TI Efficacy and safety of oral NSAIDs and analgesics in the management of osteoarthritis: Evidence from real-life setting trials and surveys
SO SEMINARS IN ARTHRITIS AND RHEUMATISM
LA English
DT Review
DE Analgesics; Coxibs; Cyclo-oxygenase-2 (COX-2) inhibitors; Knee osteoarthritis; Oral non-steroidal anti-inflammatory drugs (NSAIDs); Tramadol
ID nonsteroidal antiinflammatory drugs; upper gastrointestinal complications; knee osteoarthritis; double-blind; cardiovascular risk; tramadol; celecoxib; recommendations; release; placebo
AB Non-steroidal anti-inflammatory drugs (NSAIDs) are at the cornerstone of treatment for osteoarthritis (OA). In recent years, the widespread use of oral NSAIDs has been called into question due to the appearance of significant upper gastrointestinal (GI) complications and cardiovascular (CV) adverse events (AEs). However, NSAIDs are non-homogeneous, and there are noticeable differences between them in AE risk for GI and CV events. Nevertheless, if properly prescribed oral NSAIDs can provide an effective and safe treatment for OA in real-life situations. The identification of patients with significant CV and/or GI risk is critical, and the European Society for Clinical and Economic Aspects of Osteoporosis and Osteoarthritis (ESCEO) treatment algorithm provides guidance on appropriate treatments for OA patients with elevated risk. Among non-selective NSAIDs, ibuprofen and naproxen seem preferable to diclofenac, the latter being associated with higher CV risk. Recommendation has been made by some that naproxen may be the preferred agent in patients at high CV risk because of its lower risk of CV events. Low dose celecoxib (200 mg/day) is also associated with a lower risk of CV events compared with other coxibs. In addition, drugs with a demonstrated low GI risk profile may be of benefit, such as coxibs and nabumetone. Among patients who fail to respond adequately to sequential ESCEO algorithm Step 1 and Step 2 treatments, the short-term use of weak opioids, such as tramadol, for severely symptomatic OA patients is recommended. Although studies exploring the efficacy of tramadol in OA are limited, there is good evidence that tramadol works if prescribed properly. The sustained-release (SR) formulation of tramadol is preferred as it avoids the peak plasma concentrations reached with immediate-release tramadol, and is believed to reduce the incidence of AEs. Furthermore, slow upwards titration of tramadol SR is recommended to improve

tolerability and minimize treatment discontinuations. (C) 2015 The Authors. Published by Elsevier HS Journals, Inc.

TI The controversial relationship between osteoarthritis and osteoporosis: an update on hand subtypes
SO INTERNATIONAL JOURNAL OF RHEUMATIC DISEASES
LA English
DT Article
DE bone mineral density; erosive hand osteoarthritis; osteoarthritis; osteoporosis; phalangeal radioabsorptiometry
ID bone-mineral density; postmenopausal women; erosive osteoarthritis; knee osteoarthritis; hip; fracture; risk; polymorphisms; association; metabolism
AB Aim: To compare hand osteoarthritis (HOA) subtypes and to examine possible links with local bone mineral density (BMD). Method: Fifty-five patients with erosive

hand osteoarthritis (EHOA) and 21 patients with nodal hand osteoarthritis (NOA) fulfilling American College of Rheumatology criteria for HOA were evaluated. Subjects showing at least two erosions of the interphalangeal joints were assigned to the EHOA group; the others were considered NOA. Disease duration, number of active joints and radiological scores were assessed. All patients and 174 controls underwent phalangeal radiographic absorptiometry (pRA) of the middle phalanges of the non-dominant hand to assess BMD, T- and Z-scores. Results: BMD was higher in EHOA with respect to NOA and controls (P = 0.05); T- and Z-scores were significantly higher in EHOA (P = 0.01 and P < 0.01). Values suggestive of osteopenia were found in 32% of EHOA and 22% of NOA patients, and in 44% of controls (P = 0.05 EHOA vs. NOA); a T- score < -2.5 standard deviations was present in 15% of EHOA and 28% of NOA patients, and in 21% of controls (P = 0.05 EHOA vs. NOA). Conclusion: Phalangeal BMD was higher in EHOA compared to NOA and controls. This characteristic could potentially be exploited to differentiate the two hand OA subtypes.

TI Mortality with musculoskeletal disorders as underlying cause in Sweden 1997-2013: a time trend aggregate level study
SO BMC MUSCULOSKELETAL DISORDERS
LA English
DT Article
DE Mortality; Musculoskeletal disorders; Temporal trend; Sweden
ID systemic-lupus-erythematosus; rheumatoid-arthritis; death certificates; prevalence; france; burden; osteoarthritis; statistics; cancer; impact
AB Background: The aim was to assess time trend of mortality with musculoskeletal disorders (MSD) as underlying cause of death in Sweden from 1997 to 2013. Methods: We obtained data on MSD as underlying cause of death across age and sex groups from the National Board of Health and Welfare's Cause of Death Register. Age-standardized mortality rates per million population for all MSD, its six major subgroups, and all other ICD-10 (International Classification of Disease) chapters were calculated. We computed the average annual percent change (AAPC) in the mortality rates across age/sex groups using joinpoint regression analysis by fitting a regression line to the natural logarithm of the age-standardized mortality rates and calendar year as a predictor. Results: There were a total of 7 976 deaths (0.5 % of all causes deaths) with MSD as the underlying cause of death (32.5 % of these deaths caused by rheumatoid arthritis [RA]). The overall age-standardized mortality rates (95 % CI) were 16.0 (15.4 to 16.7) and 24.9 (24.1 to 25.7) per million among men and women, respectively (women/men rate ratio 1.55; 95% CI 1.47 to 1.63). On average, mortality rate declined by 2.3 % per year and only circulatory system mortality had a more favourable decline than mortality with MSD as underlying cause. Among MSD the highest decline was observed in RA (3.7 % per year) during study period. Across age groups, while there were generally stable or declining trends, spondylopathies and osteoporosis mortality among people >= 75 years increased by 2 and 1.5 % per year, respectively. Conclusion: In overall, mortality with MSD as underlying cause has declined in Sweden over last two

decades, with the highest decline for RA. However, there are variations across MSD subgroups which warrants further investigations.

AB Single nucleotide polymorphisms (SNPs) are the most abundant genetic variants that contribute to the heritability of bone mass. MicroRNAs (miRNAs, miRs) are key post-transcriptional regulators that modulate the differentiation and function of skeletal cells by targeting multiple genes in the same or distinct signaling pathways. SNPs in miRNA genes and miRNA binding sites can alter miRNA abundance and mRNA targeting. This review describes the potential impact of miRNA-related SNPs on skeletal phenotype. Although many associations between SNPs and bone mass have been described, this review is limited to gene variants for which a function has been experimentally validated. SNPs in miRNA genes (miR-SNPs) that impair miRNA processing and alter the abundance of mature miRNA are discussed for miR-146a, miR-125a, miR-196a, miR-149 and miR-27a. SNPs in miRNA targeting sites (miR-TS-SNPs) that alter miRNA binding are described for the bone remodeling genes bone morphogenetic protein receptor 1 (Bmpr1), fibroblast growth factor 2 (Fgf2), osteonectin (Sparc) and histone deacetylase 5 (Hdac5). The review highlights two aspects of miRNA-associated SNPs: the mechanism for altering miRNA mediated gene regulation and the potential of miR-associated SNPs to alter osteoblast, osteoclast or chondrocyte differentiation and function. Given the polygenic nature of skeletal diseases like osteoporosis and osteoarthritis, validating the function of additional miRNA-associated SNPs has the potential to enhance our understanding of the

genetic determinants of bone mass and predisposition to selected skeletal diseases. (C) 2015 Elsevier Inc All rights reserved.

TI Chondroprotective effects of the combination chondroitin sulfate-glucosamine in a model of osteoarthritis induced by anterior cruciate ligament transection in ovariectomised rats
SO BIOMEDICINE & PHARMACOTHERAPY
LA English
DT Article
DE Anterior cruciate ligament transection model; Osteoarthritis; Chondroitin sulfate-glucosamine; Ovariectomised rats
ID knee osteoarthritis; articular-cartilage; biological markers; identify patients; gene-expression; bone-resorption; will respond; high-risk; kappa-b; osteoporosis
AB Context: The efficacy of the combination chondroitin sulfate-glucosamine (CS-GlcN) in the treatment of knee osteoarthritis (OA) has been suggested in recent clinical studies. In vitro reports have also suggested anti-inflammatory and anti-resorptive effects of this combination. Objective: The aim of this study was to characterize the effects of CS-GlcN on joint degradation in vivo including the assessment of inflammation and bone metabolism in a model of OA. Materials and methods: We have used the OA model induced by anterior cruciate ligament transection (ACLT) in ovariectomised rats. CS-GlcN was administered daily (oral gavage) from week 0 until week 12 after ovariectomy at the dose of 140 (CS) + 175 (GlcN)(HCl) mg/kg. Histochemical analyses were performed, the levels of biomarkers and inflammatory mediators were measured by luminex or ELISA and bone microstructure was determined by mu CT. Results: CS-GlcN protected against cartilage degradation and reduced the levels of inflammatory mediators such as interleukin-1 beta and tumor necrosis factor-a in the affected knee. In addition, serum biomarkers of inflammation and cartilage and bone degradation including matrix metalloproteinase-3, C-telopeptide of type II collagen and the ratio receptor activator of nuclear factor kappa B ligand/osteoprotegerin were significantly decreased by CS-GlcN. This treatment also tended to improve some bone microstructural parameters without reaching statistical significance. Discussion and conclusions: These results demonstrate the chondroprotective effects of CS-GlcN in vivo, in the experimental model of ACLT in ovariectomised rats, and suggest that this combination may be useful to control the joint catabolic effects of inflammatory stress. These findings could have clinical relevance related to the prevention of joint degradation by CS-GlcN and support the potential development of OA treatments based on this combination. TI Interventional Techniques for Management of Pain in Older Adults
SO CLINICS IN GERIATRIC MEDICINE
LA English
DT Article
DE Interventional pain management; Chronic pain; Osteoarthritis; Steroid injection; Osteoporosis; Vertebral compression fracture
ID platelet-rich plasma; sacroiliac joint pain; medicare population; growth-patterns; united-states; osteoarthritis; injections; viscosupplementation; diagnosis; epidemiology
AB Chronic pain in older patients is often treated with pain medications, physical rehabilitation, interventional pain management, and/or psychological interventions. The administration of pain medications is the most common form of chronic pain treatment. Physiologic changes in older adults make them more susceptible to the potential side effects of oral pain medications, especially opioids. Interventional pain management offers an alternative treatment option. This article reviews some of the interventional techniques used to treat the most common sites of pain in older adults: back, knee, and hip.

TI A review of glucosamine for knee osteoarthritis: why patented crystalline glucosamine sulfate should be differentiated from other glucosamines to maximize clinical outcomes
SO CURRENT MEDICAL RESEARCH AND OPINION
LA English

DT Review
DE Glucosamine; Osteoarthritis; Symptomatic slow-acting drugs for osteoarthritis
ID placebo-controlled trials; total joint replacement; chondroitin sulfate; cartilage explants; double-blind; task-force; management; recommendations; chondrocytes; progression
AB The European Society for Clinical and Economic Aspects of Osteoporosis and Osteoarthritis (ESCEO) treatment algorithm for knee osteoarthritis (OA) recommends symptomatic slow-acting drugs for osteoarthritis (SYSADOAs) first line for the medium to long term management of OA, due to their ability to control pain, improve function, and delay joint structural changes. Among SYSADOAs, glucosamine is probably the most widely used intervention. In the present review of glucosamine for knee OA, we have investigated whether the evidence is greater for the patented crystalline glucosamine sulfate (pCGS) preparation (Rottapharm/Meda) than for other glucosamine formulations. Glucosamine is actually widely available in many forms, as the prescription-grade pCGS preparation, generic and over-the-counter formulations of glucosamine sulfate (GS) and food supplements containing glucosamine hydrochloride (GH), which vary substantially in molecular form, pharmaceutical formulation and dose regimens. Only pCGS is given as a highly bioavailable once daily dose (1500mg) with a proven pharmacological effect. pCGS consistently reaches the plasma levels of around 10 mu M required to inhibit interleukin-1 induced expression of genes involved in the pathophysiology of joint inflammation and tissue destruction, compared with sub-therapeutic levels achieved with GH. It is evident, from careful consideration of the evidence base, that only the pCGS formulation of glucosamine reliably provides an effect size on pain that is higher than that of paracetamol and equivalent to that provided by non-steroidal antiinflammatory drugs. In comparison, the effect size on pain of non-crystalline GS preparations and GH from randomized controlled trials is repeatedly demonstrated to be zero. In addition, there is evidence that chronic administration of pCGS has disease-modifying effects, with a reduction in the need for total joint replacement surgery lasting for at least 5 years after treatment cessation. Consequently, the pCGS preparation (Rottapharm/Meda) is the logical choice, with demonstrated medium-term control of pain and lasting impact on disease progression.

TI Identifying Patient-Specific Pathology in Osteoarthritis Development Based on MicroCT Analysis of Subchondral Trabecular Bone
SO JOURNAL OF ARTHROPLASTY
LA English

DT Article
DE osteoarthritis; subchondral bone; microCT; osteoclasts; VEGF
ID osteochondral junction; articular-cartilage; growth-factor; knee; osteoporosis; model; pathogenesis; hip; angiogenesis; arthritis
AB The goal of this study was to identify alternative mechanisms of osteoarthritis pathology by analyzing subchondral bone. Femoral condyle samples were collected from post-menopausal female patients with knee osteoarthritis undegoing total knee arthroplasty. In the majority of patients, subchondral trabecular bone volume doubled under a region of the medial femoral condyle with full-thickness cartilage deterioration. However, in a subset of patients the bone volume in this region remained constant. This subset also had larger areas of vascular penetration in the calcified cartilage of the lateral condyle concurrent with increased vascular endothelial growth factor expression. Subtyping by subchondral bone characteristics identified a unique population, which lacked the sclerotic bone characteristic of late-stage osteoarthritis. Identification of subtypes within the osteoarthritis population allows investigation of alternate disease pathologies. (C) 2016 Elsevier Inc. All rights reserved.

TI Measuring the musculoskeletal aging phenotype
SO MATURITAS
LA English
DT Review
DE Sarcopenia; Osteoporosis; Osteoarthritis; Frailty; Aging
ID older-adults; sarcopenia; osteoarthritis; prevalence; definition; frailty; epidemiology; consensus; criteria
AB The world is aging. The population aged over sixty years worldwide is predicted

to rise from 841 million in 2013 to more than 2 billion by 2050. Musculoskeletal (MSK) disease is a significant burden on the aging population, contributing 7.5% of the disease burden in those aged over 60 years. MSK diseases have a pronounced effect on disability level and independence in old age, with a consequent significant public health burden and impact on quality of later life. As numbers of older individuals and their disease burden increase, it is important to examine MSK disease in older life in detail. The musculoskeletal aging phenotype comprises four often interwoven key elements osteoporosis, osteoarthritis, sarcopenia and frailty and this review will focus on these four themes. It is crucial that we are able to accurately measure each phenotype in order that we might identify those individuals at greatest risk of developing these conditions, and design trials of therapeutic agents that might impact their development. Accurate measurement of the musculoskeletal aging phenotype is necessary firstly to document the burden of each condition, and then to enable factors to be identified which may accelerate or retard their development or progression. In some areas of MSK disease, this work is more advanced (osteoporosis); in other areas (sarcopenia) the field is currently very rapidly evolving. We will explore the tools currently used to measure the musculoskeletal aging phenotype and how they compare, as well as highlight areas where more work is needed. (C) 2016 Elsevier Ireland Ltd. ID standardized scoring method; foot-preference; age estimation; tibiofibular syndesmosis; entheseal changes; pulp/tooth ratio; osteoarthritis; enthesopathy; epidemiology; arthritis
AB Objectives: The objective of this study was to investigate the relationship of degenerative joint disease (DJD) features (marginal lipping, porosity, surface osteophytes, eburnation, and loss of joint morphology) with sex, age, and occupation. Materials and Methods: We devised a recording method for scoring the single features in the shoulder, elbow, wrist, hip, knee, and ankle of an Italian skeletal sample of 332 individuals (males = 161, females = 171) of known sex, age, and occupation from the Frassetto collection (Sassari, Sardinia, 19th-20th century). Results: Our data revealed that: (1) the frequency of all features increases with age; (2) porosity is the first feature to appear, being in general the most frequent feature in young adults; (3) sex differences are especially found in the upper limbs of mature and elderly adults; (4) marginal lipping and surface osteophytes show a

lesser age correlation and, in general, higher frequencies in the left lower limb; (5) no differences were found among different occupations. Discussion: We explain these results in light of different metabolic and adaptive processes in relation to age and sex. Static (weight-bearing) rather than dynamic mechanical stress could play a pivotal role in the distribution of the features observed in the lower limbs. The considerable increase in marginal lipping and surface osteophytes in elderly adults may be an adaptation for sustaining mechanical loading, balancing the loss of bone tissue which is characteristic of ageing processes (osteopenia, osteoporosis). TI The polymorphism of rs1799750 in matrix metallopeptidase 1 (MMP-1) gene contributes to osteoarthritis risk: a meta-analysis
SO INTERNATIONAL JOURNAL OF CLINICAL AND EXPERIMENTAL MEDICINE
LA English
DT Review
DE Osteoarthritis; MMP-1 rs1799750; SNP; meta-analysis

ID single nucleotide polymorphism; genome-wide association; knee osteoarthritis; clinical-trials; candidate genes; susceptibility; promoter; population; expression; osteoporosis
AB Since 2010, many studies have investigated the association between common single nucleotide polymorphism (SNP) rs1799750 located on matrix metallopeptidase 1 (MMP-1) and osteoarthritis (OA) risk; however, the results were inconclusive. To shed light on these contradictory results, we investigated the association between MMP-1 rs1799750 and OA risk by meta-analytic techniques, combining all published data up to December 2015. A total number of 783 knee or temporomandibular joint (TMJ) OA cases and 748 controls in 5 case-control studies were included in this study and the odds ratios (ORs) with 95% confidence intervals (CIs) were calculated. Finally, individuals in homozygote comparison (1G1G vs. 2G2G: OR = 0.528, 95% CI: 0.285-0.979), heterozygote comparison (1G2G vs. 2G2G: OR = 0.599, 95% CI: 0.387-0.927) and dominant model (1G2G/1G1G vs. 2G2G: OR = 0.562, 95% CI: 0.346-0.913) were associated with a significantly decreased risk of OA. Sub-group analysis revealed that the homozygote comparison (1G1G vs. 2G2G: OR = 0.432, 95% CI: 0.251-0.746), heterozygote comparison (1G2G vs. 2G2G: OR = 0.411, 95% CI: 0.276-0.612) and dominant model (1G2G/1G1G vs. 2G2G: OR = 0.415, 95% CI: 0.285-0.603) still showed a decreased risk of OA in TMJ. As for ethnicity, in European, there was a statistically decreased OA risk in homozygote (1G1G vs. 2G2G: OR = 0.609, 95% CI: 0.378-0.980) and dominant model (1G2G/1G1G vs. 2G2G: OR = 0.591, 95% CI: 0.357-0.979). Together with the reported functional studies, the results suggested that MMP-1 rs1799750 was associated with a significantly decreased risk of OA, especially the TMJ OA.

TI Pathology of Mouse Models of Accelerated Aging
SO VETERINARY PATHOLOGY
LA English
DT Review
DE aging; mice; mouse models of human disease; pathology; phenotype; progeria; review
ID cardiovascular-disease enterprises; age-related-changes; intervertebral disc degeneration; regenerative hair waves; causes early-onset; skeletal-muscle; mutant mice; macular degeneration; major shareholders; stem-cells
AB Progeroid mouse models display phenotypes in multiple organ systems that suggest premature aging and resemble features of natural aging of both mice and humans. The prospect of a significant increase in the global elderly population within the next decades has led to the emergence of geroscience, which aims at elucidating the molecular mechanisms involved in aging. Progeroid mouse models are frequently used in geroscience as they provide insight into the molecular mechanisms that are involved in the highly complex process of natural aging. This review provides an overview of the most commonly reported nonneoplastic macroscopic and microscopic pathologic findings in progeroid mouse models (eg, osteoporosis, osteoarthritis, degenerative joint disease, intervertebral disc degeneration, kyphosis, sarcopenia, cutaneous atrophy, wound healing, hair loss, alopecia, lymphoid atrophy, cataract, corneal endothelial dystrophy, retinal degenerative diseases, and vascular remodeling). Furthermore, several shortcomings in pathologic analysis and descriptions of these models are discussed. Progeroid mouse models are valuable models for aging, but thorough knowledge of both the mouse strain background and the progeria-related phenotype is required to guide interpretation and translation of the pathology

data.

DT Article
DE Atraumatic avascular necrosis; AVN; Diagnosis; Ilomedin; Bisphosphonate; Core decompression; Bone grafting; Bone transplant; Total hip replacement; Total hip arthroplasty
ID bone-marrow-edema; total hip-arthroplasty; transtrochanteric rotational osteotomy; rapidly destructive arthropathy; systemic-lupus-erythematosus; porous tantalum implant; term-follow-up; avascular necrosis; core decompression; early osteonecrosis
AB The treatment of adult non-traumatic avascular necrosis of the femoral head (AVN; N-ANFH) within an estimated incidence of 5000-7000 cases per annum in Germany remains a challenge. Risk factors include steroids, alcohol abuse, chemotherapy and immunosuppressive medication, but a genetic predisposition has been suggested. Early diagnosis of this often bilateral disease process is essential for successful conservative or joint preserving surgical management. In this review, we present the update German consensus S3 guideline "diagnosis and management for N-ANFH" as a concise summary. This systematic review is based on the published literature from January 1, 1970 to April 31, 2013 (German and English language). Inclusion criteria were systematic reviews, meta-analyses and relevant peer review publications. We identified a total of 3715 related publications, of which 422 were suitable according to the SIGN criteria, but only 159 fulfilled our inclusion criteria. Clinical suspicion of N-ANFH mandates radiographic evaluation. If radiographs are normal MRI scans are recommended, which should be evaluated according to the ARCO-classification. Differential diagnoses include transient osteoporosis, bone bruise, insufficiency fracture and destructive arthropathy. Untreated, subchondral fractures commonly occur within 2

years, during which the risk for contralateral involvement is high-thereafter unlikely. Conservative management with Ilomedin and Alendronat can be tried, but other pharmacological or physical treatments are inappropriate. No specific joint preserving procedure can be recommended, but core decompression should be considered in early stages if necrosis is < 30 %. In ARCO stages IIIc or IV total hip arthroplasty (THA) should be contemplated, which offers similar outcome compared to osteoarthritis. Young age is the main risk factor for higher revision rates after THA for N-ANFH.

