end of adolescence and were contacted 14 to 17 years later when VDDR1B diagnosis was carried out in their niece and nephews. These three patients had undetectable 25-OH vitamin D, but normal levels of plasma 1-25(OH)(2) vitamin D. All patients had a hip bone mineral density and a normal vertebral despite osteoarthritis degenerative lesions which may impact BMD evaluation. These findings show that vitamin D supplementation has a questionable effect, if any, for osteoporosis prevention in adulthood in contrast to its crucial importance during infancy and adolescence.

TI The Role of Autophagy and Mitophagy in Bone Metabolic Disorders
SO INTERNATIONAL JOURNAL OF BIOLOGICAL SCIENCES
LA English
DT Review
DE autophagy; mitophagy; bone metabolic disorder; osteoblast; osteoclast
ID pi3k/akt/mtor signaling pathway; coupled estrogen-receptor; peri-implant osteolysis; mesenchymal stem-cells; inflammatory response; oxidative stress; pink1/parkin-mediated mitophagy; mitochondrial dysfunction; osteoclast formation; human chondrocytes
AB Bone metabolic disorders include osteolysis, osteoporosis, osteoarthritis and rheumatoid arthritis. Osteoblasts and osteoclasts are two major types of cells in bone constituting homeostasis. The imbalance between bone formation by osteoblasts and bone resorption by osteoclasts has been shown to have a direct contribution to the onset of these diseases. Recent evidence indicates that autophagy and mitophagy, the selective autophagy of mitochondria, may play a vital role in regulating the proliferation, differentiation and function of osteoblasts and osteoclasts. Several signaling pathways, including PINK1/Parkin, SIRT1, MAPK8/FOXO3, Beclin-1/BECN1, p62/SQSTM1, and mTOR pathways, have been implied in the regulation of autophagy and mitophagy in these cells. Here we review the current progress about the regulation of autophagy and mitophagy in osteoblasts and osteoclasts in these bone metabolic disorders, as well as the molecular signaling activated or deactivated during this process. Together, we hope to draw attention to the role of autophagy and mitophagy in bone metabolic disorders, and their potential as a new target for the treatment of bone metabolic diseases and the requirements of further mechanism studies.

TI Age-Related Variances in Patients with Tibial Plateau Fractures
SO JOURNAL OF KNEE SURGERY
LA English
DT Article
DE Tibial Plateau Fracture; posttraumatic osteoarthritis; knee replacement; elderly
ID total knee arthroplasty; internal-fixation; open reduction; operative treatment; risk-factors; replacement
AB Tibial plateau fractures account for approximately 8% of fractures in the elderly population. Treatment strategies in the elderly are similar to those for younger patients; however, practitioners must account for the elevated comorbidity burden in this population. To date, few studies have analyzed age-based outcomes in patients with tibial plateau fractures. Therefore, the purpose of this study was to determine age-related variances in demographics, fracture characteristics, mechanism of injury, and complications. A 10-year retrospective review was conducted to identify patients who received treatment for a tibial plateau fracture. There were 351 patients (360 tibial plateau fractures) who were identified and subsequently stratified according to their age at the time of injury. Patients were classified as elderly if they were 65 years of age or older at the time of injury; all other patients were included in the control cohort. These two cohorts were analyzed using bivariate analysis to isolate for age-related variations with respect to risk factors, mechanism of injury, and complications. There were 351 patients (360 tibial plateau fractures) with a median follow-up of 1.84 +/- 2.44 years who

met inclusion criteria. There were a greater proportion of women in the elderly cohort as compared with the younger cohort (60.0 vs. 43.4%, p = 0.06). Elderly patients were significantly more likely to present with diabetes (33.3 vs. 16.1%, p = 0.01) or osteoporosis (14.3 vs. 1.6%, p = 0.001). Younger patients were significantly more likely to require further surgery to address ligament (12.6 vs. 0%, p = 0.008), meniscus (20.9 vs. 7.1%, p = 0.036), or cartilage pathology (13.6 vs. 0%, p = 0.005). There was no difference in the arthroplasty conversion rate (4.8% elderly vs. 7.9% control, p = 0.755). While elderly patients presented with a greater comorbidity burden, they had equivalent or better short-term outcomes when compared with their younger peers when treated with open reduction and internal fixation (ORIF). Despite the recent interest in primary total knee arthroplasty for elderly patients with tibial plateau fractures, the results of this study suggest that elderly patients may respond well when treated with ORIF following a tibial plateau fracture.

TI Bone status and aortic calcifications in chondrocalcinosis patients
SO REVISTA ROMANA DE MEDICINA DE LABORATOR
LA English
DT Article
DE chondrocalcinosis; osteocalcin; osteoprotegerin; beta cross laps; abdominal aortic calcifications
ID crystal deposition disease; vascular calcification; cartilage calcification; arterial calcification; pyrophosphate; association; osteoarthritis; prevalence; menopause; serum
AB Aim: We aimed to examine the association between several circulating bone turnover markers [osteocalcin (OC), osteoprotegerin (OPG). beta-CrossLaps (beta-CTx)], hip and spine bone mineral density (BMD) and abdominal aortic calcification (AAC) in patients with chondrocalcinosis (CC). Methods: Thirty-six patients with CC and thirty-seven controls were consecutively enrolled in this pilot case-control, cross-sectional study. The following parameters were assessed: serum levels of OC, OPG and beta-CTx by enzyme-linked immunosorbent assay (ELISA); hip and spine BMD by dual-energy X-ray absorptiometry and AAC score by lateral radiography. Results: Patients with CC had higher levels of serum bone turnover markers and AAC score than the control group: OC [6.5 (3.5-9.9) vs 4.5 (2.6-7.2) ng/ml; p=0.05]. OPG [(7.7 (6.2-9.4) vs 6.5 (5.5-8.12) pmol/ml; p=0.021, beta-CTx [6078 (5870-6171) vs 5851 (5465-6109) pg/ml; p=0.02] and AAC score (3.6 +/- 6.2 vs 0.5 +/- 2; p=0.006). Conversely, even if statistical significance was not reached, hip and spine BMD was lower in patients with CC. Additionally, we found a positive correlation between OPG and AAC, but also between OPG and osteoporosis in patients with CC. Conclusion: Patients with CC are characterized by higher circulating OC, OPG and beta-CTx. The presence of AAC was more common in patients with CC, being only associated with serum OPG.

TI Knee arthroplasty for acute fractures around the knee
SO EFORT OPEN REVIEWS
LA English
DT Article
DE elderly; fracture; knee; osteoporosis; total knee arthroplasty
ID distal femoral fractures; osteoporotic fractures; revision; replacement; management; femur; hip
AB Results of open reduction and internal fixation for com-plex articular fractures around the knee are poor, particularly in elderly osteoporotic patients. Open reduction and internal fixation may lead to an extended hospital stay and non-weight-bearing period. This may lead to occurrence of complications related to decubitus such as thrombo-embolic events, pneumonia and disorientation. Primary arthroplasty can be a valuable option in a case based and patient-specific approach. It may reduce the number of procedures and allow early full weightbearing, avoiding the above-mentioned complications. There are four main indications: 1) Elderly (osteoporotic) patients with pre-existing (symptomatic) end-stage osteoarthritis. 2) Elderly (osteoporotic) patients with severe articular and metaphyseal destruction. 3) Pathological fractures of the distal femur and/or tibia. 4) Young patients with complete destruction of the distal femur and/or tibia. The principles of knee (revision) arthroplasty should be applied; choice of implant and level of constraint should be considered depending on the type of fracture and involvement of stabilizing ligaments. The aim of treatment is to obtain a stable and functional joint. Long-term data remain scarce in the literature due to limited indications.

ID inhibiting oxidative stress; cellular senescence; induced osteoporosis; satellite cells; mouse model; stem-cells; cancer; osteoarthritis; atherosclerosis; progression
AB Cellular senescence is a state of stable cell cycle arrest associated with macromolecular alterations and secretion of proinfiammatory cytokines and molecules. From their initial discovery in the 1960s, senescent cells have been hypothesized as potential contributors to the age-associated loss of regenerative potential. Here, we discuss recent evidence that implicates cellular senescence as a central regulatory mechanism of the aging process. We provide a comprehensive overview of age-associated pathologies in which cellular senescence has been implicated. We describe mechanisms by which senescent cells drive aging and diseases, and we discuss updates on exploiting these mechanisms as therapeutic targets. Finally, we critically analyze the use of senotherapeutics and their translation to the clinic, highlighting limitations and suggesting ideas for future applications and developments.

TI Cathepsin K: The Action in and Beyond Bone
SO FRONTIERS IN CELL AND DEVELOPMENTAL BIOLOGY
LA English
DT Review
DE Cathepsin K; osteoclast; bone resorption; osteoporosis; osteoarthritis; Cathepsin K inhibitor; cardiovascular diseases; lung fibrosis
ID lysosomal cysteine proteases; rheumatoid-arthritis; postmenopausal osteoporosis; collagenolytic activity; cartilage degeneration; molecular-cloning; expression; deficiency; inhibition; gene
AB Cathepsin K (CatK) is one of the most potent proteases in lysosomal cysteine proteases family, of which main function is to mediate bone resorption. Currently, CatK is among the most attractive targets for anti-osteoporosis drug development. Although many pharmaceutical companies are working on the development of selective inhibitors for CatK, there is no FDA approved drug till now. Odanacatib (ODN) developed by Merck & Co. is the only CatK inhibitor candidate which demonstrated high therapeutic efficacy in patients with postmenopausal osteoporosis in Phase III clinical trials. Unfortunately, the development of ODN was

finally terminated due to the cardio-cerebrovascular adverse effects. Therefore, it arouses concerns on the undesirable CatK inhibition in non-bone sites. It is known that CatK has far-reaching actions throughout various organs besides bone. Many studies have also demonstrated the involvement of CatK in various diseases beyond the musculoskeletal system. This review not only summarized the functional roles of CatK in bone and beyond bone, but also discussed the potential relevance of the CatK action beyond bone to the adverse effects of inhibiting CatK in non-bone sites.

AB Objective: Abnormal remodeling of subchondral bone (SB) induced by estrogen deficiency has been shown to be involved in osteoarthritis (OA). Raloxifene (RAL) is commonly used to treat postmenopausal osteoporosis (OP). However, little is known about its effects on OA combined with estrogen deficiency. This study was performed to evaluate the efficacy of RAL on patella baja-induced patellofemoral joint OA (PFJOA) in an ovariectomized rat model. Design: Patellar ligament shortening (PLS) and ovariectomy (OVX) were performed simultaneously in 3-month-old female Sprague-Dawley rats, which were treated with RAL (10 mg/kg/day) or vehicle at 72 h postoperatively for 10 weeks. PFJOA was assessed by immunohistochemistry (IHC), real-time polymerase chain reaction (PCR), tartrate-resistant acid phosphatase (TRAP) staining, enzyme-linked immunosorbent assay (ELISA), micro-computed tomography (mu CT), histomorphology and behavioral analyses. Results: X-ray examinations showed that patella baja was successfully established by PLS. Histomorphological analysis revealed that PFJOA was significantly exacerbated by OVX and markedly alleviated by RAL. Moreover, RAL improved cartilage metabolism by decreasing MMP-13, ADAMTS-4, and caspase-3 and increasing Col-II and aggrecan at both the protein and mRNA levels. Furthermore, RAL markedly improved bone mass and SB microarchitecture and reduced osteoclast numbers and the serum osteocalcin and CTX-I levels. Although RAL showed a trend toward reducing pain sensitivity based on mechanical allodynia testing, this result was not statistically significant. Conclusion: These findings demonstrate that RAL treatment retards PFJOA progression in an ovariectomized rat model, suggesting that it may be a potential candidate for amelioration of the progression of PFJOA accompanied by postmenopausal OP. TI Prevalence of Comorbidities in Individuals Diagnosed and Undiagnosed with Alzheimer's Disease in Leon, Spain and a Proposal for Contingency Procedures to Follow in the Case of Emergencies Involving People with Alzheimer's Disease
SO INTERNATIONAL JOURNAL OF ENVIRONMENTAL RESEARCH AND PUBLIC HEALTH
LA English
DT Article
DE Alzheimer's disease; comorbidity; older adults; elderly
ID risk; dementia; association
AB Background: Alzheimer's disease (AD) which is the most common type of

dementia is characterized by mental or cognitive disorders. People suffering with this condition find it inherently difficult to communicate and describe symptoms. As a consequence, both detection and treatment of comorbidities associated with Alzheimer's disease are substantially impaired. Equally, action protocols in the case of emergencies must be clearly formulated and stated. Methods: We performed a bibliography search followed by an observational and cross-sectional study involving a thorough review of medical records. A group of AD patients was compared with a control group. Each group consisted of 100 people and were all Leon residents aged >= 65 years. Results: The following comorbidities were found to be associated with AD: cataracts, urinary incontinence, osteoarthritis, hearing loss, osteoporosis, and personality disorders. The most frequent comorbidities in the control group were the following: eye strain, stroke, vertigo, as well as circulatory and respiratory disorders. Comorbidities with a similar incidence in both groups included type 2 diabetes mellitus, glaucoma, depression, obesity, arthritis, and anxiety. We also reviewed emergency procedures employed in the case of an emergency involving an AD patient. Conclusions: Some comorbidities were present in both the AD and control groups, while others were found in the AD group and not in the control group, and vice versa.

TI Exercise as an Adjuvant to Cartilage Regeneration Therapy
SO INTERNATIONAL JOURNAL OF MOLECULAR SCIENCES
LA English
DT Review
DE exercise; osteoarthritis; osteoporosis; mesenchymal stem cells; hematopoietic stem cells; stem cell transplantation; chondroblasts; chondrocytes; cytokines
ID mesenchymal stem-cells; autologous chondrocyte implantation; modulates cytokine profile; articular-cartilage; bone-marrow; osteogenic differentiation; moderate exercise; physical-activity; stromal cells; defects
AB This article provides a brief review of the pathophysiology of osteoarthritis and the ontogeny of chondrocytes and details how physical exercise improves the

health of osteoarthritic joints and enhances the potential of autologous chondrocyte implants, matrix-induced autologous chondrocyte implants, and mesenchymal stem cell implants for the successful treatment of damaged articular cartilage and subchondral bone. In response to exercise, articular chondrocytes increase their production of glycosaminoglycans, bone morphogenic proteins, and anti-inflammatory cytokines and decrease their production of proinflammatory cytokines and matrix-degrading metalloproteinases. These changes are associated with improvements in cartilage organization and reductions in cartilage degeneration. Studies in humans indicate that exercise enhances joint recruitment of bone marrow-derived mesenchymal stem cells and upregulates their expression of osteogenic and chondrogenic genes, osteogenic microRNAs, and osteogenic growth factors. Rodent experiments demonstrate that exercise enhances the osteogenic potential of bone marrow-derived mesenchymal stem cells while diminishing their adipogenic potential, and that exercise done after stem cell implantation may benefit stem cell transplant viability. Physical exercise also exerts a beneficial effect on the skeletal system by decreasing immune cell production of osteoclastogenic cytokines interleukin-1 beta, tumor necrosis factor-alpha, and interferon-gamma, while increasing their production of antiosteoclastogenic cytokines interleukin-10 and transforming growth factor-beta. In conclusion, physical exercise done both by bone marrow-derived mesenchymal stem cell donors and recipients and by autologous chondrocyte donor recipients may improve the outcome of osteochondral regeneration therapy and improve skeletal health by downregulating osteoclastogenic cytokine production and upregulating antiosteoclastogenic cytokine production by circulating immune cells.

AB Guidance is provided in an international setting on the assessment and specific treatment of postmenopausal women at low, high and very high risk of fragility fractures. Introduction The International Osteoporosis Foundation and European Society for Clinical and Economic Aspects of Osteoporosis and Osteoarthritis published guidance for the diagnosis and management of osteoporosis in 2019.

This manuscript seeks to apply this in an international setting, taking additional account of further categorisation of increased risk of fracture, which may inform choice of therapeutic approach. Methods Clinical perspective and updated literature search. Results The following areas are reviewed: categorisation of fracture risk and general pharmacological management of osteoporosis. Conclusions A platform is provided on which specific guidelines can be developed for national use to characterise fracture risk and direct interventions.

TI Prevalence and risk factors for bone loss in Southern Chinese with rheumatic diseases
SO BMC MUSCULOSKELETAL DISORDERS
LA English
DT Article
DE Rheumatic patients; Bone mineral density; Osteopenia; Osteoporosis
ID body-mass index; serum uric-acid; systemic-sclerosis; mineral density; osteoporosis; women; health; lupus; glucocorticoids; mechanisms
AB Backgroud This study is to explore the prevalence of different stages of bone loss and the potential risk factors in rheumatic patients. Method A cross-sectional study recruits 1398 rheumatic patients and 302 healthy subjects. Demographic data, blood, and bone mineral density (BMD) tests are collected. Risk factors for bone loss in rheumatic patients are analyzed by logistic regression. Results (1) Rheumatic patients are consisted of 40.0% rheumatoid arthritis (RA), 14.7% systemic lupus erythematosus (SLE), 14.2% osteoarthritis (OA), 9.2% ankylosing spondylosis (AS), 7.9% gout, 7.0% primary Sjogren syndrome (pSS), 3.8% systemic sclerosis (SSc), and 3.2% mixed connective tissue disease (MCTD). (2) In male patients aged under 50 and premenopausal female patients, the bone mineral density score of AS (53.9%,P < 0.001) and SLE (39.6%,P = 0.034) patients is lower than the healthy controls (18.2%). (3) Osteopenia and osteoporosis are more prevailing in male patients aged or older than 50 and postmenopausal female patients with RA (P < 0.001), OA (P = 0.02) and SLE (P = 0.011) than healthy counterparts. (4) Those with SLE, RA and AS gain the highest odd ratio of 'score below the expected range for age', osteopenia and osteoporosis, respectively. (5) Age, female, low BMI and hypovitaminosis D are found negatively associated with bone loss. Dyslipidemia and hyperuricemia could be protective factors. Conclusion Young patients with AS and SLE have a significant higher occurrence of bone loss, and older patients with RA, OA and SLE had higher prevalence than healthy counterparts. SLE, RA, SSc and AS were founded significant higher risks to develop into bone loss after adjustment. Age, BMI and gender were commonly-associated with bone loss in all age-stratified rheumatic patients. These findings were not markedly different from those of previous studies.

TI Osteogenic and Anti-Inflammatory Behavior of Injectable Calcium Phosphate Loaded with Therapeutic Drugs
SO NANOMATERIALS
LA English
DT Article
DE injectable biomaterials; bone tissue regeneration; calcium phosphates; inflammation treatment; drug loaded biomaterials; sol-gel method and in vitro model
ID harpagophytum-procumbens; devils claw; bone; alendronate; differentiation; biomaterials; regeneration; fractures; cells
AB Bone fractures related to musculoskeletal disorders determine long-term disability in older people with a consequent significant economic burden. The recovery of pathologically impaired tissue architecture allows avoiding bone loss-derived consequences such as bone height reduction, deterioration of bone structure, inflamed bone pain, and high mortality for thighbone fractures. Actually, standard therapy for osteoporosis treatment is based on the systemic administration of biphosphonates and anti-inflammatory drugs, which entail several side effects including gastrointestinal (GI) diseases, fever, and articular pain. Hence, the demand of innovative therapeutic approaches for locally treating bone lesions has been increasing in the last few years. In this scenario, the development of injectable materials loaded with therapeutically active agents (i.e., anti-inflammatory drugs, antibiotics, and peptides mimicking growth factors) could be an effective tool to treat bone loss and inflammation related to musculoskeletal

diseases, including osteoporosis and osteoarthritis. According to this challenge, here, we propose three different compositions of injectable calcium phosphates (CaP) as new carrier materials of therapeutic compounds such as bisphosphonates (i.e., alendronate), anti-inflammatory drugs (i.e., diclofenac sodium), and natural molecules (i.e., harpagoside) for the local bone disease treatment. Biological quantitative analyses were performed for screening osteoinductive and anti-inflammatory properties of injectable drug-loaded systems. Meanwhile, cell morphological features were analyzed through scanning electron microscopy and confocal investigations. The results exhibited that the three systems exerted an osteoinductive effect during later phases of osteogenesis. Simultaneously, all compositions showed an anti-inflammatory activity on inflammation in vitro models.

TI Oral Administration of Strontium Gluconate Effectively Reduces Articular Cartilage Degeneration Through Enhanced Anabolic Activity of Chondrocytes and Chondrogenetic Differentiation of Mesenchymal Stromal Cells
SO BIOLOGICAL TRACE ELEMENT RESEARCH
LA English
DT Article
DE Osteoarthritis (OA); Cartilage; Strontium gluconate; Chondrogenic differentiation
ID subchondral bone; ranelate; osteoarthritis; osteoporosis; expression; model
AB Osteoarthritis (OA), a common degenerative disease affecting articular cartilage,

is caused by multiple factors, and currently, there are few approaches to effectively delay its progression. This study aimed to evaluate whether a strontium compound (in the form of strontium gluconate, Glu-Sr) could reduce OA pathology severity in osteoarthritic rat models by directly targeting chondrocytes, including catabolic/anabolic activities and/or chondrogenic differentiation. Glu-Sr was administered to OA rats by oral gavage beginning during OA induction and continuing for 8 weeks. Glu-Sr treatment was found to significantly reduce cartilage degeneration and delay OA progression. Further examination showed that collagen II, Sox9, and aggrecan (ACAN) genes were up-regulated whereas IL-1 beta was down-regulated in chondrocytes isolated from Glu-Sr-treated rats. Glu-Sr also antagonized the catabolic effects of IL-1 beta on chondrocytes. Furthermore, Glu-Sr was shown to promote the chondrogenic differentiation of bone marrow mesenchymal stem cells (BMMSCs), possibly through promoting chondrogenic gene expression, including CTGF and FGF1, as revealed by RNA-sequencing (RNA-seq). These results suggest that systemic administration of Glu-Sr may be useful in prophylactic and therapeutic treatment of chronic cartilage degradation through affecting multiple steps from chondrogenic differentiation of progenitors to matrix formation in mature chondrocytes.

TI Effects of intra-articular corticosteroid injections on lumbar trabecular density
SO SKELETAL RADIOLOGY
LA English
DT Article
DE Intra-articular corticosteroid injection; Computed tomography (CT); Opportunistic CT; Lumbar spine; Trabecular density
ID bone-mineral density; pituitary-adrenal axis; symptomatic osteoarthritis; postmenopausal women; cartilage loss; osteoporosis; knee; hip; glucocorticoids; recommendations
AB Purpose To determine the effect of intra-articular corticosteroid injections on lumbar spine trabecular density. Materials and methods This retrospective study was IRB-approved and HIPAA-compliant. We identified 50 patients (26 F, 24 M, mean age 69 +/- 14 years) who had undergone at least three medium or large joint corticosteroid injections using insoluble corticosteroids and a subsequent non-contrast abdominal CT within 5 years of the first injection. About 126 age- and sex-matched controls without history of prior corticosteroid use who had undergone non-contrast abdominal CT were identified. Cumulative corticosteroid dose was calculated. Density measurements (HU) of trabecular bone of L1 to L4 were performed, and measurements of L1 were compared to established normative data. Groups were compared using a two-sided paired t-test or a chi-squared test. Linear regression analysis between cumulative corticosteroid dose and trabecular density was performed. Results Patients underwent a mean of 4 corticosteroid injections (range 3 to 11) with a mean cumulative corticosteroid dose of 232 +/- 100 mg triamcinolone equivalent (range 120 mg to 480 mg). There was no significant difference in trabecular density of L1 to L4 between cases and controls, and there was no significant difference in trabecular density at L1 compared to normative data ($p > 0.2$). There was no association between cumulative intra-articular corticosteroid dose and mean lumbar trabecular density ($p > 0.3$). Conclusion Patients who underwent repetitive intra-articular insoluble corticosteroid injections showed no increased risk of bone loss compared to controls. Cumulative intra-articular corticosteroid dose was not associated with lumbar trabecular density.

TI Systematic review of economic evaluations investigating education, exercise, and dietary weight management to manage hip and knee osteoarthritis: protocol
SO SYSTEMATIC REVIEWS
LA English
DT Review
DE Osteoarthritis; Hip osteoarthritis; Knee osteoarthritis; Education; Patient education; Health education; Exercise; Exercise therapy; Diet; Weight loss; Diet therapy; Cost-effectiveness analysis; Cost-utility analysis; Cost-benefit analysis
ID cost-effectiveness; european-society; consensus; quality; care; transferability; osteoporosis
AB Background: International guidelines recommend education, exercise, and dietary weight management as core treatments to manage osteoarthritis (OA) regardless of disease severity or co-morbidity. Evidence supports the clinical effectiveness of OA management programs, but the cost-effectiveness of core treatments remains unclear. We will systematically review, synthesize, and assess the literature in economic evaluations of core treatments (education, exercise, and dietary weight management) for the management of hip and/or knee OA. Methods: We will search the following elecftronic databases (from inception onwards): MEDLINE, EMBASE, Cochrane Central Register of Controlled Trials (CENTRAL), National Health Services Economic Evaluation Database, and EconLit. Economic evaluations alongside randomized or nonrandomized clinical trials investigating OA education, exercise, and dietary weight management interventions will be included. Title, abstract, and full text of relevant publications will be screened independently by two reviewers. A content matter expert will resolve any conflicts between two reviewers. Key information from relevant papers will be extracted and tabulated to provide an overview of the published literature. Methodological quality will be evaluated using the Consensus on Health Economic Criteria list. A narrative synthesis without meta-analysis will be conducted. Subgroup analysis will attempt to find trends between research methods, intervention characteristics, and results. Discussion: The findings of this review will evaluate the breadth and quality of economic evaluations conducted alongside clinical trials for core treatments in OA management. Systematic review registration PROSPERO CRD42020155964

ID activated receptor-gamma; ppar-gamma; stem-cells; rosiglitazone; adipocytes; expression; osteoclastogenesis; differentiation; histopathology; osteoarthritis
AB Marrow adipocytes and osteoblasts differentiate from common mesenchymal progenitors in a mutually exclusive manner, and diversion of these progenitors toward adipocytes in old age has been proposed to account for the decline in osteoblasts and the development of involutional osteoporosis. This idea has been supported by evidence that thiazolidinedione (TZD)-induced activation of PPAR gamma, the transcription factor required for adipocyte differentiation, increases marrow fat and causes bone loss. We functionally tested this hypothesis using C57BL/6J mice with conditional deletion of PPAR gamma from early mesenchymal progenitors targeted by the Prx1-Cre transgene. Using a longitudinal littermate-controlled study design, we observed that PPAR gamma is indispensable for TZD-induced increase in marrow adipocytes in 6-month-old male mice, and age-associated increase in marrow adipocytes in 22-month-old female mice. In contrast, PPAR gamma is dispensable for the loss of cortical and trabecular bone caused by TZD or old age. Instead, PPAR gamma restrains age-dependent development of cortical porosity. These findings do not support the long-standing hypothesis that increased marrow adipocyte differentiation contributes to bone loss in old age but reveal a novel role of mesenchymal cell PPAR gamma in the maintenance of cortical integrity.