TI Effectors of mTOR-autophagy pathway: targeting cancer, affecting the skeleton
SO CURRENT OPINION IN PHARMACOLOGY
LA English
DT Article
ID regulates autophagy; bone-resorption; cell-death; inhibition; tumorigenesis; suppression; cartilage; rapamycin; deletion; growth
AB Although some modulators of autophagy are emerging as drugs or supplements for anti-cancer therapy, the effects of these compounds on normal tissues must be examined carefully. Here, I review the role of autophagy in skeletal tissues in this context.First, I briefly review preclinical studies indicating the role of autophagy in cancer, as well as related on-going clinical trials. Thereafter, the role of autophagy in the physiology of skeletal tissues is discussed, with a focus on recent genetic preclinical studies. Specifically, I discuss the mTOR-autophagy pathway in relationship to epiphyseal chondrocytes, articular chondrocytes, osteoblasts, osteocytes and osteoclasts and potential side effects of targeting either mTOR pathway or autophagy in general in connection with anti-cancer therapy.Current preclinical findings indicate that inhibiting autophagy will not seriously reduce bone mass and enhance osteoporosis. However, inhibition of autophagy might damage articular cartilage and cause osteoarthritis, whereas treatment with rapalogs might result in relatively beneficial effects on articular cartilage. Modulation of the mTOR pathway or autophagy during childhood may have an undesirable influence on adult height, as well as acquisition of bone mass.

TI The impact of serial radon and hyperthermia exposure in a therapeutic adit on pivotal cytokines of bone metabolism in rheumatoid arthritis and osteoarthritis
SO CLINICAL RHEUMATOLOGY
LA English
DT Article
DE Anti-CCP antibodies (ACPA); Osteoprotegerin; Receptor activator of NF kappa-B ligand; Rheumatoid arthritis; Serial radon (adit) therapy; TNF-alpha
ID low-dose radon; kappa-b ligand; ankylosing-spondylitis; receptor activator; serum-levels; osteoporosis; inflammation; destruction; disease
AB Secondary osteoporosis is a frequent complication of rheumatoid arthritis (RA) and the result of an imbalance of catabolic and anabolic mechanisms of bone metabolism. The effects of serial low-dose radon and hyperthermia (LDRnHT) exposure in a therapeutic adit (12 applications in 3 weeks) on the serum levels of the cytokines osteoprotegerin (OPG), receptor activator of NF kappa-B ligand (RANKL), tumor necrosis factor-alpha (TNF-alpha), and also on the RANKL/OPG ratio were investigated in 25 RA patients and an age-matched control of 24 patients with osteoarthritis (OA). Cytokine measurements were performed at baseline and after completion of LDRnHT. Anti-CCP antibodies (ACPA) were measured in RA patients in parallel. Medication in both groups was limited to non-steroidal anti-inflammatory drugs, and low-dose prednisolone (16 of 24 RA patients) as needed. RA and OA patients showed a significant decrease of TNF-alpha levels ($p < 0.001$). Both groups showed significantly decreased levels of RANKL (RA: $p < 0.001$, OA: $p < 0.01$). Only the RA patients presented a significant increase of OPG ($p < 0.01$) and decrease of the RANKL/OPG ratio ($p < 0.01$), and the ACPA levels ($p < 0.001$). LDRnHT results in a reduction of osteocatabolic and an

increase of osteoanabolic cytokines, which represents the molecular basis for inhibiting osteoclastic activity in secondary osteoporosis and explains in part the effect of LDRnHT this physical therapy modality in a key inflammatory disease. Although reduced ACPA levels were observed under the therapy and although this could potentially contribute to an osteoprotective effect, in this case, it is rather uncertain as the reduction was only minor in magnitude.

TI Implant-derived magnesium induces local neuronal production of CGRP to improve bone-fracture healing in rats
SO NATURE MEDICINE
LA English
DT Article
ID gene-related peptide; traumatic brain-injury; in-vitro; vivo; osteoporosis; alloys; differentiation; osteoarthritis; innervation; expression
AB Orthopedic implants containing biodegradable magnesium have been used for fracture repair with considerable efficacy; however, the underlying mechanisms by which these implants improve fracture healing remain elusive. Here we show the formation of abundant new bone at peripheral cortical sites after intramedullary implantation of a pin containing ultrapure magnesium into the intact distal femur in rats. This response was accompanied by substantial increases of neuronal calcitonin gene-related polypeptide-alpha (CGRP) in both the peripheral cortex of the femur and the ipsilateral dorsal root ganglia (DRG). Surgical removal of the periosteum, capsaicin denervation of sensory nerves or knockdown in vivo of the CGRP-receptor-encoding genes Cakrl or Ramp1 substantially reversed the magnesium-induced osteogenesis that we observed in this model. Overexpression of these genes, however, enhanced magnesium-induced osteogenesis. We further found that an elevation of extracellular magnesium induces magnesium transporter 1 (MAGT1)-dependent and transient receptor potential cation channel, subfamily M, member 7 (TRPM7)-dependent magnesium entry, as well as an increase in intracellular adenosine triphosphate (ATP) and the accumulation of terminal synaptic vesicles in isolated rat DRG neurons. In isolated rat periosteum-derived stem cells, CGRP induces CALCRL- and RAMP1-dependent activation of cAMP-responsive element binding protein 1 (CREB1) and SP7 (also known as osterix), and thus enhances osteogenic differentiation of these stem cells. Furthermore, we have developed an innovative, magnesium containing intramedullary nail that facilitates femur fracture repair in rats with ovariectomy-induced osteoporosis. Taken together, these findings reveal a previously undefined role of magnesium in promoting CGRP-mediated osteogenic differentiation, which suggests the therapeutic potential of this ion in orthopedics.

TI A Novel Method for Studying the Pharmacokinetics of [14C]Umeclidinium After

Application to the Axilla or Palm of Healthy Male Subjects
SO CTS-CLINICAL AND TRANSLATIONAL SCIENCE
LA English
DT Article
ID obstructive pulmonary-disease; topical glycopyrrolate; percutaneous-absorption; double-blind; hyperhidrosis; skin; umeclidinium; safety
AB Umeclidinium (UMEC), a long-acting muscarinic antagonist approved for chronic obstructive pulmonary disease (COPD), was investigated for primary hyperhidrosis as topical therapy. This study evaluated the pharmacokinetics, safety, and tolerability of a single dose of [C-14]UMEC applied to either unoccluded axilla (UA), occluded axilla (OA), or occluded palm (OP) of healthy males. After 8 h the formulation was removed. [C-14]UMEC plasma concentrations (Cp) were quantified by accelerator mass spectrometry. Occlusion increased systemic exposure by 3.8-fold. Due to UMEC absorption-limited pharmacokinetics, Cp data from the OA were combined with intravenous data from a phase I study. The data were described by a two-compartment population model with sequential zero and first-order absorption and linear elimination. Simulated systemic exposure following q.d. doses to axilla was similar to the exposure from the inhaled therapy, suggesting that systemic safety following dermal administration can be bridged to the inhaled program, and offering the potential for a reduced number of studies and/or subjects.

TI A single nucleotide polymorphism in the TGF-β1 gene (rs1982073 C>T) may contribute to increased risks of bone fracture, osteoporosis, and osteoarthritis: a meta-analysis
SO CLINICAL RHEUMATOLOGY
LA English
DT Article
DE Bone fracture; Meta-analysis; Osteoarthritis; Osteoporosis; Single nucleotide polymorphism; Transforming growth factor-beta 1
ID growth-factor-beta; transforming growth-factor-beta-1; japanese women; osteoblast differentiation; knee osteoarthritis; mineral density; in-vivo; association; expression; susceptibility
AB Genetic factors have been shown to be of great importance for the pathogenesis of bone diseases, such as fracture, osteoporosis (OP), and osteoarthritis (OA). However, published studies on the correlations of transforming growth factor-beta 1 (TGF-beta 1) gene polymorphisms with bone diseases have been hampered by small sample sizes or inconclusive findings. We hence aimed at examining the relationships between a single nucleotide polymorphism in the TGF-beta 1 gene (rs1982073 C > T) with bone fracture, OP, and OA risks in this meta-analysis. A systematic electronic search of literature was conducted to identify all published studies in English or Chinese on the association between the TGF-beta 1 gene and fracture, OP, or OA risks. Data were abstracted independently by two reviewers. To investigate the strength of this relationship, crude odds ratios with 95 % confidence intervals were used. An updated meta-analysis based on nine independent case-control studies were chosen (patients with fracture, OP, or OA =

1569; healthy controls = 1638). Results identified a higher frequency of rs1982073 C > T in patients with fracture, OP, or OA than in healthy controls. Ethnicity and genotyping method-stratified analysis under both models implied that the rs1982073 C > T polymorphism was positively correlated with the risk of fracture, OP, and OA among Asians under detection via the non-PCR-RFLP method. Disease-stratified results yielded that rs1982073 C > T may increase the risk of fracture, OP, and OA under the allele model, but was only significantly related to OP under the dominant model. According to the sample size-stratified analysis, subjects with the rs1982073 C > T polymorphism in the allele model were more likely to develop the three bone diseases in both the small and large sample size groups, and only in the large sample size under the dominant model. Our findings show that TGF-beta 1 rs1982073 C > T has a modest effect in increasing susceptibility to bone fracture, OP, and OA.

TI The relationships between bone mineral density and radiographic features of hand or knee osteoarthritis in older adults: data from the Dong-gu Study
SO RHEUMATOLOGY
LA English
DT Article
DE osteoarthritis; bone mineral density; radiography
ID osteoporotic fractures; degenerative disease; postmenopausal women; elderly men; hip; association; population; cartilage; mass; rotterdam
AB Objective. The relationship between OA and osteoporosis has exhibited contradictory features over the past four decades. The aim of this study was to determine using separate analysis of the radiographic features of OA whether various radiographic features of OA were associated differently with BMD in the Korean elderly. Methods. Data were derived from the Dong-gu cohort; 2354 subjects were enrolled in the present cross-sectional study. Baseline characteristics, the BMDs of the lumbar spine and femoral neck measured by DXA, and X-rays of knees and hands were collected. A semi-quantitative grading system was used to estimate the severities of individual radiographic features. We adjusted for confounders using multiple linear regression modelling to analyse the relationships. Results. After adjustment for confounders, hand and knee OA total scores were negatively associated with the BMDs of the lumbar spine and femoral neck, except for the total knee OA score and lumbar spine BMD. In detail, hand osteophytes and sclerosis exhibited positive relationships with the BMDs of the lumbar spine and femoral neck, except for hand osteophytes and femoral neck BMD. On the contrary, however, knee joint space narrowing (JSN), hand JSN, and hand subchondral cysts were negatively associated with the BMD of the lumbar spine and femoral neck. Knee JSN and hand subchondral cysts exerted the greatest effects on BMD. Conclusion. Separate analysis of the radiographic features of OA better reveals associations of OA with the BMD of the lumbar spine and femoral neck.

TI Prevalence of hand osteoarthritis and its relationship to hand pain and grip strength in Japan: The third survey of the ROAD study
SO MODERN RHEUMATOLOGY
LA English
DT Article
DE Erosion; Hand; Osteoarthritis; Population-based; Prevalence

ID united-states; erosive osteoarthritis; beijing osteoarthritis; general-population; association; determinants; disability; progression; rotterdam; profile
AB Objectives: To examine the prevalence and pattern of hand osteoarthritis (HOA), and determine its relationship with grip strength and hand pain. Methods: Among the participants of the third survey of the Research on Osteoarthritis/Osteoporosis Against Disability (ROAD) study, 507 Japanese men and 1028 Japanese women were included. Radiographs of both hands were graded for osteoarthritis (OA) using the modified Kellgren-Lawrence (KL) scale. HOA was defined as the presence of at least one affected joint. The absence or presence of subchondral erosion was also scored. Results: The prevalence of HOA (KL grade >= 2) was 89.9% in men and 92.3% in women (p = 0.11), and it was significantly associated with age. OA in the distal interphalangeal (DIP) joint was the highest overall. After adjusting for age, sex, body mass index, and the residing area, both severity (KL grade >= 3) and erosion were significantly related to low grip strength and hand pain. With regard to the joint groups, severe OA in the DIP and first carpometacarpal joints were related to hand pain. Conclusion: This study showed a high prevalence of radiographic HOA and a significant relationship between hand pain and the severity of HOA, in addition to erosion.

TI Merge of motion analysis, multibody dynamics and finite element method for the subject-specific analysis of cartilage loading patterns during gait: differences between rotation and moment-driven models of human knee joint
SO MULTIBODY SYSTEM DYNAMICS
LA English
DT Article
DE Menisci; Fibril-reinforced; Kinesiology; Computational model; Cartilage; Fibril-reinforced; Poroelastic
ID split-line pattern; anterior cruciate ligament; articular-cartilage; stance phase; in-vivo; unconfined compression; mechanical-behavior; collagen network; contact stresses; muscle forces
AB Understanding joint loading is important when evaluating sports training methods, sports equipment design, preventive training regimens, post-op recovery procedures, or in osteoarthritis' etiology research. A number of methods have been introduced to estimate joint loads but they have been limited by the lack of accuracy in the joint models, including primarily the lack of patient-specific motion inputs in the models with sophisticated, fibril-reinforced material models. The method reported here records and applies patient-specific human motion for in-depth cartilage stress estimation. First, the motion analysis of a subject was conducted. Due to skin motion, multibody simulation was used to correct motion capture. These data was used as an input in a finite element model. The model geometry was based on magnetic resonance imaging and cartilage was modeled as a fibril-reinforced poroviscoelastic material. Based on the experimental motion data (motion analysis and multibody simulation), two models were created: a rotation-controlled and a moment-controlled model. For comparison, a model with motion input from the literature was created. The rotation-controlled model showed the most even stress distribution between lateral and medial compartments and smallest stresses and strains in a depth-wise manner. The model based on the literature motion simulated very high stresses and uneven stress distribution between the joint compartments. Our new approach to determine dynamic knee cartilage loading enables estimations of stresses and strains for a specific subject over the entire motion cycle.

TI The Mandibles of Castrated Male Rhesus Macaques (Macaca mulatta): The Effects of Orchidectomy on Bone and Teeth
SO AMERICAN JOURNAL OF PHYSICAL ANTHROPOLOGY
LA English
DT Article
DE testosterone; osteoporosis; oral pathology; life span; Cayo Santiago
ID individual life-history; sex steroid-hormones; cayo-santiago; postmenopausal women; periodontal-disease; prostate-cancer; nonhuman-primates; dental pathology; controlled-trial; mineral density
AB Objectives: The objectives of this study were to evaluate the long-term effects of orchidectomy and low testosterone on the craniofaciodental development and maintenance of skeletal and oral health in rhesus macaques. Materials and Methods: Mandibles of four castrated and intact age-matched male rhesus monkeys (Macaca mulatta) from Cayo Santiago were compared for mandibular morphology and teeth, abnormalities, pathology, and cortical bone thickness and density using a digital sliding caliper and analysis of three-dimensional X-ray images. Results: Although all four castrates were generally comparable to intact males in overall mandible and teeth size, there were some significant differences. In the castrates, (1) the distance between the two rami was narrower than in intact males leading to a relatively narrower and longer face; (2) both the mandibular body and ramus had thinner cortical bone leading to less total bone mass; and (3) the canines and molar teeth were slender with lower and less robust tooth cusps. In addition, the alveolar bone of two geriatric castrates was greatly receded with signs of periodontitis more severe than in intact aged males. Old castrates also had severe temporomandibular joint osteoarthritis. Discussion: The findings suggest the importance of testosterone in craniofaciodental development, and maintenance of skeletal and oral health in male macaques. These results suggest that dental health professionals might want to include in their medical history questionnaires whether or not male patients have taken hormone (testosterone) replacement therapy. TI Evolving Role of Molecular Imaging with 18F-Sodium Fluoride PET as a Biomarker for Calcium Metabolism
SO CURRENT OSTEOPOROSIS REPORTS
LA English
DT Review
DE 18F-sodiumfluoride; Metabolic bone disease; Positron emission tomography; Quantitative radionuclide imaging; Regional bone formation
ID positron-emission-tomography; regional bone metabolism; early-stage osteoarthritis; f-18-fluoride pet; parathyroid-hormone; ankylosing-spondylitis; postmenopausal women; risk-factors; vascular inflammation; plaque inflammation
AB F-18-sodium fluoride (NaF) as an imaging tracer portrays calcium metabolic activity either in the osseous structures or in soft tissue. Currently, clinical use of NaF-PET is confined to detecting metastasis to the bone, but this approach reveals indirect evidence for disease activity and will have limited use in the future in favor of more direct approaches that visualize cancer cells in the read marrow where they reside. This has proven to be the case with FDG-PET imaging in most cancers. However, a variety of studies support the application of NaF-PET to assess benign osseous diseases. In particular, bone turnover can be measured from NaF uptake to diagnose osteoporosis. Several studies have evaluated the efficacy of bisphosphonates and their lasting effects as treatment for osteoporosis using bone turnover measured by NaF-PET. Additionally, NaF uptake in vessels tracks calcification in the plaques at the molecular level, which is relevant to coronary artery disease. Also, NaF-PET imaging of diseased joints is able to project disease progression in osteoarthritis, rheumatoid arthritis, and ankylosing spondylitis. Further studies suggest potential use of NaF-PET in domains such as back pain, osteosarcoma, stress-related fracture, and bisphosphonate-induced osteonecrosis of the jaw. The critical role of NaF-PET in disease detection and characterization of many musculoskeletal disorders has been clearly demonstrated in the literature, and these methods will become more widespread in the future. The data from PET imaging are quantitative in nature, and as such, it adds a major dimension to assessing disease activity.

TI Balancing benefits and risks of glucocorticoids in rheumatic diseases and other inflammatory joint disorders: new insights from emerging data. An expert

consensus paper from the European Society for Clinical and Economic Aspects of Osteoporosis and Osteoarthritis (ESCEO)
SO AGING CLINICAL AND EXPERIMENTAL RESEARCH
LA English
DT Review
DE Rheumatoid arthritis; Rheumatic diseases; Osteoporosis; Cohort studies; Glucocorticoids; Inflammation
ID low-dose prednisone; modifying antirheumatic drugs; tight control strategy; to-target strategy; cardiovascular events; eular recommendations; myocardial-infarction; oral corticosteroids; diabetes-mellitus; serious infection
AB This consensus review article considers the question of whether glucocorticoid (GC) therapy is still relevant in the treatment of rheumatic diseases, with a particular focus on rheumatoid arthritis (RA), and whether its side effects can be adequately managed. Recent basic and clinical research on the molecular, cellular and clinical effects of GCs have considerably advanced our knowledge in this field. An overview of the subject seems appropriate. This review is the result of a multidisciplinary expert working group, organised by European Society for Clinical and Economic Aspects of Osteoporosis and Osteoarthritis. The recent literature was surveyed and the salient evidence synthetized. The pathophysiological basis of RA (and other inflammatory rheumatic diseases) now strongly implicates the adaptive immune system in addition to innate mechanisms. The molecular effect of GCs and differential GC sensitivity is better understood, although exploiting this knowledge is still in its infancy. The newer treatment strategies of early and aggressive control of RA have gr eatly improved clinical outcomes, but improvements are still possible. Newer targeted anti-inflammatory drugs have made an important impact, yet they too are associated with numerous side effects. Short durations of moderate doses of GCs are generally well tolerated and have a positive benefit/risk ratio. Patients should be assessed for fracture risk and bone preserving agents and be prescribed calcium and vitamin D supplementation. Within a strategy of a disease modifying approach to inflammatory disease, combination therapy including a GC is effective approach.

TI Treatment of bone disorders with parathyroid hormone: success and pitfalls
SO PHARMAZIE
LA English
DT Review
ID vertebral fracture risk; postmenopausal women; strontium ranelate; biochemical markers; osteoporosis; teriparatide; denosumab; metastases; disease; protein
AB Bone diseases such as osteoporosis, osteoarthritis, bone tumours and bone fractures are rather common and not just in the elderly. Parathyroid hormone (PTH) is responsible for maintaining calcium homeostasis, increasing bone mineral density (BMD), increasing cortical and trabecular bone thickness and thus increasing bone strength. Teriparatide (PTH 1-34) has the same effects as endogenous PTH and is pharmacologically used to treat bone diseases such as osteoporosis, osteoarthritis, bone fractures and bone tumours. This review discusses how PTH 1-34 plays a role in managing bone diseases. Clinical studies have shown that short or intermittent dosing of PTH 1-34 has minimal adverse effects, while long-term dosing (over two years) has been linked to de novo osteoarthritis and bone deformation. Currently PTH therapy is only approved in the treatment of post-menopausal osteoporosis, however it is also proven to have effects in treating osteoarthritis, bone tumours and bone fractures. If the patient undergoing therapy is closely monitored, the major pitfalls are very unlikely to take place, thus it is highly recommended that patients be closely monitored by a medical practitioner.

TI u Effects of Dairy Products Consumption on Health: Benefits and Beliefs-A Commentary from the Belgian Bone Club and the European Society for Clinical and Economic Aspects of Osteoporosis, Osteoarthritis and Musculoskeletal Diseases
SO CALCIFIED TISSUE INTERNATIONAL
LA English
DT Review
DE Dairy products; Cardiovascular disease; Osteoporosis; Arthritis; Weight management; Lactose intolerance
ID randomized controlled-trials; nutrition examination survey; vitamin-d supplementation; placebo-controlled trial; dietary-protein intake; hip fracture; postmenopausal women; calcium supplementation; rheumatoid-arthritis; prospective cohort
AB Dairy products provide a package of essential nutrients that is difficult to obtain in low-dairy or dairy-free diets, and for many people it is not possible to achieve recommended daily calcium intakes with a dairy-free diet. Despite the established benefits for bone health, some people avoid dairy in their diet due to beliefs that dairy may be detrimental to health, especially in those with weight management issues, lactose intolerance, osteoarthritis, rheumatoid arthritis, or trying to avoid cardiovascular disease. This review provides information for health professionals to enable them to help their patients make informed decisions about consuming dairy products as part of a balanced diet. There may be a weak association between dairy consumption and a possible small weight reduction, with decreases in fat mass and waist circumference and increases in lean body mass. Lactose intolerant individuals may not need to completely eliminate dairy products from their diet, as both yogurt and hard cheese are well tolerated. Among people with arthritis, there is no evidence for a benefit to avoid dairy consumption. Dairy products do not increase the risk of cardiovascular disease, particularly if low fat. Intake of up to three servings of dairy products per day appears to be safe and may confer a favourable benefit with regard to bone health.