DT Review
DE senolytics; dasatinib; quercetin; fisetin; senescent cell anti-apoptotic pathways; unitary theory of fundamental aging processes
ID cellular senescence; secretory phenotype; in-vivo; aurora kinase; stem-cells; inhibition; p16(ink4a); tissue; age; replication
AB Senolytics are a class of drugs that selectively clear senescent cells (SC). The first senolytic drugs Dasatinib, Quercetin, Fisetin and Navitoclax were discovered using a hypothesis-driven approach. SC accumulate with ageing and at causal sites of multiple chronic disorders, including diseases accounting for the bulk of morbidity, mortality and health expenditures. The most deleterious SC are resistant to apoptosis and have up-regulation of anti-apoptotic pathways which defend SC

against their own inflammatory senescence-associated secretory phenotype (SASP), allowing them to survive, despite killing neighbouring cells. Senolytics transiently disable these SCAPs, causing apoptosis of those SC with a tissue-destructive SASP. Because SC take weeks to reaccumulate, senolytics can be administered intermittently - a 'hit-and-run' approach. In preclinical models, senolytics delay, prevent or alleviate frailty, cancers and cardiovascular, neuropsychiatric, liver, kidney, musculoskeletal, lung, eye, haematological, metabolic and skin disorders as well as complications of organ transplantation, radiation and cancer treatment. As anticipated for agents targeting the fundamental ageing mechanisms that are 'root cause' contributors to multiple disorders, potential uses of senolytics are protean, potentially alleviating over 40 conditions in preclinical studies, opening a new route for treating age-related dysfunction and diseases. Early pilot trials of senolytics suggest they decrease senescent cells, reduce inflammation and alleviate frailty in humans. Clinical trials for diabetes, idiopathic pulmonary fibrosis, Alzheimer's disease, COVID-19, osteoarthritis, osteoporosis, eye diseases and bone marrow transplant and childhood cancer survivors are underway or beginning. Until such studies are done, it is too early for senolytics to be used outside of clinical trials.

TI Denosumab prevents periprosthetic bone mineral density loss in the tibial metaphysis in total knee arthroplasty
SO KNEE

LA English
DT Article
DE Periprosthetic bone; Bone mineral density; Osteoporosis; Total knee arthroplasty; Denosumab; Treatment
ID postmenopausal women; vertebral fractures; bisphosphonate use; controlled-trial; early migration; proximal tibia; follow-up; alendronate; discontinuation; bmd
AB Background: Periprosthetic bone quality is one of the most important factors preventing early prosthesis migration and long-term failure. Although denosumab, which binds to the receptor activator of nuclear factor kappa-B ligand (RANKL), has been linked with periprosthetic bone mineral density (BMD), the effectiveness of denosumab against bone loss remains unclear. We hypothesized that denosumab treatment after total knee arthroplasty (TKA) could prevent periprosthetic bone resorption. Methods: In this prospective cohort study. 28 patients with primary knee osteoarthritis were divided into two groups: denosumab (denosumab and vitamin D) and control (vitamin D only) groups. All patients underwent TKA with the same implant model and received medication after surgery. We used dual-energy X-ray absorptiometry to measure periprosthetic BMD after TKA. Results: In the control group, the BMD of the proximal medial tibia decreased drastically at 12 months after TKA (- 19.7%). Denosumab treatment significantly preserved this BMD loss (0.7%). The linear regression analysis revealed that denosumab intervention had the highest significantly positive relationship with BMD. Conclusions: Our results indicate that denosumab treatment significantly reduces periprosthetic BMD loss, even at the early stages after TKA. This therapeutic strategy may facilitate early stable fixation of the prosthesis which, in turn, may help to prevent early implant migration and reduce the need for revision surgery. TI Tomatidine suppresses inflammation in primary articular chondrocytes and attenuates cartilage degradation in osteoarthritic rats
SO AGING-US
LA English
DT Article

DE tomatidine; osteoarthritis; interleukin-1 beta; chondrocyte; NF-kappa B
ID nf-kappa-b; tumor-necrosis-factor; matrix degradation; european-society; economic-aspects; expression; pathway; osteoporosis; activation; management
AB In this study, we investigated whether the anti-inflammatory effects of tomatidine alleviate osteoarthritis (OA)-related pathology in primary articular chondrocytes and a rat OA model. STITCH database analysis identified 22 tomatidine-target genes that were enriched in 78 Kyoto Encyclopedia of Genes and Genomes (KEGG) pathways. Moreover,39 of the 105 OA-related KEGG pathways were related to tomatidine-target genes. The top two OA-related KEGG pathways with tomatidine-target genes were the MAPK and neutrophin signaling pathways. Pretreating primary chondrocytes with tomatidine suppressed interleukin-1 beta (IL-1 beta)-induced expression of iNOS, COX-2, MMP1, MMP3, MMP13, and ADAMTS-5. Tomatidine also suppressed IL-1 beta-induced degradation of collagen-II and aggrecan proteins by inhibiting NF-kappa B and MAPK signaling. In a rat OA model, histological and immunohistochemical analyses showed significantly less cartilage degeneration in thetibiofemoral joints of rats treated for 12 weeks with tomatidine after OA induction (experimental group) than in untreated OA group rats. However, micro-computed tomography (mu-CT) showed that tomatidine did not affect remodeling of the subchondral bone at the tibial plateau. These data shows that tomatidine suppresses IL-1 beta-induced inflammation in primary chondrocytes by inhibiting the NF-kappa B and MAPK signaling pathways, and protects against cartilage destruction in a rat OA model.

TI Tumor-Induced Osteomalacia Caused by a Phosphaturic Mesenchymal Tumor of

the Sole Presenting as a Crippling Illness in a Postmenopausal Woman
SO JOURNAL OF FOOT & ANKLE SURGERY
LA English
DT Article
DE definite diagnosis; fibroblast growth factor 23; fine-needle aspiration biopsy; hypophosphatemia; oncogenic osteomalacia; osteoporosis
ID oncogenic osteomalacia; osteoporosis; diagnosis
AB Tumor-induced osteomalacia, a rare and intriguing paraneoplastic syndrome that is usually caused by a phosphaturic mesenchymal tumor, leads to severe pain and hypophosphatemia. However, during clinical practice, most patients suffer from significant delay of diagnosis and treatment because the symptoms are similar to those of some very common diseases, such as osteoporosis and osteoarthritis. Moreover, physical complaints from postmenopausal women usually exacerbate the possibility of such delays. We describe a case of a postmenopausal woman with crippling bone pain and weakness, who had been diagnosed with a case of simple osteoporosis and osteoarthritis for 3 years, even with fine-needle aspiration biopsy of the offending phosphaturic mesenchymal tumor. After surgical removal of the 2 x 3-cm(2) tumor in her sole, we observed immediate relief of her systemic symptoms, with visual analogue scale improvement from 5 of 10 preoperatively to 2 of 10 5 days after surgery. There were no signs of recurrence during 2-year follow-up. This case highlights the significance of thorough history-taking as a fundamental tool for diagnosis even in the era of advanced technology, and that the awareness of tumor-induced osteomalacia should be raised. Otherwise, such a small localized soft tissue mass would seldom be associated with the severe systemic symptoms. (C) 2020 by the American College of Foot and Ankle Surgeons. All rights reserved.

TI Nuclear mechanosensing controls MSC osteogenic potential through HDAC epigenetic remodeling
SO PROCEEDINGS OF THE NATIONAL ACADEMY OF SCIENCES OF THE UNITED STATES OF AMERICA
LA English
DT Article
DE hMSCs; epigenetic remodeling; phototunable hydrogels
ID mesenchymal stem-cells; matrix elasticity; gene-expression; stromal cells; differentiation; mechanisms; osteoporosis; organization; acetylation; induction
AB Cells sense mechanical cues from the extracellular matrix to regulate cellular behavior and maintain tissue homeostasis. The nucleus has been implicated as a key mechanosensor and can directly influence chromatin organization, epigenetic modifications, and gene expression. Dysregulation of nuclear mechanosensing has been implicated in several diseases, including bone degeneration. Here, we exploit photostiffening hydrogels to manipulate nuclear mechanosensing in human mesenchymal stem cells (hMSCs) in vitro. Results show that hMSCs respond to matrix stiffening by increasing nuclear tension and causing an increase in histone acetylation via deactivation of histone deacetylases (HDACs). This ultimately induces osteogenic fate commitment. Disrupting nuclear mechanosensing by disconnecting the nucleus from the cytoskeleton up-regulates HDACs and prevents osteogenesis. Resetting HDAC activity back to healthy levels rescues the epigenetic and osteogenic response in hMSCs with pathological nuclear mechanosensing. Notably, bone from patients with osteoarthritis displays similar defective nuclear mechanosensing. Collectively, our results reveal that nuclear mechanosensing controls hMSC osteogenic potential mediated by HDAC epigenetic remodeling and that this cellular mechanism is likely relevant to bone-related diseases.

TI Comprehensive analysis of skeletal muscle- and bone-derived mesenchymal stem/stromal cells in patients with osteoarthritis and femoral neck fracture

SO STEM CELL RESEARCH & THERAPY
LA English
DT Article
DE Mesenchymal stem; stromal cells; Skeletal muscle; Trabecular bone; Osteoarthritis; Osteoporosis; Controls; Leptin receptor
ID stem-cells; stromal cells; gene-expression; osteoporosis; obesity; leptin; system; mscs
AB Background Mesenchymal stem/stromal cells (MSCs) can replenish the aged cells of the musculoskeletal system in adult life. Stem cell exhaustion and decrease in their regenerative potential have been suggested to be hallmarks of aging. Here, we investigated whether muscle- and bone-derived MSCs of patients with osteoarthritis and osteoporosis are affected by this exhaustion, compared to healthy donors. Methods Patients with primary osteoarthritis, femoral neck fractures due to osteoporosis, and healthy donors (controls) were included. MSCs were isolated from the skeletal muscle and subchondral bone from each patient and compared using ex vivo and in vitro analyses, including immunophenotyping, colony-forming unit fibroblast assays, growth kinetics, cell senescence, multilineage potential, and MSC marker gene expression profiling. Results Freshly isolated cells from muscle from patients with osteoarthritis showed a lower proportion of CD45/CD19/CD14/CD34-negative cells compared to patients with osteoporosis and healthy donors. Freshly isolated muscle cells from patients with osteoarthritis and osteoporosis also showed higher clonogenicity compared to healthy donors. MSCs from both tissues of osteoarthritis patients showed significantly reduced osteogenesis and MSCs from the bone also reduced adipogenesis. Chondrogenic pellet diameter was reduced in bone-derived MSCs from both patient groups compared to healthy donors. A significant positive correlation was observed between adipogenesis and CD271 expression in muscle-derived MSCs. CD73 was significantly lower in bone-derived MSCs from osteoarthritis patients, compared to osteoporosis patients. Gene expression profiling showed significantly lower expression of MSC marker gene leptin receptor, LEPR, previously identified as the major source of the bone and adipocytes in the adult bone marrow, in bone-derived MSCs from patients with osteoarthritis in comparison with osteoporotic patients and healthy donors. Conclusions Our results show deficient ex vivo and in vitro properties of both skeletal muscle- and bone-derived MSCs in osteoarthritis and osteoporosis patients, compared to healthy donors. In bone-derived MSCs from patients with osteoarthritis, we also identified a lower expression of the leptin receptor, a marker of MSCs that present a major source of MSCs in the adult bone marrow. This suggests that exhaustion of skeletal muscle- and bone-derived MSCs is a hallmark of osteoarthritis and osteoporosis, which defines the need for further clinical trials of stem cell transplantation in these patients.

TI Effect of Cholecystectomy on the Occurrence of Knee Osteoarthritis
SO ORTHOPAEDIC SURGERY
LA English
DT Article
DE Cholecystectomy; Disease occurrence; KOA; Osteoporosis; Subchondral trabeculae
ID bone-mineral density; laparoscopic cholecystectomy; osteoporosis; population
AB Objective To evaluate the effect of cholecystectomy on the occurrence of knee osteoarthritis (KOA). Methods The present study was a case-control study with a retrospective, cross-sectional, and longitudinal study design. The clinical data for knee osteoarthritis in the Second Hospital of Shanxi Medical University from January 2016 to September 2018 was analyzed. Clinical data, including gender, age, height, weight, smoking, alcohol abuse, prior medical history, and previous surgical history, were recorded. A logistic regression model was used for the univariate and multivariate analysis. Results A total of 1659 patients with KOA (KOA group) and 1195 limb fracture patients (control group) were included in this study. Among the 1659 patients with KOA, 388 patients were male and 1271 were female, while among the 1195 patients in the control group, 638 patients were male and 557 patients were female. The period between cholecystectomy and knee osteoarthritis onset ranged from 0.5 years to 17 years; the average interval time was 8.73 +/- 2.11 years. The age at disease onset was significantly older when compared to the control group, while the body mass index in the KOA group was significantly higher when compared to the control group ($P < 0.05$). There were 97 patients undergoing cholecystectomy in the KOA group and there were 15 patients undergoing cholecystectomy in the control group. The proportion of cholecystectomy in the two groups was statistically significant. After the univariate

analysis, there was a statistically significant difference in distribution between the two groups ($P < 0.05$). The multivariate logistic regression analysis revealed that there was a significant difference in the distribution of these two groups ($P < 0.05$), indicating that cholecystectomy is associated with the occurrence of KOA. Conclusion There is a close relationship between cholecystectomy and KOA. However, the specific mechanism remains unknown and should be further researched.

TI Cellular senescence in age-related disorders
SO TRANSLATIONAL RESEARCH
LA English
DT Review
ID secretory phenotype; cells; osteoarthritis; clearance; fisetin; tissue; atherosclerosis; inhibition; expression; biomarker
AB Much of the population is now faced with an enormous burden of age-associated chronic diseases. Recent discoveries in geroscience indicate that

healthspan in model organisms such as mice can be manipulated by targeting cellular senescence, a hallmark mechanism of aging, defined as an irreversible proliferative arrest that occurs when cells experience oncogenic or other diverse forms of damage. Senescent cells and their proinflammatory secretome have emerged as contributors to age-related tissue dysfunction and morbidity. Cellular senescence has causal roles in mediating osteoporosis, frailty, cardiovascular diseases, osteoarthritis, pulmonary fibrosis, renal diseases, neurodegenerative diseases, hepatic steatosis, and metabolic dysfunction. Therapeutically targeting senescent cells in mice can prevent, delay, or alleviate each of these conditions. Therefore, senotherapeutic approaches, including senolytics and senomorphics, that either selectively eliminate senescent cells or interfere with their ability to promote tissue dysfunction, are gaining momentum as potential realistic strategies to abrogate human senescence to thereby compress morbidity and extend healthspan.

TI Progranulin Regulates the Differentiation of Bone Marrov Mesenchymal Stem Cells Under Inflammation Through Focal Adhesion Kinase (FAK)/Mitogen-Activated Protein Kinase (MAPK) Pathway
SO JOURNAL OF BIOMATERIALS AND TISSUE ENGINEERING
LA English
DT Article
DE Inflammatory; BMSCs; Proliferation; FAK/MAPK; Osteogenesis
ID cartilage; cancer
AB Osteogenic differentiation of BMSCs is beneficial to the treatment of osteoarthritis. Progranulin (PGRN) is a chondrogenic factor. However, the role of progranulin in the differentiation of BMSCs under inflammation remains unclear. Rat BMSCs were isolated and divided into control group, inflammation group (treated with LPS), and PGRN group (5 and 10 /mu M) followed by analysis of survival rate of BMSCs by MTT assay, Caspase 3 activity, ALP activity, expression of Runx2 and OP by real time PCR, level of MMP-3, TIMP-1, FAK and MAPK by Western blot and IL-6 and IL-10 secretion by ELISA. LPS treatment significantly inhibited BMSCs proliferation, increased Caspase 3 activity, decreased ALP activity, expression of Runx2 and OP, increased IL-6 secretion, decreased IL-10 secretion,

increased MMP-3 expression, decreased expression of TIMP-1, FAK and p-P38 ($P < 0.05$). PGRN treatment on BMSCs under inflammation significantly promoted cell proliferation, decreased Caspase 3 activity, increased ALP activity, expression of Runx2 and OP, decreased IL-6 secretion, increased IL-10 secretion, decreased MMP-3 expression, and increased TIMP-1, FAK and p-P38 expression ($P < 0.05$) with more significant changes in the higher concentration. Under inflammation, BMSCs proliferation was inhibited, apoptosis was increased, and osteogenic differentiation was weakened. PGRN inhibits the proliferation of BMSCs and apoptosis, and promotes osteogenic differentiation by regulating FAK/MAPK pathway.

TI Comparative transcriptome analysis identifies CARM1 and DNMT3A as genes associated with osteoporosis
SO SCIENTIFIC REPORTS
LA English
DT Article
ID bone-mineral density; insulin-resistance; expression; risk; standardization; metaanalysis; methylation; secretion; tool
AB To identify new candidate genes in osteoporosis, mainly involved in epigenetic mechanisms, we compared whole gene-expression in osteoblasts (OBs) obtained from women undergoing hip replacement surgery due to fragility fracture and severe osteoarthritis. Then, we analyzed the association of several SNPs with BMD in 1028 women. Microarray analysis yielded 2542 differentially expressed transcripts belonging to 1798 annotated genes, of which 45.6% (819) were overexpressed, and 54.4% (979) underexpressed (fold-change between-7.45 and 4.0). Among the most represented pathways indicated by transcriptome analysis were chondrocyte development, positive regulation of bone mineralization, BMP signaling pathway, skeletal system development and Wnt signaling pathway. In the translational stage we genotyped 4 SNPs in DOT1L, HEY2, CARM1 and DNMT3A genes. Raw data analyzed against inheritance patterns showed a statistically significant association between a SNP of DNMT3A and femoral neck-(FN) sBMD and primarily a SNP of CARM1 was correlated with both FN and lumbar spine-(LS) sBMD. Most of these associations remained statistically significant after adjusting for confounders. In analysis with anthropometric and clinical variables, the SNP of CARM1 unexpectedly revealed a close association with BMI (p=0.000082), insulin (p=0.000085), and HOMA-(IR) (p=0.000078). In conclusion, SNPs of the DNMT3A and CARM1 genes are associated with BMD, in the latter case probably owing to a strong correlation with obesity and fasting insulin levels.

TI Fibrodysplasia Ossificans Progressiva (FOP): A Segmental Progeroid Syndrome
SO FRONTIERS IN ENDOCRINOLOGY
LA English
DT Review
DE progeroid syndrome; fibrodysplasia ossificans progressiva; activin A; ACVR1; cell senescence
ID nf-kappa-b; activin-a; cellular senescence; heterotopic ossification; protein; remyelination; cells; follistatin; mortality; skeleton
AB Segmental progeroid syndromes are commonly represented by genetic conditions which recapitulate aspects of physiological aging by similar, disparate, or unknown mechanisms. Fibrodysplasia ossificans progressiva (FOP) is a rare genetic disease caused by mutations in the gene for ACVR1/ALK2 encoding Activin A receptor type I/Activin-like kinase 2, a bone morphogenetic protein (BMP) type I receptor, and results in the formation of extra-skeletal ossification and a constellation of others features, many of which resemble accelerated aging. The median estimated lifespan of individuals with FOP is approximately 56 years of age. Characteristics of precocious aging in FOP include both those that are related to dysregulated BMP signaling as well as those secondary to early immobilization. Progeroid features that may primarily be associated with mutations in ACVR1 include osteoarthritis, hearing loss, alopecia, subcutaneous lipodystrophy, myelination defects, heightened inflammation, menstrual abnormalities, and perhaps nephrolithiasis. Progeroid features that may secondarily be related to immobilization from progressive heterotopic ossification include decreased vital capacity, osteoporosis, fractures, sarcopenia, and predisposition to respiratory infections. Some manifestations of precocious aging may be attributed to both primary and secondary effects of FOP. At the level of lesion formation in FOP, soft tissue injury resulting in hypoxia, cell damage, and inflammation may lead to the accumulation of senescent cells as in aged tissue. Production of Activin A, platelet-derived growth factor, metalloproteinases, interleukin 6, and other inflammatory cytokines as part of the senescence-associated secretory phenotype could conceivably mediate the initial signaling cascade that results in the intense fibroproliferative response as well as the tissue-resident stem cell reprogramming leading up to ectopic endochondral bone formation. Consideration of FOP as a segmental progeroid syndrome offers a unique perspective into potential mechanisms of normal aging and may also provide insight for identification of new

targets for therapeutic interventions in FOP.

ID transchondral fractures; dissecans
AB Recent literature suggests that adults do not necessarily develop osteoarthritis if they have an osteochondral lesion of the talus (OLT). The purpose of this study was to determine if children with OLT are at risk to develop any radiographic evidence of early joint degeneration despite treatment efforts. Fifty-six ankles were identified over 6 years with stable OLT that underwent operative treatment. Preoperatively, each lesion was classified according to Berndt-Hardy for radiographs, Hepple for MRI, and Ferkel and Sgaglione for computed tomography. Radiographs were also evaluated for physeal status, OLT characteristics (location, border, size), and signs of osteoarthritis (Kellgren and Lawrence Scale). Despite incomplete treatment to radiographic resolution, the Kellgren-Lawrence scores still worsened in 23% of the children (pre-op score: mean 0.42 and median 0 versus post-op score: mean 0.69 and median 1). No risk factors (preoperative classification, age, physeal patency) were associated with advancing radiographic evidence of articular degeneration utilizing univariate analysis. However, a classification and regression tree analysis revealed that a patient age of 11.5 years old could be predictive of advancing Kellgren-Lawrence scores with one-third of older children worsening (P = 0.038). Despite active treatment of OLT, the ultimate prognosis is guarded with approximately one out of four children advancing their Kellgren and Lawrence score during treatment. In contrast to the natural history of adult OLT, the short-term advancement of degenerative disease in childhood OLT suggests a potentially different outcome and warrants further investigation into better treatment methods to preserve ankle health in these young patients.

TI Modeling-Based Bone Formation in the Human Femoral Neck in Subjects Treated With Denosumab
SO JOURNAL OF BONE AND MINERAL RESEARCH
LA English
DT Article
DE ANTIRESORPTIVES; BONE HISTOMORPHOMETRY; BONE MODELING AND REMODELING; OSTEOPOROSIS
ID postmenopausal women; zoledronic acid; hip fracture; osteoporosis; teriparatide; risedronate; alendronate; increase; density; trial
AB Denosumab is associated with continued gains in hip and spine BMD with up to 10 years of treatment in postmenopausal women with osteoporosis. Despite potent inhibition of bone remodeling, findings in nonhuman primates suggest modeling-based bone formation (MBBF) may persist during denosumab treatment.

This study assessed whether MBBF in the femoral neck (FN) is preserved in the context of inhibited remodeling in subjects receiving denosumab. This open-label study enrolled postmenopausal women with osteoporosis who had received two or more doses of denosumab (60 mg subcutaneously every 6 months [Q6M]) per standard of care and were planning elective total hip replacement (THR) owing to osteoarthritis of the hip. Transverse sections of the FN were obtained after THR and analyzed histomorphometrically. MBBF, based on fluorochrome labeling and presence of smooth cement lines, was evaluated in cancellous, endocortical, and periosteal envelopes of the FN. Histomorphometric parameters were used to assess MBBF and remodeling-based bone formation (RBBF) in denosumab-treated subjects (n = 4; mean age = 73.5 years; range, 70 to 78 years) and historical female controls (n = 11; mean age = 67.8 years; range, 62 to 80 years) obtained from the placebo group of a prior study and not treated with denosumab. All analyses were descriptive. All subjects in both groups exhibited MBBF in the periosteal envelope; in cancellous and endocortical envelopes, all denosumab-treated subjects and 81.8% of controls showed evidence of MBBF. Compared with controls, denosumab-treated subjects showed 9.4-fold and 2.0-fold higher mean values of MBBF in cancellous and endocortical envelopes, respectively, whereas RBBF mean values were 5.0-fold and 5.3-fold lower. In the periosteal envelope, MBBF and RBBF rates were similar between subjects and controls. These results demonstrate the occurrence of MBBF in the human FN and suggest that denosumab preserves MBBF while inhibiting remodeling, which may contribute to the observed continued gains in BMD over time after remodeling is maximally inhibited. TI Obesity in midlife: lifestyle and dietary strategies
SO CLIMACTERIC
LA English
DT Article
DE Obesity; menopause; midlife weight gain; lifestyle therapy; dietary strategies; physical activity; behavioral support
ID weight-loss; clinical endocrinologists; american association; practice guidelines; position statement; physical-activity; medical-care; body-weight; health; management
AB As the rate of obesity increases globally, so does the incidence of other non-communicable diseases such as diabetes, cardiovascular disease, cancer, osteoporosis, osteoarthritis, and dementia, which have been referred to as

'adiposity-based chronic disease'. With timely lifestyle modification such as behavioral changes, implementation of a healthy diet, and proper physical activity, many of these diseases can be prevented. Weight gain is one of the major health concerns of midlife. Midlife body changes are the result of aging, menopause, and other influences unique to menopausal women which interfere with adoption of a healthy lifestyle. Reduced metabolism levels lead to low energy levels, which discourage physical activity. In addition, with the onset of bone loss, menopausal women begin to lose muscle mass and gain more fat, resulting in osteopenic sarco-obesity. Adoption of a healthy lifestyle is a first-line option in the treatment for these midlife changes. Lifestyle medicine offers a broad set of network-based interventions, which need to be brought to the forefront in preventing and managing obesity at all stages. This review article focuses on evidence-based lifestyle changes and their benefits for reducing morbidity and mortality related to obesity and its complications prevalent at midlife and beyond.