TI High-Resolution Peripheral Quantitative Computed Tomography (HR-PQCT) and Dual Energy X-Ray Absorptiometry (DXA) Measurements of Proximal Tibia in Patients Undergoing Total Knee Arthroplasty
SO INTERNATIONAL SURGERY
LA English
DT Article
DE pQCT; Proximal tibia; Osteoporosis; Osteoarthritis
ID bone-mineral density; total hip-arthroplasty; trabecular bone; osteoarthritis; osteoporosis; women; microarchitecture; bmd
AB The aim of the study was to assess bone morphometric indices of the proximal tibia and compare it with bone mineral density (BMD) at hip and lumbar spine and compare with the pQCT. Fifty consecutive patients who underwent total knee arthroplasty (TKA) had a dual energy X-ray absorptiometry (DXA) scan of the upper femur and lumbar spine. Upper tibial cuts were harvested from the tibial condyles and a DXA of tibial cuts was done during TKA. Bone morphometry studies were carried out using HR-pQCT. The bone mineral density at the hip was 0.54 +/- 0.08 g/cm(2) and spine was 0.73 +/- 0.1 with a T score at the hip -2.23 +/- 0.44 and spine -2.61 +/- 0.45. The bone mineral density of the tibial cut was 0.356 +/- 0.03 g/cm(2) ($P < 0.001$) and Tscore was 6.58 +/- 2.87 ($P < 0.001$). The average bone volume (BV) was 115.27 +/- 40.45 mm(3), trabecular number (Tb.N) was 1.45 +/- 0.32 (1.009-2.37) and trabecular thickness (Tb.Th) was 0.181 +/- 0.03 mm (0.111-0.268). The mean bone mineral density measured was 206.24 +/- 50.58 mg HA/ccm. This study shows that there is highly significant difference between BMD measured by DXA and pQCT, and that bone morphometric analysis indicates that there is marked decrease in the mechanical properties of the bone in the proximal tibia due to knee Osteoarthritis and Osteoporosis indicating poor bone architecture

and quality.

TI A comprehensive fracture prevention strategy in older adults: The European Union Geriatric Medicine Society (EUGMS) statement
SO JOURNAL OF NUTRITION HEALTH & AGING
LA English
DT Article
DE Falls; fragility fracture; older people; prevention; position statement
ID bone-mineral density; fall prevention; hip-fracture; postmenopausal women; cost-effectiveness; zoledronic acid; risk-factors; pharmacological-treatments; strontium ranelate; liaison service
AB Prevention of fragility fractures in older people has become a public health priority, although the most appropriate and cost-effective strategy remains unclear. In the present statement, the Interest Group on Falls and Fracture Prevention of the European Union Geriatric Medicine Society (EUGMS), in collaboration with the International Association of Gerontology and Geriatrics for the European Region (IAGG-ER), the European Union of Medical Specialists (EUMS), the International Osteoporosis Foundation - European Society for Clinical and Economic Aspects of Osteoporosis and Osteoarthritis, outlines its views on the main points in the current debate in relation to the primary and secondary prevention of falls, the diagnosis and treatment of bone fragility, and the place of combined falls and fracture liaison services for fracture prevention in older people.

TI Are estrogen-related drugs new alternatives for the management of osteoarthritis?
SO ARTHRITIS RESEARCH & THERAPY
LA English
DT Review
DE Osteoarthritis; Estrogen; Selective estrogen receptor modulators; Joint; Bazedoxifene
ID radiographic knee osteoarthritis; receptor-alpha gene; bone-acting agents; middle-aged women; postmenopausal women; subchondral bone; human chondrocytes; ovariectomized rats; replacement-therapy; bazedoxifene/conjugated estrogens
AB Osteoarthritis (OA) is a chronic degenerative disease involving multiple physiopathological mechanisms. The increased prevalence of OA after menopause and the presence of estrogen receptors in joint tissues suggest that estrogen could help prevent development of OA. This review summarizes OA research with a focus on the effects of estrogen and selective estrogen receptor modulators (SERMs). Preclinical studies and clinical trials of estrogen therapy have reported inconsistent results. However, almost all studies assessing SERM treatment have obtained more consistent and favorable effects in OA with a relatively safety and tolerability

profiles. At present, some SERMs including raloxifene and bazedoxifene have been approved for the treatment of osteoporosis. In summary, estrogen-related agents may exert both a direct effect on subchondral bone and direct and/or indirect effects upon the surrounding tissues, including the articular cartilage, synovium, and muscle, to name a few. Estrogen and SERMs may be particularly favorable for postmenopausal patients with early-stage OA or osteoporotic OA, a phenotype defined by reduced bone mineral density related to high remodeling in subchondral bone. At present, no single drug exists that can prevent OA progression. Although estrogen-related drugs provide insight into the continued work in the field of OA drug administration, further research is required before SERMs can become therapeutic alternatives for OA treatment.

TI Prevalence of radiographic hip osteoarthritis and its association with hip pain in Japanese men and women: the ROAD study
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE Osteoarthritis; Hip; Prevalence; Pain; Cross-sectional
ID acetabular dysplasia; physical-activity; united-states; population; community; knee; epidemiology; definitions; disability; britain
AB Objective: Although hip osteoarthritis (OA) is a major cause of hip pain and disability in elderly people, few epidemiologic studies have been performed. We investigated the prevalence of radiographic hip OA and its association with hip pain in Japanese men and women using a large-scale population of a nationwide cohort study, Research on Osteoarthritis/osteoporosis Against Disability (ROAD). Methods: From the baseline survey of the ROAD study, 2975 participants (1043 men and 1932 women), aged 23-94 years (mean 70.2 years), living in urban, mountainous, and coastal communities were analyzed. The radiographic severity at both hips was determined by the Kellgren/Lawrence (K/L) grading system. Radiographic hip OA was defined as K/L >= 2, and severe radiographic hip OA as K/L >= 3. Results: The crude prevalence of radiographic hip OA was 18.2% and 14.3% in men and women, respectively, that of severe radiographic hip OA was 1.34% and 2.54%, and that of symptomatic K/L >= 2 OA was 0.29% and 0.99%, respectively. The crude prevalence of hip OA, including severe OA, was not age-dependent in men or women. Male sex was a risk factor for radiographic hip OA, whereas female sex was a risk factor for severe radiographic hip OA and hip pain. Compared with K/L = 0/1, hip pain was significantly associated with K/L >= 3, but not with K/L = 2. Conclusion: The present cross-sectional study revealed the prevalence of radiographic hip OA and severe hip OA in Japanese men and women. Hip pain was strongly associated with K/L >= 3. TI Sarcopenia in daily practice: assessment and management
SO BMC GERIATRICS

LA English
DT Article
DE Sarcopenia; Daily practice; Assessment; Management; Tools
ID anthropometric prediction equations; bioelectrical-impedance analysis; appendicular skeletal-muscle; x-ray absorptiometry; lean soft-tissue; physical performance; european-society; economic-aspects; protein-intake; vitamin-d
AB Background: Sarcopenia is increasingly recognized as a correlate of ageing and is associated with increased likelihood of adverse outcomes including falls, fractures, frailty and mortality. Several tools have been recommended to assess muscle mass, muscle strength and physical performance in clinical trials. Whilst these tools have proven to be accurate and reliable in investigational settings, many are not easily applied to daily practice. Methods: This paper is based on literature reviews performed by members of the European Society for Clinical and Economic Aspects of Osteoporosis and Osteoarthritis (ESCEO) working group on frailty and sarcopenia. Face-to-face meetings were afterwards organized for the whole group to make amendments and discuss further recommendations. Results: This paper proposes some user-friendly and inexpensive methods that can be used to assess sarcopenia in real-life settings. Healthcare providers, particularly in primary care, should consider an assessment of sarcopenia in individuals at increased risk; suggested tools for assessing risk include the Red Flag Method, the SARC-F questionnaire, the SMI method or different prediction equations. Management of sarcopenia should primarily be patient centered and involve the combination of both resistance and endurance based activity programmes with or without dietary interventions. Development of a number of pharmacological interventions is also in progress. Conclusions: Assessment of sarcopenia in individuals with risk factors, symptoms and/or conditions exposing them to the risk of disability will become particularly important in the near future.

TI Efficacy and safety of hyaluronic acid in the management of osteoarthritis: Evidence from real-life setting trials and surveys
SO SEMINARS IN ARTHRITIS AND RHEUMATISM
LA English
DT Review
DE Hyaluronic acid; Intra-articular injection; Knee osteoarthritis
ID randomized controlled-trial; knee osteoarthritis; molecular-weight; double-blind; hylan g-f-20; intraarticular hyaluronan; non-inferiority; metaanalysis; viscosupplementation; injections
AB The European Society for Clinical and Economic Aspects of Osteoporosis and Osteoarthritis (ESCEO) treatment algorithm recommends intra-articular (IA) hyaluronic acid (HA) for management of knee osteoarthritis (OA) as second-line treatment in patients who remain symptomatic despite use of non steroidal anti-inflammatory drugs (NSAIDs). This recommendation is based upon accumulating evidence that IA HA provides a significant benefit in knee OA. There is good evidence that IA HA injections reduce pain and increase function in knee OA, and the benefits are long-lasting as compared with IA corticosteroids. Evidence from real-life studies of repeat courses of IA HA demonstrates an improvement in pain or function lasting up to 40 months (12 months after the last injection cycle), a reduction in use of concomitant analgesia by up to 50%, and suggests that there may be a delay in the need for total knee replacement (TKR) of around 2 years. The

clinical benefit of IA HA on knee OA may be 2-fold: (i) mechanical viscosupplementation of the joint (allowing lubrication and shock absorption) and (ii) the re-establishment of joint homeostasis through induction of endogenous HA production, which continues long after the exogenous injection has left the joint. The magnitude of the clinical effect may be different for different HA products, but this has not been proven so far and requires further investigation. IA HA injections are generally considered to be safe, although a slightly higher number of cases of local reactions and post-injection non-septic arthritis has been reported with high molecular weight cross-linked HAs. The use of IA HA in knee OA patients with mild-moderate disease, and for more severe patients wishing to delay TKR surgery, is recommended by the ESCEO task force. Further investigation into the OA patient types most likely to benefit from IA HA is warranted. Viscosupplementation with IA HA is a safe and effective component of the multi-modal management of knee OA.

TI Fructus Ligustri Lucidi ethanol extract inhibits osteoclastogenesis in RAW264.7 cells via the RANKL signaling pathway
SO MOLECULAR MEDICINE REPORTS
LA English
DT Article
DE Fructus ligustri Lucidi; oleanolic acid; ursolic acid; osteoclast; receptor activator of nuclear factor kappa B ligand
ID bone-mineral density; differentiation; osteoporosis; expression; identification; insights
AB Fructus ligustri Lucidi (FLL) is the fruit of Ligustrum lucidum Ait and a traditional Chinese medicine, primarily known for its role in osteoporosis prevention and treatment. The present study aimed to elucidate the effect and underlying mechanism of action of ethanol extract of FLL on osteoclast differentiation and bone resorption, and to identify the active compounds within it. RAW264.7 murine monocyte/macrophage cells were stimulated with the receptor activator of nuclear factor kappa B ligand (RANKL) to induce osteoclast differentiation in vitro. The present study demosntrated that FLL extract and its two primary components, oleanolic acid (OA) and ursolic acid (UA), significantly suppressed RANKL-induced tartrate resistant acid phosphatase (TRAP) activity and multinucleate osteoclast formation without inducing cytotoxicity; however, no effect was observed on the apoptosis of mature osteoclasts. Additionally, RANKL-induced mRNA expression levels of the key transcription factors, tumor necrosis factor receptor associated factor-6, nuclear factor of activated T cell-c1 and c-Fos, and the osteoclast markers, TRAP, cathepsin K and matrix metalloproteinase-9 were suppressed by FLL, OA and UA. However, no effect was observed on RANKL-induced mRNA expression levels of Src. These results demonstrated that FLL may inhibit osteoclastogenesis in RAW264.7 cells via RANKL signaling pathways. OA and UA are active compounds in inducing this effect; however, their specific roles remain to be elucidated.

TI A comparison of the femur heads histomorphometrically regarding trabecular bone properties in the patients with osteoporosis and osteoarthritis
SO AGING CLINICAL AND EXPERIMENTAL RESEARCH
LA English
DT Article
DE Osteoarthritis; Osteoporosis; Bone densitometry; Bone Turnover Marker
ID hip osteoarthritis; structural basis; fracture; fragility; density; disease
AB The purpose was to compare the bone samples histomorphometrically regarding trabecular bone properties in the patients with osteoarthritis (OA) and osteoporosis (OP). Femoral head specimens were obtained from 18 patients with OA and 17 patients with femoral neck fracture due to OP during hip arthroplasty. Histomorphometric analyses were performed by soft ware program (Carl Zeiss) to measure trabecular area (Tb.a, mm(3)), trabecular thickness (Tb.th, A mu m) and trabecular separation (Tb.s, A mu m). In the results, Tb.a and Tb.th values were significantly lower ($p < 0.05$), Tb.s was higher in the patients with OP ($p < 0.05$). Bone metabolism parameters were different between the groups ($p < 0.05$). All histomorphometric parameters were highly correlated with the BMDs ($p < 0.01$). This study showed inverse relation between OA and OP regarding trabecular bone properties, BMD and bone turnover metabolism markers. The strong relations between results suggest that either BMDs or bone turnover markers can be used for prescience of the fractures.

TI Validation of the Chinese version 10-item Perceived Efficacy in Patient-Physician Interactions scale in patients with osteoarthritis
SO PATIENT PREFERENCE AND ADHERENCE
LA English
DT Article
DE assessment of osteoarthritis; patient-physician communication; self-efficacy; instrument validation
ID self-efficacy; communication; pain; hip
AB Objectives: This study aimed to assess the reliability and validity of the Chinese version of the 10-item Perceived Efficacy in Patient-Physician Interaction (PEPPI-10) scale in hospitalized patients with severe knee osteoarthritis in the People's Republic of China. Methods: Between January and March 2015, the Chinese versions of PEPPI, self-efficacy for exercise scale, osteoporosis self-efficacy scale, and modified fall efficacy scale were applied to assess 110 severe knee osteoarthritis patients who were hospitalized in the second ward of the department of arthroplasty surgery of Tianjin Hospital. Results: The Chinese version of the PEPPI-10 scale had a high coefficient of internal consistency (Cronbach's alpha coefficient, 0.907). The score of the Chinese version of PEPPI was weakly correlated with the scores of the Chinese versions of self-efficacy for exercise scale, osteoporosis self-efficacy scale, and modified fall efficacy scale. Conclusion: The Chinese version of the PEPPI-10 scale exhibits sufficient internal consistency and convergent validity in hospitalized patients with severe knee osteoarthritis in the People's Republic of China.

TI Cancellous and Cortical Bone Microarchitectures of Femoral Neck in Rheumatoid Arthritis and Osteoarthritis Compared with Donor Controls
SO CALCIFIED TISSUE INTERNATIONAL
LA English
DT Article
DE 3D microarchitecture; Rheumatoid arthritis; Osteoarthritis; Femoral neck; Cancellous/cortical bones
ID age-related-changes; hip fracture; ultradistal radius; microstructure; osteoporosis; head; quantification; connectivity; thickness; women
AB This study investigated the 3D microarchitecture of cancellous and cortical bones of the femoral neck in rheumatoid arthritis (RA), osteoarthritis (OA) and donor controls. 26 femoral necks (including heads) were harvested during total hip replacement surgeries in 11 patients with RA (mean age 66.7 +/- 12.8 years) and 15

patients with OA (67.3 +/- 8.4 years). Femoral heads/necks were also harvested from 8 donors (74.9 +/- 10.2 years). Bone samples of 10 mm thickness were prepared from each femoral neck and scanned with micro-CT to evaluate microarchitectural parameters. The RA and OA samples showed no significant differences in microarchitectural parameters in cancellous or cortical bone. Compared with the donor controls, bone volume fraction in RA and OA cancellous bone was significantly greater, the structure model index in OA was significantly lower, and the surface density in RA was significantly greater. The RA bone tissues showed erosion and marked osteophyte formation. This study demonstrated that RA and OA have similar trends of overall microarchitectural degeneration in the femoral neck, despite marked erosion in RA bone and osteophyte formation in OA bone. However, we could not eliminate the possibility of local differences between RA and OA bone. The age-related bone loss in RA and OA was less severe than those of normal ageing and osteoporosis, suggesting a compensatory effect of the diseases to increase bone density.

TI A randomized, double-blind, multicenter, placebo-controlled study to evaluate the efficacy and safety of oral salmon calcitonin in the treatment of osteoporosis in postmenopausal women taking calcium and vitamin D
SO BONE

LA English
DT Article
DE Osteoporosis; Calcitonin; Fractures; Efficacy; Safety
ID cancer-risk; nasal spray; fractures; osteoarthritis; trials
AB This randomized, double-blind, placebo-controlled phase III study was conducted to assess the efficacy and safety of oral calcitonin (SMC021) for the treatment of postmenopausal osteoporosis. A total of 4665 postmenopausal women with osteoporosis were randomized 1:1 to receive calcium and vitamin D plus either SMC021 tablets (0.8 mg/d) or placebo for 36 months. The primary endpoint was the proportion of patients with a new vertebral fracture. The two groups were well balanced at baseline with regards to demographic and clinical data. No effect of SMC021 on preventing new vertebral fractures was observed, nor was any effect seen on new hip or non vertebral fractures. Women receiving SMC021 had a mean 1.02% (+/- 0.12%) increase in lumbar spine bone mineral density (BMD) compared with a mean 0.18% (+/- 0.12%) increase in the placebo group by the end of the study ($p < 0.0001$). Similarly, small increases in BMD were observed at the femoral neck and hip in both groups. Levels of the biomarkers of bone turnover, urinary CTX-I and CTX-II, were 15% lower in the SMC021 group than in the placebo arm at 12 and 24 months, but not at 36 months. No change in quality of life between groups, assessed by the Qualeffo-14 questionnaire, was observed in either group between baseline and month 36. Pharmacokinetics analysis confirmed exposure to SMC021, but the drug levels were markedly lower than expected. Approximately 92% of subjects in each treatment group experienced an adverse event (AE), the majority of which were mild or moderate in intensity. AEs associated with SMC021 were primarily of gastrointestinal origin and included nausea, vomiting and abdominal pain, as well as hot flushes which were the reason for the slightly higher drop-out rate in the active treatment arm compared to placebo. The number of severe AEs was low in both groups. Thirty-five deaths were reported but none were considered treatment-related. Due to the lack of efficacy in preventing fractures, the development of the orally formulated calcitonin was terminated despite the promising results in earlier studies. (C) 2016 Elsevier Inc. TI Epidemiology of Fracture Nonunion in 18 Human Bones
SO JAMA SURGERY
LA English
DT Article
ID tibial shaft fractures; midshaft clavicular fractures; external fixation; nonoperative treatment; risk-factors; open reduction; plate osteosynthesis; intramedullary nail; internal-fixation; complications
AB IMPORTANCE Failure of bone fracture healing occurs in 5% to 10% of all patients. Nonunion risk is associated with the severity of injury and with the surgical treatment technique, yet progression to nonunion is not fully explained by these risk factors. OBJECTIVE To test a hypothesis that fracture characteristics and patient-related risk factors assessable by the clinician at patient presentation can indicate the probability of fracture nonunion. DESIGN, SETTING, AND PARTICIPANTS An inception cohort study in a large payer database of patients with fracture in the United States was conducted using patient-level health claims for medical and drug expenses compiled for approximately 90.1 million patients in calendar year 2011. The final database collated demographic descriptors, treatment procedures as per Current Procedural Terminology codes; comorbidities as per International Classification of Diseases, Ninth Revision codes; and drug prescriptions as per National Drug Code Directory codes. Logistic regression was used to calculate odds ratios (ORs) for variables associated with nonunion. Data analysis was performed from January 1, 2011, to December 31, 2012, EXPOSURES Continuous enrollment in the database was required for 12 months after fracture to allow sufficient time to capture a nonunion diagnosis. RESULTS The final analysis of 309 330 fractures in 18 bones included 178 952 women (57.9%); mean (SD) age was 44.48 (13.68) years. The nonunion rate was 4.9%. Elevated nonunion risk was associated with severe fracture (eg, open fracture, multiple fractures), high body mass index, smoking, and alcoholism. Women experienced more fractures, but men were more prone to nonunion. The nonunion rate also varied with fracture location: scaphoid, tibia plus fibula, and femur were most likely to be nonunion. The ORs for nonunion fractures were significantly increased for risk factors, including number of fractures (OR, 2.65; 95% CI, 2.34-2.99), use of nonsteroidal anti-inflammatory drugs plus opioids (OR, 1.84; 95% CI, 1.73-1.95), operative treatment (OR, 1.78; 95% CI, 1.69-1.86), open fracture (OR, 1.66; 95% CI, 1.55-1.77), anticoagulant use (OR, 1.58; 95% CI, 1.51-1.66), osteoarthritis with rheumatoid arthritis (OR, 1.58; 95% CI, 1.38-1.82), anticonvulsant use with benzodiazepines (OR, 1.49; 95% CI, 1.36-1.62), opioid use (OR, 1.43; 95% CI, 1.34-1.52), diabetes (OR, 1.40;

95% CI, 1.21-1.61), high-energy injury (OR, 1.38; 95% CI, 1.27-1.49), anticonvulsant use (OR, 1.37; 95% CI, 1.31-1.43), osteoporosis (OR, 1.24; 95% CI, 1.14-1.34), male gender (OR, 1.21; 95% CI, 1.16-1.25), insulin use (OR, 1.21; 95% CI, 1.10-1.31), smoking (OR, 1.20; 95% CI, 1.14-1.26), benzodiazepine use (OR, 1.20; 95% CI, 1.10-1.31), obesity (OR, 1.19; 95% CI, 1.12-1.25), antibiotic use (OR, 1.17; 95% CI, 1.13-1.21), osteoporosis medication use (OR, 1.17; 95% CI, 1.08-1.26), vitamin D deficiency (OR, 1.14; 95% CI, 1.05-1.22), diuretic use (OR, 1.13; 95% CI, 1.07-1.18), and renal insufficiency (OR, 1.11; 95% CI, 1.04-1.17) (multivariate P < .001 for all). CONCLUSIONS AND RELEVANCE The probability of fracture nonunion can be based on patient-specific risk factors at presentation. Risk of nonunion is a function of fracture severity, fracture location, disease comorbidity, and medication use.

AB Background: Although articular cartilage is the primary tissues affected by osteoarthritis (OA), the underlying subchondral bone also undergoes noticeable changes. Despite the growing body of research into the biophysical and mechanical properties of OA bone there are few studies that have analysed the structure of the subchondral sclerosis at the nanoscale. In this study, the composition and nano-structural changes of human osteoarthritis (OA) subchondral bone were investigated to better understand the site-specific changes. Methods: OA bone samples were collected from patients undergoing total knee replacement surgery and graded according to disease severity (grade I: mild OA; grade IV: severe OA). Transmission electron microscopy (TEM), Electron Diffraction, and Elemental Analysis techniques were used to explore the cross-banding pattern, nature of mineral phase and orientation of the crystal lattice. Subchondral bone nano-hydroxyapatite powders were prepared and characterised using high resolution transmission electron microscopy (HR-TEM) and fourier transform

infrared spectroscopy (FTIR). Subchondal bone mechanical properties were investigated using a nano-indentation method. Results: In grade I subchondral bone samples, a regular periodic fibril banding pattern was observed and the c-axis orientation of the apatite crystals was parallel to the long axis of the fibrils. By contrast, in grade IV OA bone samples, the bulk of fibrils formed a random and undulated arrangement accompanied by a circular oriented pattern of apatite crystals. Fibrils in grade IV bone showed non-hierarchical intra-fibrillar mineralization and higher calcium (Ca) to phosphorous (P) (Ca/P) ratios. Grade IV OA bone showed higher crystallinity of the mineral content, increased modulus and hardness compared with grade I OA bone. Conclusions: The findings from this study suggest that OA subchondral sclerotic bone has an altered mineralization process which results in nano-structural changes of apatite crystals that is likely to account for the compromised mechanical properties of OA subchondral bones.