TI Unknown osteoporosis in older patients admitted to post-acute rehabilitation
SO AGING CLINICAL AND EXPERIMENTAL RESEARCH
LA English
DT Article
DE Osteoporosis; Screening or diagnosis or detection; Older patients; Rehabilitation
ID bone-mineral density; vertebral fracture assessment; hip fracture; lumbar spine; instrumental activity; women; risk; diagnosis; men; osteoarthritis
AB Background Osteoporotic fractures are associated with increased morbidity, mortality, and increased health care use. As the number of older adults increases, identifying those at increased risk for osteoporotic fractures has become of utmost importance to providing them with preventive and therapeutic interventions. Aims To determine the prevalence of unknown clinical and densitometric osteoporosis and to investigate the performance of different diagnostic strategies for osteoporosis in elderly patients admitted to rehabilitation. Method This is an observational study. Eligible participants were older adults admitted to rehabilitation in an academic hospital in Switzerland over an 11-month period. Patients with previously unknown osteoporosis underwent dual-energy X-ray absorptiometry (DXA), vertebral fracture assessment (VFA), and history review for past fractures. Results Complete assessment was available for 252 patients. Previously undiagnosed osteoporosis was identified in 62.3% of these patients, a proportion that was higher among women (71.5%) than men (44.8%). DXA proved most sensitive, followed by VFA and history review. Results differed across gender: DXA remained the most sensitive single test among women, but VFA proved most sensitive in men. The best test to combine with history review was DXA in women (detection increasing from 47.5 to 93.2%) and VFA in men (detection increasing

from 35.9 to 84.6%). Conclusions Prevalence of previously unknown osteoporosis appears very high in elderly patients admitted to post-acute rehabilitation. The combination of history review of previous fractures with DXA in women and with VFA in men appears the best two-step strategy to improving detection of osteoporosis in this population.

TI Successful total hip arthroplasty for autosomal dominant osteopetrosis complicated by hip osteoarthritis: A case report and review of the literature
SO EXPERIMENTAL AND THERAPEUTIC MEDICINE
LA English
DT Review
DE total hip arthroplasty (THA); osteopetrosis; osteoarthritis; hip pain; operative difficulties; osteoclast
ID malignant infantile osteopetrosis; stem-cell transplantation; management
AB Osteopetrosis is a rare congenital bone disorder, characterized by systemic osteosclerosis due to a deficiency of or functional defect in osteoclasts. Autosomal dominant osteopetrosis (ADOP) is the most common form with a late onset, a stable condition, relatively few symptoms and a good prognosis. Few studies to date have reported successful total hip arthroplasty (THA) in patients with ADOP and its operative difficulties. We herein describe a case of left hip osteoarthritis in a patient with OP via THA in order to share our experience during the treatment process. The patient was a 52-years-old female with osteopetrosis who was referred to our department due to a history of left hip pain with activity limitation for 20 years. The patient reported no history of fracture or family history. The patient underwent THA in the left hip. At the 6-month, 1- and 2-year follow-up, the components were in a good position and the patient remained asymptomatic and pain-free. Therefore, THA may be a feasible treatment option when patients with ADOP suffer from painful hip osteoarthritis.

TI Characteristics of medial condyle sagittal fracture of distal femur involving intercondylar notch in geriatric patients
SO ARCHIVES OF ORTHOPAEDIC AND TRAUMA SURGERY
LA English
DT Article
DE Fragility fracture; Unicondylar fractures; Distal femur
ID unicondylar fractures; fragility fracture
AB Introduction Unicondylar femoral fractures are uncommon injuries, known to occur primarily in young people, with high energy trauma. However, according to our experiences, unicondylar femoral fractures in geriatric patients generally involved the medial femoral condyle, unlike previously reported. In addition, the fractures of medial femoral condyle (FMFC) showed a characteristic fracture pattern. To date, there has been no published article focusing on the FMFC in geriatric patients. Thus, the aim of this study was to determine the characteristics of FMFC in geriatric patients and to present their outcomes. Materials and methods We retrospectively reviewed the medical records of 13 patients over age of 65 who underwent surgery for FMFC (AO-OTA 33B2). Of the 13, 10 patients were treated with Tomofix medial distal femoral plate (MDF) (Synthes GmbH, Switzerland) and additional screws fixation; the other three were treated with screw fixation and cast application. Results The mean age of patients was 76.8 years, and 10 patients were females. The fracture was due to low-energy trauma in all of the cases. Eight patients had medial knee osteoarthritis, and 2 patients were on osteoporosis treatment. A characteristic fracture pattern was observed. The fracture line extended from the lateral aspect of the intercondylar notch to the posteromedial column of the distal femur, with a characteristic medial beak. All fractures belonged to AO classification 33B2.1; there were no cases of AO classification 33B2.2 or 33B2.3. The postoperative joint function was graded according to the Kolmert functional criteria: ten cases were excellent, one case was good, one case was fair, and one case was poor. Conclusion FMFC caused by low-energy trauma in geriatric patients tend to have a characteristic pattern. We believe that anatomic reduction and firm fixation with Tomofix MDF plate and cannulated screw for low-energy trauma FMFC in geriatric patients would yield good outcomes.

DT Article
DE Bone marrow edema (BME); magnetic resonance imaging (MRI); management; diagnosis; treatment
ID mr-imaging findings; osteochondral autograft transplantation; recurrent multifocal osteomyelitis; femoral-head; transient osteoporosis; knee osteoarthritis; nontraumatic osteonecrosis; avascular necrosis; articular defects; surgical options

AB Bone marrow edema (BME) is a descriptive term for a common finding in magnetic resonance imaging (MRI). Although pain is the major symptom, BME differs in terms of its causal mechanisms, underlying disease, as well as treatment and prognosis. This complexity together with the lack of evidence-based guidelines, frequently makes the identification of underlying conditions and its management a major challenge. Unnecessary multiple consultations and delays in diagnosis as well as therapy indicate a need for interdisciplinary clinical recommendations. Therefore, an interdisciplinary task force was set up within our large osteology center consisting of specialists from internal medicine, endocrinology/diabetology, hematology/oncology, orthopedics, pediatrics, physical medicine, radiology, rheumatology, and trauma surgery to develop a consenus paper. After review of literature, review of practical experiences (expert opinion), and determination of consensus findings, an overview and an algorithm were developed with concise summaries of relevant aspects of the respective underlying disease including diagnostic measures, clinical features, differential diagnosis and treatment of BME. Together, our single-center consensus review on the management of BME may help improve the quality of care for these patients.

TI Acromial Fractures Following Reverse Total Shoulder Arthroplasty: A Cohort Controlled Analysis
SO ORTHOPEDICS

LA English
DT Article
ID computed-tomography; glenohumeral joint; hounsfield units; proximal humerus; 4-part fractures; scapula; osteoarthritis; radiographs; prosthesis; angle
AB Fractures of the acromion can develop after reverse total shoulder arthroplasty (RTSA). This study sought to identify risk factors for acromial fracturesin patients with RTSA. A total of 1146 RTSAs were performed at theauthors' institution between 1999 and 2016. In 21 patients (1.8%), the authors identified an acromial fracture during the postoperative course. These patients were compared with a matched cohort of 84 patients who had not developed an acromial fracture postoperatively. As an indicator of changes in pre- to postoperative deltoid loading, the authors created an angle called the "delta angle." There was an elevated risk for acromial fractures with lower lateralization of the humerus from pre- to postoperatively (4.1 +/- 7.1 mm vs 8.4 +/- 6.1 mm; P=.006), lower preoperative anteroposterior acromial slope (117.3 degrees +/- 11.2 degrees vs 121.7 degrees +/- 17.0 degrees; P=.044), and higher glenoid inclination (beta angle, 72.0 degrees +/- 5.5 degrees vs 76.5 degrees +/- 6.8 degrees; P=.005). Pre- topostoperative changes in the beta angle (9.2 degrees +/- 8.0 degrees vs 4.4 degrees +/- 9.4 degrees; P=.022) and the delta angle (29.4 degrees +/- 8.1 degrees vs 19.5 degrees +/- 9.7 degrees; P<.001) were larger in the fracture group. In addition, diagnosed and treated osteoporosis appeared to be a risk factor for acromial fractures (33% vs 13%; P=.047). The delta angle after RTSA seems to correlate with the risk of developing an acromial fracture. Patients with a high glenoid inclination and/or osteoporosis should be informed that they are at risk. Further, surgeons should be aware that lower distalization together with greater medialization of the center of rotation was associated with more acromial fractures in this study.

TI Underestimation and undertreatment of osteoporosis in patients awaiting primary total knee arthroplasty
SO ARCHIVES OF ORTHOPAEDIC AND TRAUMA SURGERY
LA English
DT Article
DE Total knee arthroplasty; Osteoporosis; Prevalence; Treatment
ID bone-mineral density; periprosthetic fractures; osteoarthritis; prevalence; diagnosis; women; classification; korea; risk; hip
AB Introduction Osteoporosis is generally regarded as a risk factor for periprosthetic fracture during or after primary total knee arthroplasty (TKA).

Despite this, little is known about osteoporosis in patients undergoing elective primary TKA Therefore, we sought to investigate the prevalence of osteoporosis and rates of pharmacologic osteoporosis treatment prior to primary TKA. We hypothesized that preoperative osteoporosis is underestimated and undertreated in the primary TKA population. Materials and methods This retrospective study included consecutive 1972 patients scheduled for elective primary TKA at a single tertiary hospital (age, 50-89 years). Charts were reviewed for patient demographics, prior pharmacologic osteoporosis treatment and Knee Society (KS) scoring system and WOMAC score. Dual energy X-ray absorptiometry (DEXA) measurement of the lumbar vertebrae and proximal femur was performed in all patients on the day before surgery. The associations of BMD with age, sex, body mass index (BMI), and clinical outcome were analyzed. Results The prevalence of osteoporosis was 50.0% (53.4% in women and 7.0% in men). Among patients with osteoporosis, only 15.1% (149/986) of patients (15.0% in women and 30.0% in men) had pharmacological osteoporosis treatment prior to primary TKA. Age, sex and WOMAC stiffness showed association with osteoporosis. Sex (odds ratio (OR): 20.83, $p < 0.001$) was the most significant factor associated with osteoporosis. Conclusion Osteoporosis was highly prevalent in patients awaiting TKA, but the rates of diagnosis and pharmacologic osteoporosis treatment were low. Therefore, more attention needs to estimate and treat osteoporosis in patients awaiting primary TKA, especially in female patients.

TI Raloxifene Prevents Early Periprosthetic Bone Loss for Postmenopausal Women after Uncemented Total Hip Arthroplasty: A Randomized Placebo-Controlled Clinical Trial
SO ORTHOPAEDIC SURGERY
LA English
DT Article
DE Bone loss; Postmenopausal osteoporosis; Raloxifene; Total hip arthroplasty (THA)
ID follow-up; mineral density; 2-year rsa; alendronate; pathways; cups; stem; dxa; bmd
AB Objective To examine the results of raloxifene for prevention of periprosthetic bone loss around the femoral stem in patients undergoing total hip arthroplasty (THA). Methods Between January 2015 and May 2017, 240 female patients between 55 and 80 years underwent primary THA and were randomly allocated to receive 60 mg raloxifene hydrochloride per day (treatment group, TG, n = 120) or placebo (control group, CG, n = 120) orally at bedtime using computer-generated randomization sequence generation. Baseline data, the Western Ontario McMaster Universities Osteoarthritis Index (WOMAC), women's quality of life (QoL) score, bone mineral density (BMD) around the prosthesis, and adverse events were compared between the two groups. The measuring range of BMD around the prosthesis was divided into seven regions of interest (ROI). The sample size was calculated to detect a mean difference in BMD of 0.15 g/cm(2)with a standard

deviation (SD) of 0.3. The error was set at 0.05 and the power level at 90% with additional compensation for a possible dropout rate of 20%. Results A total of 240 participants in the study up to 24 months after THA. There were no significant differences in the mean BMD of all the zones between groups before surgery (allP> 0.05). However, there were significant differences in the BMD of Gruen zones 4 and 7 between groups at 6 months postoperatively (bothP< 0.05); there were significant differences in Gruen zones 1, 4, 6, and 7 at 12 months postoperatively (allP< 0.01); there were significant differences in Gruen zones 1, 2, 4, 6, and 7 at 24 months postoperatively (allP< 0.001). Patients taking raloxifene reported higher QoL scores, with better improvement in BMD in all areas except in zones 3 and 5 compared with the control group. There were no significant differences in WOMAC pain (P= 0.4045), WOMAC function (P= 0.4456) and women's QoL scores (P= 0.5983) between groups before surgery. However, WOMAC pain, WOMAC function and women's QoL score in the treatment group were significantly better at all time points (allP< 0.05). Patients in the treatment group showed no increased adverse events, including cardiac events, stroke, venous thromboembolism, and gynecological cancer (allP> 0.05), but did show decreased odds of breast cancer in comparison with those using a placebo (P= 0.0437). Conclusion Raloxifene can help inhibit bone loss around the prosthesis and improve the QoL of postmenopausal women after THA with no increased adverse events, and can even decrease the odds of breast cancer.

TI The Association of Gait Speed and Frontal Lobe among Various Cognitive Domains: The Korean Frailty and Aging Cohort Study (KFACS)
SO JOURNAL OF NUTRITION HEALTH & AGING
LA English
DT Article
DE Gait; cognitive function; frontal lobe function; elderly
ID walking; decline; impairment; activation; disorders; dementia; people; adults
AB Objective The aim of this study was to determine how gait speed and frontal lobe functionsin community-dwelling older adults in Korea. Design This was a

cross-sectional study. Setting The study used data from the Korean Frailty and Aging Cohort Survey (KFACS), a multi-center longitudinal study addressing 10 centers across urban, rural, and suburban communities in Korea, between 2016 and 2017. Participants A total of 1552 older adults who underwent both gait speed tests and cognitive functions tests during the investigation of the KFACS. Measurements Gait speed was assessed by asking participants to walk from a starting point to a point 4 meters away at a normal gait. Cognitive functions were evaluated using various standardized cognitive functions tests. Results Gait speed was slower when participants were older or less educated The percentage of women, higher BMI, people with lower incomes, singles, smokers, and drinkers was high in the slower gait group. Also, all cognitive function scores were low and depression score was high in the group with slower walking speed. The slower walking speed showed low physical activity score and high prevalence of hypertension, osteoarthritis and osteoporosis. Among the seven cognitive functions (MMSE, memory, TMT, Recall, Recognition, digit span, and Fab), only TMT showed no significant difference between different gait speed groups. The other six cognitive functions showed higher results in the fastest gait speed group (T3), Participants in middle gait speed group (T2) also showed higher results in five of the seven cognitive function scores as well (Memory, Recall, Recognition, digit span, and Fab). Conclusion In this study, we found correlation between the slower gait speeds and the decrease in cognitive function, and especially the frontal lobe dysfunction was most prominent of all cognitive dysfunctions.

TI Sulfurous thermal waters stimulate the osteogenic differentiation of human mesenchymal stromal cells - An in vitro study
SO BIOMEDICINE & PHARMACOTHERAPY
LA English
DT Article
DE Sulfurous thermal water; Osteogenesis; Hydrogen sulfide; Mesenchymal stromal cells; Mineralization; Complementary medicine
ID hydrogen-sulfide; fluorescent-probes; double-blind; spa therapy; balneotherapy; osteoporosis; inhalations; expression; ions; osteoarthritis
AB Strategies aimed at delaying the onset of bone tissue degeneration and the resulting skeletal fragility are key to decrease the risk of bone fracture correlated to ageing. The therapeutic properties of sulfurous thermal waters (STWs), rich in hydrogen sulfide (H2S), have been claimed for centuries. However, the direct regulation of bone cells by STWs has not been investigated yet. Here we aimed at analyzing the effect of STWs on cultured human mesenchymal stromal cells (hMSCs) derived from bone tissue. Two concentrations of STWs from 2 health spa centers in Italy (here named STW-1 and STW-2) containing, respectively, high and moderate quantities of H2S, were added to the culture media. Cytotoxicity and osteogenic differentiation were evaluated. We provided first evidence that treatment of hMSCs with STWs results in a sharp increase in intracellular H2S content, coherent with the different concentrations of H2S, thereby reveling that STWs-released H2S is internalized by cells. STWs treatment significantly induced osteogenic differentiation of hMSCs. In particular, mineral apposition was increased with a similar pattern by the two STWs, while mRNA expression of osteogenic markers (BSP, OC, RUNX-2, OPN) was differently affected. Only STW-2 induced a significant, dose-dependent increase in these gene expression. These findings support the rationale for the use of STWs as a complementary treatment of bone wasting diseases.

TI Alterations in DNA methylation profiles in cancellous bone of postmenopausal women with osteoporosis

SO FEBS OPEN BIO
LA English
DT Article
DE differentially methylated genes; DNA methylation profiles; osteoporosis; postmenopausal women; signaling pathways
ID expression profile; fracture; cells; identification; microarray; strength; modulus; density; risk; rna
AB Osteoporosis is characterized by systemic microarchitecture impairment and bone loss, which ultimately lead to fragility fractures. This disease is most common in older people, especially in postmenopausal women. Cancellous bone is affected by osteoporosis earlier than cortical bone, and DNA methylation microarray analysis of the hip cancellous bone of patients with osteoarthritis revealed differential methylation. In view of the important role of cancellous bone in bone development, we examined genome-wide DNA methylation profiles in the cancellous bone from patients with postmenopausal osteoporosis versus healthy postmenopausal women using Illumina 850K methylation microarray analysis. Under a threshold ofP < 0.05, we obtained a total of 8973 differentially methylated genes, such asSOX6,ACE,SYKandTGFB3. Under a threshold ofP 0.2, a total of 17 and 34 key differentially methylated genes were further identified at the promoter region and cytosine- phosphate- guanine (CpG) islands (such asPRKCZ,GNA11andCOL4A1), respectively.PLEKHA2,PLEKHB1,PNPLA7,SCD,MGST3andTSNAXwere the most common differentially methylated genes at both the promoter region and CpG islands. Five important signaling pathways, including the calcium signaling pathway, the cyclic guanosine phospho-protein kinase G (cGMP-PKG) signaling pathway, endocytosis, the Rap1 signaling pathway and the AMPK signaling pathway were identified. Our study may be suitable as a basis for exploring the mechanisms underlying osteoporosis in postmenopausal women.

TI Probing Trace Elements in Human Tissues with Synchrotron Radiation

SO CRYSTALS
LA English
DT Review
DE synchrotron; X-ray fluorescence; X-ray absorption spectroscopy; trace elements; biological tissues; medicine; diseases
ID x-ray-fluorescence; invasive ductal carcinoma; human bone; arsenic microdistribution; absorption spectroscopy; chemical speciation; oxidation-state; iron compounds; breast-cancer; zinc
AB For the past several decades, synchrotron radiation has been extensively used to measure the spatial distribution and chemical affinity of elements found in trace concentrations (<few mu g/g) in animal and human tissues. Intense and highly focused (lateral size of several micrometers) X-ray beams combined with small steps of photon energy tuning (2-3 eV) of synchrotron radiation allowed X-ray fluorescence (XRF) and X-ray absorption spectroscopy (XAS) techniques to nondestructively and simultaneously detect trace elements as well as identify their chemical affinity and speciation in situ, respectively. Although limited by measurement time and radiation damage to the tissue, these techniques are commonly used to obtain two-dimensional and three-dimensional maps of several elements at synchrotron facilities around the world. The spatial distribution and chemistry of the trace elements obtained is then correlated to the targeted anatomical structures and to the biological functions (normal or pathological). For example, synchrotron-based in vitro studies of various human tissues showed significant differences between the normal and pathological distributions of metallic trace elements such as iron, zinc, copper, and lead in relation to human diseases ranging from Parkinson's disease and cancer to osteoporosis and osteoarthritis. Current research effort is aimed at not only measuring the abnormal elemental distributions associated with various diseases, but also indicate or discover possible biological mechanisms that could explain such observations. While a number of studies confirmed and strengthened previous knowledge, others revealed or suggested new possible roles of trace elements or provided a more accurate spatial distribution in relation to the underlying histology. This area of research is at the intersection of several current fundamental and applied scientific inquiries such as metabolomics, medicine, biochemistry, toxicology, food science, health physics, and environmental and public health.

TI The 2019 Revised Version of Association Research Circulation Osseous Staging System of Osteonecrosis of the Femoral Head
SO JOURNAL OF ARTHROPLASTY
LA English
DT Article
DE staging; hip; osteonecrosis; avascular necrosis; Delphi
ID total hip-arthroplasty; nontraumatic osteonecrosis; rotational osteotomy; avascular necrosis; asymptomatic osteonecrosis; classification-system; natural-history; reproducibility; interobserver; collapse
AB Background: The Association Research Circulation Osseous (ARCO) presents the 2019 revised staging system of osteonecrosis of the femoral head (ONFH) based on the 1994 ARCO classification. Methods: In October 2018, ARCO established a task force to revise the staging system of ONFH. The task force involved 29 experts who used a web-based survey for international collaboration. Content validity ratios for each answer were calculated to identify the levels of agreement. For the rating queries, a consensus was defined when more than 70% of the panel members scored a 4 or 5 rating on a 5-point scale. Results: Response rates were 93.1%-100%, and through the 4-round Delphi study, the 1994 ARCO classification for ONFH was successfully revised. The final consensus resulted in the following 4-staged system: stage I-X-ray is normal, but either magnetic resonance imaging or bone scan is positive; stage II-X-ray is abnormal (subtle signs of osteosclerosis, focal osteoporosis, or cystic change in the femoral head) but without any evidence of subchondral fracture, fracture in the necrotic portion, or flattening of the femoral head; stage III-fracture in the subchondral or necrotic zone as seen on X-ray or

computed tomography scans. This stage is further divided into stage IIIA (early, femoral head depression <= 2 mm) and stage IIIB (late, femoral head depression >2 mm); and stage IV-X-ray evidence of osteoarthritis with accompanying joint space narrowing, acetabular changes, and/or joint destruction. This revised staging system does not incorporate the previous subclassification or quantitation parameters, but the panels agreed on the future development of a separate grading system for predicting disease progression. Conclusion: A staging system has been developed to revise the 1994 ARCO classification for ONFH by an expert panel-based Delphi survey. ARCO approved and recommends this revised system as a universal staging of ONFH. (C) 2019 Published by Elsevier Inc.

TI PP121 suppresses RANKL-Induced osteoclast formation in vitro and LPS-Induced bone resorption in vivo
SO EXPERIMENTAL CELL RESEARCH
LA English
DT Article
DE PP121; Osteoclasts; RANKL; Bone resorption; Src
ID nf-kappa-b; induced osteolysis; osteoporosis; proliferation; inhibition; expression; tyrosine; cancer; roles
AB Bone resorption, caused by osteoclasts (OCs), is important to bone homeostasis. The abnormalities of bone resorption may induce a series of diseases, including osteoarthritis, osteoporosis and aseptic peri-implant loosening. The latest research developed,a novel tyrosine and phosphoinositide kinase dual inhibitor, named PP121, inhibited Src in anaplastic thyroid carcinoma cell. However, the therapeutic function of PP121 on abnormal bone resorption is still uncertain. In the present study, we showed that PP121 could potently suppress osteoclast differentiation, osteoclast-specific gene expression and bone resorption via suppressing Src/MAPK (ERK and p38)/Akt-mediated NFATc1 induction in vitro. \It was found that PP121 could suppress the formation of osteoclasts from bone marrow macrophages (BMMs) without causing cytotoxicity, inhibit bone resorption and downregulate the mRNA level of osteoclast-specific markers, including calcitonin receptor (CTR), tartrate resistant acid phosphatase (TRAP), cathepsin K (CTSK), matrix metalloproteinase 3 (MMP3), Cellular oncogene fos (C-Fos) and nuclear factor of activated T-cells cytoplasmic 1 (NFATc1). Consistent with in vitro observation, we found that PP121 greatly ameliorated LPS-induced bone resorption. Our results

provide promising evidence of the therapeutic potential of PP121 for osteolytic diseases related to excessive osteoclast-mediated bone resorption.

TI Efficacy of low-magnitude high-frequency vibration (LMHFV) on musculoskeletal health of participants on wheelchair: a study protocol for a single-blinded randomised controlled study
SO BMJ OPEN
LA English
DT Article
DE musculoskeletal disorders; geriatric medicine; bone diseases
ID whole-body vibration; muscle performance; sitting balance; blood-flow; bone loss; expression; exercise; tests
AB Background Osteoporosis is an age-related disease with progressive loss of bone, leading to fragile bone. It is one of the major health issues in older adults and causes medical, social and economic impacts globally. Patients with osteoporosis have high risk of osteoporotic fractures. Low-magnitude high-frequency vibration (LMHFV) is a non-invasive biophysical intervention providing whole-body mechanical stimulation. Previous studies showed that LMHFV is beneficial to muscle strength, postural control, balancing ability, new bone formation, spinal bone mineral density (BMD) and blood circulation. During the LMHFV treatment, older adults need to stand upright on the platform for 20 min/day. However, some physically weak elderlies with poor musculoskeletal ability cannot stand for a long period. Therefore, the design of vibration platform is modified for the disabled patients to treat at sitting position and the efficacy of LMHFV on this group of elderlies will be verified. It is hypothesised that new design of LMHFV is beneficial to wheelchair users in terms of vertebral BMD, muscle health and musculoskeletal functions. Methods This study is a single-blinded randomised

controlled trial to investigate the effect of LMHFV on vertebral BMD, muscle health, balancing ability and functional ability in wheelchair users (mainly on wheelchair for outdoor activities). Healthy elderlies aged 65 years or above with walking difficulties and using wheelchair are eligible. Exclusion criteria are those: (1) who cannot stand and walk independently, (2) who have vibration treatment before, (3) with malignancy, (4) with acute fractures or severe osteoarthritis, (5) with cardiovascular concern such as with pacemaker in situ, (6) with chronic inflammatory conditions known to affect muscle metabolism such as rheumatoid arthritis and (7) with high frequency of physical activities, such as participants who participated in regular exercise five times a week or more. Recruited participants will be randomised to either LMHFV or control group. Participant assigned to LMHFV group will receive LMHFV (35 Hz, 0.3g (g=gravitational acceleration), 20 min/day, at least three times/week) for 6 months. The primary outcome is BMD at the lumbar spine to be assessed by dual-energy X-ray absorptiometry that is clinically recommended for the diagnosis of osteoporosis. All primary and secondary outcome assessments for all groups will be performed in the investigators' institute at baseline and 6 months post treatment. Discussion This study aims to investigate the effects of LMHFV on wheelchair users. The findings of this study will help to confirm the efficacy of LMHFV on vertebral BMD, muscle health, balancing ability and functional outcomes in wheelchair using elderlies. LMHFV therapy is an intervention strategy that is easy to implement at the community healthcare level or individually at home that has previously been proven to reduce fall risk and muscle strength at the lower limb. The ultimate goal is to improve their bone and muscle quality of wheelchair users, as well as enhancing their quality of life.