TI Autologous Bone Marrow Concentrate in a Sheep Model of Osteoarthritis: New Perspectives for Cartilage and Meniscus Repair
SO TISSUE ENGINEERING PART C-METHODS
LA English
DT Article
ID mesenchymal stem-cells; articular-cartilage; knee osteoarthritis; mononuclear-cells; in-vitro; scaffold; transplantation; microfracture; rationale; mechanics
AB Introduction: Cell-based therapies are becoming a valuable tool to treat osteoarthritis (OA). This study investigated and compared the regenerative potential of bone marrow concentrate (BMC) and mesenchymal stem cells (MSC), both engineered with Hyaff (R)-11 (HA) for OA treatment in a sheep model. Methods: OA was induced via unilateral medial meniscectomy. Bone marrow was aspirated from the iliac crest, followed by concentration processes or cell isolation and expansion to obtain BMC and MSC, respectively. Treatments consisted of autologous BMC and MSC seeded onto HA. The regenerative potential of bone, cartilage, menisci, and synovia was monitored using macroscopy, histology, immunohistochemistry, and micro-computed tomography at 12 weeks post-op. Data were analyzed using the general linear model with adjusted Sidak's multiple comparison and Spearman's tests. Results: BMC-HA treatment showed a greater repair ability in inhibiting OA progression compared to MSC-HA, leading to a reduction of inflammation in cartilage, meniscus, and synovium. Indeed, the decrease of inflammation positively contributed to counteract the progression of fibrotic and hypertrophic processes, known to be involved in tissue failure. Moreover, the treatment with BMC-HA showed the best results in allowing meniscus regeneration. Minor healing effects were noticed at bone level for both cell strategies; however, a downregulation of subchondral bone thickness (Cs.Th) was found in both cell treatments compared to the OA group in the femur. Conclusion: The transplantation of BMC-HA provided the best effects in supporting regenerative processes in cartilage, meniscus, and synovium and at less extent in

bone. On the whole, both MSC and BMC combined with HA reduced inflammation and contributed to switch off fibrotic and hypertrophic processes. The observed regenerative potential by BMC-HA on meniscus could open new perspectives, suggesting its use not only for OA care but also for the treatment of meniscal lesions, even if further analyses are necessary to confirm its healing potential at long-term follow-up.

TI Increased trabecular bone and improved biomechanics in an osteocalcin-null rat model created by CRISPR/Cas9 technology
SO DISEASE MODELS & MECHANISMS
LA English
DT Article
DE Osteocalcin; Bone strength; Bone structure; Genetic animal models; Osteocalcin knockout
ID cleidocranial dysplasia; gene; inhibition; expression; differentiation; osteoporosis; adiponectin; promoter; protein; system
AB Osteocalcin, also known as bone gamma-carboxyglutamate protein (Bglap), is expressed by osteoblasts and is commonly used as a clinical marker of bone turnover. A mouse model of osteocalcin deficiency has implicated osteocalcin as a mediator of changes to the skeleton, endocrine system, reproductive organs and central nervous system. However, differences between mouse and human osteocalcin at both the genome and protein levels have challenged the validity of extrapolating findings from the osteocalcin-deficient mouse model to human disease. The rat osteocalcin (Bglap) gene locus shares greater synteny with that of humans. To further examine the role of osteocalcin in disease, we created a rat model with complete loss of osteocalcin using the CRISPR/Cas9 system. Rat osteocalcin was modified by injection of CRISPR/Cas9 mRNA into the pronuclei of fertilized single cell Sprague-Dawley embryos, and animals were bred to

homozygosity and compound heterozygosity for the mutant alleles. Dual-energy X-ray absorptiometry (DXA), glucose tolerance testing (GTT), insulin tolerance testing (ITT), microcomputed tomography (mu CT), and a three-point break biomechanical assay were performed on the excised femurs at 5 months of age. Complete loss of osteocalcin resulted in bones with significantly increased trabecular thickness, density and volume. Cortical bone volume and density were not increased in null animals. The bones had improved functional quality as evidenced by an increase in failure load during the biomechanical stress assay. Differences in glucose homeostasis were observed between groups, but there were no differences in body weight or composition. This rat model of complete loss of osteocalcin provides a platform for further understanding the role of osteocalcin in disease, and it is a novel model of increased bone formation with potential utility in osteoporosis and osteoarthritis research.

TI Determinants of Serum 25-Hydroxyvitamin D Concentrations and a Screening Test for Moderate-to-Severe Hypovitaminosis D in Chinese Patients Undergoing Total Joint Arthroplasty
SO JOURNAL OF ARTHROPLASTY
LA English

DT Article
DE vitamin D; sunlight; determinants; total joint arthroplasty; screening test
ID vitamin-d-status; d insufficiency; d deficiency; hong-kong; adults; osteoporosis; prevalence; exposure; women; supplementation
AB Background: Hypovitaminosis D is associated with adverse surgical outcomes. We quantified the environmental, demographic, and modifiable determinants of serum 25-hydroxyvitamin D (25-OHD) concentration and assessed the potential impact of a preoperative screening questionnaire for moderate-to-severe hypovitaminosis D (25-OHD < 30 nmol/L). Methods: In a retrospective cohort study of 227 Chinese patients (69 males and 158 females) undergoing 261 joint arthroplasty, we collected information on recent sun exposure, dietary vitamin D intake, vitamin D supplementation, and Western Ontario and McMaster Universities osteoarthritis index using a questionnaire and measured a fasting 25-OHD concentration using a liquid chromatographyetandem mass spectrometry before surgery. Results: The multiple regression model on the determinants of 25-OHD concentration described 14% of the total variance, with the greatest relative contribution from ambient ultraviolet radiation (42%). A 4-item screening test for moderate-to-severe hypovitaminosis D had acceptable discrimination (area under receiver operating characteristic curve = 0.76, 95% CI, 0.65-0.87), good calibration (HosmereLemeshow goodness-of-fit; P = .93). Decision curve analysis showed that the screening test can potentially reduce unnecessary 25-OHD testing by 390 per 1000 patients at a threshold probability of 10%. Conclusion: The screening test appears moderately useful in avoiding a substantial number of unnecessary 25-OHD testing in a setting where the prevalence of moderate-to-severe hypovitaminosis D is less than 10%. TI Orthopedic tissue regeneration: cells, scaffolds, and small molecules
SO DRUG DELIVERY AND TRANSLATIONAL RESEARCH
LA English
DT Review
DE Osteoporosis; Osteoarthritis; Bone; Cartilage; Stemcells; Scaffolds; Small molecules
ID mesenchymal stem-cells; osteoarthritic subchondral bone; articular-cartilage defect; in-vitro chondrogenesis; platelet-rich plasma; strontium ranelate; osteogenic differentiation; knee osteoarthritis; adipose-tissue; cathepsin-k
AB Orthopedic tissue regeneration would benefit the aging population or patients with degenerative bone and cartilage diseases, especially osteoporosis and osteoarthritis. Despite progress in surgical and pharmacological interventions, new regenerative approaches are needed to meet the challenge of creating bone and articular cartilage tissues that are not only structurally sound but also functional, primarily to maintain mechanical integrity in their high load-bearing environments. In this review, we discuss new advances made in exploiting the three classes of materials in bone and cartilage regenerative medicine-cells, biomaterial-based scaffolds, and small molecules-and their successes and challenges reported in the

clinic. In particular, the focus will be on the development of tissue-engineered bone and cartilage ex vivo by combining stem cells with biomaterials, providing appropriate structural, compositional, and mechanical cues to restore damaged tissue function. In addition, using small molecules to locally promote regeneration will be discussed, with potential approaches that combine bone and cartilage targeted therapeutics for the orthopedic-related disease, especially osteoporosis and osteoarthritis.

DE Vacuum extraction; Operative delivery; Occipito-posterior position; Adverse outcome; Delivery
ID occiput posterior position; instrumental vaginal delivery; operative delivery; risk-factors; intrapartum sonography; 2nd-stage; labor; cohort; laceration; duration
AB Objective To estimate the association of fetal head position prior to vacuum extraction (VE) and pregnancy outcome. Study design A retrospective cohort study of singleton pregnancies who underwent VE. Pregnancy outcome of occipito-anterior (OA) position of the fetal head was compared to those with occipito-posterior (OP) position. Results Amongst overall 12,063 women undergoing trial of labor, there were 1118 (9.2 %) VE deliveries. Of them, 871 (77.9 %) had OA and 247 (22.1 %) had OP position of the fetal head. Except for a higher rate of nulliparity in the OA group, no significant differences between the groups regarding pregnancy complications and birthweight were noted. In the OP group, there were higher rates of prolonged 2nd-stage of labor as an indication for VE (49.8 vs. 36.5 %, p< 0.001) and single detachment of vacuum cup (11.3 vs. 6.7 %, p = 0.02) without any increased risk of failed extraction. Higher risks for sub-galeal hematoma (aOR = 4.36, p = 0.03) and low 5-min Apgar score (aOR = 4.63, p = 0.02) were observed in the OP group with otherwise similar rates of adverse maternal and neonatal outcomes. Conclusion Among women undergoing VE, OP position is associated with higher rate of vacuum cup detachment, low 5-min Apgar score and increased risk for sub-galeal hematoma with otherwise similar rates of adverse maternal and neonatal outcomes.

TI The role of sarcopenia with and without fracture
SO INJURY-INTERNATIONAL JOURNAL OF THE CARE OF THE INJURED
LA English
DT Article
DE Sarcopenia; Osteoporosis; Osteoarthritis; Hip fracture; Aging; Risk of falling; Muscle fibre atrophy; Satellite cells; BMP2; Myostatin
ID bone-mineral density; femoral-neck; tgf-beta; muscle; osteoporosis; exercise; dysfunction; diseases; obesity; cells
AB Introduction: Bone and muscle tissues are in a close relationship. They are linked from a biological and functional point of view and both are related to an increased fracture risk in the elderly. The aging process is involved in the loss of functionality of both bones and muscles. In particular, aging-induced decline in muscle size and quality accompanies catabolic alterations in bone tissue; furthermore, age-related changes in bone alter its response to muscle-derived stimulation. The increased fracture risk in individuals with sarcopenia and osteoporosis is due to the decline of muscle mass and strength, the decrease in bone mineral density (BMD) and limited mobility. In this study, we investigated the role of sarcopenia and the main age-related bone diseases, osteoporosis (OP) and osteoarthritis (OA). Methods: Muscular performance status was evaluated using the

Physical Activity Scale for the Elderly (PASE) test in 27 female patients with OP who underwent total hip arthroplasty for hip fracture, and in 27 age-matched female patients with OA who underwent total hip arthroplasty. Dual-energy X-ray absorptiometry (DEXA) was performed and the T-score values were used to discriminate between OP and OA patients. Body Mass Index (BMI) was calculated. As part of a multiparametric model of evaluation, biopsies of vastus lateralis muscle were analysed by immunohistochemical reaction to find a correlation with the above mentioned functional index. Results: The PASE test showed that the OP patients had a low or moderate level of physical activity before fracture occurred, whereas the OA patients had more intensive pre-fracture physical performances. Histological analysis showed that osteoporosis is characterised by a preferential type II fibre atrophy; in particular, data correlation showed that lower PASE test scores were related to lower diameter of type II fibres. No correlation was found between bone mineral density (BMD) and PASE test results. Discussion and conclusion: Osteoporosis is closely related to sarcopenia before and after fracture. Bone remodelling is influenced by muscle morphological and functional impairment and sarcopenia is considered one of the major factors for functional limitation and motor dependency in elderly osteoporotic individuals. Therefore, physical activity should be strongly recommended for OP patients at diagnosis. (C) 2016 Elsevier Ltd. All rights reserved.

TI Efficacy and safety of topical NSAIDs in the management of osteoarthritis: Evidence from real-life setting trials and surveys
SO SEMINARS IN ARTHRITIS AND RHEUMATISM
LA English

DT Review
DE Hand osteoarthritis; Knee osteoarthritis; Topical non-steroidal anti-inflammatory drugs (NSAIDs); Personalized medicine
ID diclofenac solution; knee pain; double-blind; gel; recommendations; metaanalysis; ketoprofen; therapy; hand
AB Topical non-steroidal anti-inflammatory drugs (NSAIDs) are recommended in international and national guidelines as an early treatment option for the symptomatic management of knee and hand osteoarthritis (OA), and may be used ahead of oral NSAIDs due to their superior safety profile. The European Society for Clinical and Economic Aspects of Osteoporosis and Osteoarthritis (ESCEO) treatment algorithm recommends topical NSAIDs for knee OA in addition to the pharmacological background of symptomatic slow-acting drugs for osteoarthritis (SYSADOAs) and rescue analgesia with paracetamol and non-pharmacological treatment, if the patient is still symptomatic. Topical NSAIDs have a moderate effect on pain relief, with efficacy similar to that of oral NSAIDs, with the advantage of a better risk: benefit ratio. In real-life studies, topical and oral NSAIDs demonstrate an equivalent effect on knee pain over 1 year of treatment, with fewer adverse events due to lower systemic absorption of topical NSAIDs compared with oral NSAIDs. As a result, topical NSAIDs may be the preferred treatment option, especially in OA patients aged >= 75 years, and those with co-morbidities or at an increased risk of cardiovascular, gastrointestinal, or renal side effects. Furthermore, using topical NSAIDs in inflammatory rheumatic diseases leads to a 40% reduction in the need for concomitant oral NSAIDs. When selecting a topical NSAID, absorption and bioavailability are important because of heterogeneity among topical drug formulations. Molecules like etofenamate have a bioavailability of >20% and evidence for accumulation in synovial tissues, with efficacy demonstrated as improvement in pain and function in real-life studies of OA patients. Diclofenac also shows good efficacy alongside evidence that diclofenac accumulates in the synovium. (C) 2015 The Authors. Published by Elsevier HS Journals, Inc.

TI Contribution of mechanical unloading to trabecular bone loss following non-invasive knee injury in mice
SO JOURNAL OF ORTHOPAEDIC RESEARCH
LA English
DT Article
DE post-traumatic osteoarthritis; hindlimb unloading; trabecular bone; knee injury; mechanical loading
ID anterior cruciate ligament; posttraumatic osteoarthritis; computed tomography;

disuse osteoporosis; hindlimb suspension; skeletal-muscle; bed rest; model; rat; atrophy
AB Development of osteoarthritis commonly involves degeneration of epiphyseal trabecular bone. In previous studies, we observed 30-44% loss of epiphyseal trabecular bone (BV/TV) from the distal femur within 1 week following non-invasive knee injury in mice. Mechanical unloading (disuse) may contribute to this bone loss; however, it is unclear to what extent the injured limb is unloaded following injury, and whether disuse can fully account for the observed magnitude of bone loss. In this study, we investigated the contribution of mechanical unloading to trabecular bone changes observed following non-invasive knee injury in mice (female C57BL/6N). We investigated changes in gait during treadmill walking, and changes in voluntary activity level using Open Field analysis at 4, 14, 28, and 42 days post-injury. We also quantified epiphyseal trabecular bone using CT and weighed lower-limb muscles to quantify atrophy following knee injury in both ground control and hindlimb unloaded (HLU) mice. Gait analysis revealed a slightly altered stride pattern in the injured limb, with a decreased stance phase and increased swing phase. However, Open Field analysis revealed no differences in voluntary movement between injured and sham mice at any time point. Both knee injury and HLU resulted in comparable magnitudes of trabecular bone loss; however, HLU resulted in considerably more muscle loss than knee injury, suggesting another mechanism contributing to bone loss following injury. Altogether, these data suggest that mechanical unloading likely contributes to trabecular bone loss following non-invasive knee injury, but the magnitude of this bone loss cannot be fully explained by disuse. TI Kinematic TKA using navigation: Surgical technique and initial results
SO ORTHOPAEDICS & TRAUMATOLOGY-SURGERY & RESEARCH
LA English
DT Article
DE Knee Arthroplasty; Navigation; TKA; Technique; Outcomes; Kinematic
ID total knee arthroplasty; mechanical axis alignment; lower-extremity; follow-up; replacements; thickness; survival
AB Background: Kinematic alignment for total knee arthroplasty (TKA) may be one way of improving outcomes. Previous studies have either used patient-specific instrumentation, which adds cost, or standard instrumentation, which provides no intraoperative feedback on resection alignment. Hypothesis: To determine if computer navigation could reproduce native patient anatomy and simplify ligament balance during TKA whilst giving satisfactory improvements in functional scores at early follow-up. Materials and methods: Computer navigation was used for kinematic distal femoral and proximal tibial cuts in 100 consecutive and unselected TKAs. Resections were modified only if measured angles fell outside a

pre-defined safe range of combined coronal orientation within +/- 3 degrees of neutral and/or independent femoral or tibial cuts within +/- 5 degrees. Pre- and postoperative measurements of the hip-knee-ankle (HKA) angle, the lateral distal femoral angle (LDFA) and the medial proximal tibial angle (MPTA) were taken using long-leg standing radiographs. Clinical evaluation was with the WOMAC and KOOS scales. Results: Mean follow-up was 2.4 years (range 1.0-3.7, SD 0.8). The mean pre-op LDFA was 2.1 degrees valgus (9.2 valgus to 3.7 varus, SD 2.5) and 1.8 degrees valgus post-op (5.7 valgus to 4.2 varus, SD 2.0) (P=0.41). The mean pre-op MPTA was 3.0 degrees varus (10.6 valgus to 10.2 varus, SD 3.2) and 2.4 degrees varus post-op (4.0 valgus to 6.8 varus, SD 2.2) (P=0.03). The mean WOMAC score improved from 49.4 (29-85, SD 12.8) to 24.7 (0-73, SD 16.5) (P<0.001) and the mean KOOS score from 37.1 (7.2-77.2, SD 13.0) to 65.1 (26.8-100, SD 16) (P<0.001). Five knees (5%) required additional ligament release, four with valgus OA and one with varus OA. Two knees (2%) required lateral retinacular release for patellar tracking. Discussion: Computer navigation for kinematic TKA provides the operating surgeon with full control and feedback at each step, whilst also allowing partial correction of more extreme anatomy that might be unsuitable for recreation during TKA. This technique helps to preserve ligament isometry and produces satisfactory improvements in functional scores. (C) 2015 Elsevier Masson SAS. All rights reserved.

TI Integrative analysis of genome-wide association studies and gene expression profiles identified candidate genes for osteoporosis in Kashin-Beck disease patients
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE Gene expression profile; Genome-wide association study; Kashin-Beck disease; Osteoporosis; Pleiotropy
ID inflammatory markers; articular-cartilage; hip fracture; apoptosis; osteopontin; growth; osteoarthritis; chondrocytes; osteoclasts; activate
AB A Summary The molecular mechanism of osteoporosis (OP) in Kashin-Beck disease (KBD) patients was unclear. Our results suggest that KBD and OP shared some common causal genes, functionally involved in skeletal growth and development and chronic inflammation. Our results provide novel clues for clarifying the molecular mechanism of OP in KBD patients. Introduction KBD is a chronic skeletal disorder with osteopenia and OP. The pathogenesis of OP in KBD patients remains elusive. Methods A total of 1717 subjects participated in this study. KBD was diagnosed according to the clinical diagnosis criteria of China (GB16395-1996). The bone mineral density (BMD) and bone areas of the ulna and radius, hip, and lumbar (L1-L4) were measured with a Hologic 4500 W dual-energy X-ray absorptiometry scanner. Genotyping was conducted using Affymetrix SNP Array 6.0. Gene expression profiling of peripheral blood mononuclear cells of KBD and OP patients were compared using Affymetrix HG-U133 plus 2.0 arrays and Agilent Human 1A arrays, respectively. Genome-wide association studies (GWAS) were conducted by PLINK. SCEA and DAVID were applied for pleiotropy and functional enrichment analysis, respectively. Results SCEA analysis observed significant pleiotropic effects between KBD and the ulna and radius BMD (P value(-) 5.99 x 10(-3)). GWAS meta-analysis identified six candidate genes with pleiotropic effects, including PDGFD, SOX5, DPYD, CTR9, SPP1, and COL4A1. GO analysis identified 16 significant GO shared by KBD and the ulna and radius BMD, involved in cell morphogenesis and apoptosis. Pathway enrichment analysis detected two common pathways for KBD and the ulna and radius BMD, including calcium signaling pathway and vascular smooth muscle contraction pathway. Gene expression analysis detected three up-regulated inflammation-related genes for KBD and OP, including IL1B, IL8, and CCL1. Conclusion This study reported several candidate genes involved in the development of OP in KBD patients.

TI Effects of acupuncture on quality of life and pain in patients with osteoporosis-a pilot randomized controlled trial
SO ARCHIVES OF OSTEOPOROSIS
LA English
DT Article
DE Osteoporosis; Acupuncture; Pain; Quality of life; QUALEFFO-41
ID low-back-pain; postmenopausal women; vertebral fractures; auricular acupuncture; hip-arthroplasty; risk; multicenter; bone; osteoarthritis; questionnaire
AB A Summary In this sham-controlled study, 53 patients received 10 sessions of acupuncture treatment over 5 weeks to investigate the effects of acupuncture on the pain and quality of life of patients with osteoporosis. The results showed significant favorable effects of verumacupuncture on quality of life. Both interventions showed sustained and clinically relevant effects on pain. Purpose Standard analgesic treatment is associated with adverse events in patients with osteoporosis, especially elderly and/or comorbid patients. As acupuncture has gained widespread acceptance as a complementary treatment modality with few side effects, the aim of this study was to evaluate the effects of acupuncture on the pain and quality of life of patients with osteoporosis. Methods In total, 53 patients with vertebral compression fractures, osteoporosis-associated spinal deformities, and resultant pain were randomly allocated to the verum acupuncture with deep needling of specific points following the principles of traditional Chinese medicine (n = 29) or control acupuncture group with superficial needling of non-acupuncture points (n = 24). All patients received 10 sessions of standardized verum or control acupuncture treatment over 5 weeks. Pain (VAS score 1-100) and quality of life (QUALEFFO-41) were measured at the start of treatment (T0), before each acupuncture session (T1), and at 1 (T2) and 3 months (T3) post-treatment. Results Both acupuncture treatments significantly reduced activity-related pain and pain at rest over time. The verum acupuncture group experienced a significantly greater reduction in mean pain intensity at rest than the control group. In the control group, quality of life improved only temporarily post-treatment (T2) and slightly declined at the end of the follow-up period (T3). In contrast, patients in the verum acupuncture group experienced continuous and significant improvements in

quality of life up to 3 months after treatment (T3). Conclusions Both types of acupuncture were equally effective in producing sustained, clinically relevant pain relief in patients with osteoporosis. Verum acupuncture had stronger and longer-lasting effects on quality of life and pain at rest. The possible reasons for these findings include the specificity of acupuncture point selection and the performance of needle stimulation.

TI Diacerein: Benefits, Risks and Place in the Management of Osteoarthritis. An Opinion-Based Report from the ESCEO
SO DRUGS & AGING
LA English
DT Article
ID nonsteroidal antiinflammatory drugs; human articular chondrocytes; acute liver-failure; factor-kappa-b; knee osteoarthritis; rhein reduce; double-blind; task-force; diacerhein; efficacy
AB Diacerein is a symptomatic slow-acting drug in osteoarthritis (SYSADOA) with anti-inflammatory, anti-catabolic and pro-anabolic properties on cartilage and synovial membrane. It has also recently been shown to have protective effects against subchondral bone remodelling. Following the end of the revision procedure by the Pharmacovigilance Risk Assessment Committee of the European Medicines Agency, the European Society for Clinical and Economic Aspects of Osteoporosis and Osteoarthritis (ESCEO) constituted a panel of 11 experts to better define the real place of diacerein in the armamentarium for treating OA. Based on a literature review of clinical trials and meta-analyses, the ESCEO confirms that the efficacy of diacerein is similar to that of non-steroidal anti-inflammatory drugs (NSAIDs) after the first month of treatment, and superior to that of paracetamol. Additionally, diacerein has shown a prolonged effect on symptoms of several months once treatment was stopped. The use of diacerein is associated with common gastrointestinal disorders such as soft stools and diarrhoea, common mild skin reactions, and, uncommonly, hepatobiliary disorders. However, NSAIDs and paracetamol are known to cause potentially severe hepatic, gastrointestinal, renal, cutaneous and cardiovascular reactions. Therefore, the ESCEO concludes that the benefit-risk balance of diacerein remains positive in the symptomatic treatment of hip and knee osteoarthritis. Furthermore, similarly to other SYSADOAs, the ESCEO positions diacerein as a first-line pharmacological background treatment of osteoarthritis, particularly for patients in whom NSAIDs or paracetamol are contraindicated.

TI Imaging of occult hip fractures: CT or MRI?
SO INJURY-INTERNATIONAL JOURNAL OF THE CARE OF THE INJURED
LA English
DT Article
DE CT; MRI; Occult hip fractures
ID proximal femur; osteoporosis; osteoarthritis; diagnosis; mortality
AB Objectives: Patients presenting with hip pain but normal plain radiographs may ultimately be shown on further investigation to have suffered an occult hip fracture (OHF). This diagnosis can be made with CT or MRI. Traditionally MRI has been considered a superior modality. We performed a retrospective review of all patients presenting to our service with a suspected OHF over a four-year period, investigated with either CT or MRI. Design: Retrospective review. Setting: Urban trauma centre. Patients: Patients with suspected hip fractures and negative radiographs. Intervention: CT or MRI. Main outcome measures: Detection rate; delay in request for further imaging; delay to theatre; representations with missed fractures. Results: A total of 179 patients were investigated, with a mean age of 82 +/- 13 years. The ultimate diagnosis was of an OHF in 71 cases and pelvic or acetabular fracture in 34. The average time from presentation plain radiograph to further imaging was 2.0 +/- 2.7 days, but was significantly shorter for CT. No patient re-presented with unidentified fractures or other localised hip pathology within a 12-month period. Conclusions: Modern imaging technology does not appear to miss clinically significant fractures. As CT is usually more accessible than MRI, the results of our study should encourage surgeons to consider CT as a first line investigation for occult hip fractures. We advocate a high index of suspicion and early imaging referral for elderly patients presenting with non-specific hip pain

following a fall. (C) 2016 Elsevier Ltd. All rights reserved.

TI Evidence for Altered Canonical Wnt Signaling in the Trabecular Bone of Elderly Postmenopausal Women with Fragility Femoral Fracture
SO BIOMED RESEARCH INTERNATIONAL
LA English
DT Article
ID mesenchymal stem-cells; gene-expression; differentiation; osteoarthritis; osteoporosis; osteoblasts; marrow; repair; runx2
AB Wnt signaling, a major regulator of bone formation and homeostasis, might be involved in the bone loss of osteoporotic patients and the consequent impaired response to fracture. Therefore we analyzed Wnt-related, osteogenic, and adipogenic genes in bone tissue of elderly postmenopausal women undergoing hip replacement for either femoral fracture or osteoarthritis. Bone specimens derived from the intertrochanteric region of the femurs of 25 women with fracture (F) and 29 with osteoarthritis without fracture (OA) were analyzed. Specific miRNAs were analyzed in bone and in matched blood samples. RUNX2, BGP, and OPG showed lower expression in F than in OA samples, while OSX, OPN, BSP, and RANKL were not different. Inhibitory genes of Wnt pathway were lower in F versus OA. beta-Catenin protein levels were higher in F versus OA, whereas its cotranscriptional regulator (Lef1) was lower in F group. miR-204, which targets RUNX2, and miR-130a, which inhibits PPAR gamma, were lower and higher, respectively, in F versus OA serum samples. The present study showed an inefficient Wnt signal transduction in F group despite higher beta-catenin protein levels, consistent with the expected overall postfracture systemic activation towards osteogenesis. This transcriptional inefficiency could contribute to the osteoporotic bone fragility.

TI Wrist bone mineral density utility in diagnosing hip osteoporosis in postmenopausal women
SO THERAPEUTIC ADVANCES IN ENDOCRINOLOGY AND METABOLISM
LA English
DT Article
DE dual-energy X-ray absorptiometry; menopause; osteoporosis; wrist joint
ID lumbar spine; dxa; classification; osteoarthritis; degeneration; discordance;

fracture; risk; men
AB Background: Osteoporosis is a common bone disease that increases with age. Wrist bone mineral density (BMD) has significant correlation with other skeletal sites and it could be used as a diagnostic method for osteoporosis. The purpose of this study was to evaluate the role of wrist BMD in diagnosing osteoporosis in postmenopausal women. Methods: In this cross-sectional study, 99 postmenopausal women with mean age of 57 +/- 6.9 (range 50-76) years were evaluated. BMD of nondominant wrist, lumbar spine (L2-L4) and femur bone using a dual-energy X-ray absorptiometry (DXA) device as well as lateral lumbosacral X-ray for degenerative joint disease (DJD) evaluation were measured. Mean T-score of wrist was lower than hip and lumbar area. Results: Osteopenia and osteoporosis were observed in 40.4% and 59.6% in the wrist, 38.4% and 24.2% in the hip and 36.4% and 49.5% in lumbar-spine BMD measurements, respectively. There was positive correlation between wrist BMD with hip BMD ($r = 0.468$, $p < 0.001$) and lumbar BMD ($r = 0.322$, $p = 0.001$). DJD due to lumbosacral X-ray was reported in 84 cases (84.8%) including mild DJD in 45 (53.5%), moderate DJD in 33 (39.3%) and severe DJD in 6 (7.2%). Conclusions: Our results showed that wrist BMD has better accuracy than lumbar BMD in diagnosing osteoporosis in postmenopausal women.

TI The use of damage control orthopaedics to minimize negative sequelae of surgery delay in elderly comorbid patients with hip fracture
SO EUROPEAN REVIEW FOR MEDICAL AND PHARMACOLOGICAL SCIENCES
LA English
DT Article
DE Hip fracture; Elderly; Older patient; Frail; Damage control orthopaedics; Surgery; ASA; P-POSSUM; Comorbidity; Algorithm
ID fall-related fractures; rheumatoid-arthritis; parkinsons-disease; increased risk; older women; united-states; osteoarthritis; osteoporosis; mortality; association
AB Hip surgeries count to the most frequent orthopaedic operations in older patients. Nonelective surgeries for hip fractures cause substantial economic burden because of high costs of medical treatment and high associated mortality. Surgery for hip fracture in the elderly comorbid patient still presents a challenge to orthopaedic surgeons. It is recommended that this surgery is performed within 48 hours after sustaining the hip fracture to decrease mortality. Yet the recommended early surgery (i.e. 48 hours after the incident) is not always feasible due to the frequent overall frailty of the patients or conditions of concomitant disease. The care of patients unfit for early surgery has been not adequately addressed in the literature. We have previously introduced an algorithm based on ASA-PS and P-POSSUM scores to stratify elderly comorbid patients for early vs delayed hip surgery, and used principles of Damage Control Orthopaedics to minimized negative sequelae of surgery delay (Dong C et al., PLoS One 2016). In this paper, we elaborate on Damage Control Orthopaedics and the proposed approach in the context of frequent comorbidities in the elderly orthopaedic patients. Further studies on this subject are urgently needed to establish international consensus on hip fracture surgery delayed due to overall patient frailty or extensive comorbidities.

TI Outcome of balloon kyphoplasty for the treatment of osteoporotic vertebral compression fracture in patients with rheumatoid arthritis
SO BMC MUSCULOSKELETAL DISORDERS
LA English
DT Article
DE Rheumatoid osteoarthritis; Osteoporotic vertebral compression fracture; Kyphoplasty
ID bone-mineral density; vertebroplasty; risk; cement; women
AB Background: Osteoporosis and osteoporotic fractures are widely known as complications of rheumatoid arthritis. Kyphoplasty (KP) is known as an effective treatment modality for reducing pain and correcting kyphotic deformity in osteoporotic vertebral compression fracture (OVCF). However, cutcomes of KP in rheumatoid patients are not well known. The purpose of the study was to investigate the clinical and radiological outcomes of balloon KP on OVCF in patients with rheumatoid arthritis. Methods: A total of 23 patients (31 vertebral bodies) with rheumatoid arthritis who received KP for OVCF and could be followed up for at least 1 year were examined. For clinical outcomes, visual analogue scale (VAS) and the Korean version of the Oswestry disability index (KODI) were evaluated. For radiological outcomes, changes in anterior vertebral height and local kyphotic angle were measured, alongside cement leakage, adjacent fracture, and the recollapse of cemented vertebra. Results: The anterior vertebral height was significantly restored after surgery compared with prior to surgery ($p < 0.001$). Cement leakage was found in 14 cases (45.1 %), and disc space leakage was prevalent (50 %), while vascular cement leakage was found in one case. Adjacent fracture was found in 3 patients (11.5 %). VAS for lumbago showed a significant decrease ($p < 0.001$) after surgery (VAS = 2.4) compared with that before (VAS = 8.1); it was somewhat increased after the 1-year follow-up (VAS = 2.8; $p = 0.223$). KODI also decreased (48.8 %) after surgery compared with before (84.6 %). However, it increased somewhat (49.9 %) after the 1-year follow-up. Conclusion: KP on rheumatoid arthritis patients for OVCF was effective for reducing pain in the early stage and restoring vertebral body height. Recollapse of the treated vertebral body was found relatively frequently alongside the correction loss of local kyphotic angle.

TI Silencing of Wnt5a prevents interleukin-1β-induced collagen type II degradation in rat chondrocytes
SO EXPERIMENTAL AND THERAPEUTIC MEDICINE
LA English
DT Article
DE osteoarthritis; Wnt5a signaling pathway; small interfering RNA; gene silencing; collagen type II

ID cartilage degeneration; osteoarthritis; expression; osteoporosis; arthritis; therapy; culture; wnt-5a; cells; model
AB Osteoarthritis (OA) is a joint disease, and few treatments to date have been able to delay OA progression. The degradation of collagen type II (COL2) in the cartilage matrix is an important initiating factor for OA progression; the upregulation of Wnt5a protein activates COL2 degradation. In the present study, small interfering RNA of Wnt-5a was delivered by a lentiviral vector (LV-Wnt5a-RNAi) to silence Wnt-5a mRNA and prevent COL2 degradation. To determine the function of LV-Wnt5a-RNAi, the OA chondrocyte model (OA-like chondrocytes) were constructed using interleukin (IL)-1 beta. Detected using reverse transcription-quantitative polymerase chain reaction (RT-qPCR), Wnt-5a mRNA in the OA-like chondrocytes were upregulated in a time-dependent manner, indicating that OA-like chondrocytes were successfully constructed. The bioactivity of OA-like chondrocytes was determined using Live-Dead staining, and the result illustrated that the OA-like chondrocytes stimulated with IL-1 beta for 6 h remained viable, and these were used in Wnt5a silencing. The OA-like chondrocytes were divided into three groups: Group I, cultivated with common medium; group II, cultivated with common medium supplemented with empty lentiviral vector; group III, cultivated with common medium supplemented with LV-Wnt5a-RNAi. The efficiency of LV-Wnt5a-RNAi transfection was determined using fluorescence microscopy, the result of which indicated that LV-Wnt5a-RNAi could efficiently be transfected into the OA-like chondrocytes. The LV-Wnt5a-RNAi efficiency for the Wnt5a mRNA silencing was determined using RT-qPCR. The result illustrated that the mRNA of Wnt5a in group III was significantly lower in group I compared with that in group II ($P<0.05$), indicating that the LV-Wnt5a-RNAi could successfully silence Wnt5a mRNA. To further verify whether the silencing of Wnt5a mRNA could prevent COL2 degradation, western blotting and immunohistochemical analyses were performed. The results demonstrated that COL2 in group III was significantly higher compared with that in groups I and II ($P<0.05$), which illustrated that the silencing of Wnt5a mRNA could prevent COL2 degradation. In conclusion, LV-Wnt5a-RNAi was formed successfully and could efficiently silence Wnt5a mRNA expressed by OA-like chondrocytes. In addition, the silencing of Wnt5a mRNA could prevent the degradation of COL2 in OA-like chondrocytes, confirming that LV-Wnt5a-RNAi may be used as a novel tool for OA treatment.

TI Novel effects of sarcopenic osteoarthritis on metabolic syndrome, insulin resistance, osteoporosis, and bone fracture: the national survey
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE Insulin resistance; Metabolic syndrome; Osteoarthritis; Sarcopenia
ID skeletal-muscle mass; knee osteoarthritis; mineral density; prospective cohort; body-composition; korean adults; visceral fat; obesity; association; prevalence
AB This study compared the effects sarcopenic osteoarthritis on metabolic syndrome, insulin resistance, osteoporosis, and bone fracture. By using national survey data, we suggest that the relationship between sarcopenia and metabolic syndrome or insulin resistance is potentiated by the severity of osteoarthritis and is independent of body weight. Sarcopenia and osteoarthritis are known risk factors for metabolic syndrome. However, their combined effects on metabolic syndrome, insulin resistance and osteoporosis remain uncertain. We used data from the fifth Korean National Health and Nutrition Examination Survey using a total of 3158 adults (age > 50 years). Sarcopenia was defined as a skeletal muscle index score (appendicular skeletal muscle mass/body weight) within the fifth percentile of

sex-matched younger reference participants. Radiographic knee osteoarthritis was defined as a Kellgren-Lawrence (K-L) grade of 2 or greater. Metabolic syndrome was diagnosed using the National Cholesterol Education Program criteria. Insulin resistance was evaluated using the homeostasis model assessment-estimated insulin resistance index (HOMA-IR). Osteoporosis was defined using the World Health Organization T-score criteria. In multivariable logistic regression analysis, the sarcopenic osteoarthritis group had a higher odds ratio (OR) for metabolic syndrome (OR = 11.00, 95 % confidential interval (CI) = 2.12-56.99, p = 0.013) than the non-sarcopenic osteoarthritis (OR = 1.02, 95 % CI = 0.65-1.62, p = 0.972) and sarcopenic non-osteoarthritis groups (OR = 7.15, 95 % CI = 1.57-32.53, p = 0.027). Similarly, sarcopenic osteoarthritis had a greater OR of highest HOMA-IR quartiles (OR = 8.19, 95 % CI = 2.03-33.05, p = 0.003) than the other groups. Overall, the association between the K-L grade and body mass index was significant; however, this significance was lower in individuals with sarcopenia and was lost in those with sarcopenic osteoarthritis. Additionally, osteoporosis and bone fracture were not associated to sarcopenic osteoarthritis (p > 0.05). These results suggest that the relationship between sarcopenia and metabolic syndrome or insulin resistance is potentiated by the severity of osteoarthritis and is independent of body weight.

TI Osteoarthritis guidelines: Barriers to implementation and solutions
SO ANNALS OF PHYSICAL AND REHABILITATION MEDICINE
LA English
DT Review
DE Osteoarthritis; Clinical practice guidelines; Implementation
ID nonpharmacological core management; knee osteoarthritis; eular recommendations; european-society; economic-aspects; hip; care; osteoporosis; epidemiology
AB Osteoarthritis (OA) is a leading cause of disability worldwide. Clinical practice guidelines (CPGs) have been developed to facilitate improved OA management. Scientific communities worldwide have proposed CPGs for OA treatment. Despite the number of highly prominent guidelines available and their remarkable consistency, their uptake has been suboptimal. Possibly because of the multitude of barriers related to the implementation of CPGs. For example, different guidelines show contradictions, some lack evidence, and they lack a hierarchy or tools to facilitate their translation and application. Also, the guidelines do not acknowledge the effect of comorbidities on choosing the treatments. Finally, poor integration of multidisciplinary services within and across healthcare settings is a major barrier to the effective implementation of management guidelines. Here we describe the main problems related to the OA guidelines and some solutions so as to offer some guidance on the elaboration of future CPGs and their implementation in primary care. TI Calcitonin attenuates cartilage degeneration and nociception in an experimental rat model of osteoarthritis: role of TGF-β in chondrocytes
SO SCIENTIFIC REPORTS
LA English
DT Article
ID canine experimental osteoarthritis; growth-factor-beta; articular-cartilage; salmon-calcitonin; postmenopausal women; osteophyte formation; ovariectomized rats; ii degradation; bone changes; pain
AB We investigated the role of the calcitonin (Miacalcin) in the progression of osteoarthritis (OA) and in nociceptive behavior in an experimental rat model of OA and osteoporosis. OA was induced by anterior cruciate ligament transection (ACLT)

of the right knee and by bilateral ovariectomy (OVX) in Wistar rats. Nociceptive behaviors (secondary mechanical allodynia and weight-bearing distribution of the hind paws) were analyzed prior to surgery and every week, beginning at 12 weeks after surgery, up to 20 weeks. At 20 weeks, histopathological studies were performed on the cartilage of the knee joints. Immunohistochemical analysis was performed to examine the effect of calcitonin on transforming growth factor (TGF)-beta 1 expression in articular cartilage chondrocytes. Rats subjected to ACLT + OVX surgery showed obvious OA changes in the joints. Animals subjected to ACLT + OVX and treated with calcitonin showed significantly less cartilage degeneration and improved nociceptive tests compared with animals subjected to ACLT + OVX surgeries alone. Moreover, calcitonin increased TGF-beta 1 expression in chondrocytes in ACLT + OVX-affected cartilage. Subcutaneous injection of calcitonin (1) attenuated the development of OA, (2) concomitantly reduced nociception, and (3) modulated chondrocyte metabolism, possibly by increasing cellular TGF-beta 1 expression.

TI Correlation between neuropeptide distribution, cancellous bone microstructure and joint pain in postmenopausal women with osteoarthritis and osteoporosis
SO NEUROPEPTIDES
LA English
DT Article
DE Osteoarthritis; Osteoporosis; Neuropeptide; Microstructure; Pain
ID gene-related peptide; vasoactive-intestinal-peptide; necrosis-factor-alpha;

spinal-cord-injury; substance-p; in-vitro; biomechanical property; rheumatoid-arthritis; subchondral bone; rat model
AB Objectives: To explore the relationship between the distribution of neuropeptides, cancellous bone microstructure and joint pain in postmenopausal women with osteoarthritis (OA) and osteoporosis (OP). Methods: Cancellous bone of the femoral head was obtained at the time of hip arthroplasty from 20 postmenopausal women, 10 with OA and 10 with OP. Pain intensity was evaluated using the visual analog scale (VAS) before the operation. The microstructural parameters were measured with micro-CT and the neuropeptides of the cancellous bone were stained by an immunohistochemical method. Results: We observed that BV/TV, Tb.Th and Th.N values in the OP were significantly decreased compared to those in the OA. Immunohistochemical analysis revealed that the mean optical density (MOD) values for SP, CGRP, and VIP in the OA group were significantly higher than those in the OP, and the MOD value for NPY in the OA was significantly lower than that in the OP. We also observed that the MOD values for SP were positively correlated with AD, BV/TV, Tb.Th, Tb.N and Conn.D and negatively with MD, Tb.Sp and SMI in all patients. The MOD values for CGRP were positively correlated with AD, BV/TV and Tb.Th. MOD values for VIP were positively correlated with BV/TV and Tb.Th and negatively with SMI. The VAS score was correlated positively with the MOD values for SP, CGRP, VIP and negatively with NPY in all patients. Conclusions: Neuropeptides play an important role in the pathogenesis of OA and OP, which may cause pain and influence the bone microstructure. (C) 2015 Elsevier Ltd. All rights reserved.

TI Association Between Physical Therapy and Risk of Coronary Artery Disease and Dyslipidemia Among Osteoarthritis Patients: A Nationwide Database Study
SO ARCHIVES OF PHYSICAL MEDICINE AND REHABILITATION
LA English
DT Article
DE Comorbidity; Dyslipidemias; Osteoarthritis; Physical therapy modalities; Rehabilitation
ID cross-sectional analysis; whole-body vibration; bone-density; older-adults; exercise; population; knee; interventions; health; individuals
AB Objective: To provide empirical evidence on the effect of early physical therapy (PT) within the first year of osteoarthritis (OA) diagnosis on reduction in OA-related comorbidities in patients with OA. Design: Retrospective cohort study. Setting: The study was conducted using a nationally representative sample of 1 million National Health Insurance enrollees. Participants: Newly diagnosed patients with OA (N=13,545). One-to-one propensity score matching was used to match patients who received PT within the first year of OA diagnosis (PT group; n=3403) with an equal number of patients with OA who did not receive PT (non-PT group). Interventions: Not applicable. Main Outcome Measures: The 4-year cumulative risk of comorbidities including coronary artery disease (CAD), diabetes mellitus, dyslipidemia, osteoporosis, gastrointestinal tract ulcer, and renal failure was estimated. A Cox proportional hazards regression analysis was performed to identify the dose-response relation between the PT dosage and the risk of OA-related comorbidities. Results: A total of 3403 patients (25.1%) received PT within the first year of OA diagnosis. The PT group had a significantly lower 4-year cumulative risk of dyslipidemia (P=.05) and a potentially lower 4-year cumulative risk of CAD (P=.09). After adjusting for other potential confounders, the Cox proportional hazards regression analysis showed that patients with OA who received a high PT dosage had a low risk of CAD and dyslipidemia. Conclusions: Patients with OA who received PT had a lower risk of OA-related comorbidities such as dyslipidemia or CAD. (C) 2016 by the American Congress of Rehabilitation Medicine

DT Review
DE Bone; fat; MAPK phosphatase-1; muscle; pathophysiology; signaling
ID cyclooxygenase-2 messenger-rna; innate immune-responses; hormone-related protein; skeletal-muscle differentiation; distinct signaling pathways; osteoblast gene-expression; focal adhesion kinase; map kinase; parathyroid-hormone; adipocyte differentiation
AB In this review, we have highlighted work that has clearly demonstrated that mitogen-activated protein kinase (MAPK) phosphatase-1 (MKP-1), a negative regulator of MAPKs, is an important signaling mediator in bone, muscle, and fat tissue homeostasis and differentiation. Further, we examined recent studies with particular focus on MKP-1 overexpression or deletion and its impact on tissues connected to bone. We also summarized regulation of MKP-1 by known skeletal regulators like parathyroid hormone (PTH)/PTH-related peptide (PTHrP) and bone morphogenic proteins. MKP-1's integration into the pathophysiological state of osteoporosis, osteoarthritis, rheumatoid arthritis, obesity, and muscular dystrophy are examined to emphasize possible involvement of MKP-1 both at the molecular level and in disease complications such as sarcopenia- or diabetes-related osteoporosis. We predict that understanding the mechanism of MKP-1-mediated signaling in bone-muscle-fat crosstalk will be a key in coordinating their activities and developing therapeutics to improve clinical outcomes for diseases associated with advanced age.