TI Prevalence and Factors Associated with Analgesic Prescribing in Poly-Medicated Elderly Patients
SO DRUGS & AGING
LA English
DT Article
ID drug-metabolism; pain; management; risk; osteoarthritis; polypharmacy; pharmacokinetics; recommendations; frail; falls

AB Background Pain is common in older patients and management guidelines rarely consider the effect of multiple comorbidities and concurrent medications on analgesic selection. Objectives The objectives of this study were to identify the prevalence and pattern of analgesic prescribing and associated factors in older patients with polypharmacy. Methods Older patients (aged >= 75 years) admitted to the Royal Adelaide Hospital between September 2015 and August 2016 and with polypharmacy were included and their comorbidities and medications prescribed at discharge were recorded. Drug Burden Index and Charlson Comorbidity Index were calculated. The number of medications that increased the risk of orthostatic hypotension were recorded. Logistic regression was used to compute the association between analgesic use and participant characteristics, and results were presented as odds ratios and 95% confidence intervals, adjusted for age, sex, Charlson Comorbidity Index, Drug Burden Index and orthostatic hypotension. Results Over 15,000 admissions were identified, of which 1192 patients were included, 824 (69%) of whom were prescribed an analgesic medication. Paracetamol (used by 89% of analgesic users), opioids (34%) and adjuvants (17%) were used more frequently than non-steroidal anti-inflammatory drugs (8%). Analgesic users had a higher Drug Burden Index, were prescribed more medications and were less likely to be male compared with non-users. Charlson Comorbidity Index across the cohort was high (7.3 +/- 1.9) but there was no difference between analgesic users and non-users, but analgesic users were more likely to have a documented diagnosis of osteoarthritis, osteoporosis and falls. Opioid use was associated with the Drug Burden Index, while adjuvant use was associated with orthostatic hypotension. Opioid use was associated with having a diagnosis of osteoporosis and falls. Conclusions In our cohort of poly-medicated elderly patients, prescription of analgesic medications was common, and these patients are likely to have an increased rate of adverse drug reactions and falls compared with those who were not prescribed analgesic medications.

TI Phenotype changes of subchondral plate osteoblasts based on a rat model of ovariectomy-induced osteoarthritis
SO ANNALS OF TRANSLATIONAL MEDICINE
LA English
DT Article
DE Osteoarthritis (OA); osteoblasts; ovariectomy; phenotype; subchondral bone
ID anterior cruciate ligament; ii collagen degradation; cartilage turnover; bone; differentiation; cells; mineralization; proliferation; osteoporosis; transection
AB Background: Osteoarthritis (OA) is prevalent in postmenopausal women. Subchondral bone in ovariectomized (OVX) rats might play a more important role in cartilage degeneration compared with other types of OA. How subchondral osteoblast changes in OVX rats is still unclear. Understanding of osteoblast changes obtained from OVX subchondral bone might be helpful to clarify pathogenesis of OVX-OA. Methods: Female Sprague-Dawley rats were randomly divided into two groups: Sham (n=20) and OVX (n=20). Serum levels of Alkaline phosphatase (ALP) and C-telopeptide of type I collagen (CTX-I) were measured every one or two weeks. All rats were executed at week 9 post surgery. The weight of rats and the wet weight of uterus were assessed. Micro-computed Tomography (micro-CT) was used to analyze the knee microstructure, and toluidine blue staining was employed to evaluate cartilage erosion. Subchondral osteoblast proliferation ability by cell counting kit-8 assay, osteogenic genes expressions by reverse transcription polymerase chain reaction (RT-PCR), differentiation and mineralization ability by ALP staining and alizarin red staining were evaluated and compared between Sham and OVX. Results: Ovariectomy induced significant increases of serum ALP and CTX-I as early as at week 2. At week 9 after surgery, the body

weight of OVX rats was significantly increased, and uterus weight of OVX rats was remarkably decreased. OVX rats demonstrated significant subchondral bone change and cartilage erosion compared with Sham rats. mRNA levels of early markers of osteogenic differentiation (ALP, type I collagen, Runx2) were enhanced in OVX rats, but the late marker (osteocalcin) was not significantly different. ALP activity of osteoblasts increased, but the mineralization capacity decreased in OVX rats. Conclusions: Subchondral osteoblasts in OVX rats exhibited different proliferation, differentiation and mineralization abilities from normal counterparts.

TI Specific inhibition of FAK signaling attenuates subchondral bone deterioration and articular cartilage degeneration during osteoarthritis pathogenesis
SO JOURNAL OF CELLULAR PHYSIOLOGY
LA English
DT Article
DE FAK; H-type vessels; osteoarthritis; subchondral bone; Y15
ID focal adhesion kinase; promotes angiogenesis; vessel formation; knee; cells; osteogenesis; replacement; progression
AB Osteoarthritis (OA), a disease of the entire joint, is characterized by abnormal bone remodeling and coalescent degradation of articular cartilage. We have previously found that elevated levels of H-type vessels in subchondral bone correlate with OA and that focal adhesion kinase (FAK) is critical for H-type vessel formation in osteoporosis. However, the potential role of FAK in OA remains unexplored. Here, we demonstrate that the p-FAK level was dramatically elevated in subchondral bone following anterior cruciate ligament transection (ACLT) in rats. Specific inhibition of FAK signaling with Y15 in subchondral bone resulted in the suppression of subchondral bone deterioration and this effect was mediated by H-type vessel-induced ectopic bone formation. Further, articular cartilage degeneration was also alleviated after Y15 treatment. In vitro, the p-FAK level was significantly elevated in mesenchymal stem cells (MSCs) from vehicle-treated ACLT rats as compared to that in MSCs from sham controls and Y15-treated ACLT rats. Elevated p-FAK level in MSCs promoted vascular endothelial growth factor (VEGF) expression, as demonstrated from the high VEGF level in the blood, subchondral bone, and conditioned medium (CM) of MSCs from vehicle-treated ACLT rats. The CM of MSCs from vehicle-treated ACLT rats might promote the angiogenesis of endothelial cells and the catabolic response of chondrocytes through the FAK-growth factor receptor-bound protein 2-mitogen-activated protein kinase-mediated expression of VEGF. The effect of the CM from MSCs of Y15-treated ACLT rats or that treated with a VEGF-neutralizing antibody on vessel formation and the catabolic response was lowered. Thus, the specific inhibition of FAK signaling may be a promising avenue for the prevention or early treatment of OA.

ID hip osteoarthritis; relevant outcm; european-society; economic-aspects; recommendations; epidemiology; osteoporosis; validation; management; state
AB Objective: CR4056 is a selective imidazoline-2 (I2) receptor ligand with potent analgesic activity in animal pain models. This proof-of-concept study tested CR4056 efficacy and safety in patients with knee osteoarthritis (OA) and different phenotypes. Design: This is a multicenter, randomized, double-blind, placebo-controlled trial. Knee OA patients with moderate to severe pain received CR4056 (women 100 mg bid; men 200 mg bid) or placebo (both genders) for 14 days. The primary outcome was the change in WOMAC pain score (0-100 scale) compared to placebo, analyzed in the intention-to-treat population and pre-defined OA phenotypes. Results: 213 patients were treated with CR4056 (92 women; 52 men) or placebo (69 overall). After 14 days, median WOMAC pain improvements were 10 points on placebo and 14, 20 and 16 in women, men, and pooled CR4056 groups (P = 0.184, 0.030 and 0.070 vs placebo, respectively). Pre-specified subgroup analysis in the metabolic OA phenotype (BMI >= 27.5 kg/m(2), N = 156) showed statistically significant differences in all CR4056-treated groups vs placebo of 12-18 points. Conversely, there were too few patients with a neuropathic or inflammatory phenotype for a meaningful analysis. CR4056 was well tolerated; the most common adverse event was mild headache. Conclusions: Although the primary endpoint was met in males only, this exploratory phase 2 trial shows that CR4056 might be an effective analgesic against knee OA pain, especially in overweight patients representing the metabolic OA phenotype. These findings, along with the broad-spectrum analgesic activity of CR4056 in animal models, warrant further clinical investigation in OA and other pain conditions. Clinical trial

TI Stress Distributions and Micromovement of Fragment Bone of Pilon Fracture

Treated With External Fixator: A Finite Element Analysis
SO JOURNAL OF FOOT & ANKLE SURGERY
LA English
DT Article
DE external fixator; finite element; micromovement; osteoarthritis; osteoporosis; pilon
ID biomechanical evaluation; internal-fixation; plafond fractures; proximal femur; plate; foot; optimization; simulation; management; ligaments
AB Osteoporosis and osteoarthritis are common pathological problems of the human bone tissue. There are some cases of pilon fractures associated with these 2 pathological conditions. In terms of treatment, for a normal and healthy bone with pilon fracture, the use of the Delta external fixator is a favorable option because it can allow early mobilization for patients and provide stability for the healing process. However, the stability of the external fixator differs when there is low bone stiffness, which has not been previously investigated. Therefore, this study was conducted to determine the stability of the external fixator to treat pilon fracture associated with osteoporosis and osteoarthritis, particularly to differentiate the stress distribution and micromovement of fracture fragment. Three-dimensional finite element models of the ankle and foot bones were reconstructed based on the computed tomography datasets. The bones consisted of 5 metatarsal, 3 cuneiform, and 1 each of cuboid, navicular, calcaneus, talus, fibula, and tibia bones. They were assigned with linear isotropic behavior. The ankle joint consisted of liga-ment and cartilage, and they were assigned with the use of linear links and the Mooney-Rivlin model, respectively. During simulation of the gait cycle, 70 N and 350 N were applied axially to the tibia bone to represent the swing and stance phases, respectively. The metatarsal and calcaneus bones were fixed to prevent any movement of the rigid body. The study found that the greatest von Mises stress value was observed at the pin-bone interface for the osteo-porosis (108 MPa) model, followed by the osteoarthritis (87 MPa) and normal (44 MPa) models, during the stance phase. For micromovement, the osteoporosis model had the largest value at 0.26 mm, followed by the osteoarthritis (0.09 mm) and normal (0.03 mm) models. In conclusion, the greatest magnitudes of stress and micromovement were observed for the osteoporosis bone and extra care should be taken to treat pilon fracture associated with this patho-logical condition. DT Article
DE Multimorbidities; Physical function; Disablement process
ID change-point model; quality-of-life; cognitive decline; disability; multimorbidity; older; association; comorbidity; population; strength
AB Background: Chronic medical conditions (CMCs) often emerge and accumulate during the transition from mid- to late-life, and the resulting multimorbidity can greatly impact physical function. We assessed the association of CMC presence and incidence on trajectories of physical function from mid- to early late-life in the Study of Women's Health Across the Nation. Methods: Physical function was assessed at eight clinic visits (average 14 years follow-up) using the physical function subscale of the Short Form-36. CMCs included osteoarthritis, diabetes, stroke, hypertension, heart disease, cancer, osteoporosis, and depressive symptomatology, and were considered cumulatively. Repeated-measures Poisson models estimated longitudinal change (expressed as percent difference) in physical function by chronic CMCs. Change-points assessed physical function change coincident with the development of a new condition. Results: Women (N = 2,283) followed from age 50.0 +/- 2.7 to 64.0 +/- 3.7 years; 7.3% had zero CMCs through follow-up, 22.5% (N = 513) had no baseline CMCs but developed >= 1, 22.7% women had >= 1 baseline CMC but never developed another, and 47.6% had >= 1 baseline CMC and developed >= 1 more. Each additional baseline CMC was associated with 4.0% worse baseline physical function and annual decline of 0.20%/year. Women with more baseline CMCs had greater decline in physical function with a new CMC (-1.90% per condition); and annual decline when developing a new condition accelerated by -0.33%/year per condition. Conclusions: Self-reported physical function changes are evident from mid- to early late-life with the development of CMCs. Preventing or delaying CMCs may delay declines in physical function, and these potential pathways to disability warrant further research.

DE aging; cancer; coronary artery disease; diabetes type 2; dyslipidemia; estradiol; hormone therapy; insulin resistance; menopause; midlife transition; metabolic syndrome; steroid and insulin receptors; systemic inflammatory state; visceral adiposity; waist circumference; window of opportunity
ID coronary-heart-disease; postmenopausal hormone-therapy; estrogen plus progestin; body-mass index; breast-cancer; womens health; metabolic syndrome; diabetes-mellitus; insulin-receptor; united-states
AB Heart disease and cancer are the leading causes of death in the United States. In women, the clinical appearance of both entities-coronary heart disease and cancer (breast, endometrium, and ovary)-escalate during the decades of the midlife transition encompassing the menopause. In addition to the impact of aging, during the interval between the age of 40 and 65 years, the pathophysiologic components of metabolic syndrome also emerge and accelerate. These include visceral adiposity (measured as waist circumference), hypertension, diabetes, and dyslipidemia. Osteoporosis, osteoarthritis, sarcopenia, depression, and even cognitive decline and dementia appear, and most, if not all, are considered functionally related. Two clinical reports confirm the interaction linking the emergence of disease: endometrial cancer and metabolic syndrome. One describes the discovery of unsuspected endometrial cancer in a large series of elective hysterectomies performed in aged and metabolically susceptible populations. The other is from the Women's Health Initiative Observational Study, which found a positive interaction between endometrial cancer and metabolic syndrome regardless of the presence or absence of visceral adiposity. Both provide additional statistical support for the long-suspected causal interaction among the parallel but variable occurrence of these common entities-visceral obesity, heart disease, diabetes, cancer, and the prevalence of metabolic syndrome. Therefore, 2 critical clinical questions require analysis and answers: 1: Why do chronic diseases of adulthood-metabolic, cardiovascular, endocrine- and, in women, cancers of the breast and endometrium (tissues and tumors replete with estrogen receptors) emerge and their incidence

trajectories accelerate during the postmenopausal period when little or no endogenous estradiol is available, and yet the therapeutic application of estrogen stimulates their appearance? 2: To what extent should identification of these etiologic driving forces require modification of the gynecologist's responsibilities in the care of our patients in the postreproductive decades of the female life cycle? Part I of this 2-part set of "expert reviews" defines the dimensions, gravity, and interactive synergy of each clinical challenge gynecologists face while caring for their midlife (primarily postmenopausal) patients. It describes the clinically identifiable, potentially treatable, pathogenic mechanisms driving these threats to quality of life and longevity. Part 2 (accepted, American Journal of Obstetrics & Gynecology) identifies 7 objectives of successful clinical care, offers "triage" prioritization targets, and provides feasible opportunities for insertion of primary preventive care initiatives. To implement these goals, a reprogrammed, repurposed office visit is described.YY

TI Epidemiology of the association between serum 25-hydroxyvitamin D levels and musculoskeletal conditions among elderly individuals: a literature review
SO JOURNAL OF PHYSIOLOGICAL ANTHROPOLOGY
LA English
DT Review
ID bone-mineral density; vitamin-d status; hip fracture risk; d deficiency; physical performance; muscle strength; japanese women; older-adults; falls; population
AB Background Vitamin D deficiency is associated with osteoporosis, fracture, muscle weakness, falls, and osteoarthritis in adults. Elderly individuals are more likely to present with poor musculoskeletal conditions. Recently, several epidemiological studies have assessed the correlation between serum

25-hydroxyvitamin D (25(OH)D) levels and musculoskeletal conditions in elderly individuals. Main text Osteoporosis is a skeletal disease characterized by low bone mass and microarchitectural deterioration of bone tissue, with a consequent increase in bone fragility and susceptibility to fracture. Numerous studies have shown a positive association between serum 25(OH)D levels and bone mineral density. Only a few studies have reported an association between serum 25(OH)D levels and quantitative ultrasound (QUS) parameters. Low serum 25(OH)D level may be a risk factor for hip fracture. However, data on the association between vitamin D deficiency and the incidence of non-hip fracture are contrasting. Falls are a major cause of mortality and morbidity in older adults. Several prospective population-based cohort studies have shown that low 25(OH)D levels are associated with an increased risk of falls. Reduced muscle strength and physical performance are risk factors for adverse events, including disability, institutionalization, and mortality. The role of vitamin D in musculoskeletal functionality (muscle weakness and physical performance) among elderly individuals is still controversial. Osteoarthritis (OA) is the most common form of arthritis and is a leading cause of disability among older adults. Data on the association between serum 25(OH)D levels and OA are contrasting. Conclusion Some studies have shown that vitamin D deficiency may be a risk factor for poor musculoskeletal conditions, such as osteoporosis, fracture, muscle weakness, falls, and osteoarthritis in adults. However, other studies did not find an association between serum 25(OH)D levels and musculoskeletal conditions.

TI Development and evaluation of an osteoarthritis risk model for integration into primary care health information technology
SO INTERNATIONAL JOURNAL OF MEDICAL INFORMATICS
LA English
DT Article
DE Prognostic prediction model; Risk; Electronic medical record; Osteoarthritis; CPCSSN
ID clinical-prediction models; knee osteoarthritis; hip; recommendations; surveillance; prevention; imputation; weight; injury; hand
AB Background: We developed and evaluated a prognostic prediction model that estimates osteoarthritis risk for use by patients and practitioners that is designed to be appropriate for integration into primary care health information technology systems. Osteoarthritis, a joint disorder characterized by pain and stiffness, causes significant morbidity among older Canadians. Because our prognostic prediction model for osteoarthritis risk uses data that are readily available in primary care settings, it supports targeting of interventions delivered as part of clinical practice that are aimed at risk reduction. Methods: We used the CPCSSN (Canadian Primary Sentinel Surveillance Network) database, which contains aggregated electronic health information from a cohort of primary care practices, to develop and evaluate a prognostic prediction model to estimate 5-year osteoarthritis risk, addressing contextual challenges of data availability and missingness. We constructed a retrospective cohort of 383,117 eligible primary care patients who were included in the cohort if they had an encounter with their primary care practitioner between 1 January 2009 and 31 December 2010. Patients were excluded if they had a diagnosis of osteoarthritis prior to their first visit in this time period. Incident cases of osteoarthritis were observed. The model was constructed to predict incident osteoarthritis based on age, sex, BMI, previous leg injury, and osteoporosis. Evaluation of the model used internal 10-fold cross-validation; we argue that internal validation is particularly appropriate for a model that is to be integrated into the same context from which the data were derived. Results: The resulting prediction model for 5-year risk of osteoarthritis diagnosis demonstrated state-of-the-art discrimination (estimated AUROC 0.84) and good calibration (assessed visually.) The model relies only on information that is readily available in Canadian primary care settings, and hence is appropriate for integration into Canadian primary care health information technology. Conclusions: If the contextual challenges arising when using primary care electronic medical record data are appropriately addressed, highly discriminative models for osteoarthritis risk may be constructed using only data commonly available in primary care. Because the models are constructed from data in the same setting where the model is to be applied, internal validation provides strong evidence that the

resulting model will perform well in its intended application.

TI Operative and nonoperative management of anterior cruciate ligament injury: Differences in gait biomechanics at 5 years
SO JOURNAL OF ORTHOPAEDIC RESEARCH
LA English
DT Article
DE ACL; joint contact force; kinematics and kinetics; knee; rehabilitation
ID knee osteoarthritis; deficient knee; reconstruction; individuals; kinematics; patient; asymmetry; predictors; mechanics; walking
AB Gait biomechanics after anterior cruciate ligament (ACL) injury are associated with functional outcomes and the development of posttraumatic knee osteoarthritis. However, biomechanical outcomes between patients treated nonoperatively compared with operatively are not well understood. The primary purpose of this study was to compare knee joint contact forces, angles, and moments during loading response of gait between individuals treated with operative compared with nonoperative management at 5 years after ACL injury. Forty athletes treated operatively and 17 athletes treated nonoperatively completed gait analysis at 5 years after ACL reconstruction or completion of nonoperative rehabilitation. Medial compartment joint contact forces were estimated using a previously validated, patient-specific electromyography-driven musculoskeletal model. Knee joint contact forces, angles, and moments were

compared between the operative and nonoperative group using mixed model 2 x 2 analyses of variance. Peak medial compartment contact forces were larger in the involved limb of the nonoperative group (Op: 2.37 +/- 0.47 BW, Non-Op: 3.03 +/- 0.53 BW; effect size: 1.36). Peak external knee adduction moment was also larger in the involved limb of the nonoperative group (Op: 0.25 +/- 0.08 Nm/kg center dot m, Non-Op: 0.32 +/- 0.09 Nm/kg center dot m; effect size: 0.89). No differences in radiographic tibiofemoral osteoarthritis were present between the operative and nonoperative groups. Overall, participants treated nonoperatively walked with greater measures of medial compartment joint loading than those treated operatively, while sagittal plane group differences were not present. Statement of clinical relevance: The differences in medial knee joint loading at 5 years after operative and nonoperative management of ACL injury may have implications on the development of posttraumatic knee osteoarthritis.

TI Growth Arrest Specific Gene 6 Affects Osteogenesis of Bone Marrow Mesenchymal Stem Cells in Inflammatory Environment via MAPK/AKT Signaling Pathway
SO JOURNAL OF BIOMATERIALS AND TISSUE ENGINEERING
LA English
DT Article
DE Gas6; Osteoarthritis; MAPK/AKT Signaling Pathway; Oxidative Stress; Inflammatory Factors; BMSCs
ID differentiation; replacement
AB The osteogenic differentiation of bone marrow mesenchymal stem cells (BMSCs) is beneficial for the treatment of osteoarthritis (OA). Gas6 is a vitamin K-dependent protein and associated with inflammation. Whether Gas6 regulates BMSCs differentiation under inflammatory environment is unknown. Rat BMSCs were isolated and divided into control group and inflammation group (addition of 1 mu g/ml lipopolysaccharide, LPS), and Gas6 group (200 ng/ml Gas6 was added to LPS-stimulated BMSCs cells) followed by analysis of Gas6, Runx2 and OP expression by Real time PCR, ALP activity, ROS content and SOD activity, TNF-alpha and IL-1 beta secretion by ELISA, MAPK/AKT signaling protein expression by Western blot. LPS treatment significantly reduced Gas6 expression, inhibited ALP activity, decreased Runx2 and OP expression, increased ROS content and the secretion of TNF-alpha and IL-1 beta and reduced SOD activity and p-AKT expression compared to control ($P < 0.05$); Gas6 addition to BMSCs in inflammatory environment significantly promoted Gas6 expression and ALP activity, upregulated Runx2 and OP, decreased ROS content and secretion of

TNF-alpha and IL-1 beta, increased SOD activity and p-AKT level ($P < 0.05$). Gas6 expression in BMSCs is reduced in inflammatory environment. Promoting Gas6 expression in BMSCs in inflammatory environment can regulate oxidative stress and MAPK/AKT signaling pathway, inhibit the secretion of TNF-alpha and IL-10, and then promote the osteogenic differentiation of BMSCs.

TI High-Impact Exercise Increased Femoral Neck Bone Density With No Adverse Effects on Imaging Markers of Knee Osteoarthritis in Postmenopausal Women
SO JOURNAL OF BONE AND MINERAL RESEARCH
LA English
DT Article
DE DXA; EXERCISE; FRACTURE PREVENTION; OSTEOARTHRITIS; OSTEOPOROSIS

ID t2 relaxation-time; physical-activity; mineral density; articular-cartilage; marrow lesions; older-adults; strength; men; prevalence; barriers
AB High-impact exercise can improve femoral neck bone mass but findings in postmenopausal women have been inconsistent and there may be concern at the effects of high-impact exercise on joint health. We investigated the effects of a high-impact exercise intervention on bone mineral density (BMD), bone mineral content (BMC), and section modulus (Z) as well as imaging biomarkers of osteoarthritis (OA) in healthy postmenopausal women. Forty-two women aged 55 to 70 years who were at least 12 months postmenopausal were recruited. The 6-month intervention consisted of progressive, unilateral, high-impact exercise incorporating multidirectional hops on one randomly assigned exercise leg (EL) for comparison with the contralateral control leg (CL). Dual-energy X-ray absorptiometry (DXA) was used to measure BMD, BMC, and Z of the femoral neck. Magnetic resonance imaging (MRI) of the knee joint was used to analyze the biochemical composition of articular cartilage using T2 relaxometry and to analyze joint pathology associated with OA using semiquantitative analysis. Thirty-five participants (61.7 +/- 4.3 years) completed the intervention with a mean adherence of 76.8% +/- 22.5%. Femoral neck BMD, BMC, and Z all increased in the EL (+0.81%, +0.69%, and +3.18%, respectively) compared to decreases in the CL (-0.57%, -0.71%, and -0.75%: all interaction effects $p < 0.05$). There was a significant increase in mean T2 relaxation times (main effect of time $p = 0.011$) but this did not differ between the EL and CL, indicating no global effect. Semiquantitative analysis showed high prevalence of bone marrow lesions (BML) and cartilage defects, especially in the patellofemoral joint (PFJ), with no indication that the intervention caused pathology progression. In conclusion, a high-impact exercise intervention that requires little time, cost, or specialist equipment improved femoral neck BMD with no negative effects on knee OA imaging biomarkers. Unilateral high-impact exercise is a feasible intervention to reduce hip fracture risk in healthy postmenopausal women. (c) 2019 American Society for Bone and Mineral Research.

TI Multifaceted Functions and Novel Insight Into the Regulatory Role of RNA N6-Methyladenosine Modification in Musculoskeletal Disorders
SO FRONTIERS IN CELL AND DEVELOPMENTAL BIOLOGY
LA English
DT Review
DE RNA N-6-methyladenosine; METTL3; FTO; musculoskeletal disorders; epigenetics
ID single-nucleotide-resolution; skeletal-muscle; messenger-rna; dna methylation; rheumatoid-arthritis; demethylase alkbh5; m(6)a rna; fto gene; osteosarcoma; cells
AB RNA modifications have emerged as key regulators of transcript expression in diverse physiological and pathological processes. As one of the most prevalent types of RNA modifications, N-6-methyladenosine (m(6)A) has become the highlight in modulation of various diseases through interfering RNA splicing,

translation, nuclear export, and decay. In many cases, the detailed functions of m(6)A in cellular processes and diseases remain unclear. Notably, recent studies have determined the relationship between m(6)A modification and musculoskeletal disorders containing osteosarcoma, osteoarthritis, rheumatoid arthritis, osteoporosis, etc. Herein, this review comprehensively summarizes the recent advances of m(6)A modification in pathogenesis and progression of musculoskeletal diseases. Specifically, the underlying molecular mechanisms, detection technologies, regulatory functions, clinical implications, and future perspectives of m(6)A in musculoskeletal disorders are discussed, with the aim to provide a novel insight into their association.