TI miRNAs Related to Skeletal Diseases
SO STEM CELLS AND DEVELOPMENT
LA English

DT Review
ID mesenchymal stem-cells; fatty-acid synthase; article. see april; suppresses osteogenic differentiation; regulates chondrogenic differentiation; pre-osteoblast differentiation; osteosarcoma tumor-growth; down-regulation; microrna expression; circulating micrornas
AB miRNAs as non-coding, short, double-stranded RNA segments are important for cellular biological functions, such as proliferation, differentiation, and apoptosis. miRNAs mainly contribute to the inhibition of important protein translations through their cleavage or direct repression of target messenger RNAs expressions. In the last decade, miRNAs got in the focus of interest with new publications on miRNAs in the context of different diseases. For many types of cancer or myocardial damage, typical signatures of local or systemically circulating miRNAs have already been described. However, little is known about miRNA expressions and their molecular effect in skeletal diseases. An overview of published studies reporting miRNAs detection linked with skeletal diseases was conducted. All regulated miRNAs were summarized and their molecular interactions were illustrated. This review summarizes the involvement and interaction of miRNAs in different skeletal diseases. Thereby, 59 miRNAs were described to be deregulated in tissue, cells, or in the circulation of osteoarthritis (OA), 23 miRNAs deregulated in osteoporosis, and 107 miRNAs deregulated in osteosarcoma (OS). The molecular influences of miRNAs regarding OA, osteoporosis, and OS were illustrated. Specific miRNA signatures for skeletal diseases are described in the literature. Some overlapped, but also unique ones for each disease exist. These miRNAs may present useful targets for the development of new therapeutic approaches and are candidates for diagnostic evaluations.

TI Efficacy and safety of glucosamine sulfate in the management of osteoarthritis: Evidence from real-life setting trials and surveys
SO SEMINARS IN ARTHRITIS AND RHEUMATISM
LA English
DT Review
DE Chondroitin; Glucosamine; Knee osteoarthritis; Symptomatic slow-acting drugs for osteoarthritis (SYSADOAs)
ID placebo-controlled trials; controlled clinical-trial; total joint replacement; knee osteoarthritis; chondroitin sulfate; double-blind; cartilage explants; metaanalysis; progression; recommendations
AB The European Society for Clinical and Economic Aspects of Osteoporosis and Osteoarthritis (ESCEO) treatment algorithm recommends chronic symptomatic slow-acting drugs for osteoarthritis (SYSADOAs) including glucosamine sulfate (GS) and chondroitin sulfate (CS) as first-line therapy for knee osteoarthritis (OA). Numerous studies are published on the use of SYSADOAs in OA; however, the efficacy of this class is still called into question largely due to the regulatory status, labeling and availability of these medications which differ substantially across the world. Examination of the evidence for the prescription patented crystalline GS (pCGS) formulation at a dose of 1500 mg once-daily demonstrates superiority over other GS and glucosamine hydrochloride (GH) formulations and dosage regimens.

Thus, the ESCEO task force advocates differentiation of prescription pCGS over other glucosamine preparations. Long-term clinical trials and real-life studies show that pCGS may delay joint structural changes, suggesting potential benefit beyond symptom control when used early in the management of knee OA. Real-life pharmacoeconomic studies demonstrate a long-term reduction in the need for additional pain analgesia and non-steroidal anti-inflammatory drugs (NSAIDs) with pCGS, with a significant reduction of over 50% in costs associated with medications, healthcare consultations and examinations over 12 months. Furthermore, treatment with pCGS for at least 12 months leads to a reduction in the need for total joint replacement for at least 5 years following treatment cessation. Thus, pCGS (1500 mg od) is a logical choice to maximize clinical benefit in OA patients, with demonstrated medium-term control of pain and lasting impact on disease progression. (C) 2015 The Authors. TI Reduced Sirtuin1 expression at the femoral neck in women who sustained an osteoporotic hip fracture
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE d Femoral neck; Osteoarthritis; Osteoporotic hip fracture; Sclerostin; Sirtuin1
ID bone-formation; beta-catenin; sirt1; osteoarthritis; sclerostin; regulator; mass
AB To investigate the role of Sirtuin1 in osteoporosis, Sirtuin1 was determined at the femoral neck in female patients undergoing hip operation for fractured hip or osteoarthritis. Reduced Sirtuin1 was found in osteoporotic patients. Pharmacologic activation of Sirtuin1 reduced sclerostin, an inhibitor of bone formation. Activation of Sirtuin1 may be a new direction to generate therapies for osteoporosis. The aim of the study are to investigate the role of Sirtuin1 (Sirt1), an anti-aging factor and a player in age-associated diseases, in osteoporotic hip fractures, and test the hypothesis that Sirt1 is a negative regulator of sclerostin, a bone formation inhibitor, in human femoral bone marrow mesenchymal cells (BM-MSCs). Sirt1 and sclerostin were determined by western blot in bone samples obtained intra-operatively from the inferior medial cortex of the femoral neck (calcar region) in female patients undergoing partial hip replacement for fractured neck of femur (N = 10) or hip replacement for osteoarthritis (N = 8) (mean +/- SD age 81 +/- 8.1 vs. 68 +/- 9.3 years; BMI 26.2 +/- 3.6 vs. 25.9 +/- 7.1 kg/m(2) in osteoporotic and osteoarthritis patients). Calcar thickness and femoral bone mineral density (BMD) were determined preoperatively by X-ray using a digital TraumaCad((TM)) software and DEXA. Femoral BM-MSCs were collected intra-operatively and treated with SRT3025, a Sirt1 activator. Sclerostin and dentin matrix acidic phosphoprotein (DMP1) were determined by western blot and messenger RNA (mRNA) expression of Lef1 and DMP1 was evaluated by quantitative real-time PCR. Osteoporotic (OP) patients had reduced cortical thickness, femoral neck, and total hip BMD compared

to osteoarthritis (OA) patients. Calcar Sirt1 expression was significantly reduced, while sclerostin was markedly increased in OP compared to OA patients. Sirt1 and sclersotin expressions were inversely correlated (r = -0.49, P = 0.047). SRT3025 administration down-regulated sclerostin and up-regulated DMP1 protein level and increased LEF1 and DMP1 mRNA expressions in OP patient-derived BM-MSCs. Reduced femoral neck Sirt1 may play a role in osteoporotic hip fractures in part via influencing local sclerostin expression. The therapeutic potential of Sirt1 activation in osteoporosis warrants further investigation.

TI Romosozumab Treatment in Postmenopausal Women with Osteoporosis
SO NEW ENGLAND JOURNAL OF MEDICINE
LA English
DT Article
ID bone-formation; fracture; sclerostin; sost; wnt; teriparatide; density; protein; product; costs
AB BACKGROUND Romosozumab, a monoclonal antibody that binds sclerostin, increases bone formation and decreases bone resorption. METHODS We enrolled 7180 postmenopausal women who had a T score of -2.5 to -3.5 at the total hip or femoral neck. Patients were randomly assigned to receive subcutaneous injections of romosozumab (at a dose of 210 mg) or placebo monthly for 12 months; thereafter, patients in each group received denosumab for 12 months, at a dose of 60 mg, administered subcutaneously every 6 months. The coprimary end points were the cumulative incidences of new vertebral fractures at 12 months and 24 months. Secondary end points included clinical (a composite of nonvertebral and symptomatic vertebral) and nonvertebral fractures. RESULTS At 12 months, new vertebral fractures had occurred in 16 of 3321 patients (0.5%) in the romosozumab group, as compared with 59 of 3322 (1.8%) in the placebo group (representing a 73% lower risk with romosozumab; P<0.001). Clinical fractures had occurred in 58 of 3589 patients (1.6%) in the romosozumab group, as compared with 90 of 3591 (2.5%) in the placebo group (a 36% lower risk with romosozumab; P = 0.008). Nonvertebral fractures had occurred in 56 of 3589 patients (1.6%) in the romosozumab group and in 75 of 3591 (2.1%) in the placebo group (P = 0.10). At 24 months, the rates of vertebral fractures were significantly lower in the romosozumab group than in the placebo group after each group made the transition to denosumab (0.6% [21 of 3325 patients] in the romosozumab group

vs. 2.5% [84 of 3327] in the placebo group, a 75% lower risk with romosozumab; P<0.001). Adverse events, including instances of hyperostosis, cardiovascular events, osteoarthritis, and cancer, appeared to be balanced between the groups. One atypical femoral fracture and two cases of osteonecrosis of the jaw were observed in the romosozumab group. CONCLUSIONS In postmenopausal women with osteoporosis, romosozumab was associated with a lower risk of vertebral fracture than placebo at 12 months and, after the transition to denosumab, at 24 months. The lower risk of clinical fracture that was seen with romosozumab was evident at 1 year.

TI The effect of sphingosine-1-phosphate on bone metabolism in humans depends on its plasma/bone marrow gradient
SO JOURNAL OF ENDOCRINOLOGICAL INVESTIGATION
LA English
DT Article
DE Plasma S1P; Bone marrow S1P; Gradient; Hip fracture; Osteoporosis
ID sphingosine 1-phosphate levels; postmenopausal women; osteoblastic cells; osteoclast differentiation; mineral density; osteoporosis; fracture; homeostasis; prevention; receptors
AB Background Although recent studies provide clinical evidence that sphingosine-1-phosphate (S1P) may primarily affect bone resorption in humans, rather than bone formation or the osteoclast-osteoblast coupling phenomenon, those studies could not determine which bone resorption mechanism is more important, i.e., chemorepulsion of osteoclast precursors via the blood to bone marrow S1P gradient or receptor activator of NF-kappa B ligand (RANKL) elevation in osteoblasts via local S1P. Aim To investigate how S1P mainly contributes to increased bone resorption in humans, we performed this case-control study at a clinical unit in Korea. Methods Blood and bone marrow samples were contemporaneously collected from 70 patients who underwent hip surgery due to either osteoporotic hip fracture (HF) (n = 10) or other causes such as osteoarthritis (n = 60). Results After adjusting for sex, age, BMI, smoking, alcohol, previous

fracture, diabetes, and stroke, subjects with osteoporotic HF demonstrated a 3.2-fold higher plasma/bone marrow S1P ratio than those without HF, whereas plasma and bone marrow S1P levels were not significantly different between these groups. Consistently, the risk of osteoporotic HF increased 1.38-fold per increment in the plasma/bone marrow S1P ratio in a multivariate adjustment model. However, the odds ratios for prevalent HF according to the increment in the plasma and bone marrow S1P level were not statistically significant. Conclusion Our current results using simultaneously collected blood and bone marrow samples suggest that the detrimental effects of S1P on bone metabolism in humans may depend on the S1P gradient between the peripheral blood and bone marrow cavity.

ID idiopathic skeletal hyperostosis; mineral density; cortical bone; radiographic absorptiometry; postmenopausal women; logistic-regression; spinal involvement; osteoarthritis; prevalence; dish
AB ObjectivesRecent biomedical research suggests that, in modern human populations, individuals may vary in their inherent tendency toward bone formation at skeletal and extra-skeletal locations. However, the nature of this phenomenon is incompletely understood, and the extent to which it might apply to past populations is unclear. It is hypothesized that if there is inter-individual variation in some overall tendency toward bone formation in skeletal and extra-skeletal sites then there should be a positive relationship between ligamentous ossification and thickness of cortical bone. This work is a test of this hypothesis in an archaeological population. Materials and MethodsThe study material comprises adult skeletons (N=137 individuals) of documented age at death from 18th to 19th century London. It examines the relationship between bone deposition in the anterior longitudinal ligament (ALL) in the thoracic spine and cortical index (CI) at the metacarpal measured by radiogrammetry. ResultsControlling for the potential confounders age, sex, skeletal completeness, occupation (males) and parity (females), there was a positive association between ossification into the ALL and CI. This reflects lesser medullary cavity width in those showing ALL ossification. DiscussionLigamentous ossification in the axial skeleton and peripheral cortical bone status are linked, individuals with ALL ossification showing lesser resorption of cortical bone at the endosteal surface. This is consistent with the idea of inter-individual variation in some general bone-forming/bone-losing tendency in this 200 year old study population, but there was no evidence of a link between ALL ossification and increased skeletal subperiosteal bone deposition. Am J Phys Anthropol 159:577-584, 2016. (c) 2015 The Authors American Journal of Physical Anthropology Published by Wiley Periodicals, Inc.

TI Solid-state NMR study of discrete environments of bone mineral nanoparticles using phosphorus-31 relaxation
SO JOURNAL OF APPLIED BIOMEDICINE
LA English
DT Article
DE Apatite; Bone; Nanomaterial; Osteoarthritis; Osteoporosis; Nuclear magnetic resonance
ID nuclear-magnetic-resonance; cortical bone; mas nmr; mechanical-property; postmenopausal women; reference intervals; cationic sites; femoral-head; bound water; in-vivo
AB Bone mineral nanoparticles, residing between collagenous fibres, contain a crystalline apatite core (CAC) covered by an amorphous hydrated surface layer (AHSL). The main objectives of this work were to characterize the nanoparticles of human bone mineral and their discrete CAC and AHSL regions and relate this

information to bone diseases. This pilot study involved 18 postmenopausal women suffering from osteoarthritis together with osteoporosis or osteopenia. Trabecular tissue specimens were acquired from the femoral intertrochanteric region during total hip arthroplasty. The specimens of whole bone were examined by P-31 solid-state NMR (ssNMR) to measure the concentration ratio of phosphorus in the AHSL and CAC locations, together with their P-31 linewidths and spin-lattice relaxation times. It was found that the AHSL region of the studied specimens contained 13-24% apatite phosphorus. The magnitude, hydration and structural order of AHSL and CAC were dependent on the progress of the pertinent diseases. Thus, the P-31 ssNMR spectroscopy can be used ex vivo to selectively analyse the discrete nanoapatite environments in whole bone specimens and possibly assist in postoperative medical diagnostics. TI Segmentation of joint and musculoskeletal tissue in the study of arthritis
SO MAGNETIC RESONANCE MATERIALS IN PHYSICS BIOLOGY AND MEDICINE
LA English
DT Review
DE MRI; Image segmentation; Osteoarthritis; Rheumatoid arthritis; Knee; Hip; Wrist
ID anterior cruciate ligament; early rheumatoid-arthritis; magnetic-resonance images; marrow edema pattern; of-the-art; mr-images; articular-cartilage; quantitative assessment; hip-joint; bone edema
AB As the most frequent cause of physical disability, musculoskeletal diseases such as arthritis and osteoporosis have a great social and economical impact. Quantitative magnetic resonance imaging (MRI) biomarkers are important tools that allow clinicians to better characterize, monitor, and even predict musculoskeletal disease progression. Post-processing pipelines often include image segmentation. Manually identifying the border of the region of interest (ROI) is a difficult and time-consuming task. Manual segmentation is also affected by inter- and intrauser variability, thus limiting standardization. Fully automatic or semi-automatic methods that minimize the user interaction are highly desirable. Unfortunately, an ultimate, highly reliable and extensively evaluated solution for joint and musculoskeletal tissue segmentation has not yet been proposed, and many clinical studies still adopt fully manual procedures. Moreover, the clinical translation of several promising quantitative MRI techniques is highly affected by the lack of an established, fast, and accurate segmentation method. The goal of this review is to present some of the techniques proposed in recent literature that have been adopted in clinical studies for joint and musculoskeletal tissue analyses in arthritis patients. The most widely used MRI sequences and image processing algorithms employed to accomplish segmentation challenges will be discussed in this paper.

TI Non-Communicable Disease Clinical Practice Guidelines in Brazil: A Systematic Assessment of Methodological Quality and Transparency
SO PLOS ONE
LA English
DT Article
ID agree ii; primary-care; multimorbidity; management; appraisal; china; instrument
AB Background Annually, non-communicable diseases (NCDs) kill 38 million people worldwide, with low and middle-income countries accounting for three-quarters of these deaths. High-quality clinical practice guidelines (CPGs) are fundamental to improving NCD management. The present study evaluated the methodological rigor and transparency of Brazilian CPGs that recommend pharmacological treatment for the most prevalent NCDs. Methods We conducted a systematic search for CPGs of the following NCDs: asthma, atrial fibrillation, benign prostatic hyperplasia, chronic obstructive pulmonary disease, congestive heart failure, coronary artery disease and/or stable angina, dementia, depression, diabetes, gastroesophageal reflux disease, hypercholesterolemia, hypertension, osteoarthritis, and osteoporosis. CPGs comprising pharmacological treatment recommendations were included. No language or year restrictions were applied. CPGs were excluded if they were merely for local use and referred to NCDs not listed above. CPG quality was independently assessed by two reviewers using the Appraisal of Guidelines Research and Evaluation instrument, version II (AGREE II).

Main Findings "Scope and purpose" and "clarity and presentation" domains received the highest scores. Sixteen of 26 CPGs were classified as low quality, and none were classified as high overall quality. No CPG was recommended without modification (77% were not recommended at all). After 2009, 2 domain scores ("rigor of development" and "clarity and presentation") increased (61% and 73%, respectively). However, "rigor of development" was still rated <30%. Conclusion Brazilian healthcare professionals should be concerned with CPG quality for the treatment of selected NCDs. Features that undermined AGREE II scores included the lack of a multidisciplinary team for the development group, no consideration of patients' preferences, insufficient information regarding literature searches, lack of selection criteria, formulating recommendations, authors' conflict of interest disclosures, and funding body influence.

TI Phase IV randomized preference study in patients eligible for calcium and vitamin D supplementation
SO CURRENT MEDICAL RESEARCH AND OPINION
LA English
DT Article
DE Acceptability; Calcium; Osteoporosis; Preference; Supplement; Vitamin D
ID cost-effectiveness; european-society; economic-aspects; dairy-products; osteoporotic fractures; postmenopausal women; plus vitamin-d-3; prevention; health; osteoarthritis
AB Introduction/objectives: Preference for supplement formulation helps determine an individual's adherence to long-term medication and can improve clinical benefit for chronic illnesses such as osteoporosis. This study compared the preference, acceptability and tolerability of a reformulation of Calcichew D3(1) 500mg/400IU and Calcichew D3 500mg/800IU (Takeda UK Ltd, Wobrun Green, UK) with Adcal-D3(2) 500mg/400IU (ProStrakan Ltd, Galashiels, UK) and Kalcipos-D 500mg/800IU (Meda Pharmaceuticals Ltd, Bishop's Stortford, UK), respectively.Method: This phase IV, randomized, open-label, two-period, cross-over study was conducted at nine sites in the UK and Germany. Eligible subjects (65 years requiring calcium/vitamin D supplementation for prevention/treatment of deficiencies, or 18 years requiring supplementation as an adjunct to osteoporosis treatment) were randomly assigned to one of two 2 week treatment sequences - Group 1: Calcichew D3 500/400 then Adcal-D3 500/400 (or vice versa), or Group 2: Calcichew D3 500/800 then Kalcipos-D 500/800 (or vice versa). After each treatment period, patients rated the treatment for acceptability using 100mm visual analogue scales. After the second treatment period, patients indicated their treatment preference. The primary endpoint, the percentage of patients with a preference for each treatment, was analyzed with a logistic regression model.Results: Two hundred and seventy-six patients were randomly assigned by treatment sequence, 138 to each group. Preference questionnaires among patients who preferred Calcichew or comparator revealed the odds for patients preferring Calcichew 500/400 (77.6%) over Adcal-D3 was 3.46 ([95% CI 2.24, 5.36], $p<0.001$) in Group 1, and Calcichew D3 500/800 (63.2%) over Kalcipos-D was 1.72 ([1.19, 2.47], $p=0.004$) in Group 2. Adverse events were mostly gastrointestinal and were comparable between groups. The new formulation of Calcichew D3 is acceptable and consistent with its known tolerability profile.Conclusions: In this short-term 30day study, patients preferred Calcichew D3 500/400 and Calcichew D3 500/800 over respective comparators. A trend towards better compliance with Calcichew D3 preference observed in Group 1 warrants a longer term study to identify treatment compliance.Trial registration: Clinicaltrials.gov: NCT02457247.

TI Novel heterocyclic ring-fused oleanolic acid derivatives as osteoclast inhibitors for osteoporosis
SO MEDCHEMCOMM
LA English
DT Article
ID nitric-oxide production; ursane triterpenoids; synthetic oleanane; nfat; differentiation; molecules; pyrazole; targets; design; roles
AB Osteoporosis is a major public health problem in our aging society. In the present study, a series of novel oleanolic acid (OA) derivatives were synthesized via modifications in the A-ring and C-28 position of OA, and their anti-bone resorption activities were evaluated. Screening results revealed that most of the derivatives inhibited RANKL-induced osteoclast formation from RAW264.7 cells. Among the derivatives, 6g exhibited a potent inhibitory activity with an IC50 of 24 nM. Furthermore, 6g prevented ovariectomy-induced bone loss in rats. The preliminary mechanism investigation demonstrated that 6g suppressed the protein and mRNA expressions of c-Fos and NFATc1, and downregulated the mRNA of other osteoclastogenic markers. The results suggested that the OA derivatives might serve as potential leads for the development of novel agents for the treatment of osteoporosis.