DT Review

DE Obesity; Osteoarthritis; Osteoporosis; Nutrition; Treatment
ID bone-mineral density; body-mass index; infrapatellar fat pad; necrosis-factor-alpha; knee osteoarthritis; fracture risk; postmenopausal women; synovial-fluid; adipose-tissue; in-vitro
AB Obesity is characterized by adipose tissue expansion and chronic low-grade inflammation. Among the inflammatory mediators related to obesity development are the adipokines. These cytokines are released from fatty tissues and act in an autocrine, paracrine, or endocrine manner. Adipocytes influence the comorbidities of obesity such as osteoporosis (OP) and osteoarthritis (OA). It is still controversial as to whether OP is associated with either a low or high body mass index, but it is quite clear that the latter condition increases the risk for OA development. Bone marrow adipocytes (BMAs) have the same precursors of osteoblasts, which are the primary cells involved in bone formation, and the amount of BMAs appears to be inversely related to bone mineral density. Although adipokines released by these adipocytes influence bone loss progress, their exact role remains controversial. Differently, the infrapatellar fat pad (IPFP) is indicated to protect the function of joint regarding OA. However, there is relatively limited information about the secretion of adipokines and other inflammatory mediators by the IPFP. Despite some inconsistencies, nutritional interventions targeting obesity may also benefit patients with OP and OA. The association among obesity, OP, and OA is quite complex, and many factors need to be explored that are mainly related to the role of adipokines derived locally rather than from visceral and subcutaneous adipose tissue. Also, nutritional intervention may affect fatty tissue mass and secretion of inflammatory mediators that may, at least in part, influence other tissues in the organism such as bone and articular cartilage. The aim of this review was to present the latest knowledge about the interrelationship between obesity and OA or OP and to discuss whether a dietary intervention for obesity will hold promise for patients with OA or OP. TI Effects of Ten-Eleven Translocation 2 on Osteogenic Differentiation of Bone Marrow Mesenchymal Stem Cells in Osteoarthritis by Regulating Extracellular-Signal-Regulated Kinase (ERK) Signaling Pathway
SO JOURNAL OF BIOMATERIALS AND TISSUE ENGINEERING
LA English
DT Article
DE TET2; Inflammation; BMSCs; Osteogenic Differentiation; Adipogenic Differentiation
ID tet2
AB Inflammation affects BMSCs differentiation. TET2 (ten-eleven translocation 2) regulates mammalian genome transcription and promotes development. However, TET2's role in BMSCs osteogenic differentiation in inflammatory environment is unknown. Rat BMSCs were assigned into control group, inflammation group (addition of LPS), TET2 group and TET2 siRNA group, in which TET2 plasmid and TET2 siRNA were transfected into inflammatory BMSCs, respectively followed by analysis of TET2 expression by real-time PCR analysis, cell proliferation by MTT assay, Caspase3 activity, ALP activity, Runx2, OP and FABP4 level by real time PCR, and ERK signaling protein level by Western blot. In inflammatory environment, TET2 expression was significantly decreased, BMSCs proliferation was inhibited, Caspase3 activity was increased along with decreased ALP activity and expression of Runx2 and OP, increased FABP4 level and reduced ERK phosphorylation ($P < 0.05$). TET2 siRNA transfection into inflammatory BMSCs could further significantly aggravate the above changes ($P < 0.05$). Transfection of TET2 plasmid promotes TET2 expression, which can significantly promote BMSCs proliferation, decrease Caspase3 activity, increase ALP activity and Runx2 and OP expression, decrease FABP4 expression and increase ERK phosphorylation ($P < 0.05$). TET2 expression is reduced in BMSCs under inflammation. Up-regulating TET2 in inflammation can inhibit inflammatory factors secretion, regulate BMSCs proliferation, promote their differentiation into osteoblasts, and alleviates osteoarthritis.

TI Relationship between the AB0 Blood System and Proximal Femoral Fracture Patterns in the Turkish Population
SO BIOMED RESEARCH INTERNATIONAL
LA English
DT Article
ID association; osteoporosis
AB Objective. AB0 blood groups have shown to be associated with increased risk of several orthopedic disorders such as Achilles tendon rupture and hip osteoarthritis. The objective of this study was to investigate relationships between the AB0 blood system and hip fracture patterns, duration of hospitalization, and amount of blood transfusion. Methods. Data of 308 patients treated due to hip fractures in our hospital between 2017 and 2019 were evaluated. Epicrisis reports and X-rays of the patients included in this study were retrospectively screened, and hip fractures were classified as intracapsular and extracapsular fractures. Patients were divided into A, B, 0, and AB groups according to blood groups. Results. The mean age of the patients was 75.54 +/- 13.5 years. Of all patients, 103 had an intracapsular fracture and 205 had an extracapsular fracture. No statistically significant correlation was found between blood groups and fracture patterns. No statistically significant difference was found between the amounts of transfusion according to the blood groups, and no significant difference between the durations of hospitalizations according to the blood groups. Conclusion. In our study population, we could not find a significant relationship between the AB0 blood

system and fracture patterns. We think that these potential relationships could be explained with further comprehensive studies with larger populations.

TI Mechanisms of action of neuropeptide Y on stem cells and its potential applications in orthopaedic disorders
SO WORLD JOURNAL OF STEM CELLS
LA English

DT Review
DE Neuropeptide Y; Bone marrow mesenchymal stem cells; Hematopoietic stem cells; Fracture; Osteoporosis; Osteoarthritis
ID gene-related peptide; induced bone loss; substance-p; osteoblast differentiation; hematopoietic stem; angiogenic factor; induced obesity; stromal cells; regulate bone; nerve-fibers
AB Musculoskeletal disorders are the leading causes of disability and result in reduced quality of life. The neuro-osteogenic network is one of the most promising fields in orthopaedic research. Neuropeptide Y (NPY) system has been reported to be involved in the regulations of bone metabolism and homeostasis, which also provide feedback to the central NPY systemviaNPY receptors. Currently, potential roles of peripheral NPY in bone metabolism remain unclear. Growing evidence suggests that NPY can regulate biological actions of bone marrow mesenchymal stem cells, hematopoietic stem cells, endothelial cells, and chondrocytesviaa local autocrine or paracrine manner by different NPY receptors. The regulative activities of NPY may be achieved through the plasticity of NPY receptors, and interactions among the targeted cells as well. In general, NPY can influence proliferation, apoptosis, differentiation, migration, mobilization, and cytokine secretion of different types of cells, and play crucial roles in the development of bone delayed/non-union, osteoporosis, and osteoarthritis. Further basic research should clarify detailed mechanisms of action of NPY on stem cells, and clinical investigations are also necessary to comprehensively evaluate potential applications of NPY and its receptor-targeted drugs in management of musculoskeletal disorders.

TI Hyponatremia, Hypokalemia, and Fragility Fractures in Old Patients: More than an Association?
SO CALCIFIED TISSUE INTERNATIONAL
LA English
DT Article
DE Hyponatremia; Fracture; Osteoporosis; Sodium; Potassium
ID potassium citrate supplementation; idiopathic hyponatremia; bone; osteoporosis; sodium; vasopressin; fruit; sex
AB Purpose Hyponatremia and hypokalemia are common among elderly and have been associated with osteoporosis, we evaluate the role of these electrolytes as risk for fragility fractures. Methods This study is divided in two parts: one retrospective and one prospective. We retrospectively collected data on urgently admitted patients for femoral fragility fractures (Fx) or for acute myocardial infarction (AMI),

and patients admitted for elective hip/knee replacement surgery for osteoarthrosis (OA). Age, sex, serum sodium, potassium, creatinine, and comorbidities were recorded. We enrolled prospectively in-patients from our unit: age, sex, comorbidities, drugs, and fragility fractures were recorded. Blood electrolytes were measured. Cognitive function, nutrition, muscular strength, and balance were evaluated by standard tests. The mortality rate was recorded with a follow-up after hospital discharge. Results The retrospective study included 2166 subjects: 702 Fx and 1464 controls (907 AMI, 557 OA): the prevalence of hyponatremia was similar in Fx and AMI, whereas it was higher in Fx with respect to OA ($p < 0.001$) as well as hypokalemia ($p < 0.001$). Sodium decrease was associated with higher fracture risk. Among the 284 subjects included in the prospective study, 50 patients were hyponatremic, more likely malnourished, and presented a higher prevalence of fragility fractures ($p = 0.008$). They had a higher mortality after hospital discharge (HR = 1.80, $p = 0.005$), however, this association disappears after correction for confounding variables. Conclusions We suggest that hyponatremia and hypokalemia have to be considered as a marker of poor health more than an independent fracture risk.

TI An in-depth study of the associations between osteoarthritis- and osteoporosis-related phenotypes at different skeletal locations
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE Bone mineral density; Hand; Knee; Osteoarthritis; Osteoporosis; Spine
ID bone-mineral density; radiographic knee osteoarthritis; lumbar disc degeneration; hand osteoarthritis; general-population; fractures; incident; women; risk; classification
AB The relationship between OA and osteoporosis characteristics remains

controversial. This study revealed that age-adjusted hand OA is associated with lower hand/arm BMD levels. Wrist fracture occurrence is associated with increased OA hand scores and low arm BMD. Conversely, age-adjusted knee and spine OA is associated with high spine, hip, and total BMDs. Introduction Osteoarthritis (OA) and osteoporosis are two common musculoskeletal diseases which contribute a high burden of disability, yet assessments of their relationship remains controversial. The aim of this study was to clarify the association between bone mineral densities (BMD) of the hand, arm, spine, hip, and total body, and OA of the hand and knee and lumbar disc degeneration in two different ethnic groups. Methods Radiographic assessments of the hand, knee, and spine were collected and coded for joint space narrowing, osteophytes, and the Kellgren-Lawrence score from Chuvashian (n = 1504) and British (n = 2280) individuals. BMD measurements of standard skeletal sites were estimated by dual X-ray absorptiometry. Age- and familial-adjusted regression analyses were conducted to determine associations. Results Knee OA affection was positively associated with elevated hip, spine, and total body BMD levels ($p < 0.001$). Additionally, disc degeneration phenotypes showed significant positive associations with the hip, spine, and total BMD ($p < 0.001$). However, increased hand OA scores was significantly negatively correlated with arm and hand BMD measurements in males and females in both samples ($p < 0.001$). Additionally, higher hand OA scores were significantly associated with wrist fracture. Conclusions We discovered a clear pattern of association between hand OA and low hand and arm BMD, with increased risk of wrist fracture, as well as reproducing previous associations between knee and spine OA and elevated spine, hip, and total body BMD. It appears that hand OA manifests differently in comparison to hip and knee OA.

TI Silicon supplementation mitigates salinity stress on Ocimum basilicum L. via improving water balance, ion homeostasis, and antioxidant defense system
SO ECOTOXICOLOGY AND ENVIRONMENTAL SAFETY
LA English
DT Article
DE Antioxidant system; Oxidative impairment; Salinity; Silicon; Sweet basil
ID salt stress; essential oil; osmotic-stress; tolerance; drought; growth; plants; melatonin; responses; photosynthesis
AB Salinity is a key worldwide ecological restriction to sustainable crop production and food security. Various methods were used for inducing salinity tolerance including biotechnological approaches or application of stress tolerance-inducing substances. Silicon supplementation has a decisive role in alleviating of salinity injury, however, the definite mechanisms behind stay scantily understood, and must be examined. The imperative roles of sodium metasilicate (Si, 100 ppm) application methods (foliar spraying at 100 mg/l; soil additive at 100 mg/kg soil; foliar spraying at 100 mg/l plus soil additive at 100 mg/kg soil), in improving growth and essential oil yield, maintaining water status, activating antioxidant system, and keeping ion homeostasis of salt affected-sweet basil (6000 mg NaCl/kg soil) were studied. Salinity induced a notable increase in oxidative biomarkers, coupled with higher osmolyte concentration and osmotic potential (OP) values, as well as increased superoxide dismutase and peroxidase activities. Alternatively, sweet basil growth, essential oil yield, and catalase activity were reduced under salinity. Furthermore, salinity aggravated ion imbalance, decreased photosynthetic pigment and disrupted the plants' water status. Silicon application drastically

increased osmolyte accumulation associated with sustained water status, increased OP, and improved osmotic adjustment (OA) capacity. Additionally, Si application enhanced antioxidant aptitude associated with decreased oxidative biomarkers and improved growth, photosynthetic pigment, and essential oil yield. Greater outcomes were achieved with the foliar spraying method, compared with other application methods. Salinity stress evoked modification in protein assimilation capacity and possibly will withdraw protein biosynthesis and reduce total protein band number; however, Si application may adjust the expression of salinity inducible proteins. Foliar spraying of Si with or without soil additive accelerates the expression of peroxidase isozyme over salinized or control plants. Collectively, Si foliar spraying alleviated salinity-related injuries on sweet basil by maintaining water status, increasing osmolyte assimilation, improving OA, enhancing redox homeostasis, and antioxidant capacity.

TI Yes-Associated Protein 1: Role and Treatment Prospects in Orthopedic Degenerative Diseases
SO FRONTIERS IN CELL AND DEVELOPMENTAL BIOLOGY
LA English
DT Review
DE yes-associated protein 1; osteoarthritis; osteoporosis; chondrocyte; mesenchymal stem cells
ID mesenchymal stem-cells; hippo signaling pathway; organ size control; articular-cartilage; in-vitro; chondrocyte differentiation; adipogenic differentiation; yap; osteoporosis; taz
AB The Hippo/yes-associated protein 1 signaling pathway is an evolutionarily conserved signaling pathway. This signaling pathway is primarily involved in the regulation of stem cell self-renewal, organ size and tissue regeneration by regulating cell proliferation, differentiation and apoptosis. It plays an important role in embryonic development and tissue organ formation. Yes-associated protein 1 (YAP1) is a key transcription factor in the Hippo signaling pathway and is negatively regulated by this pathway. Changes in YAP1 expression levels affect the occurrence and development of a variety of tumors, but the specific mechanism associated with this phenomenon has not been thoroughly studied. Recently, several studies have described the role of YAP1 in osteoarthritis (OA). Indeed, YAP1 is involved in orthopedic degenerative diseases such as osteoporosis (OP) in addition to OA. In this review, we will summarize the significance of YAP1 in orthopedic degenerative diseases and discuss the potential of the targeted modulation of YAP1 for the treatment of these diseases.

TI Validation of the Western Ontario and McMaster Universities Arthritis Index Short Form (WOMAC-SF) and Its Relevance to Disability and Frailty
SO YONSEI MEDICAL JOURNAL
LA English
DT Article
DE WOMAC; musculoskeletal disorders; disability; frailty
ID questionnaire length; health; osteoarthritis; adaptation; hip
AB Purpose: This study aimed to evaluate the validity of the Western Ontario and McMaster Universities Arthritis Index Short Form (WOMAC-SF) for the assessment of musculoskeletal disorders. We evaluated whether WOMAC-SF correlated with the World Health Organization Disability Assessment Schedule 12 (WHODAS-12) and Kaigo-Yobo questionnaires for assessing health-outcomes in Korea. Materials and Methods: This cross-sectional study used data from the Namgaram-2 cohort. WOMAC, WOMAC-SF, WHODAS-12, and Kaigo-Yobo questionnaires were administered to patients with musculoskeletal disorders, including radiology-confirmed knee osteoarthritis (RKOA), sarcopenia, and osteoporosis. The

relationships among WOMAC-SF, WHODAS-12, and Kaigo-Yobo scores were analyzed by stepwise multiple regression analysis. Results: WOMAC-SF was associated with the WOMAC questionnaire. The results of confirmatory factor analysis for the hypothesized model with two latent factors, pain and function, provided satisfactory fit indices. WOMAC-SF pain and function were associated with RKOA. Kaigo-Yobo was associated with WOMAC-SF pain (B=0.140, p=0.001) and WOMAC-SF function (B=0.042, p=0.004). WHODAS-12 was associated with WOMAC-SF pain (B=0.679, p=0.003) and WOMAC-SF function (B=0.804, p<0.001). Conclusion: WOMAC-SF was validated for the evaluation of low extremity musculoskeletal disorders and health-related quality of life in a community-based population. Furthermore, we confirmed that WOMAC-SF were reflective of disability and frailty, which affect health outcomes.

TI Denosumab Prevents Early Periprosthetic Bone Loss After Uncemented Total Hip Arthroplasty: Results from a Randomized Placebo-Controlled Clinical Trial
SO JOURNAL OF BONE AND MINERAL RESEARCH
LA English
DT Article
DE DXA; BIOCHEMICAL MARKERS OF BONE TURNOVER; IMPLANTS; ANTIRESORPTIVES; CLINICAL TRIALS
ID 4-year follow-up; postmenopausal women; vertebral fractures; zoledronic acid; double-blind; total knee; discontinuation; osteoporosis; migration; density
AB Implant loosening is the most common indication for revision surgery after total hip arthroplasty (THA). Although bone resorption around the implants plays a pivotal role in the pathophysiology of loosening, it is unknown whether potent early inhibition of osteoclasts could mitigate this process and thus reduce the need for revision surgery. We performed a randomized, double-blind, placebo-controlled phase 2 trial in 64 patients aged 35 to 65 years with unilateral osteoarthritis of the hip. They underwent surgery with an uncemented THA and were randomized to either two subcutaneous doses of denosumab (n = 32) or placebo (n = 32) given 1 to 3 days and 6 months after surgery. Patients were followed for 24 months. Primary outcome was periprosthetic bone mineral density (BMD) of the hip at 12 months as measured by dual-energy X-ray absorptiometry (DXA). In addition, [F-18] sodium fluoride positron emission tomography/CT (F-PET) was performed in half of the patients for analysis of periprosthetic standardized uptake value (SUV). Analyses were made according to intention-to-treat principles. The trial was registered at ClinicalTrials.gov 2011-001481-18, NCT01630941. Denosumab potently inhibited early periprosthetic

bone loss. After 12 months, BMD in the denosumab group was 32% (95% confidence interval [CI] 22-44) higher in Gruen zone 7 and 11% (95% CI 8-15) higher in zones 1 to 7. After 24 months, the difference in BMD between groups had decreased to 15% (95% CI 4-27) in zone 7 and 4% (95% CI 0-8) in zones 1 to 7. In both groups, SUV increased after surgery, but the increase was less pronounced in the denosumab group. Biochemical markers of bone metabolism decreased in the denosumab group in the first 12 months, but a rebound effect with marker concentrations above baseline was observed after 24 months. Denosumab potently prevents early periprosthetic bone loss after uncemented THA; however, the effect diminishes after discontinuation of treatment. Further research is needed to determine whether this bone loss will prove to be of clinical importance and, if so, whether the positive effect observed in this study could be preserved by either prolonged treatment with denosumab or additional antiresorptive treatment. TI Communications Between Bone Marrow Macrophages and Bone Cells in Bone Remodeling
SO FRONTIERS IN CELL AND DEVELOPMENTAL BIOLOGY
LA English
DT Review

DE macrophages; intracellular communication; macrophage-derived exosome; bone remodeling; bone diseases
ID tumor-associated macrophages; mesenchymal stem-cells; protein mnsf-beta; osteoblast differentiation; m1 macrophages; tissue-repair; in-vitro; expression; polarization; galectin-3
AB The mammalian skeleton is a metabolically active organ that continuously undergoes bone remodeling, a process of tightly coupled bone resorption and formation throughout life. Recent studies have expanded our knowledge about the interactions between cells within bone marrow in bone remodeling. Macrophages resident in bone (BMMs) can regulate bone metabolism via secreting numbers of cytokines and exosomes. This review summarizes the current understanding of factors, exosomes, and hormones that involved in the communications between BMMs and other bone cells including mensenchymal stem cells, osteoblasts, osteocytes, and so on. We also discuss the role of BMMs and potential therapeutic approaches targeting BMMs in bone remodeling related diseases such as osteoporosis, osteoarthritis, rheumatoid arthritis, and osteosarcoma.

TI MiR-17-3p inhibits osteoblast differentiation by downregulating Sox6 expression
SO FEBS OPEN BIO

DT Article
DE E1; miR‐ 17‐ 3p; osteoblast; Sox6
ID mesenchymal stem-cells; osteogenic differentiation; target; apoptosis
AB Osteoporosis and osteoarthritis are orthopedic disorders that affect millions of elderly people worldwide; stimulation of bone formation is a potential therapeutic strategy for the treatment of these conditions. As the only bone-forming cells, osteoblasts play a key role in bone reconstruction. The microRNA miR-17-3p is downregulated during osteogenic differentiation of human bone marrow mesenchymal stem cells, but its precise role in this process is unknown. Here, we investigated the role of miR-17-3p in osteoblast differentiation. An in vitro model

of osteogenesis was established by treating MC3T3-E1 murine preosteoblast cells with bone morphogenetic protein 2 (BMP2). The expression of miR-17-3p in BMP2-induced MC3T3-E1 cells was detected by reverse transcription-quantitative PCR, and its effects on cells transfected with miR-17-3p mimic or inhibitor were evaluated by Alizarin Red staining, alkaline phosphatase (ALP) activity assay, and by detection of osteoblast markers including the ALP, collagen type I alpha 1 chain, and osteopontin genes. Bioinformatics analysis was carried out to identify putative target genes of miR-17-3p, and the luciferase reporter assay was used for functional validation. Rescue experiments were performed to determine whether SRY-box transcription factor 6 (Sox6) plays a role in the regulation of osteoblast differentiation by miR-17-3p. We report that miR-17-3p was downregulated upon BMP2-induced osteoblast differentiation in MC3T3-E1 cells, and this was accompanied by decreased differentiation and mineralization, ALP activity, and expression of osteogenesis-related genes. Sox6 was confirmed to be a target gene of miR-17-3p in osteoblasts, and the inhibitory effect of miR-17-3p on osteoblast differentiation was observed to occur via Sox6. These results suggest the existence of a novel mechanism underlying miRNA-mediated regulation of osteogenesis, which has potential implications for the treatment of orthopedic disorders.

TI Defactinib attenuates osteoarthritis by inhibiting positive feedback loop between H-type vessels and MSCs in subchondral bone
SO JOURNAL OF ORTHOPAEDIC TRANSLATION
LA English
DT Article
DE Defactinib; FAK; H-type vessels; MSCs; Osteoarthritis; Subchondral bone
ID mesenchymal stem-cells; focal adhesion kinase; knee osteoarthritis; articular-cartilage; angiogenesis; pericytes; origin; osteogenesis; replacement; migration

AB Background: Abnormal bone formation in subchondral bone resulting from uncoupled bone remodeling is considered a central feature in osteoarthritis (OA) pathogenesis. H-type vessels can couple angiogenesis and osteogenesis. We previously revealed that elevated H-type vessels in subchondral bone were correlated with OA and focal adhesion kinase (FAK) in MSCs is critical for H-type vessel formation in osteoporosis. The aim of this study was to explore the correlation between H-type vessels and MSCs in OA pathogenesis through regulation of H-type vessel formation using defactinib (an FAK inhibitor). Methods: In vivo: 3-month-old male C57BL/6J (WT) mice were randomly divided into three groups: sham controls, vehicle-treated ACLT mice, and defactinib-treated ACLT mice (25 mg/kg, intraperitoneally weekly). In vitro: we explored the role of conditioned medium (CM) of MSCs from subchondral bone of different groups on the angiogenesis of endothelial cells (ECs). Flow cytometry, Western blotting, ELISA, real time (RT)-PCR, immunostaining, CT-based microangiography, and bone micro-CT (uCT) were used to detect changes in relative cells and tissues. Results: This study demonstrated that inhibition of H-type vessels with defactinib alleviated OA by inhibiting H-type vessel-linked MSCs in subchondral bone. During OA pathogenesis, H-type vessels and MSCs formed a positive feedback loop contributing to abnormal bone formation in subchondral bone. Elevated H-type vessels provided indispensable MSCs for abnormal bone formation in subchondral bone. Flow cytometry and immunostaining results confirmed that the amount of MSCs in subchondral bone was obviously higher in vehicle-treated ACLT mice than that in sham controls and defactinib-treated ACLT mice. In vitro, p-FAK in MSCs from subchondral bone of vehicle-treated ALCT mice increased significantly relative to other groups. Further, the CM from MSCs of vehicle-treated ACLT mice enhanced angiogenesis of ECs through FAK-Grb2-MAPK-linked VEGF expression. Conclusions: Our results demonstrate that defactinib inhibits OA by suppressing the positive feedback loop between H-type vessels and MSCs in subchondral bone. The translational potential of this article: Our results provide a mechanistic rationale for the use of defactinib as an effective candidate for OA treatment.

TI Identification of the specific microRNAs and competitive endogenous RNA mechanisms in osteoporosis
SO JOURNAL OF INTERNATIONAL MEDICAL RESEARCH
LA English
DT Article
DE Osteoarthritis; Wnt/beta-catenin pathway; competitive endogenous RNA; interleukin-6; microRNA; osteoporosis
ID bone; differentiation; expression; gene; malat1; osteoclastogenesis; proliferation; osteosarcoma; osteoblasts; inhibition
AB Objective: Osteoporosis and osteoarthritis are metabolic skeletal disorders. This study aimed to identify specific networks of competitive endogenous RNA (ceRNA) in osteoporosis that differ from those in osteoarthritis. Methods: The dataset GSE74209 was downloaded from the Gene Expression Omnibus, and differentially expressed microRNAs (DEmiRNAs) in osteoporotic samples and osteoarthritic samples were identified. After predicting target genes and linked long noncoding (lnc)RNAs, ceRNA networks of DEmiRNAs were constructed. The nodes that overlapped between ceRNA networks and the Comparative Toxicogenomics Database were selected as key candidates. Results: Fifteen DEmiRNAs (including 2 downregulated and 13 upregulated miRNAs) were identified in osteoporotic

samples versus osteoarthritic samples; these targeted 161 genes and linked to 60 lncRNAs. The ceRNA network consisted of 6 DEmiRNAs, 63 target genes, and 53 lncRNAs. After searching the Comparative Toxicogenomics Database and mining the literature, 2 lncRNAs (MALAT1andNEAT1), 2 DEmiRNAs (hsa-miR-32-3p, downregulated; andhsa-miR-22-3p, upregulated) and 6 genes (SP1,PTEN,ESR1,ERBB3,CSF1R, andCDK6) that relate to cell death, growth, and differentiation were identified as key candidates separating osteoporosis from osteoarthritis. Conclusions: Two miRNA-ceRNA networks (includingNEAT1/MALAT1-hsa-miR-32-3p-SP1/FZD6andNEAT1/MALAT1-hsa-miR-22-3p-PTEN/ESR1/ERBB3/CSF1R/CDK6) might have crucial and specific roles in osteoporosis.