TI Dual effect of WIN-34B on osteogenesis and osteoclastogenesis in cytokine-induced mesenchymal stem cells and bone marrow cells
SO JOURNAL OF ETHNOPHARMACOLOGY
LA English
DT Article
DE WIN-34B; Osteogenesis; Osteoclastogenesis; Mesenchymal stem cells; Bone marrow cells; Osteoporosis
ID in-vitro; osteoporosis; differentiation; phosphorylation; osteoarthritis; mineralization; activation; pathways; therapy; runx2
AB Ethnopharmacological relevance: As an n-butanol fractionated extracted mixture of Lonicera japonica Thunb, dried flowers and Anemarrhena asphodeloides Bunge, root, WIN-34B has been reported the analgesic, anti-inflammatory, cartilage-repairing and protective effects in previous studies. Aim of the study: To investigate the effect of WIN-34B on osteogenesis and osteoclastogenesis in cytokine-induced mesenchymal stem cells and bone marrow cells. Materials and methods: To examine the effect of WIN-34B on osteogenic differentiation, human mesenchymal stem cells (hMSCs) were treated with WIN-34B (1 mu g/mL and 10 mu g/mL). Alkaline phosphatase (ALP) activity was evaluated and Von Kossa staining was conducted. Mice bone marrow macrophages (BMMs) were obtained and treated with receptor activator of nuclear factor-kappa B ligand (RANKL) and macrophage colony stimulating factor (m-CSF) to induce osteoclastogenesis. To investigate osteoclast differentiation, tartrate-resistant acid phosphatase (TRAP) staining was conducted after treatment with WIN-34B. Osteoclastogenic conditions were induced by stimulating the cells with interleukin (IL)-1 alpha, IL-17, and tumor necrosis factor (TNF-alpha) in hMSCs and BMMs co-culture systems. The expression levels of osteoprotegerin (OPG), RANKL, runt-related transcription factor 2 (RUNX2), IL-17, c-Fos, TNF-alpha, and glyceraldehyde-3-phosphate dehydrogenase (GAPDH) were measured by reverse transcription polymerase chain reaction (RT-PCR). The expression levels of nuclear factor-kappaB (NF-KB), inhibitory kappa B-alpha (I kappa B alpha), phospho-NF-kappa B, phospho-I kappa B alpha, beta-actin, p38 MAPK, phospho-c-Jun N-terminal kinase UNK), phospho-extracellular-signal regulated kinase (ERK), phospho-p38 mitogen-activated protein kinase (MAPK), phospho-JNK, and phospho-ERK were measured by western blot analysis. Results: WIN-34B promoted ALP activity and mineralization of hMSCs. In TRAP-stained BMMs, the number of multinucleated cells decreased after WIN-34B treatment. WIN-34B increased the OPG/RAN-KL ratio and the expression of RUNX2, and suppressed the expression of IL-17, c-Fos, and TNF-alpha. It also suppressed the activation of NF-kappa B, I kappa B alpha, p38 MAPK, and JNK in a dose-dependent manner. Conclusions: These results

demonstrated that WIN-34B increased osteogenesis and decreased osteoclastogenesis in cytokine-induced mesenchymal stem cells and bone marrow cells via inhibition of the NF-kappa B, JNK, and p38 MAPK pathways. (C) 2016 Elsevier Ireland Ltd. All rights reserved.

TI Robust and stimuli-responsive POSS hybrid PDMAEMA hydrogels for controlled drug release
SO JOURNAL OF BIOMEDICAL MATERIALS RESEARCH PART A
LA English
DT Article
DE POSS; double stimulus responsiveness; nanocomposite hydrogels; drug release
ID polyhedral oligomeric silsesquioxane; delivery; poly(n-isopropylacrylamide); nanocomposites; nanoparticles; polymers; carriers
AB A new polyhedral oligomeric silsesquioxane (POSS) hybrid hydrogels were desinged and fabricated by introducing cationic octa-ammonium (Oa)-POSS) into chemically cross-linked cationic PDMAEMA hydrogels via in situ radical freezing polymerization. The prepared gels (shorten as OP-PD gels) show considerably improved properties through the effective incorporation and dispersion of Oa-POSS particles in gels. Comparing to the Oa-POSS-free gels, the hybrid gels own better mechanical properties with higher tensile and compressive strength. Meantime, except the decreased swelling ratio in acid condition, the OP-PD gels still keep excellent swelling ability with obvious pH and temperature double responsiveness, which is affected by the content of Oa-POSS slightly. All OP-PD gels exhibit an ultrarapid deswelling rate due to the interconnected micropores structure caused by freezing and the formation of microhydrophobic region around POSS particles. Moreover, the application potential of OP-PD gels in drug release was exploited by using flutamide as target drug, the result showed that the increased Oa-POSS could improve the drug loading ability, and OP-PD gels showed well controlled-release effect in simulated human stomachic condition. TI Microhardness of human cancellous bone tissue in progressive hip osteoarthritis
SO JOURNAL OF THE MECHANICAL BEHAVIOR OF BIOMEDICAL MATERIALS
LA English
DT Article
DE Microhardness; Osteoarthritis; Hip; Cancellous bone; Mineralization
ID mechanical-property; trabecular bone; femoral-head; hardness; osteoporosis; microindentation
AB Bone tissue is a biological system in which the dynamic processes of, among others, bone formation or internal reconstruction will determine the spatial structure of the tissue and its mechanical properties. The appearance of a factor disturbing the balance between biological processes, e.g. a disease, will cause changes in the spatial structure of bones, thus affecting its mechanical properties. One of the bone diseases most common in an increasingly ageing population is osteoarthritis, also referred to as degenerative joint disease. It is estimated that in 2050 about 1300 million people will show symptoms of OA. The appearance of a

pathological stimulus disturbs the balance of the processes of degradation and synthesis of articular cartilage, chondrocytes and the extracellular matrix, and the subchondral bone layer. As osteoarthritis progresses, study of the epiphysis reveals increasingly widespread changes of the articular surface and the internal structure of bone tissue. In this paper, the authors point out the differences in the mechanical properties of cancellous bone tissue forming the proximal epiphysis of the femoral bone during the progressive stages of OA. In order to determine microproperties of bone trabeculae, specimens from different stages of the disease (N=9) were subjected to microindentation testing, which made it possible to determine the material properties of bone tissue, such as microhardness HV and Young's modulus E. In addition, mechanical tests were supplemented with Raman spectroscopy, which determine the degree of bone mineralization, and measurements of structural properties based on analysis using microCT. The conducted tests were used to establish both quantitative and quantitative description of changes in the structural and mechanical properties connected with reorganization of trabeculae making up the bone in the various stages of osteoarthritis. The proposed description will supplement existing knowledge in the literature about identification of the processes occurring during the development of this disease. (C) 2016 Elsevier Ltd. TI Celastrol, an NF-κB inhibitor, ameliorates hypercalciuria and articular cartilage lesions in a mouse model of secondary osteoporosis
SO JOURNAL OF PHARMACOLOGICAL SCIENCES
LA English
DT Article
DE Celastrol; NF-kappa B inhibitor; Secondary osteoporosis; Cartilage lesions
ID antiinflammatory activity; subchondral bone; i collagen; osteoarthritis; inflammation; degradation; suppression; activation; expression; turnover
AB Notwithstanding compelling contribution of NF-kappa B to the progression of osteoporosis has been reported, little is known regarding direct inhibition of NF-kappa B benefiting osteoporosis. In this study, therefore, we evaluated the role of celastrol, an NF-kappa B inhibitor, in a mouse model of secondary osteoporosis. Animals were divided into three groups as Sham (control), SO (secondary osteoporosis) and SO + CA (secondary osteoporosis treated with celastrol). Significant decreases in body weight and body fat were observed following celastrol treatment in SO group, but leptin levels were much higher. Celastrol also exhibited a significant decrease in urinary calcium excretion. Moreover, other important events were observed after celastrol treatment, covering substantial decrements in serum concentrations of PTH, TRAP-5b, CTX and DPD, improved structure of articular cartilage and cancellous bone (revealed by H&E and safranin-O staining), and significant decline in levels of NF-kappa B (P65), MMP-1, and MMP-9. These findings demonstrated that celastrol treatment not only improved abnormal lipid metabolism and hypercalciuria in mice subjected to secondary osteoporosis, but also ameliorated articular cartilage lesions. Our results provided evidence of targeted therapy for NF-kappa B in the clinical treatment of secondary osteoporosis. (C) 2016 The Authors. ID green-lipped mussel; bone-mineral density; proton pump inhibitors; c-reactive protein; gut microbiota; calcium-absorption; perna-canaliculus; rheumatoid-arthritis; mucosal inflammation; postmenopausal women
AB Recently, we have begun to realize that the billions of microorganisms living in symbiosis with us have an influence on disease. Evidence is mounting that the alimentary tract microbiome, in particular, influences both host metabolic potential and its innate and adaptive immune system. Inflammatory states characterize many bone and joint diseases of aging. This prompts the hypothesis that the gut microbiome could alter the inflammatory state of the individual and directly influence the development of these common and burdensome clinical problems. Because the microbiome is easily modifiable, this could have major therapeutic impact. This perspective discusses evidence to date on the role of the microbiome and the highly prevalent age-related disorders of osteoporosis, osteoarthritis, gout, rheumatoid arthritis, sarcopenia, and frailty. It also reviews data on the effects of probiotics and prebiotic interventions in animal and human models. Despite suggestive findings, research to date is not conclusive, and we identify priorities for research to substantiate and translate findings. (c) 2015 American Society for Bone and Mineral Research.

TI Metabolic analysis of osteoarthritis subchondral bone based on UPLC/Q-TOF-MS
SO ANALYTICAL AND BIOANALYTICAL CHEMISTRY
LA English
DT Article
DE Metabolomics; UPLC/Q-TOF-MS; Osteoarthritis; Subchondral bone; Metabolic pathways
ID magnetic-resonance-spectroscopy; mesenchymal stem-cells; l-carnitine fumarate; induced osteoporosis; knee osteoarthritis; hplc-ms; taurine; osteoblast; differentiation; cartilage
AB Osteoarthritis (OA), one of the most widespread musculoskeletal joint diseases among the aged, is characterized by the progressive loss of articular cartilage and

continuous changes in subchondral bone. The exact pathogenesis of osteoarthritis is not completely clear. In this work, ultra-performance liquid chromatography coupled with quadrupole time-of-flight tandem mass spectrometry (UPLC/Q-TOF-MS) in combination with multivariate statistical analysis was applied to analyze the metabolic profiling of subchondral bone from 42 primary osteoarthritis patients. This paper described a modified two-step method for extracting the metabolites of subchondral bone from primary osteoarthritis patients. Finally, 68 metabolites were identified to be significantly changed in the sclerotic subchondral bone compared with the non-sclerotic subchondral bone. Taurine and hypotaurine metabolism and beta-alanine metabolism were probably relevant to the sclerosis of subchondral bone. Taurine, l-carnitine, and glycerophospholipids played a vital regulation role in the pathological process of sclerotic subchondral bone. In the sclerotic process, beta-alanine and l-carnitine might be related to the increase of energy consumption. In addition, our findings suggested that the intra-cellular environment of sclerotic subchondral bone might be more acidotic and hypoxic compared with the non-sclerotic subchondral bone. In conclusion, this study provided a new insight into the pathogenesis of subchondral bone sclerosis. Our results indicated that metabolomics could serve as a promising approach for elucidating the pathogenesis of subchondral bone sclerosis in primary osteoarthritis.

TI Potential of PET-MRI for imaging of non-oncologic musculoskeletal disease
SO QUANTITATIVE IMAGING IN MEDICINE AND SURGERY
LA English
DT Review
DE Positron emission tomography-magnetic resonance imaging (PET-MRI); musculoskeletal imaging; nuclear medicine; arthritis; osteoporosis
ID positron-emission-tomography; early-stage osteoarthritis; contrast-enhanced mri; magnetic-resonance; in-vivo; rheumatoid-arthritis; attenuation correction; cartilage composition; f-18-fdg pet/mri; skeletal-muscle
AB Early detection of musculoskeletal disease leads to improved therapies and patient outcomes, and would benefit greatly from imaging at the cellular and molecular level. As it becomes clear that assessment of multiple tissues and functional processes are often necessary to study the complex pathogenesis of musculoskeletal disorders, the role of multi-modality molecular imaging becomes increasingly important. New positron emission tomography-magnetic resonance imaging (PET-MRI) systems offer to combine high-resolution MRI with simultaneous molecular information from PET to study the multifaceted processes involved in numerous musculoskeletal disorders. In this article, we aim to outline the potential clinical utility of hybrid PET-MRI to these non-oncologic musculoskeletal diseases. We summarize current applications of PET molecular imaging in osteoarthritis (OA), rheumatoid arthritis (RA), metabolic bone diseases and neuropathic peripheral pain. Advanced MRI approaches that reveal

biochemical and functional information offer complementary assessment in soft tissues. Additionally, we discuss technical considerations for hybrid PET-MR imaging including MR attenuation correction, workflow, radiation dose, and quantification.

TI Health benefits of tai chi What is the evidence?
SO CANADIAN FAMILY PHYSICIAN
LA English
DT Review
ID quality-of-life; practitioner-based complementary; obstructive pulmonary-disease; cognitive-behavioral therapy; randomized controlled-trial; improving aerobic capacity; coronary-heart-disease; older-adults; risk-factors; parkinsons-disease
AB Objective To summarize the evidence on the health benefits of tai chi. Sources of information A literature review was conducted on the benefits of tai chi for 25 specific conditions, as well as for general health and fitness, to update a 2014 review of systematic reviews. Systematic reviews and recent clinical trials were assessed and organized into 5 different groups: evidence of benefit as excellent, good, fair, or preliminary, or evidence of no direct benefit. Main message During the past 45 years more than 500 trials and 120 systematic reviews have been published on the health benefits of tai chi. Systematic reviews of tai chi for specific conditions indicate excellent evidence of benefit for preventing falls, osteoarthritis, Parkinson disease, rehabilitation for chronic obstructive pulmonary disease, and improving cognitive capacity in older adults. There is good evidence of benefit for depression, cardiac and stroke rehabilitation, and dementia. There is fair evidence of benefit for improving quality of life for cancer patients, fibromyalgia,

hypertension, and osteoporosis. Current evidence indicates no direct benefit for diabetes, rheumatoid arthritis, or chronic heart failure. Systematic reviews of general health and fitness benefits show excellent evidence of benefit for improving balance and aerobic capacity in those with poor fitness. There is good evidence for increased strength in the lower limbs. There is fair evidence for increased well-being and improved sleep. There were no studies that found tai chi worsened a condition. A recent systematic review on the safety of tai chi found adverse events were typically minor and primarily musculoskeletal; no intervention-related serious adverse events have been reported. Conclusion There is abundant evidence on the health and fitness effects of tai chi. Based on this, physicians can now offer evidence-based recommendations to their patients, noting that tai chi is still an area of active research, and patients should continue to receive medical follow-up for any clinical conditions.

DT Review
DE De novo degenerative lumbar scoliosis; Adult's scoliosis; Prognostic factors;

Curve progression; Systematic review
ID low-back; nonoperative treatment; health; adults; pain; osteoarthritis; prevalence; quality; burden; impact
AB To identify prognostic factors for curve progression in de novo degenerative lumbar scoliosis (DNDLS) by performing a systematic review of the literature. Studies were selected for inclusion following a systematic search in the bibliographic databases PubMed and EMBASE prior to September 2015 and hand searches of the reference lists of retrieved articles. Two authors independently assessed methodological quality. Data were extracted and presented according to a best evidence synthesis. The literature search generated a total of 2696 references. After removing duplicates and articles that did not meet inclusion criteria, 12 studies were included. Due to the lack of statistical analyses, pooling of data was not possible. Strong evidence indicates that increasing intervertebral disk degeneration, lateral vertebral translation a parts per thousand yen6 mm, and an intercrest line through L5 (rather than L4) are associated with DNDLS curve progression. Moderate evidence suggests that apical vertebral rotation Grade II or III is associated with curve progression. For the majority of other prognostic factors, we found limited, conflicting, or inconclusive evidence. Osteoporosis, a coronal Cobb angle < 30A degrees, lumbar lordosis, lateral osteophytes difference of a parts per thousand yen5 mm, and degenerative spondylolisthesis have not been shown to be risk factors. Clinical risk factors for progression were not identified. This review shows strong evidence that increased intervertebral disk degeneration, an intercrest line through L5, and apical lateral vertebral translation a parts per thousand yen6 mm are associated with DNDLS curve progression. Moderate evidence was found for apical vertebral rotation (Grade II/III) as a risk factor for curve progression. These results, however, may not be directly applicable to the individual patient.

TI Analgesic Effects of 1st Generation Anti-histamines in Mice
SO BIOLOGICAL & PHARMACEUTICAL BULLETIN
LA English
DT Article
DE anti-histamine; analgesic effect; non-steroidal anti-inflammatory drug; cyproheptadine; pain; histamine-H1-receptor
ID pain perception; histamine; receptor; roles; muscle; diphenhydramine; hyperalgesia; pharmacology; antagonists; mechanisms
AB Pain is sensed, transmitted, and modified by a variety of mediators and receptors. Histamine is a well-known mediator of pain. In addition to their anti-histaminic effects, the classical, or 1st generation, anti-histamines (1st AHs) possess, to various degrees, anti-muscarinic, anti-serotonergic, anti-adrenergic, and other pharmacologic effects. Although there have been attempts to use 1st Ails as analgesics and/or analgesic adjuvants, the advent of non-steroidal anti-inflammatory drugs (NSAIDs) discouraged such trials. We previously reported that in patients with temporomandibular disorders, osteoporosis, and/or osteoarthritis, the analgesic effects of certain 1st AHs (chlorpheniramine and diphenhydramine) are superior to those of the NSAIDs flurbiprofen and indomethacin. Here, we compared analgesic effects among 1st AHs and NSAIDs against responses shown by mice to intraperitoneally injected 0.7% acetic acid. Since 1st Ails are water soluble, we selected water-soluble NSAIDs. For direct

comparison, drugs were intravenously injected 30min before the above tests. Histamine-H1-receptor-deficient (H1R-KO) mice were used for evaluating 111-receptor-independent effects. The tested 1st Ails (especially cyproheptadine) displayed or tended to display analgesic effects comparable to those of NSAIDs in normal and H1R-KO mice. Our data suggest that the anti-serotonergic and/or anti-adrenergic effects of 1st Ails make important contributions to their analgesic effects. Moreover, combination of a 1st AH with an NSAID (cyclooxygenase-1 inhibitor) produced remarkably potent analgesic effects. We propose that a 1st Ail, by itself or in combination with a cyclooxygenase-1 inhibitor, should undergo testing to evaluate its usefulness in analgesia.

TI An insertion/deletion polymorphism within the 3′-untranslated region of COL1A2 confers susceptibility to osteoporosis
SO MOLECULAR MEDICINE REPORTS
LA English
DT Article
DE polymorphism; COL1A2; 3 '-untranslated region; osteoporosis
ID bone-mineral density; hepatocellular-carcinoma; genetic-determinants; microrna function; chinese; heritability; targets; women; mass; osteoarthritis
AB Polymorphisms located in microRNA (miRNA) binding sites may interfere with the interaction between miRNAs and mRNAs, and thereby alter the expression of genes. The current study aimed to investigate the association between an insertion/deletion (INS/DEL) polymorphism in the 3'-untranslated region (3'-UTR) of COL1A2 and the risk of developing osteoporosis. In the present study, COL1A2 was identified as a target gene of let-7g in osteoblast cells obtained from patients, using a luciferase reporter system. This was further confirmed by the observation that exogenous overexpression of let-7g in the osteoblast cells downregulated the expression of COL1A2 in the cells in the INS/INS group, however not in the DEL/DEL group. In addition, a total of 487 subjects were enrolled in the present study and their bone mineral density (BMD) was measured. The BMD at the four tested sites, the femoral neck, total left hip, L1-L4 and intertrochanteric areas, were significantly reduced in the INS/DEL or DEL/DEL group compared with the INS/INS group. Furthermore, the levels of COL1A2 and let-7g were measured in the primary osteoblasts obtained from 48 patients with osteoporosis. While the let-7g levels were comparable between each genotype group, the expression level of COL1A2 in the DEL/DEL and INS/DEL group was significantly greater compared with the

INS/INS group. In conclusion, the present study demonstrated that the INS/DEL polymorphism in the 3'-UTR of COL1A2 is able to interfere with the interaction between miRNA and mRNA. In addition, it is the first study, to the best of our knowledge, to indicate that the minor allele (Del) is associated with a reduced risk of developing osteoporosis.

TI The phenolic acids of Agen prunes (dried plums) or Agen prune juice concentrates do not account for the protective action on bone in a rat model of postmenopausal osteoporosis
SO NUTRITION RESEARCH
LA English
DT Article
DE Osteoporosis; Agen prunes; Chlorogenic acid; Fiber osteoblast; Rat
ID alkaline-phosphatase; host metabolism; dietary boron; ii collagen; vitamin-d; calcium; health; supplementation; women; osteoarthritis
AB Dietary supplementation with dried plum (DP) has been shown to protect against and reverse established osteopenia in ovariectomized rodents. Based on in vitro studies, we hypothesized that DP polyphenols may be responsible for that bone-sparing effect. This study was designed to (1) analyze whether the main phenolic acids of DP control preosteoblast proliferation and activity in vitro; (2) determine if the polyphenolic content of DP or DP juice concentrate is the main component improving bone health in vivo; and (3) analyze whether DP metabolites directly modulate preosteoblast physiology ex vivo. In vitro, we found that neochlorogenic, chlorogenic, and caffeic acids induce the proliferation and repress the alkaline phosphatase activity of primary preosteoblasts in a dose-dependent manner. In vivo, low-chlorogenic acid Agen prunes (AP) enriched with a high-fiber diet and low-chlorogenic acid AP juice concentrate prevented the decrease of total femoral bone mineral density induced by estrogen deficiency in 5-month-old female rats and positively restored the variations of the bone markers osteocalcin and deoxypyridinoline. Ex vivo, we demonstrated that serum from rats fed with low-chlorogenic acid AP enriched with a high-fiber diet showed repressed

proliferation and stimulated alkaline phosphatase activity of primary preosteoblasts. Overall, the beneficial action of AP on bone health was not dependent on its polyphenolic content. (C) 2016 Elsevier Inc. All rights reserved.