TI The association of subchondral and systemic bone mineral density with osteoarthritis-related joint replacements in older adults
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE Bone mineral density; Hip replacement; Knee replacement; Osteoarthritis
ID radiographic knee osteoarthritis; cartilage thickness; compartment; progression; incident; hip; osteoporosis; initiation; criteria; fracture
AB Objective: To describe the association of subchondral and systemic bone mineral density (BMD) with knee and hip replacements (KR and HR, respectively) due to osteoarthritis. Design: 1,095 participants (mean age 63 years, 51% female) were included. At baseline, subchondral BMD of the medial and lateral tibia in three regions of interest (ROI) for the right knee, and systemic BMD of the lumbar spine, femoral neck, total hip and whole-body, were measured using dual-energy X-ray absorptiometry. Subchondral BMD of the hip was not measured. Competing risk regression models were used to estimate sub-distribution hazard ratios (SHRs) of KR/HR per one standard deviation (SD) higher in BMD measures, with adjustment of potential confounders. Results: Over 12.2 years, 79 (7.2%) participants underwent a KR and 56 (5.1%) an HR due to osteoarthritis. For the right side, medial subchondral BMD in ROI-3 was associated with an increased risk of KR (SHR 1.95 per SD; 95% Confidence Interval [CI], 1.57 to 2.43). In contrast, systemic BMD was not associated with the risk of KR, but higher BMD at the lumbar spine (1.42, 1.07 to 1.88) and whole-body (1.29, 1.00 to 1.66) were associated with an increased risk of HR at both sides. Conclusions: Subchondral BMD is positively associated with an increased risk of KR and systemic BMD with an increased risk of HR, suggesting a role of BMD in the progression of osteoarthritis. TI Overall adjustment acupuncture for postmenopausal osteoporosis (PMOP): a study protocol for a randomized sham-controlled trial
SO TRIALS
LA English

DT Article
DE Osteoporosis; PMOP; Acupuncture; Sham acupuncture; Protocol; Randomised controlled trial
ID chinese herbal medicine; blood-cell count; infertility; association
AB BackgroundOsteoporosis is becoming more prevalent in aging societies worldwide, and the economic burden attributable to osteoporotic fractures is substantial. The medications presently available to treat osteoporosis have side effects. Acupuncture is widely used for treating osteoporotic postmenopausal women because it is non-invasive and has fewer side effects, but the powerful clinical evidence for its efficacy remains insufficient. Our study intends to explore the effect of overall adjustment acupuncture (OA) in the treatment of postmenopausal osteoporosis (PMOP).Methods/designThis study is a randomized, sham-controlled, patient- and assessor-blinded trial and aims to evaluate the effect of OA in women with PMOP. We will recruit 104 women aged 45-70years with a diagnosis of PMOP. Participants will be randomly allocated in a 1:1 ratio to the OA group and the sham acupuncture (SA) group. Both groups will receive real herbal medicine treatment as a basic treatment twice a day for 3 months, the OA group receives real acupuncture treatment and the SA group receives placebo acupuncture treatment (non-penetrating, sham skin-needle therapy, sham cupping). All patients will receive acupuncture treatment twice per week for 3 months. The primary outcome is bone mineral density (BMD) and the secondary outcomes include estradiol (E2), follicle-stimulating hormone (FSH), bone gla protein (BGP), bone alkaline phosphatase (BALP), total antioxidant capacity (TAC), advanced oxidation protein products (AOPP), PPAR gamma, beta -catenin, FoxO3a levels, visual analog pain scale score (VAS), Traditional Chinese medicine (TCM) syndrome scores and quality of daily life score (QOL). Outcome measures will be collected at baseline, middle of the treatment (1.5months), the end of treatment (3months). The present protocol followed the SPIRIT guidelines and fulfills the SPIRIT Checklist.ConclusionThis study will be conducted to compare the efficacy of OA versus SA. This trial should help to evaluate whether OA can effectively prevent and treat PMOP by improving the estrogen levels of postmenopausal women. The mechanism is to improve the imbalance of osteogenic differentiation and lipogenesis of bone-marrow cells under oxidative stress.Trial registrationChinese Clinical Trial Registry, ID: ChiCTR1800017581. TI Bone marrow lesions: etiology and pathogenesis at the hip
SO JOURNAL OF HIP PRESERVATION SURGERY

LA English
DT Review
ID transient osteoporosis; subchondral cysts; herniation pits; femoral-neck; osteoarthritis; edema; osteonecrosis; density
AB Bone marrow lesions (BML) are painful changes in subchondral bone which can be reliably identified on magnetic resonance imaging and have been identified in patients suffering from hip osteoarthritis (OA) and related conditions. Created via repetitive microdamage at the articular surface and dysregulated subchondral healing, BML have been linked to traumatic, inflammatory, degenerative, metabolic and neoplastic processes. While BML are known to be a common pathology throughout the body, BML at the hip have not been extensively studied in comparison to those at the knee. Due to the hip's unique biomechanical architecture, function and loading, and independent risk factors leading to hip OA, hip BMLs must be independently understood. The identification of BML in the setting of a pre-osteoarthritic condition may provide a target for treatment and prevention of joint degeneration. By continuing to define and refine the relationships between BML, subchondral bone cysts and OA, prevention, diagnosis and treatment of OA could shift, leading to an improved quality of life and increased longevity of individuals' native hips.

TI Knee loading repairs osteoporotic osteoarthritis by relieving abnormal remodeling of subchondral bone via Wnt/β-catenin signaling
SO FASEB JOURNAL
LA English
DT Article
DE knee loading; osteoblast; osteoclast; osteoporotic osteoarthritis; Wnt signaling
ID femoral-head; cartilage; histopathology; pathogenesis; expression; model
AB Osteoporotic osteoarthritis (OPOA) is a common bone disease mostly in the elderly, but the relationship between Osteoporotic (OP) and osteoarthritis (OA) is complex. It has been shown that knee loading can mitigate OA symptoms. However, its effects on OPOA remain unclear. In this study, we characterized

pathological linkage of OP to OA, and evaluated the effect of knee loading on OPOA. We employed two mouse models (OA and OPOA), and conducted histology, cytology, and molecular analyses. In the OA and OPOA groups, articular cartilage was degenerated and Osteoarthritis Research Society International score was increased. Subchondral bone underwent abnormal remodeling, the differentiation of bone marrow mesenchymal stem cells (BMSCs) to osteoblasts and chondrocytes was reduced, and migration and adhesion of pre-osteoclasts were enhanced. Compared to the OA group, the pathological changes of OA in the OPOA group were considerably aggravated. After knee loading, however, cartilage degradation was effectively prevented, and the abnormal remodeling of subchondral bone was significantly inhibited. The differentiation of BMSCs was also improved, and the expression of Wnt/beta-catenin was elevated. Collectively, this study demonstrates that osteoporosis aggravates OA symptoms. Knee loading restores OPOA by regulating subchondral bone remodeling, and may provide an effective method for repairing OPOA.

TI Dehydroepiandrosterone and age-related musculoskeletal diseases: Connections and therapeutic implications
SO AGEING RESEARCH REVIEWS

LA English
DT Review
DE Dehydroepiandrosterone; Osteoporosis; Sarcopenia; Osteoarthritis; Senescence
ID bone-mineral density; sex steroid-hormones; skeletal-muscle; elderly-men; senescent cells; postmenopausal women; physical function; oxidative stress; body-composition; older-adults
AB Musculoskeletal disorders related to ageing are one of the most common causes of mortality and morbidity among elderly individuals worldwide. The typical constitutive components of the musculoskeletal system, including bone, muscle, and joints, gradually undergo a process of tissue loss and degeneration as a result of lifelong mechanical and biological stress, ultimately leading to the onset of a series of age-related musculoskeletal diseases, including osteoporosis (OP), sarcopenia, and osteoarthritis (OA). Dehydroepiandrosterone (DHEA), a precursor of androgen secreted mainly by the adrenal gland, has attracted much attention as a marker for senescence due to its unique age-related changes. This pre-hormone has been publicly regarded as an "antidote for ageing" because of its favourable effect against a wide range of age-related diseases, such as Alzheimer disease, cardiovascular diseases, immunosenescence and skin senescence, though its effect on age-related musculoskeletal diseases has been explored to a lesser extent. In the present review, we summarized the action of DHEA against OP, sarcopenia and OA. Extensive detailed descriptions of the pathogenesis of each of these musculoskeletal disorders are beyond the scope of this review; instead, we aim to highlight the association of changes in DHEA with the processes of OP, sarcopenia and OA. A special focus will also be placed on the overlapping pathogeneses among these three diseases, and the molecular mechanisms underlying the action of DHEA against these diseases are discussed or postulated.

TI Berberine and musculoskeletal disorders: The therapeutic potential and underlying molecular mechanisms
SO PHYTOMEDICINE

LA English
DT Review
DE Alkaloid; Bone; Joint; Osteoporosis; Osteoarthritis; Palmatine
ID nf-kappa-b; attenuates osteoclast differentiation; collagen-induced arthritis; mesenchymal stem-cells; wnt/beta-catenin; osteoblast differentiation; chondrocyte apoptosis; rheumatoid-arthritis; rat model; cartilage degeneration
AB Background: Musculoskeletal disorders are a group of disorders that affect the joints, bones, and muscles, causing long-term disability. Berberine, an isoquinoline alkaloid, has been previously established to exhibit beneficial properties in preventing various diseases, including musculoskeletal disorders. Purpose: This review article aims to recapitulate the therapeutic potential of berberine and its mechanism of action in treating musculoskeletal disorders. Methods: A wide range of literature illustrating the effects of berberine in ameliorating musculoskeletal disorders was retrieved from online electronic databases (PubMed and Medline) and reviewed. YResults: Berberine may potentially retard the progression of osteoporosis, osteoarthritis and rheumatoid

TI A new approach to comprehensively evaluate the morphological properties of the human femoral head: example of application to osteoarthritic joint
SO SCIENTIFIC REPORTS
LA English
DT Article
ID subchondral bone; cancellous bone; articular-cartilage; mechanical-property; osteoporosis; microarchitecture; connectivity; osteophytes; tomography; lesions
AB Osteoarthritis affects the morphological properties of the femoral head. The goal of this study was to develop a method to elucidate whether these changes are localised to discrete regions, or if the reported trends in microstructural changes may be identified throughout the subchondral bone of the human femoral head. Whole femoral heads extracted from osteoarthritic (n = 5) and healthy controls (n = 5) underwent microCT imaging 39 mu m voxel size. The subchondral bone plate was virtually isolated to evaluate the plate thickness and plate porosity. The trabecular bone region was divided into 37 volumes of interest spatially distributed in the femoral head, and bone morphometric properties were determined in each region. The study showed how the developed approach can be used to study the heterogeneous properties of the human femoral head affected by a disease such as osteoarthritis. As example, in the superior femoral head osteoarthritic specimens exhibited a more heterogeneous micro-architecture, with trends towards thicker cortical bone plate, higher trabecular connectivity density, higher trabecular bone density and thicker structures, something that could only be observed with the newly developed approach. Bone cysts were mostly confined to the postero-lateral quadrants extending from the subchondral region into the mid trabecular region. Nevertheless, in order to generalise these findings, a larger sample size should be analysed in the future. This novel method allowed a comprehensive evaluation of the heterogeneous micro-architectural properties of the human femoral head, highlighting effects of OA in the superior subchondral cortical and trabecular bone.

Further investigations on different stages of OA would be needed to identify early changes in the bone.

TI Role of microRNA in muscle regeneration and diseases related to muscle dysfunction in atrophy, cachexia, osteoporosis, and osteoarthritis
SO BONE & JOINT RESEARCH
LA English
DT Article
DE miRNA; Muscle; Atrophy; Regeneration
ID human skeletal-muscle; satellite cell; cancer cachexia; expression; differentiation; inflammation; sarcopenia; mirnas; pax3; proliferation
AB MicroRNAs (miRNAs) are a class of small non-coding RNAs that have emerged as potential predictive, prognostic, and therapeutic biomarkers, relevant to many pathophysiological conditions including limb immobilization, osteoarthritis,

sarcopenia, and cachexia. Impaired musculoskeletal homeostasis leads to distinct muscle atrophies. Understanding miRNA involvement in the molecular mechanisms underpinning conditions such as muscle wasting may be critical to developing new strategies to improve patient management. MicroRNAs are powerful post-transcriptional regulators of gene expression in muscle and, importantly, are also detectable in the circulation. MicroRNAs are established modulators of muscle satellite stem cell activation, proliferation, and differentiation, however, there have been limited human studies that investigate miRNAs in muscle wasting. This narrative review summarizes the current knowledge as to the role of miRNAs in the skeletal muscle differentiation and atrophy, synthesizing the findings of published data.

TI Prevalence and pattern of comorbidities in chronic rheumatic and musculoskeletal diseases: the COMORD study
SO SCIENTIFIC REPORTS
LA English
DT Article
ID ankylosing-spondylitis; arthritis; cancer; impact; multimorbidity; management; morbidity; mortality; burden; adults
AB Increased risk of comorbidities has been reported in Rheumatic and Musculoskeletal Diseases (RMD). We aimed to evaluate the prevalence and pattern of comorbidities in RMD patients nationwide, to identify multimorbidity clusters and to evaluate the gap between recommendations and real screening. Cross-sectional, multicentric nationwide study. Prevalence of comorbidities was calculated according to six EULAR axes. Latent Class Analysis identified

multimorbidity clusters. Comorbidities' screening was compared to international and local recommendations. In 769 patients (307 RA, 213 OA, 63 SLE, 103 axSpA, and 83 pSA), the most frequent comorbidities were cardiovascular risk factors and diseases (CVRFD) (hypertension 36.5%, hypercholesterolemia 30.7%, obesity 22.7%, smoking 22.1%, diabetes 10.4%, myocardial infarction 6.6%), osteoporosis (20.7%) and depression (18.1%). Three clusters of multimorbidity were identified: OA, RA and axSpA. The most optimal screening was found for CVRF (>=93%) and osteoporosis (53%). For malignancies, mammograms were the most optimally prescribed (56%) followed by pap smears (32%) and colonoscopy (21%). Optimal influenza and pneumococcus vaccination were found in 22% and 17%, respectively. Comorbidities were prevalent in RMD and followed specific multimorbidity patterns. Optimal screening was adequate for CVRFD but suboptimal for malignant neoplasms, osteoporosis, and vaccination. The current study identified health priorities, serving as a framework for the implementation of future comorbidity management standardized programs, led by the rheumatologist and coordinated by specialized health care professionals.

DT Article
ID extracorporeal shockwave therapy; anterior cruciate ligament; b-ligand rankl; subchondral bone; articular-cartilage; wave therapy; receptor-activator; knee; opg; manipulation
AB Osteoarthritis (OA) is a degenerative disease characterized by injury of all joint tissues. Our previous study showed that in experimental osteoporosis, chiropractic manipulation (CM) exerts protective effects on bone. We here assessed whether CM might ameliorate OA by improving subchondral bone sclerosis, cartilage integrity and synovitis. Male New-Zealand rabbits underwent knee surgery to induce OA by anterior cruciate ligament injury. CM was performed using the chiropractic instrument ActivatorV 3 times/week for 8 weeks as follows: force 2 setting was applied to the tibial tubercle of the rabbit right hind limb (TM-OA),

whereas the corresponding left hind limb received a false manipulation (FM-OA) consisting of ActivatorV firing in the air and slightly touching the tibial tubercle. After sacrifice, subchondral bone integrity was assessed in the tibiae by microCT and histology. Cartilage damage and synovitis were estimated by Mankin's and Krenn's scores, respectively, and histological techniques. Bone mineral density and content in both cortical and trabecular compartments of subchondral bone decreased in OA rabbits compared to controls, but partially reversed in the TM-OA group. Trabecular bone parameters in the latter group also showed a significant improvement compared to FM-OA group. Moreover RANKL, OPG, ALP and TRAP protein expression in subchondral bone significantly decreased in TM-OA rabbits with respect to FM-OA group. CM was associated with lower Mankin's and Krenn's scores and macrophage infiltrate together with a decreased protein expression of pro-inflammatory, fibrotic and angiogenic factors, in TM-OA rabbits with respect to FM-OA. Our results suggest that CM may mitigate OA progression by improving subchondral bone as well as cartilage and synovial membrane status.

TI Sex-Associated Differences in the Handgrip Strength of Elderly Individuals
SO WESTERN JOURNAL OF NURSING RESEARCH
LA English
DT Article
DE elderly; hand strength; health promotion; sex
ID physical function; grip strength; sarcopenia; decline; capacity; adults
AB This study aimed to identify sex-specific factors associated with handgrip strength in elderly individuals. The analysis cohort comprised 1,197 men and 1,384 women aged >= 65 years. In men, factors associated with low handgrip strength included advanced age; low body mass index; low frequency of performing flexibility exercises; limited self-care ability (which is a measure of the health-related quality of life); and the presence of diabetes, stroke, or osteoporosis (R-2 = 0.285, F = 7.52, p < .001). In women, the factors included advanced age, low body mass index, low frequency of performing muscle strengthening exercises, stress, and osteoarthritis (R-2 = 0.225, F = 4.17, p < .001). Effective health-promoting interventions for elderly individuals require the development of individualized programs that enhance handgrip strength while considering sex-related factors.

TI NADPH oxidases in bone and cartilage homeostasis and disease: A promising therapeutic target
SO JOURNAL OF ORTHOPAEDIC RESEARCH
LA English
DT Review
DE arthritis; bone; cartilage; NADPH oxidase; Nox4; osteoporosis
ID oxidative stress; ros production; osteoclast differentiation; interferon-gamma; superoxide; expression; chondrocytes; deficiency; inhibition; nox4
AB Reactive oxygen species (ROS) generated by the NADPH oxidase (Nox) enzymes are important short-range signaling molecules. They have been extensively studied in the physiology and pathophysiology of the cardiovascular system, where they have important roles in vascular inflammation, angiogenesis, hypertension, cardiac injury, stroke, and aging. Increasing evidence demonstrates that ROS and Nox enzymes also affect bone homeostasis and osteoporosis, and more recent studies implicate ROS and Nox enzymes in both inflammatory arthritis and osteoarthritis. Mechanistically, this connection may be through the effects of ROS on signal transduction. ROS affect both transforming growth factor-beta/Smad signaling, interleukin-1 beta/nuclear factor-kappa B signaling, and the resulting changes in matrix metalloproteinase expression. The purpose of this review is to describe the role of Nox enzymes in the physiology and pathobiology of bone and joints and to highlight the potential of therapeutically targeting the Nox enzymes.

TI Association of bone mineral density with the development of knee osteoarthritis in men and women: a cross-sectional study using the fourth and fifth Korea National Health and Nutrition Examination Surveys
SO ARCHIVES OF OSTEOPOROSIS
LA English
DT Article
DE Bone mineral density; Knee osteoarthritis; Sex; Cross-sectional study

ID radiographic osteoarthritis; sexual-dimorphism; femoral-neck; older-adults; elderly-men; hip; osteoporosis; fracture; age; prevalence
AB Bone mineral density (BMD) and osteoarthritis (OA) were correlated but the relationship was varied according to sex. An association between lumbar spine and femur neck BMDs and OA showed a positive relation in women, while lumbar spine and pelvis BMDs in men were associated with OA with a negative relation. Purpose The purpose of this study was to evaluate the association of BMD in various body parts in conjunction with the presence or severity of radiographic knee osteoarthritis (KOA) in relation to sex. Methods This study was a cross-sectional analysis using Korea National Health and Nutrition Examination Surveys. KOA was graded using the Kellgren-Lawrence (KL) grading system. Radiographic KOA was defined as a KL grade 2 or higher. The associations between KOA and BMD in certain body parts (femur, pelvis, lumbar, lower leg, and whole-body) were assessed. BMD was measured using dual-energy X-ray absorptiometry. The BMD of each body part was divided into quartiles and the relationship between KOA and BMD was examined according to sex. Results BMD did not show a significant tendency according to KL grade in either sex. In men, the severity of KL grade have a statistically significant relationship with total femur (R-2=0.303, p<0.05), femur neck (R-2=0.257, p<0.05), lumbar (R-2=0.137, p<0.05), and pelvis BMD (R-2=0.185, p<0.05). In women, total femur (R-2=0.466, p<0.05), lumbar (R-2=0.316, p<0.05), pelvis (R-2=0.343, p<0.05), and lower leg BMD (R-2=0.133, p<0.05) were associated with the severity of KL grade. When the BMD was divided into quartiles, lumbar (p<0.05) and pelvis BMD (p<0.05) in men had statistically significant association with knee OA as BMD decreased. In women, femur neck (p<0.05) and lumbar BMD (p<0.05) were significantly associated with knee OA as BMD increased. Conclusion The relationship between BMD and OA severity varied according to sex. In women, there was a positive association between femur neck and lumbar BMD and OA, while BMD of the lumbar and pelvis in men was negatively correlated with OA.

ID bone-mineral density; genome-wide association; gwas analysis; determinants; heritability; metaanalysis; expression; disease; risk
AB The development of high-throughput genotyping technologies and large biobank collections, complemented with rapid methodological advances in statistical genetics, has enabled hypothesis-free genome-wide association studies (GWAS), which have identified hundreds of genetic variants across many loci associated with musculoskeletal conditions. Similarly, basic scientists have valuable molecular cellular and animal data based on musculoskeletal disease that would be enhanced by being able to determine the human translation of their findings. By integrating these large-scale human genomic musculoskeletal datasets with complementary evidence from model organisms, new and existing genetic loci can be statistically fine-mapped to plausibly causal variants, candidate genes, and biological pathways. Genes and pathways identified using this approach can be further prioritized as drug targets, including side-effect profiling and the potential for new indications. To bring together these big data, and to realize the vision of creating aknowledge portal, the International Federation of Musculoskeletal Research Societies (IFMRS) established a working group to collaborate with scientists from the Broad Institute to create the Musculoskeletal Knowledge Portal (MSK-KP)(). The MSK consolidates omics datasets from humans, cellular experiments, and model organisms into a central repository that can be accessed

by researchers. The vision of the MSK-KP is to enable better understanding of the biological mechanisms underlying musculoskeletal disease and apply this knowledge to identify and develop new disease interventions. (c) 2020 American Society for Bone and Mineral Research (ASBMR).

TI Osteoporosis and Implant-Related Complications After Anatomic and Reverse Total Shoulder Arthroplasty
SO JOURNAL OF THE AMERICAN ACADEMY OF ORTHOPAEDIC SURGEONS
LA English
DT Article
ID proximal humeral fractures; total hip-arthroplasty; osteoarthritis; risk; hemiarthroplasty; epidemiology; outcm; women
AB Introduction:Osteoporosis is a widespread and growing medical condition, with significant orthopaedic implications. However, the effect of osteoporosis on outcomes after total shoulder arthroplasty (TSA) is not well understood. The goal of the present study was to characterize the incidence of osteoporosis in patients undergoing shoulder arthroplasty and to examine whether patients with osteoporosis undergoing anatomic and reverse TSA are at an increased risk of prosthetic-related complications.Methods:Complication rates were calculated for patients with osteoporosis who underwent anatomic and reverse TSA as separate cohorts within 2 years of surgery including loosening/osteolysis, periprosthetic fracture, periprosthetic dislocation, and revision shoulder arthroplasty and compared using a multivariable logistic regression analysis to control for patient demographics and comorbidities during comparisons, including the indication for reverse TSA.Results:The prevalence of an osteoporosis diagnosis at the time of surgery was 14.3% for anatomic TSA patients and 26.2% of reverse TSA patients. Anatomic TSA patients with osteoporosis experienced significantly higher rates of periprosthetic fracture (odds ratio [OR], 1.49; P = 0.017) and revision shoulder arthroplasty (OR, 1.21; P = 0.009) within 2 years of surgery compared with matched controls without osteoporosis. Patients in the reverse TSA group with osteoporosis also had significantly higher rates of periprosthetic fracture (OR, 1.86; P = 0.001) and revision shoulder arthroplasty (OR, 1.42; P = 0.005) within 2 years of surgery compared with matched controls.Discussion:A significant number of patients undergoing both anatomic and reverse TSA have a concurrent diagnosis of osteoporosis. Osteoporosis represents a significant independent risk factor for

periprosthetic fracture and revision shoulder arthroplasty within 2 years of surgery, regardless of the type of implant. Patients with osteoporosis should be counseled on their increased risk of complications after shoulder arthroplasty.

ID radiographic evaluation; clinical-assessment; strength; shoulder; system
AB Objective: This study aims to review, identify and study the determinations of the main orthopedic aspects in SCI patients. Methods: A total of 80 articles from PUBMED and three theses (MSc. /DSc.) were examined. Results: The results refer to the most essential joints. There is a chronic overload on the shoulder girdle due to the use of the upper limb as a supporting joint. The elbow presents osteoarthritis, subclinical, acute and chronic pain, mainly in quadriplegic patients. In the hand and wrist joints there are cases of paralysis, osteoporosis and osteoarthritis. Hips are the main weight-bearing joints while sitting which leads to a substantial degenerative process of this joint. Lastly, on the knee, feet and ankles, spasticity, contractures, osteoporosis and deformities can arise. Conclusion: Along with the increase in cases and research that analyze the alterations that spinal cord-injured individuals suffer, it is necessary to recognize the orthopedic changes to understand their limits and identify the relevance of the rehabilitation program to improve the muscle performance.

TI Neuropeptide Y1 receptor antagonist promotes osteoporosis and microdamage repair and enhances osteogenic differentiation of bone marrow stem cells via cAMP/PKA/CREB pathway
SO AGING-US
LA English
DT Article
DE osteoporosis; neuropeptide Y; bone microstructure; bone mcirodamage; bone marrow stromal cells
ID postmenopausal women; sympathetic activity; cancellous bone; osteoarthritis; osteoblasts; activation; expression; proliferation; metabolism; resorption
AB Osteoporosis is a common metabolic bone disorder in the elderly population. The accumulation of bone microdamage is a critical factor of osteoporotic fracture. Neuropeptide Y (NPY) has been reported to regulated bone metabolism through Y1 receptor (Y1R). In this study the effects and mechanisms of Y1R antagonist on prevention for osteoporosis were characterized. In the clinical experiment, compared with osteoarthritis (OA), osteoporosis (OP) showed significant osteoporotic bone microstructure and accumulation of bone microdamage. NPY and Y1R immunoreactivity in bone were stronger in OP group, and were both correlated with bone volume fraction (BV/TV). In vivo experiment, Y1R antagonist significantly improved osteoporotic microstructure in the ovariectomized (OVX) rats. And Y1R antagonist promoted RUNX2, OPG and inhibit RANKL, MMP9 in bone marrow. In vitro cell culture experiment, NPY inhibited osteogenesis, elevated RANKL/OPG ratio and downregulated the expression of cAMP, p-PKAs and p-CREB in BMSCs, treated with Y1R antagonist or 8-Bromo-cAMP could inhibit the effects

of NPY. Together, Y1R antagonist improved the bone microstructure and reduced bone microdamage in OVX rats. NPY-Y1R could inhibit osteoblast differentiation of BMSCs via cAMP/PKA/CREB pathway. Our findings highlight the regulation of NPY-Y1R in bone metabolism as a potential therapy strategy for the prevention of osteoporosis and osteoporotic fracture.

TI Effects of the origins and stabilization of biosolids and biowastes on their phosphorous composition and extractability
SO WASTE MANAGEMENT
LA English
DT Article
DE Alkaline-treated biosolids; Modified Hedley's fractionation; Manure; Organic amendments; Organic P mineralization
ID waste-water treatment; soil-phosphorus; manure compost; organic wastes; animal manure; fractionation; forms; release; phytoavailability; solubility
AB Phosphorous dissolution and ensuing chemical redistribution of P in organic amendments (OA) were studied by applying a modified Hedley selective fractionation to eight water-extracted and unextracted OAs. Nine 7-day, repeated

extractions were applied using a 60:1 water:dry OA (v:w) ratio at pH 8. Eight OAs were tested including five biosolids, broiler litter, dairy manure compost and municipal solid waste compost. The average PWEP9 (percent water-extractable P following nine water-extraction cycles) for the OAs was 65 +/- 9% and all of the fractions, with almost no exceptions, contributed to that figure. Organic P was depleted by mineralization (in non-stabilized sludges and broiler litter) or dissolution (stabilized composts) or both (in lime-treated biosolids) and that depletion was completed within 1-2 extraction cycles. Only the organic P of the MSWC remained undepleted. Strong linear correlations were observed between the WEP9 values of the OAs (0.8-21 g P kg(-1)) and several more easily determined properties, including total P content (r(2) = 0.84), organic N content (r(2) = 0.82), the sum of Hedley's more easily dissolved SRP (soluble reactive P) and OP (r(2) = 0.95), and the total P and SRP extracted by 16 h of shaking with the bicarbonate reagent (r(2) >= 0.90). These findings indicate that if greater P availability is desired, the stabilization of biosolids and biowastes should be minimized. These insights into the relationships between OA characteristics and P solubility may benefit the use of OAs in agricultural systems and aid assessments of the environmental significance of their use. TI Tissue Engineering and Regenerative Medicine Therapies for Cell Senescence in Bone and Cartilage
SO TISSUE ENGINEERING PART B-REVIEWS
LA English
DT Article
DE bone cell senescence; osteoporosis; bone repair; aging
ID mesenchymal stem-cells; sensing receptor antagonist; total shoulder arthroplasty; wide dna methylation; smooth-muscle-cells; knee osteoarthritis; oxidative stress; cancellous bone; mineral density; in-vitro
AB The bone repair and substitute have been developed for decades with the bone defect repair applied successfully in clinical. However, implant complications may occur in more challenging situations, bone cell senescence and osteoporosis (OP). Due to certain microenvironment conditions, including hormonal, nutritional, and aging factors, the bone cell responses are regulated to alteration and end into cell senescence and OP. Thus, the bone tissue regeneration is limited with site morbidity increased, leading to bone graft failure. In such pathological state, bone grafts and substitutes are companied with OP therapies to improve bone tissue engineering and to enhance bone graft healing. Those substitutes with OP therapeutic-based applications have been becoming a growing field of interest in bone repair. Bone grafts, such as scaffolds with antiosteoporotic drugs releasing and implants with surface therapeutic modified, are studied to significantly increase low bone density as well as improve impaired bone regeneration. In this review, we discuss a thorough understanding in bone remodeling process, bone cell senescence, and mechanisms of OA and OP. Based on the understanding, the review concentrates on the treatments to the OP and the bone grafts applied in the bone senescence model and provides a future direction in clinical trial. Impact Statement This review discusses the tissue engineering and regenerative medicine therapies for aging-related bone diseases, which have been highly concerned in

aging society. These therapies can improve the efficacy of bone tissue regeneration, enhance the quality of bone repair, and provide new insights in the field of bone clinical treatments and aging regeneration.

TI Spinal Osteoarthritis Is Associated With Stature Loss Independently of Incident Vertebral Fracture in Postmenopausal Women
SO SPINE
LA English
DT Article
DE aging; bone mineral density; degenerative joint disease; height loss; incident vertebral fracture; osteoporosis; postmenopausal women; quality of life; spinal osteoarthritis; stature loss
ID historical height loss; older women; mortality; men; accuracy; ratio
AB Study Design. Retrospective observational study from the Nagano Cohort Study. Objective. Clarify the association between spinal osteoarthritis and loss of stature in postmenopausal women. Summary of Background Data. Loss of stature

with aging is known to deteriorate health-related quality of life and has been implicated with increased mortality. Although the association of vertebral fracture with height loss has been well documented, the relationship between stature loss and spinal osteoarthritis remains unclear. Methods. We retrospectively investigated Japanese postmenopausal women recruited from the Nagano Cohort Study. The participants were outpatients at a primary care institute in Nagano prefecture, Japan. A total of 977 postmenopausal patients (mean age: 65.8 yr) completed a minimum of 1 year of follow-up, with an average observation period of 7.6 years. Quartile analysis on the prevalence of spinal osteoarthritis and occurrence of incident fracture was performed based on the rate of stature change per year (Delta cm/yr). Multiple regression analysis was also conducted to identify the determinants of stature change. Results. The lower quartiles of stature change rate (i.e., more rapid stature loss) displayed a significantly higher prevalence of spinal osteoarthritis ($P < 0.001$) and incident vertebral fracture ($P<0.001$). A statistically significant independent negative association for spinal osteoarthritis prevalence with change in stature was revealed by multiple regression analysis after adjusting for confounders including incident vertebral fracture. The partial regression coefficient for spinal osteoarthritis was -0.18 (95% confidence interval -0.33 to -0.03; $P = 0.016$). Conclusion. This study demonstrated an independent association of spinal osteoarthritis with stature loss in postmenopausal women. Adequate understanding of this relationship and appropriate treatment approaches will help improve health-related quality of life in elderly patients.

TI The role of opioid analgesics in rheumatic disorders: a position paper from the Portuguese Rheumatology Society
SO ACTA REUMATOLOGICA PORTUGUESA
LA English
DT Article
DE Opioids; Musculoskeletal pain; Pain; Rheumatic diseases

ID chronic noncancer pain; low-back-pain; evidence-based recommendations; quality-of-life; eular recommendations; knee osteoarthritis; standing-committee; fibromyalgia pain; task-force; osteoporosis
AB Pain is a common feature of most rheumatic diseases and it is often the main reason for the patient to seek for a clinical appointment. Chronic pain has a major impact on patient's quality of life, being frequently associated with functional incapacity, sleep and mood disorders. This leads to absenteeism and heavy consumption of health resources, both representing huge burdens on national economy. Managing musculoskeletal pain is pivotal but can be challenging. The use of the available pharmaceutical armamentarium should be parsimonious. Opioids are strong analgesic drugs that mostly act through their agonist action on mu-receptors in the central nervous system. Opioid-related side effects are not negligible and are mediated through both central and peripheral opioid receptors. The use of opioids is well established in the treatment of oncologic pain but their role in the management of musculoskeletal pain is still controversial. Inflammatory rheumatic diseases, osteoarthritis, osteoporotic fractures, chronic low back pain and fibromyalgia represent diverse major rheumatic conditions that frequently lead to chronic pain. In order to standardize and optimize management of musculoskeletal chronic pain in these prevalent diseases, the Portuguese Rheumatology Society elaborated this position paper. The objectives were: a) to define the importance of pain assessment and classification; b) to guide patient selection, appropriate choice of opioids, their management, and raise awareness of their adverse effects; c) to review the existent data on possible indications of opioid therapy on rheumatic diseases.

TI Clinical Study of Correlation Between Osteoporosis and Osteoarthritis of Knee Joint Using Gold Nanomaterial Contrast Agent
SO JOURNAL OF NANOSCIENCE AND NANOTECHNOLOGY
LA English
DT Article
DE Osteoporosis; Knee Arthritis; Comorbidity; GNP
ID bone-mineral density; subchondral bone; articular-cartilage; hip osteoarthritis; cancellous bone; tissue; men
AB The relationship between osteoporosis (OP) and knee osteoarthritis (OA) was studied using gold nanomaterial (GNP) contrast agent from the imaging and clinical perspectives. Patients were divided into the OA and OP comorbidity group (experimental), OA group (positive control), and OP group (negative control) and evaluated using the Lysholm knee joint score and traditional Chinese medicine syndrome score. Bone density was measured by parallel X-ray examination, magnetic resonance imaging examination, Recht classification, and arthroscopic Outerbridge classification. GNP contrast agents were used in the medical imaging tests. There were significant differences between the various factors compared between the experimental and positive control groups ($P < 0.05$). The correlation analysis of the variables and bone mineral density in all patients showed a positive linear relationship ($P < 0.05$). There was a positive correlation between OP and knee OA. GNP has good clinical value in medical imaging.

TI Loading modality and age influence teriparatide-induced bone formation in the human femoral neck
SO BONE
LA English
DT Article
DE Teriparatide; Femoral neck; Clinical study; Mechanical loading; Tension; Compression
ID body-mass index; parathyroid-hormone; postmenopausal women; mineral density; cancellous bone; cortical bone; pth treatment; osteoporosis; denosumab; therapy
AB Teriparatide (TPTD) reduces risk of both vertebral and nonvertebral fracture, but increases bone mineral density (BMD) much more at the spine than the hip. TPTD and mechanical loading may have a synergistic anabolic effect on BMD, which may help explain these site-specific differences. Under normal daily activity, the femoral neck (FN) is under bending, placing one side under tension and the other under compression. We sought to further understand the relationship between mechanical loading and TPTD at the hip by investigating the effect of tensile versus compressive loading on TPTD stimulated bone formation indices in the human FN. Thirty-eight patients receiving total hip replacements for osteoarthritis were randomized to receive placebo (PBO) or TPTD for a mean treatment duration of 6 weeks prior to surgery, and double tetracycline labeling was administered to allow assessment of bone formation. The FN was harvested during surgery and analyzed for dynamic bone formation indices in the compressive and tensile regions of the endocortical and periosteal envelopes. Regression models relating outcome measures to patient characteristics including sex, age, body weight, and FN geometry were also analyzed. Overall, bone formation was higher with TPTD versus placebo on the endocortical surface, but not the periosteal surface. The level of bone formation in both TPTD and placebo groups was greater on the tensile endocortical surface and the compressive periosteal surface. There was a trend toward decreased endocortical eroded surface with TPTD in the compressive but not the tensile region. Patient age and sex explained the greatest variability in endocortical bone formation, and patient body mass and sex explained the greatest variability in periosteal bone formation. Our data represent the first dynamic comparison of teriparatide treatment under two loading modalities in human FN samples. Future work could determine whether specific hip loading intervention could amplify the benefits of teriparatide on the hip in clinical settings.

TI Zebrafish: A Suitable Tool for the Study of Cell Signaling in Bone
SO CELLS
LA English
DT Review
DE zebrafish; bone; cartilage; osteogenesis imperfecta
ID osteoclast differentiation; expression; osteogenesis; dedifferentiation; osteoblasts; cartilage; genetics; growth; runx2; fate
AB In recent decades, many studies using the zebrafish model organism have been performed. Zebrafish, providing genetic mutants and reporter transgenic lines, enable a great number of studies aiming at the investigation of signaling pathways involved in the osteoarticular system and at the identification of therapeutic tools for bone diseases. In this review, we will discuss studies which demonstrate that many signaling pathways are highly conserved between mammals and teleost and that genes involved in mammalian bone differentiation have orthologs in zebrafish. We will also discuss as human diseases, such asosteogenesis imperfecta, osteoarthritis, osteoporosis and Gaucher disease can be investigated in the zebrafish model.

TI Prevalence of osteoporosis and osteopenia diagnosed using quantitative CT in 296 consecutive lumbar fusion patients
SO NEUROSURGICAL FOCUS

LA English
DT Article
DE osteoporosis; osteopenia; quantitative computed tomography; OCT; bone mineral density; disease prevalence; degenerative lumbar disease
ID bone-mineral density; x-ray absorptiometry; postmenopausal women; vertebral fractures; risk-factors; degenerative changes; knee osteoarthritis; computed-tomography; spine surgery; hip
AB OBJECTIVE Osteoporosis is a metabolic bone disease that increases the risk for fragility fractures. Screening and diagnosis can be achieved by measuring bone mineral density (BMD) using quantitative CT tomography (QCT) in the lumbar spine. QCT-derived BMD measurements can be used to diagnose osteopenia or osteoporosis based on American College of Radiology (ACR) thresholds. Many reports exist regarding the disease prevalence in asymptomatic and disease-specific populations; however, osteoporosis/osteopenia prevalence rates in lumbar spine fusion patients without fracture have not been reported. The purpose of this study was to define osteoporosis and osteopenia prevalence in lumbar fusion patients using QCT. METHODS A retrospective review of prospective data was performed. All patients undergoing lumbar fusion surgery who had preoperative fine-cut CT scans were eligible. QCT-derived BMD measurements were performed at L1 and L2. The L1-2 average BMD was used to classify patients as having normal findings, osteopenia, or osteoporosis based on ACR criteria. Disease prevalence was calculated. Subgroup analyses based on age, sex, ethnicity, and history of abnormal BMD were performed. Differences between categorical groups were calculated with Fisher's exact test. RESULTS Overall, 296 consecutive patients (55.4% female) were studied. The mean age was 63 years (range 21-89 years). There were 248 (83.8%) patients with ages >= 50 years. No previous clinical history of abnormal BMD was seen in 212 (71.6%) patients. Osteopenia was present in 129 (43.6%) patients and osteoporosis in 44 (14.9%). There were no prevalence differences between sex or race. Patients >= 50 years of age had a significantly higher frequency of osteopenia/osteoporosis than those who were < 50 years of age. CONCLUSIONS In 296 consecutive patients undergoing lumbar fusion surgery, the prevalence of osteoporosis was 14.9% and that for osteopenia was 43.6% diagnosed by QCT. This is the first report of osteoporosis disease prevalence in lumbar fusion patients without vertebral fragility fractures diagnosed by QCT.

TI High bone turnover state under osteoporotic changes induces pain-like behaviors in mild osteoarthritis model mice
SO JOURNAL OF BONE AND MINERAL METABOLISM
LA English
DT Article
DE Osteoporosis; Osteoarthritis; High bone turnover; Pain; Bisphosphonate
ID knee pain; marrow lesions; skeletal pain; bisphosphonates; risedronate; mechanisms; markers; p2x2/3; cells; asics
AB Introduction Our previous studies demonstrated that a high bone turnover state under osteoporotic changes decreased the threshold of skeletal pain. Recent studies reported that the incidence of joint pain due to osteoarthritis (OA) in postmenopausal women was higher than that in males even with the same radiographic OA grade. The aim of this study was to evaluate whether a high bone turnover state affects the induction of pain-like behaviors in mild OA model mice. Materials and Methods We established mild OA model mice with accompanying osteoporotic changes by monosodium iodoacetate injection after ovariectomy. We assessed pain-like behaviors by von Frey test and paw-flick test; histological changes in OA joints; the expression of Runx2, Osterix, Osteocalcin, and Rankl; bone micro-architecture by mu CT and measured serum tartrate-resistant acid-phosphatase 5b levels in the model mice. Results Pain-like behaviors in mice with OA and osteoporotic changes were significantly increased in comparison with those in OA mice without osteoporotic changes. The severity of histological OA changes did not differ significantly between the OA mice with and without osteoporotic changes. Bisphosphonate significantly improved pain-like behaviors accompanied with improvement in the high bone turnover state in the OA mice with osteoporosis, while it had no significant effect on pain-like behaviors in the OA mice without osteoporosis. In addition, the improvement was maintained for more than 4 weeks even after the discontinuation of bisphosphonate treatment. Conclusion These results indicated that a high bone turnover state under osteoporotic changes could affect the induction of pain-like behaviors in mild OA model mice.

TI Labral calcification plays a key role in hip pain and symptoms in femoroacetabular impingement
SO JOURNAL OF ORTHOPAEDIC SURGERY AND RESEARCH
LA English
DT Article
DE Femoroacetabular impingement syndrome; Arthroscopy; Synovial inflammation; Labrum; Calcification
ID nationwide prospective cohort; acetabular labrum; synovial inflammation; cam impingement; risk-factor; osteoarthritis; arthroscopy; deformity; outcm; pathophysiology
AB Background Hip osteoarthritis (HOA) is the most common hip disorder and a major cause of disability in the adult population, with an estimated prevalence of end-stage disease and total hip replacement. Thus, the diagnosis, prevention, and treatment of the early stages of the disease in young adults are crucial to reduce the incidence of end-stage HOA. The purpose of this study was to determine

whether (1) a relationship among the inflammatory status of labrum and synovium collected from patients with femoroacetabular impingement (FAI) would exist; and (2) to investigate the associations among the histopathological features of joint tissues, the pre-operative symptoms and the post-operative outcomes after arthroscopic surgery. Methods Joint tissues from 21 patients undergoing hip arthroscopy for FAI were collected and their histological and immunohistochemical features were correlated with clinical parameters. Results Synovial mononuclear cell infiltration was observed in 25% of FAI patients, inversely correlated with the hip disability and osteoarthritis outcome score (HOOS) pain and function subscales and with the absolute and relative change in total HOOS. All the labral samples showed some pattern of degeneration and 67% of the samples showed calcium deposits. The total labral score was associated with increased CD68 positive cells in the synovium. The presence of labral calcifications, along with the chondral damage worsened the HOOS post-op symptoms (adjusted R-square = 0.76 p = 0.0001). Conclusions Our study reveals a relationship between the histologic labral features, the synovial inflammation, and the cartilage condition at the time of FAI. The presence of labral calcifications, along with the cartilage damage and the synovitis negatively affects the post-operative outcomes in patients with FAI.

TI The Application of MSCs-Derived Extracellular Vesicles in Bone Disorders: Novel Cell-Free Therapeutic Strategy
SO FRONTIERS IN CELL AND DEVELOPMENTAL BIOLOGY
LA English
DT Review
DE mesenchymal stem cells; extracellular vesicles; exosomes; osteoarthritis; rheumatoid arthritis; osteoporosis; bone fracture
ID mesenchymal stem-cells; stromal cells; exosome isolation; transferrin receptor; osteoarthritis; microvesicles; transplantation; proliferation; biogenesis; secretion
AB Bone is crucial for supporting the body, protecting other organs, providing minerals, and secreting hormone to regulate other organ's function. Bone disorders result in pain and disability, severely affecting human health, reducing the quality of life and increasing costs to society. With the rapid increase in the aging population worldwide, bone disorders have become one major disease. As a result, efficacious therapies of bone disorders have become the focus of attention worldwide. Mesenchymal stem cells (MSCs) have been widely explored as a new therapeutic method for numerous diseases. Recent evidence suggests that the therapeutic effects of MSCs are mainly mediated by their extracellular vesicles (EV). MSCs-derived extracellular vesicles (MSCs-EV) is indicated as a novel cell-free alternative to cell therapy with MSCs in regenerative medicine. Here, we review the current knowledge of EV and highlight the application studies of MSCs-EV in bone

disorders by focusing on osteoarthritis (OA), rheumatoid arthritis (RA), osteoporosis (OP), and bone fracture. Moreover, we discuss the key issues and perspectives of MSCs-EV as a clinical therapeutic strategy for bone diseases.

AB Osteoporosis, related fracture/fragility, and osteoarthritis are age-related pathologies that, over recent years, have seen increasing incidence and prevalence due to population ageing. The diagnostic approaches to these pathologies suffer from limited sensitivity and specificity, also in monitoring the disease progression or treatment. For this reason, new biomarkers are desirable for improving the management of osteoporosis and osteoarthritis patients. The non-coding RNAs, called miRNAs, are key post-transcriptional factors in bone homeostasis, and promising circulating biomarkers for pathological conditions in which to perform a biopsy can be problematic. In fact, miRNAs can easily be detected in biological fluids (i.e., blood, serum, plasma) using methods with elevated sensitivity and specificity (RT-qPCR, microarray, and NGS). However, the analytical phases required for miRNAs' evaluation still present some practical issues that limit their use in clinical practice. This review reveals miRNAs' potential as circulating biomarkers for evaluating predisposition, diagnosis, and prognosis of osteoporosis (postmenopausal or idiopathic), bone fracture/fragility, and osteoarthritis, with a focus on pre-analytical, analytical, and post-analytical protocols used for their validation and thus on their clinical applicability. These evidences may support the definition of early diagnostic tools based on circulating miRNAs for bone diseases and osteoarthritis as well as for monitoring the effects of specific treatments.

TI Medical conditions and physical function deficits among multiple primary cancer survivors
SO JOURNAL OF CANCER SURVIVORSHIP
LA English
DT Article
DE Multiple primary cancers; Cancer survivors; Physical function; Comorbidities
ID mental-health status; quality-of-life; psychological distress; older-adults; prevention; prevalence; behaviors; society; risk
AB Purpose Survivors of multiple primary cancers make up a sizable proportion of all cancer survivors, yet little is known about the health of this population. We examined the prevalence of medical conditions and physical function deficits among multiple primary survivors compared with single primary survivors and individuals without a cancer history. Methods Participants were enrolled in the Cancer Prevention Study (CPS)-II Nutrition Cohort in 1992/1993. Prevalent medical conditions (diabetes, heart conditions, cerebrovascular conditions, emphysema/chronic bronchitis, osteoporosis, osteoarthritis), physical function limitations, use of a cane or walker, balance difficulties, and falls within the past year were assessed on a follow-up survey completed in 2011. We estimated age- and sex-adjusted prevalence ratios (PRs), comparing multiple primary survivors (N = 1003) to single primary survivors (N = 12,849) and participants without cancer (N = 63,578). Results The prevalence of medical conditions did not differ substantially between multiple primary survivors and either comparison group. However, multiple primary survivors were more likely to report severe limitations in physical function than the single primary (PR = 1.48 (95% CI, 1.28-1.71)) and no-cancer (PR = 1.64 (95% CI, 1.42-1.88)) groups. Using a cane or walker and balance difficulties were also significantly more common among multiple primary survivors. Conclusions Despite a similar prevalence of comorbid medical conditions, severe functional limitations were significantly more common among multiple primary survivors than single primary survivors or individuals without cancer. Implications for Cancer Survivors Assessment of functional status and treatment of physical deficits may be an especially critical component of care for older patients with a history of multiple cancer diagnoses.

TI Palmatine as an Agent Against Metabolic Syndrome and Its Related Complications: A Review
SO DRUG DESIGN DEVELOPMENT AND THERAPY
LA English
DT Review
DE anti-inflammation; antioxidant; myocardial reperfusion injury; obesity; osteoporosis; osteoarthritis
ID oxidative stress; adipose-tissue; alkaloid palmatine; rhizoma coptidis; p-glycoprotein; bone health; in-vivo; activation; expression; obesity
AB Palmatine is a naturally occurring isoquinoline alkaloid with various pharmacological properties. Given its antioxidant and anti-inflammatory properties, palmatine may be able to impede the effects of metabolic syndrome (MetS) and its related diseases triggered by inflammation and oxidative stress. This review summarises the existing literature about the effects of palmatine supplementation on MetS and its complications. The evidence shows that palmatine could protect against MetS, and cardiovascular diseases, osteoporosis and osteoarthritis, which

might be associated with MetS. These protective effects are mediated by the antioxidant and anti-inflammatory properties of palmatine. Although preclinical experiments have demonstrated the efficacy of palmatine against MetS and its related diseases, no human clinical trials have been performed to validate these effects. This research gap should be bridged to validate the efficacy and safety of palmatine supplementation in protecting humans against MetS and its related diseases.

TI Influence of anti-osteoporosis treatments on the incidence of COVID-19 in patients with non-inflammatory rheumatic conditions
SO AGING-US
LA English
DT Article
DE denosumab; zoledronate; calcium; vitamin D; anti-resorptive drugs; COVID-19
ID immune-responses; zoledronic acid; mortality; pregabalin; mechanism; diseases; calcium
AB Coronavirus disease 19 (COVID-19) is currently a global pandemic that affects patients with other pathologies. Here, we investigated the influence of treatments for osteoporosis and other non-inflammatory rheumatic conditions, such as osteoarthritis and fibromyalgia, on COVID-19 incidence. To this end, we conducted a cross-sectional study of 2,102 patients being treated at the Rheumatology Service of Hospital del Mar (Barcelona, Spain). In our cohort, COVID-19 cumulative incidence from March 1 to May 3, 2020 was compared to population estimates for the same city. We used Poisson regression models to determine the adjusted relative risk ratios for COVID-19 associated with different treatments and comorbidities. Denosumab, zoledronate and calcium were negatively associated with COVID-19 incidence. Some analgesics, particularly pregabalin and most of the studied antidepressants, were positively associated with COVID-19 incidence, whereas duloxetine presented a negative association. Oral bisphosphonates,

vitamin D, thiazide diuretics, anti-hypertensive drugs and chronic nonsteroidal anti-inflammatory drugs had no effect on COVID-19 incidence in the studied population. Our results provide novel evidence to support the maintenance of the main anti-osteoporosis treatments in COVID-19 patients, which may be of particular relevance to elderly patients affected by the SARS-CoV-2 pandemic.

TI Soluble Biomarkers of Osteoporosis and Osteoarthritis, from Pathway Mapping to Clinical Trials: An Update
SO CLINICAL INTERVENTIONS IN AGING
LA English
DT Review

DE osteoarthritis; osteoporosis; biomarkers
ID bone turnover markers; oligomeric matrix protein; c-terminal telopeptide; newly developed assay; biochemical markers; knee osteoarthritis; ctx-ii; cartilage degradation; strontium ranelate; mineral density
AB Serum biomarkers of osteoarticular diseases have been in the limelight of current clinical research trends. Laboratory validation of defined and candidate biomarkers for both osteoarthritis and osteoporosis is of key importance for future decisional algorithms in the diagnosis, monitoring, and prognosis of these diseases. The current guidelines recommend the use of collagen degradation remnants, eg, CTX-I and CTX-II, in the complementary diagnosis of both osteoporosis and osteoarthritis. Besides the collagen degradation markers, enzymes that regulate bone and articular metabolism are useful in the clinical evaluation of osteoarticular pathologies. Along these, several other recommended and new nominee molecules have been recently studied. Wnts and Wnt-related molecules have a cardinal role in the bone-joint homeostasis, making them a promising target not only for pharmaceutical modulation, but also to be considered as soluble biomarkers. Sclerostin and dickkopf, two inhibitor molecules of the Wnt/beta-catenin signaling, might have a dual role in the assessment of the clinical manifestations of the osteoarticular unit. In osteoarthritis, besides fragments of collagen type II many pathway-related molecules have been studied and proposed for biomarker validation. The most serious limitation is that a significant proportion of studies lack statistical power due to the reduced number of cases enrolled. Serum biomarkers of bone and joint turnover markers represent an encouraging possibility for the diagnosis and prognosis of osteoarticular diseases, although further studies and laboratory validations should be carried out as to solely rely on them.

TI The Role of Chronic Inflammatory Bone and Joint Disorders in the Pathogenesis and Progression of Alzheimer's Disease
SO FRONTIERS IN AGING NEUROSCIENCE
LA English
DT Review
DE Alzheimer' s disease; osteoarthritis; osteoporosis; rheumatoid arthritis; inflammation; mesenchymal stem cells
ID mesenchymal stem-cells; platelet-rich plasma; regulates osteogenic differentiation; mild cognitive impairment; vagus nerve-stimulation; necrosis-factor-alpha; rheumatoid-arthritis; knee osteoarthritis; mouse model; systemic inflammation
AB Late-onset Alzheimer's Disease (LOAD) is a devastating neurodegenerative disorder that causes significant cognitive debilitation in tens of millions of patients worldwide. Throughout disease progression, abnormal secretase activity results in the aberrant cleavage and subsequent aggregation of neurotoxic A beta plaques in the cerebral extracellular space and hyperphosphorylation and destabilization of structural tau proteins surrounding neuronal microtubules. Both pathologies ultimately incite the propagation of a disease-associated subset of microglia-the

principle immune cells of the brain-characterized by preferentially pro-inflammatory cytokine secretion and inhibited AD substrate uptake capacity, which further contribute to neuronal degeneration. For decades, chronic neuroinflammation has been identified as one of the cardinal pathophysiological driving features of AD; however, despite a number of works postulating the underlying mechanisms of inflammation-mediated neurodegeneration, its pathogenesis and relation to the inception of cognitive impairment remain obscure. Moreover, the limited clinical success of treatments targeting specific pathological features in the central nervous system (CNS) illustrates the need to investigate alternative, more holistic approaches for ameliorating AD outcomes. Accumulating evidence suggests significant interplay between peripheral immune activity and blood-brain barrier permeability, microglial activation and proliferation, and AD-related cognitive decline. In this work, we review a narrow but significant subset of chronic peripheral inflammatory conditions, describe how these pathologies are associated with the preponderance of neuroinflammation, and posit that we may exploit peripheral immune processes to design interventional, preventative therapies for LOAD. We then provide a comprehensive overview of notable treatment paradigms that have demonstrated considerable merit toward treating these disorders.

TI MicroRNA expression profiling in an ovariectomized rat model of postmenopausal osteoporosis before and after estrogen treatment
SO AMERICAN JOURNAL OF TRANSLATIONAL RESEARCH

DT Article
DE Postmenopause; osteoporosis; microRNAs; rats; estrogens
ID subchondral bone; cartilage damage; osteoarthritis; disease; serum; severity; turnover; mirnas; differentiation; homeostasis
AB Postmenopausal osteoporosis (PMOP) is a common disease that seriously threatens human health. Estrogen deficiency plays an essential role in the pathogenesis of PMOP. MicroRNAs (miRNAs) are involved in the development and progression of PMOP. Therefore, identification of miRNAs in PMOP due to estrogen deficiency may contribute to earlier diagnosis and better treatment of this disease. The rat model of PMOP was established by ovariectomy. After one month of treatment, the knee joints were evaluated by microcomputed tomography and histological analysis. The plasma estrogen levels were quantified by enzyme-linked

immunosorbent assays (ELISAs). MiRNA levels were analyzed by high-throughput sequencing and validated using quantitative real-time PCR (qRT-PCR). Two months after ovariectomy, osteoporosis occurred in the subchondral bone of the rats in the PMOP group, while fewer symptoms of osteoporosis occurred in the subchondral bone of the rats with estrogen replacement therapy. Cartilage degeneration was detected in the PMOP group. MiR-29a-3p, miR-93-5p, and miR-486 expression decreased in the PMOP group compared to the control group. After estrogen treatment for one month, the plasma levels of miR-29a-3p, miR-93-5p, and miR-486 recovered to the normal levels. Estrogen eliminated the expression changes in miR-29a-3p, miR-93-5p, and miR-486. The identification of these differentially expressed miRNAs will help elucidate the crucial role of miRNAs in the pathogenesis of PMOP. Our data could lead to the potential utilization of miRNAs in the diagnosis of PMOP and provide a possible therapeutic target for treatment of this disease.

TI Comparison of diclofenac with apigenin-glycosides rich Clinacanthus nutans extract for amending inflammation and catabolic protease regulations in osteoporotic-osteoarthritis rat model
SO DARU-JOURNAL OF PHARMACEUTICAL SCIENCES
LA English
DT Article
DE Apigenin-C-glycosides; Anti-inflammatory; Osteoarthritis; Osteoporosis
ID cartilage; osteoclastogenesis; pathogenesis; inhibition; pathway; risk
AB Background Osteoporotic-osteoarthritis is an incapacitating musculoskeletal illness of the aged. Objectives The anti-inflammatory and anti-catabolic actions of Diclofenac were compared with apigenin-C-glycosides rich Clinacanthus nutans (CN) leaf extract in osteoporotic-osteoarthritis rats. Methods Female Sprague Dawley rats were randomized into five groups (n = 6). Four groups were bilateral ovariectomised for osteoporosis development, and osteoarthritis were induced by intra-articular injection of monosodium iodoacetate (MIA) into the right knee joints. The Sham group was sham-operated, received saline injection and deionized

drinking water. The treatment groups were orally given 200 or 400 mg extract/kg body weight or 5 mg diclofenac /kg body weight daily for 28 days. Articular cartilage and bone changes were monitored by gross and histological structures, micro-CT analysis, serum protein biomarkers, and mRNA expressions for inflammation and catabolic protease genes. Results HPLC analysis confirmed that apigenin-C-glycosides (shaftoside, vitexin, and isovitexin) were the major compounds in the extract. The extract significantly and dose-dependently reduced cartilage erosion, bone loss, cartilage catabolic changes, serum osteoporotic-osteoarthritis biomarkers (procollagen-type-II-N-terminal-propeptide PIINP; procollagen-type-I-N-terminal-propeptide PINP; osteocalcin), inflammation (IL-1 beta) and mRNA expressions for nuclear-factor-kappa-beta NF-kappa beta, interleukin-1-beta IL-1 beta, cyclooxygenase-2; and matrix-metalloproteinase-13 MMP13 activities, in osteoporotic-osteoarthritis rats comparable to Diclofenac. Conclusion This study demonstrates that apigenin-C-glycosides at 400 mg CN extract/kg (about 0.2 mg apigenin-equivalent/kg) is comparable to diclofenac in suppressing inflammation and catabolic proteases for osteoporotic-osteoarthritis prevention.

TI Limited Influence of Comorbidities on Length of Stay after Total Hip Arthroplasty: Experience of Enhanced Recovery after Surgery
SO ORTHOPAEDIC SURGERY
LA English
DT Article
DE Enhanced recovery after surgery; Length of stay; predictors; Total hip arthroplasty
ID hospital stay; knee arthroplasty; patient characteristics; joint arthroplasty; united-states; outcm; chinese; replacement; predictors; feasibility
AB Objectives To identify predictors of length of stay (LOS) after total hip arthroplasty (THA) in an enhanced recovery after surgery (ERAS) program and evaluate the safety and cost-efficiency of the ERAS program with reduced LOS for unselected patients in a Chinese population. Methods A total of 311 consecutive, unselected patients undergoing primary THA at a single institution were retrospectively reviewed and divided into two groups: LOS <= 3 and LOS > 3 group. All patients were managed with the same ERAS protocol and went back home after discharge. Multivariate logistic regression analysis was used to determine independent risk factors for LOS > 3. Harris Hip Score at 90-day follow-up, 90-day readmission rate, and hospitalization costs were compared between two groups. Results Multivariate regression analysis identified female gender (odds ratio [OR] = 2.623), living alone (OR = 4.127), and primary osteoarthritis of hip (OR = 3.565) to be correlated with LOS > 3. Preoperative hemoglobin (HB), postoperative HB, drain use, blood transfusion, diabetes, respiratory disease, osteoporosis, number of comorbidities, and CCI score showed no significant influence on LOS after adjusting for other risk factors in the multivariate model. Harris Hip Score and readmission rate at 90-day follow-up showed no significant differences between two groups. Patients in LOS > 3 group had approximately 3948.6 Chinese yuan higher hospital costs. Conclusion Female gender, living alone, and primary osteoarthritis of hip were identified as independent risk factors for prolonged LOS. The experience from our institution suggested aggressive management of comorbidities in the ERAS program can minimize the influence of comorbidities on LOS. The safety, efficiency, and costs-saving benefits of the ERAS program with reduced LOS for unselected patients was confirmed in this study.

TI Effect of cadmium on the concentration of essential metals in a human chondrocyte micromass culture
SO JOURNAL OF TRACE ELEMENTS IN MEDICINE AND BIOLOGY
LA English
DT Article
DE Osteoarthritis; Chondrocytes; Cadmium; Essential elements
ID knee-joint; hip-joint; calcium; iron; cartilage; manganese
AB Background: An essential element imbalance in the joint might favor gradual degeneration of the articular cartilage. It has been reported that cadmium (Cd) plays an antagonistic role with regards to the presence of essential elements, such as zinc (Zn), iron (Fe), and manganese (Mn), which may favor the development of

disabling diseases, like osteoarthritis (OA) and osteoporosis. Methods: 3D cultures of human chondrocytes were phenotyped with the Western blot technique and structurally evaluated with histological staining. The samples were exposed to 1, 5, and 10 mu M of CdCl2 for 12 h, with a non-exposed culture as control. The concentration of Cd, Fe, Mn, Zn, chromium (Cr), and nickel (Ni) was quantified through plasma mass spectrometry (ICP-MS). The data were analyzed with a Kruskal Wallis test, a Kendall's Tau test and Spearman's correlation coefficient with the Stata program, version 14. Results: Our results suggest that Cd exposure affects the structure of micromass cultures and plays an antagonistic role on the concentration of essential metals, such as Zn, Ni, Fe, Mn, and Cr. Conclusion: Cd exposure may be a risk factor for developing joint diseases like OA, as it can interfere with cartilage absorption of other essential elements that maintain cartilage homeostasis.

TI The Roles of FoxO Transcription Factors in Regulation of Bone Cells Function
SO INTERNATIONAL JOURNAL OF MOLECULAR SCIENCES

LA English
DT Review
DE FoxOs; bone cells; antioxidant; osteogenesis; osteoclastogenesis; chondrogenesis; bone diseases
ID oxidative stress; hematopoietic stem; osteoclast differentiation; beta-catenin; chondrocytes; homeostasis; activation; resistance; expression; cancer
AB Forkhead box class O family member proteins (FoxOs) are evolutionarily conserved transcription factors for their highly conserved DNA-binding domain. In mammalian species, all the four FoxO members, FoxO1, FoxO3, FoxO4, and FoxO6, are expressed in different organs. In bone, the first three members are extensively expressed and more studied. Bone development, remodeling, and homeostasis are all regulated bymultiple cell lineages, including osteoprogenitor cells, chondrocytes, osteoblasts, osteocytes, osteoclast progenitors, osteoclasts, and the intercellular signaling among these bone cells. The disordered FoxOs function in these bone cells contribute to osteoarthritis, osteoporosis, or other bone diseases. Here, we review the current literature of FoxOs for their roles in bone cells, focusing on helping researchers to develop new therapeutic approaches and prevent or treat the related bone diseases.

TI Clinical effect of intramuscular calcitonin compared with oral celecoxib in the treatment of knee bone marrow lesions: a retrospective study
SO JOURNAL OF ORTHOPAEDIC SURGERY AND RESEARCH
LA English
DT Article
DE Calcitonin; Celecoxib; Bone marrow lesions; Osteoarthritis
ID salmon-calcitonin; edema syndrome; transient osteoporosis; postmenopausal women; osteoarthritis; pain; cartilage; degradation; progression; metabolism
AB BackgroundBone marrow lesions (BMLs) are a common finding in patients with osteoarthritis (OA), which are predictors of progression and pain related to cartilage damage in OA. The objective of the present research was to compare the short-term clinical effect of intramuscular calcitonin and oral celecoxib in treating knee BMLs.Patients and methodsBetween January 2016 and December 2018, the medical records of patients with knee BMLs treated by intramuscular calcitonin or oral celecoxib were reviewed. Visual analog scale (VAS) and the Western Ontario and McMaster University Osteoarthritis Index (WOMAC) were used to assess knee pain and function, respectively. BMLs were assessed by MRI scans and were scored by the modified Whole-Organ MRI Score (WORMS). The safety of these two medications was also evaluated.ResultsA total of 123 eligible patients who received calcitonin treatment (n = 66) or celecoxib treatment (n = 57) were included. All patients were followed up clinically and radiographically for 3months. The VAS and WOMAC scores were lower statistically in calcitonin group than celecoxib group at 4-week and 3-month follow-up. For BMLs, the WORMS scores in the calcitonin group were significantly lower than the celecoxib group. Besides, statistically higher MRI improvement rates were found in the calcitonin group compared with the celecoxib group at 4-week follow-up (21.21% vs. 7.01%; P = 0.039) and 3-month follow-up (37.88% vs. 15.79%; P = 0.006).ConclusionIntramuscular calcitonin 50IU once daily demonstrated a better short-term effect for knee BML patients compared with oral celecoxib 200mg twice per day.

TI The Emerging Roles of Long Noncoding RNAs in Bone Homeostasis and Their Potential Application in Bone-Related Diseases
SO DNA AND CELL BIOLOGY
LA English
DT Article

DE long noncoding RNAs; bone homeostasis; stem cells; bone-related diseases
ID mesenchymal stem-cells; promotes osteogenic differentiation; osteoblast differentiation; osteosarcoma cells; multiple-myeloma; regulating runx2; poor-prognosis; lncrna malat1; proliferation; metastasis
AB Increasing evidence has announced the emerging roles of long noncoding RNAs (lncRNAs) in modulating bone homeostasis due to their potential regulating effects on bone-related cells' proliferation, migration, differentiation and apoptosis. Thus, lncRNAs have been considered as a promising gene tool to facilitate the bone regeneration process and then to predict and cure bone-related diseases such as osteosarcoma, osteoporosis, and osteoarthritis. In this review, we first enumerated several kinds of dysregulated lncRNAs and concisely summarized their regulating role in bone formation as well as resorption process. The related mechanisms were also discussed, respectively. Then, the positive or negative behavior of these lncRNAs in bone-related diseases was elucidated. This review provides an in-depth sight about the lncRNA's clinical values and limitations, which is conducive to explore new gene targets and further establish new therapeutic strategies for bone-related disease.

TI Network-Based Computational Approach to Identify Delineating Common Cell Pathways Influencing Type 2 Diabetes and Diseases of Bone and Joints
SO IEEE ACCESS
LA English
DT Article
DE T2 diabetes; network-based approach; joint diseases; bone diseases
ID osteoblast differentiation; tyrosine kinase; profiles; mellitus; comorbidity; receptor; database; gene; ucp3
AB Developing type 2 diabetes (T2D) can increase patient risk of developing other common diseases and exacerbate their severity, including diseases that affect bone and joints. Such comorbidity interactions are hard to study in detail by traditional endocrinological methods. Thus, we developed tissue transcript analytical approaches to identify common pathways through which these diseases can interact. We examined RNAseq and microarray transcript datasets from studies of T2D and chronic bone and joint diseases, namely rheumatoid arthritis (RA), osteoarthritis (OA), juvenile idiopathic arthritis (JIA) and low peak bone density, a key osteoporosis (OP) determinant. These datasets contained data from affected individuals and matched controls. Differentially expressed genes (DEGs) for each condition were compared with T2D DEG. Overlapping DEGs (i.e., those common to T2D and a bone or joint condition) were subjected to gene enrichment by pathway analyses and by gene ontology methods, and the results were evaluated by using SNP-disease linkage (dbGaP) and gene-disease association (OMIM) databases that indicate gene involvement in pathologies. By examining gene targets of transcription factors (TFs) and microRNA (miRNAs), we also constructed DEG-TF and DEG-miRNA interactions networks for analysis. We identified strong candidate genes in common pathways, notably including SYK, UCP3, ROR1, PPARG, BUB1, AKT2, ADCY2 and CCR5. The DEG-TF network and DEG-miRNA interactions network analyses revealed a number of TFs (GATA2, FOXC1, USF2, YY1, E2F1, JUN, RELA, CREB1, TFAP2A, NFB1) and miRNAs (mir-335-5p, mir-16-5p, mir-26b-5p, mir-124-3p, mir-218-5p, mir-98-5p, mir-29b-3p, mir-3135b, mir-29c-3p, mir-1-1) that can regulate the identified DEGs at the transcriptional and post-transcriptional levels. Thus this data-driven approach has enabled identification and validation of regulatory factors and cell pathways by which T2D may influence bone and joint conditions, which may suggest new ways to interfere with the pathogenic processes involved.

TI Comparison study of bone strength of the proximal femur with and without hip osteoarthritis by computed tomography-based finite element analysis
SO JOURNAL OF BIOMECHANICS
LA English
DT Article
DE Finite element analysis; Bone strength; Proximal femur fracture; Osteoporosis; Hip osteoarthritis
ID femoral fractures; prediction; risk; density; women; qct
AB Proximal femoral fractures are common in elderly osteoporosis patients; however, its prevalence is clinically rare in hip fracture patients with hip osteoarthritis (OA). This study aimed to evaluate bone strength of the proximal femur with or without hip OA and proximal femoral fracture risk using computed tomography (CT)-based finite element analysis (FEA). A retrospective analysis was done on CT data of 20 patients who underwent total hip arthroplasty for unilateral hip OA. Furthermore, the fracture load between OA and contralateral sides was

compared and the association between fracture load and risk factor was analyzed. The fracture load was significantly higher in the OA side than that in the contralateral side (3819.5 +/- 1557.8 N vs. 3224.5 +/- 943.7 N, respectively; P = 0.0405). There was no significant difference in fracture load between OA and the contralateral side in Kellgren-Lawrence (KL)-3 and KL-4 grade, but the KL-4 fracture load tends to be high (P = 0.2461 and P = 0.0527, respectively). Moreover, there was no significant association between fracture load and OA severity or age. The study findings may assist in predicting bone strength and proximal femur fracture risk. The results of this FEA study indicate the bone strength of the proximal femur was affected by the severity of the osteoarthritis. (C) 2020 Elsevier Ltd. All rights reserved.

TI Bone Mineral Density and Cortical-Bone Thickness of the Distal Radius Predict Femoral Stem Subsidence in Postmenopausal Women
SO JOURNAL OF ARTHROPLASTY
LA English
DT Article
DE cementless total hip arthroplasty; radiostereometric analysis (RSA); osteoporosis; cortical bone; DXA; pulse-echo ultrasonometry
ID total hip-arthroplasty; cementless; osteoporosis; porosity; rsa; osteoarthritis; fixation; shape; fit
AB Background: The distal radius is an optional site for evaluation of bone quality in postmenopausal women before cementless total hip arthroplasty. We hypothesized that dual-energy X-ray absorptiometry (DXA) and pulse-echo ultrasonometry of the distal radius may help discriminate subjects at high risk of femoral stem subsidence. Methods: A prospective cohort of postmenopausal women with primary hip osteoarthritis underwent total hip arthroplasty with implantation of a parallel-sided femoral stem. Postoperative stem migration was measured using radiostereometric analysis. Preoperatively, subjects had multisite DXA measurement of bone mineral density (BMD) and pulse-echo ultrasonometry of the cortical-bone thickness. The diagnostic abilities of these methods to discriminate <2 mm and >= 2 mm femoral stem subsidence were tested. Results: The accuracy of the distal radius BMD and cortical-bone thickness of the distal radius were moderate (area under the curve, 0.737 and 0.726, respectively) in discriminating between <2 mm and >= 2 mm stem subsidence. Women with low cortical-bone thickness of the radius were more likely (odds ratio = 6.7; P = .002) to develop stem subsidence >= 2 mm. These subjects had lower total hip BMD (P = .007) and reduced thickness of the medial cortex of the proximal femur (P = .048) with lower middle (P < .001) and distal (P = .004) stem-to-canal fill ratios.

Conclusion: Femoral stem stability and resistance to subsidence are sensitive to adequate bone stock and unaltered anatomy. DXA and pulse-echo ultrasonometry of the distal radius may help discriminate postmenopausal women at high risk of stem subsidence. (C) 2020 The Author(s). Published by Elsevier Inc.

TI The Study of Natural Compounds Targeting RANKL Signaling Pathway for the Treatment of Bone Diseases
SO CURRENT DRUG TARGETS
LA English
DT Review
DE RANKL; NF-kappa B; MAPKs; Akt; Ca2+; osteoporosis; osteoarthritis; rheumatoid arthritis; signaling pathways
ID nf-kappa-b; induced osteoclast formation; receptor activator; in-vitro; bisphosphonate use; stewartia-koreana; oxidative stress; gallic acid; differentiation; resorption
AB Millions of people, especially for the aging people, are suffered by bone-loss diseases, such as rheumatoid arthritis (RA) and osteoporosis. Therefore, better understanding the involved mechanisms of bone metabolism is required for further treat on such diseases. Particularly, during the pathological process of bone losing, RANKL as a member of the tumor necrosis factor (TNF) superfamily, could induce osteoclast precursor cells differentiate into mature osteoclast, which grant its essential role in osteolysis. In recent years, with the increased attention paid to the natural compounds discovering studies, the therapeutic application of natural plant-derivatives have been widely recognized. Therefore, our present study aim to summarize the current novel research progressions on RANKL and its downstream signaling pathways in bone cellular differentiation, and provide a further insight for RANKL as the important drug targets in bone loss diseases. Besides that, in our current study, we also aim to briefly introduce the current application of several natural compounds for treating RANKL-mediated osteoclastic activation by modulating the RANKL signaling pathway and their therapeutic effects on the prevention of osteoporosis, osteoarthritis (OA) and RA.

TI Hypergravity as a gravitational therapy mitigates the effects of knee osteoarthritis on the musculoskeletal system in a murine model
SO PLOS ONE
LA English
DT Article
ID bone-mineral density; hip osteoarthritis; physical-activity; subchondral bone; cancellous bone; muscle; exercise; osteoporosis; metabolism; mechanisms
AB Insights into the effects of osteoarthritis (OA) and physical interventions on the musculoskeletal system are limited. Our goal was to analyze musculoskeletal changes in OA mice and test the efficacy of 8-week exposure to hypergravity, as a replacement of physical activity. 16-week-old male (C57BL/6J) mice allocated to sham control and OA groups not centrifuged (Ctrl 1g and OA 1g, respectively) or centrifuged at 2g acceleration (Ctrl 2g and OA 2g). OA 1g displayed decreased trabecular bone in the proximal tibia metaphysis and increased osteoclastic activity and local TNF alpha gene expression, all entirely prevented by 2g gravitational therapy. However, while cortical bone of tibia midshaft was preserved in OA 1g (vs. ctrl), it is thinner in OA 2g (vs. OA 1g). In the hind limb, OA at 1g increased fibers with lipid droplets by 48% in the tibialis anterior, a fact fully prevented by 2g. In Ctrl, 2g increased soleus, tibialis anterior and gastrocnemius masses. In the soleus of both Ctrl and OA, 2g induced larger fibers and a switch from type-II to type-I

fiber. Catabolic (myostatin and its receptor activin RIIb and visfatine) and anabolic (FNDC5) genes dramatically increased in Ctrl 2g and OA 2g ($p<0.01$ vs 1g). Nevertheless, the overexpression of FNDC5 (and follistatine) was smaller in OA 2g than in Ctrl 2g. Thus, hypergravity in OA mice produced positive effects for trabecular bone and muscle typology, similar to resistance exercises, but negative effects for cortical bone.

DT Article
DE Exercise; Physical activity; Exercise prescription; Therapeutic exercise
ID physical-activity; american-college; public-health; older-adults; prescription; stability; statement; rehabilitation; osteoarthritis; prevention
AB Physicians often overlook exercise as a treatment or prophylactic measure for many common diseases and ailments. It can be used to treat comorbidities including obesity, cardiovascular disease, chronic obstructive pulmonary disease, diabetes mellitus, osteoporosis, osteoarthritis, cancer, and low back pain. Education

on the general physical activity guidelines as well as easy exercise prescription methods can improve the ability of physicians to prescribe exercise as a therapeutic option. In addition, identifying barriers to compliance with exercise and ways to overcome these barriers is also necessary in order to use therapeutic exercise effectively.

TI Influence of horizontal restraints on the behaviour of vertical disproportionate collapse of RC moment frames
SO ENGINEERING FAILURE ANALYSIS
LA English
DT Article
DE RC moment frame structure; Progressive collapse; Horizontal restraints; Static test; Numerical simulation
ID reinforced-concrete frames; progressive collapse; resistance; subject; model; capacity; design
AB Current research studies on progressive collapse of reinforced concrete (RC) moment frames mainly focus on the RC frames with strong horizontal restraints in which collapse only propagates in the vertical direction. Notwithstanding, progressive collapse may propagate in the horizontal direction due to insufficient lateral stiffness and bearing capacity of the real-world structural systems, eventually triggering a wider range of damage associated with a disproportionate collapse. A static collapse test on three asymmetric beam-column substructure specimens with flange slabs was conducted to analyse the effects of different

lateral restraints on the progressive collapse behaviour of RC beam-column specimens. The three specimens, including two one-story and one two-story substructures, are designated as OP, TP and OA, in which OP and OA represent one-story penultimate and antepenult column removal scenarios, respectively, while TP represents a two-story penultimate column removal scenario. Comparing to OP, an extra bay and an extra floor were added in OA and TP, respectively, to create different horizontal restraint scenarios. Experimental results show that under the compressive arch action (CAA), the contribution of the CAA within the beams and slabs in OP and TP was significantly reduced compared to that in OA. Under the catenary action (CA), the collapse resistance of OA was found to develop rapidly to exceed even the peak resistance of CAA, whereas the resistance of OP and TP varied marginally, caused by the continuously released axial force of rebars within the beams and flange slabs. Additionally, the final failure mode of all three specimens demonstrated a compression-bending failure of the edge and penultimate columns. Subsequent to the experiments, a fibre-beam-element-based model was built to analyse the development of the internal forces within the slab-flange beams and columns. In the numerical analyses, the penultimate column in OA was found to damage prior to the edge column, owing to its larger axial force generated from the redistributed force and the additional bending moment. While in TP, the so-called Vierendeel truss action led to an uneven internal force distribution developed within the two floors, causing the failure to propagate from the lower story to the upper story. Finally, design recommendations are provided based on the results obtained from the experimental test and numerical simulation.