TI Quantification of fat deposition in bone marrow in the lumbar vertebra by proton MRS and in-phase and out-of-phase MRI for the diagnosis of osteoporosis
SO JOURNAL OF X-RAY SCIENCE AND TECHNOLOGY
LA English
DT Article
DE 1H-MRS; in-phase and out-of-phase MRI; bones; osteoporosis; dual-energy x-ray absorptiometry
ID photoacoustic tomography; mineral density; adipose-tissue; spectroscopy;

osteoarthritis; disease; adults; fnirs; women; spine
AB The goal for this study was to investigate if proton MRS(1H-MRS) and out-of-phase and in-phase MRI can quantify the fat deposition in bone marrow within the lumbar vertebra that can be used to distinguish well between osteoporosis patients and healthy control subjects. Sixty-eight subjects participated in this study. The diagnostic results from dual-energy x-ray absorptiometry served as the gold standard, which was able to separate the subjects into osteoporosis (38 subjects) and non-osteoporosis group (30 subjects). Then the 68 subjects were further scanned by 1H-MRS and in-phase and out-of-phase MRI and the findings from the imaging methods were also compared and analyzed. It was found that the measured signal intensity ratio (SIR), lipid-water ratio (LWR) and fat fraction (FF) in L2 vertebra from the two imaging methods were able to identify the fat deposition in bone marrow, which could be used to diagnose osteoporosis. Diagnostic accuracy for osteoporosis based on identified SIR, LRW and FF was analyzed by using ROC curves. Our findings suggested that statistically significant differences were identified between osteoporosis patients and healthy subjects. The sensitivity and specificity equal to 78.9% and 75.9% for SIR, 79.2% and 66.7% for LRW, 71.4% and 72.4% for FF, can be achieved when fat deposition-related parameters in bone marrow from the lumbar vertebra are used as classifiers. Our results showed that fat deposition-related parameters including fat content in bone marrow and water content in the lumbar vertebra are clearly different between the osteoporosis and non-osteoporosis group, suggesting that both 1H-MRS and in-phase and out-of-phase MRI can be used for diagnosing osteoporosis and monitoring its progression.

TI Factors predicting postoperative range of motion for anatomic total shoulder arthroplasty
SO JOURNAL OF SHOULDER AND ELBOW SURGERY
LA English
DT Article
DE Total shoulder arthroplasty; TSA; range of motion; comorbidities
ID lesser tuberosity osteotomy; degenerative joint disease; total knee arthroplasty; quality-of-life; glenohumeral osteoarthritis; subscapularis tenotomy; functional improvement; replacement; hemiarthroplasty; multicenter
AB Background: Total shoulder arthroplasty (TSA) has repeatedly been shown to be an effective and durable treatment option for end-stage arthritis with good long-term survivorship. Whereas pain relief is typically the primary goal, improvements in range of motion are typically expected as well. The factors that influence postoperative motion have not been well characterized. The purpose of the study was to examine the factors that influence ultimate postoperative motion after TSA. Methods: A retrospective review was conducted of prospectively collected data of 230 patients with minimum 1-year follow-up after TSA for end-stage arthropathy with an intact rotator cuff. Analysis was focused on factors that may correlate with postoperative measured forward flexion, abduction, external rotation, and internal rotation. Included in this analysis was perception of motion, age, body mass index (BMI), comorbidities (smoking, diabetes, osteoporosis, hypercholesterolemia, inflammatory arthritis, and thyroid disease), and number of comorbidities. Results: Preoperative motion in all directions was predictive of postoperative motion for forward flexion ($R = 0.235$; $P < .001$), abduction ($R = 0.363$; $P < .001$), external rotation ($R = 0.325$; $P < .001$), and internal

rotation (R = 0.213; P = .002). BMI and diabetes both negatively correlated with internal rotation (R = -0.134, P = .40 and R = -0.196, P = .003, respectively). Individual and total number of comorbidities were not predictive of postoperative motion. The patient's perception of preoperative motion also did not correlate with postoperative motion. Conclusions: Preoperative range of motion before TSA is most predictive of final motion achieved. Individual and total number of comorbidities are not predictive of postoperative motion. Patients with high diabetes and increased BMI have limited postoperative internal rotation. (C) 2016 Journal of Shoulder and Elbow Surgery Board of Trustees.

TI The relationship between hypertension and health-related quality of life: adjusted by chronic pain, chronic diseases, and life habits in the general middle-aged population in Japan
SO ENVIRONMENTAL HEALTH AND PREVENTIVE MEDICINE
LA English
DT Article
DE Health-related quality of life; Hypertension; Chronic pain; Sex difference
ID body-mass index; blood-pressure; impact; sf-36; association; obesity; prevalence; mortality; insomnia; validity
AB Objectives The aim of this study was to examine the relationship between hypertension and health-related quality of life (HRQoL) adjusted by chronic pain, other chronic diseases, and life habits in the general middle-aged population in Japan. Methods This study is a population-based cross-sectional study. In this

study, 1117 participants aged 40-65 years and living in Shika Town completed a self-administered questionnaire including Short Form-36 (SF-36). The scores of SF-36 among hypertensives were compared with those of normotensives. The independent association of hypertension with each SF-36 subscale was analyzed using a multiple linear regression model adjusted by age, BMI, chronic pain, chronic diseases, sleep, exercise, and occupational status. We analyzed two groups; Group 1 which contained 846 participants completed the questionnaire without coronary heart disease and cerebral vascular disease, Group 2 which contained 686 participants without coronary heart disease, cerebral vascular disease, or diseases accompanied by chronic pain (gastroduodenal ulcer, fracture, osteoarthritis, osteoporosis, rheumatoid arthritis, and disc herniation). Results In Group 2, hypertensive women had a lower general health perception than normotensive women [unstandardized coefficients; B = -8.84, 95 % confidence interval (95 % CI) = -13.3 to -4.34, standardized coefficients; beta = -0.200, p < 0.001], whereas hypertensive men had higher social functioning than normotensive men (B = 5.66, 95 % CI = 1.30-10.0, beta = 0.149, p < 0.05) after adjusting by chronic pain and life habits. Conclusions These results may be due to the sex difference in the light of the perception for health.

TI Depression risk in patients with heart failure in primary care practices in Germany
SO INTERNATIONAL PSYCHOGERIATRICS
LA English
DT Article
DE depression; primary care; risk factors; antidepressants
ID disease; prevention; prevalence; prognosis; symptoms; anxiety; history
AB Background: The goal of this study was to estimate the prevalence of and risk factors for diagnosed depression in heart failure (HF) patients in German primary care practices. Methods: This study was a retrospective database analysis in Germany utilizing the Disease Analyzer (R) Database (IMS Health, Germany). The study population included 132,994 patients between 40 and 90 years of age from 1,072 primary care practices. The observation period was between 2004 and 2013. Follow-up lasted up to five years and ended in April 2015. A total of 66,497 HF patients were selected after applying exclusion criteria. The same number of 66,497 controls were chosen and were matched (1:1) to HF patients on the basis of age, sex, health insurance, depression diagnosis in the past, and follow-up duration after index date. Results: HF was a strong risk factor for diagnosed depression ($p < 0.0001$). A total of 10.5% of HF patients and 6.3% of matched controls developed depression after one year of follow-up ($p < 0.001$). Depression was documented in 28.9% of the HF group and 18.2% of the control group after the five-year follow-up ($p < 0.001$). Cancer, dementia, osteoporosis, stroke, and osteoarthritis were associated with a higher risk of developing depression. Male gender and private health insurance were associated with lower risk of depression. Conclusions: The risk of diagnosed depression is significantly increased in patients with HF compared to patients without HF in primary care practices in Germany.

TI Increased serum fibroblast growth factor-23 (FGF-23) and bone turnover in patients with osteoarthritis of knee
SO INTERNATIONAL JOURNAL OF CLINICAL AND EXPERIMENTAL MEDICINE
LA English
DT Article
DE Fibroblast growth factor-23; osteoarthritis; osteoporosis; bone turnover
ID mineral density; kidney-disease; osteoporosis; chondrocytes; arthritis; apoptosis; damage; fgf23; mice; hip
AB Objective: This study aimed to investigate the serum fibroblast growth factor-23 (FGF-23) of patients with knee osteoarthritis (OA) and to elaborate its correlation with radiographic and symptomatic severity of OA. Methods: Sixty-three subjects were divided into three groups, including healthy controls group (n = 15), patients

with rheumatoid arthritis (RA, n = 23) and OA (n = 25). Serum FGF-23 levels were examined by ELISA, and other clinical biochemical parameters were tested based on standard methods. Results: First, we found a significant increase in FGF-23 level in the serum of patients with knee OA compared to healthy controls. Next, an increased trabecular bone formation in subchondral bone was confirmed in the patients with knee OA. In addition, FGF-23 levels were positively correlated with radiographic grading and symptomatic severity of knee OA, and this observation indicated a significant elevation in the systemic levels of FGF-23 correlation with WOMAC scores in patients with knee OA. Furthermore, the results showed that the mRNA and protein expression of FGF-23 were significantly increased in synovial fluid from OA patients as compared to those in healthy control, and the upregulation of FGF-23 could inhibit the apoptosis of mononuclear cell in synovial fluid from OA patients. Conclusions: Serum FGF-23 level was significantly higher and was a significant determinant of increased bone turnover in knee OA patients. FGF-23 might be a potential biomarker for diagnosing and evaluating the onset and development of knee OA.

TI A comprehensive fracture prevention strategy in older adults: the European Union Geriatric Medicine Society (EUGMS) statement
SO AGING CLINICAL AND EXPERIMENTAL RESEARCH
LA English
DT Article
DE Falls; Fragility fracture; Older people; Prevention; Position statement
ID bone-mineral density; fall prevention; hip-fracture; postmenopausal women;

cost-effectiveness; zoledronic acid; risk-factors; pharmacological-treatments; strontium ranelate; liaison service
AB Prevention of fragility fractures in older people has become a public health priority, although the most appropriate and cost-effective strategy remains unclear. In the present statement, the Interest Group on Falls and Fracture Prevention of the European Union Geriatric Medicine Society, in collaboration with the International Association of Gerontology and Geriatrics for the European Region, the European Union of Medical Specialists, and the International Osteoporosis Foundation-European Society for Clinical and Economic Aspects of Osteoporosis and Osteoarthritis, outlines its views on the main points in the current debate in relation to the primary and secondary prevention of falls, the diagnosis and treatment of bone fragility, and the place of combined falls and fracture liaison services for fracture prevention in older people.

TI Professional interventions for general practitioners on the management of musculoskeletal conditions
SO COCHRANE DATABASE OF SYSTEMATIC REVIEWS

LA English
DT Review
ID randomized controlled-trial; primary-care physicians; shoulder acute pain; primary-health-care; osteoporosis management; multifaceted intervention; educational intervention; reminder messages; improve; guidelines
AB Background Musculoskeletal conditions require particular management skills. Identification of interventions which are effective in equipping general practitioners (GPs) with such necessary skills could translate to improved health outcomes for patients and reduced healthcare and societal costs. Objectives To determine the effectiveness of professional interventions for GPs that aim to improve the management of musculoskeletal conditions in primary care. Search methods We searched the Cochrane Central Register of Controlled Trials (CENTRAL), 2010, Issue 2; MEDLINE, Ovid (1950 - October 2013); EMBASE, Ovid (1980 - Ocotber 2013); CINAHL, EbscoHost (1980 - November 2013), and the EPOC Specialised Register. We conducted cited reference searches using ISI Web of Knowledge and Google Scholar; and handsearched selected issues of Arthritis and Rheumatism and Primary Care-Clinics in Office Practice. The latest search was conducted in November 2013. Selection criteria We included randomised controlled trials (RCTs), non-randomised controlled trials (NRCTs), controlled before-and-after studies (CBAs) and interrupted time series (ITS) studies of professional interventions for GPs, taking place in a community setting, aiming to improve themanagement (including diagnosis and treatment) of musculoskeletal conditions and reporting any objective measure of GP behaviour, patient or economic outcomes. We considered professional interventions of any length, duration, intensity and complexity compared with active or inactive controls. Data collection and analysis Two review authors independently abstracted all data. We calculated the risk difference (RD) and risk ratio (RR) of compliance with desired practice for dichotomous outcomes, and the mean difference (MD) and standardised mean difference (SMD) for continuous outcomes. We investigated whether the direction of the targeted behavioural change affects the effectiveness of interventions. Main results Thirty studies met our inclusion criteria. From 11 studies on osteoporosis, meta-analysis of five studies (high-certainty evidence) showed that a combination of a GP alerting system on a patient's increased risk of osteoporosis and a patient-directed intervention (including patient education and a reminder to see their GP) improves GP behaviour with regard to diagnostic bone mineral density (BMD) testing and osteoporosis medication prescribing (RR 4.44; (95% confidence interval (CI) 3.54 to 5.55; 3 studies; 3,386 participants)) for BMD and RR 1.71 (95% CI 1.50 to 1.94; 5 studies; 4,223 participants) for osteoporosis medication. Meta-analysis of two studies showed that GP alerting on its own also probably improves osteoporosis guideline-consistent GP behaviour (RR 4.75 (95% CI 3.62 to 6.24; 3,047 participants)) for BMD and RR 1.52 (95% CI 1.26 to 1.84; 3.047 participants) for osteoporosis medication) and that adding the patient-directed component probably does not lead to a greater effect (RR 0.94 (95% CI 0.81 to 1.09; 2,995 participants)) for BMD and RR 0.93 (95% CI 0.79 to 1.10; 2,995

participants) for osteoporosis medication. Of the 10 studies on low back pain, seven showed that guideline dissemination and educational opportunities for GPs may lead to little or no improvement with regard to guideline-consistent GP behaviour. Two studies showed that the combination of guidelines and GP feedback on the total number of investigations requested may have an effect on GP behaviour and result in a slight reduction in the number of tests, while one of these studies showed that the combination of guidelines and GP reminders attached to radiology reports may result in a small but sustained reduction in the number of investigation requests. Of the four studies on osteoarthritis, one study showed that using educationally influential physicians may result in improvement in guideline-consistent GP behaviour. Another study showed slight improvements in patient outcomes (pain control) after training GPs on pain management. Of three studies on shoulder pain, one study reported that there may be little or no improvement in patient outcomes (functional capacity) after GP education on shoulder pain and injection training. Of two studies on other musculoskeletal conditions, one study on pain management showed that there may be worse patient outcomes (pain control) after GP training on the use of validated assessment scales. The 12 remaining studies across all musculoskeletal conditions showed little or no improvement in GP behaviour and patient outcomes. The direction of the targeted behaviour (i.e. increasing or decreasing a behaviour) does not seem to affect the effectiveness of an intervention. The majority of the studies did not investigate the potential adverse effects of the interventions and only three studies included a cost-effectiveness analysis. Overall, there were important methodological limitations in the body of evidence, with just a third of the studies reporting adequate allocation concealment and blinded outcome assessments. While our confidence in the pooled effect estimate of interventions for improving diagnostic testing and medication prescribing in osteoporosis is high, our confidence in the reported effect estimates in the remaining studies is low. Authors' conclusions There is good-quality evidence that a GP alerting system with or without patient-directed education on osteoporosis improves guideline-consistent GP behaviour, resulting in better diagnosis and treatment rates. Interventions such as GP reminder messages and GP feedback on performance combined with guideline dissemination may lead to small improvements in guideline-consistent GP behaviour with regard to low back pain, while GP education on osteoarthritis pain and the use of educationally influential physicians may lead to slight improvement in patient outcomes and guideline-consistent behaviour respectively. However, further studies are needed to ascertain the effectiveness of such interventions in improving GP behaviour and patient outcomes.

TI Relation between the stand-up test and gait speed, knee osteoarthritis, and osteoporosis using calcaneal quantitative ultrasound - Cross-sectional study
SO JOURNAL OF ORTHOPAEDIC SCIENCE
LA English

DT Article
ID sarcopenia; people; health
AB Objective: The aim of the present study was to clarify the relationship between the stand-up test and gait speed, knee osteoarthritis (OA), and osteoporosis using calcaneal quantitative ultrasound. Study design: Cross-sectional study. Methods: A total of 185 subjects (55 men, 130 women) aged >= 40 years (mean age, 63.7 years; range, 40 79 years) were evaluated using the stand-up test to screen for locomotive syndrome. We also assessed OA of the knee using X-rays and a subjective questionnaire, physical characteristics, 6-m gait speed (m/s), and bone density. If results on the stand-up test were worse than benchmarks by age group (i.e., the height at which 50% of each age group could stand-up), the subject was defined as having a risk for locomotive syndrome (L group). We analyzed the relationship between the stand-up test and other variables. Results: Of 185 subjects, 50 (27.0%) were classified into the L group. In univariate analysis, there were significant differences between the L group and non-L group in bone density ($p < 0.001$), gait speed ($p < 0.001$), osteoporosis ($p < 0.001$), slow gait speed group (SGSG) (cut off 1 m/s), and Japanese knee osteoarthritis measure score. Multivariate logistic regression analysis adjusted for age, height, weight, and gender showed a significant association between the stand-up test and bone density (OR 0.960, 95% confidence interval (95% CI) 0.927-0.994), gait speed (m/s) (OR 0.073, 95% CI 0.016-0.342), osteoporosis (OR 3.710, 95% CI 1.410-9.764), and SGSG (OR 7.849, 95% CI 1.628-37.845). Conclusions: The stand-up test to screen for the risk for locomotive syndrome was associated with bone density, gait speed, osteoporosis, SGSG. The stand-up test is an easy test to use to screen for possible disability among the elderly. (C) 2015 The Japanese Orthopaedic Association. Published by Elsevier B.V. All rights reserved.

ID modality
AB This paper presents the design of an innovative device that applies dynamic mechanical load to human knee joints. Dynamic loading is employed by applying cyclic and periodic force on a target area. The repeated force loading was considered to be an effective modality for repair and rehabilitation of long bones that are subject to ailments like fractures, osteoporosis, osteoarthritis, etc. The proposed device design builds on the knowledge gained in previous animal and mechanical studies. It employs a modified slider-crank linkage mechanism actuated by a brushless Direct Current (DC) motor and provides uniform and cyclic force. The functionality of the device was simulated in a software environment and the structural integrity was analyzed using a finite element method for the prototype construction. The device is controlled by a microcontroller that is programmed to provide the desired loading force at a predetermined frequency and for a specific duration. The device was successfully tested in various experiments for its usability and full functionality. The results reveal that the device works according to the requirements of force magnitude and operational frequency. This device is considered ready to be used for a clinical study to examine whether controlled knee-loading could be an effective regimen for treating the stated bone-related ailments.

TI Influence of high glucose and advanced glycation end-products (ages) levels in human osteoblast-like cells gene expression
SO BMC MUSCULOSKELETAL DISORDERS
LA English
DT Article
ID type-2 diabetes-mellitus; osteogenic differentiation; messenger-rna; fracture risk; in-vitro; bone; rankl; apoptosis; receptor; osteoprotegerin
AB Background: Type 2 diabetes mellitus (T2DM) is associated with an increased risk of osteoporotic fracture. Several factors have been identified as being potentially responsible for this risk, such as alterations in bone remodelling that may have been induced by changes in circulating glucose or/and by the presence of non-oxidative end products of glycosylation (AGEs). The aim of this study is to assess whether such variations generate a change in the gene expression related to the differentiation and osteoblast activity (OPG, RANKL, RUNX2, OSTERIX, and AGE receptor) in primary cultures of human osteoblast-like cells (hOB). Methods: We recruited 32 patients; 10 patients had osteoporotic hip fractures (OP group), 12 patients had osteoporotic hip fractures with T2DM (T2DM group), and 10 patients had hip osteoarthritis (OA group) with no osteoporotic fractures and no T2DM. The gene expression was analyzed in hOB cultures treated with physiological glucose concentration (4.5 mM) as control, high glucose (25 mM), and high glucose plus AGEs (2 mu g/ml) for 24 h. Results: The hOB cultures from patients with hip fractures presented slower proliferation. Additionally, the hOB cultures from the T2DM group were the most negatively affected with respect to RUNX2 and OSX gene expression when treated solely with high glucose or with high glucose plus AGEs. Moreover, high levels of glucose induced a major decrease in the RANKL/OPG ratio when comparing the OP and the T2DM groups to the OA group. Conclusions: Our data indicates an altered bone remodelling rate in the T2DM group, which may, at least partially, explain the reduced bone strength and increased incidence of non-traumatic fractures in diabetic patients.

TI Mesenchymal stem cells (MSCs) as skeletal therapeutics-an update
SO JOURNAL OF BIOMEDICAL SCIENCE
LA English
DT Review
DE MSCs; Autologous; Osteogenic imperfecta; Infantile Hypo-phosphatasia; Craniofacial; Vertebral disc; Cartilage repair; Bone fracture; Osteoporosis; Osteo-arthritis
ID marrow stromal cells; human bone-marrow; intervertebral disc repair; adipose-tissue; autologous chondrocyte; osteogenesis imperfecta; cartilage defects; knee osteoarthritis; transplantation; differentiation
AB Mesenchymal stem cells hold the promise to treat not only several congenital and acquired bone degenerative diseases but also to repair and regenerate morbid bone tissues. Utilizing MSCs, several lines of evidences advocate promising clinical outcomes in skeletal diseases and skeletal tissue repair/regeneration. In this context, both, autologous and allogeneic cell transfer options have been utilized. Studies suggest that MSCs are transplanted either alone by mixing with autogenous plasma/serum or by loading onto repair/induction supportive resorb-able scaffolds. Thus, this review is aimed at highlighting a wide range of pertinent clinical therapeutic options of MSCs in the treatment of skeletal diseases and skeletal tissue regeneration. Additionally, in skeletal disease and regenerative sections, only the early and more recent preclinical evidences are discussed followed by all the pertinent clinical studies. Moreover, germane post transplant therapeutic mechanisms afforded by MSCs have also been conversed. Nonetheless, assertive use of MSCs in the clinic for skeletal disorders and repair is far from a mature therapeutic option, therefore, posed challenges and future directions are also discussed. Importantly, for uniformity at all instances, term MSCs is used throughout the review.

DE osteoarthritis; p53; Rb; ATP; DAMPs; Rankl; BCLXL; FoxO; osteoarthritis; apoptosis; necrosis
ID growth-factor receptor; trabecular bone mass; group box-1 protein; fatigue in-vivo; articular-cartilage; cyclin d1; parathyroid-hormone; indian-hedgehog; nitric-oxide; human osteoarthritis
AB Cell death in skeletal component cells, including chondrocytes, osteoblasts, and osteocytes, plays roles in skeletal development, maintenance, and repair as well as in the pathogenesis of osteoarthritis and osteoporosis. Chondrocyte proliferation, differentiation, and apoptosis are important steps for endochondral ossification. Although the inactivation of P53 and RB is involved in the pathogenesis of osteosarcomas, the deletion of p53 and inactivation of Rb are insufficient to enhance chondrocyte proliferation, indicating the presence of multiple inhibitory mechanisms against sarcomagenesis in chondrocytes. The inflammatory processes induced by mechanical injury and chondrocyte death through the release of danger-associated molecular patterns (DAMPs) are involved in the pathogenesis of posttraumatic osteoarthritis. The overexpression of BCLXL increases bone volume with a normal structure and maintains bone during aging by inhibiting osteoblast apoptosis. p53 inhibits osteoblast proliferation and enhances osteoblast apoptosis, thereby reducing bone formation, but also exerts positive effects on osteoblast differentiation through the Akt-FoxOs pathway. Apoptotic osteocytes release ATP, which induces the receptor activator of nuclear factor kappa-B ligand (Rankl) expression and osteoclastogenesis, from pannexin 1 channels. Osteocyte death ultimately results in necrosis; DAMPs are released to the bone surface and promote the production of proinflammatory cytokines, which induce Rankl expression, and osteoclastogenesis is further enhanced.

DT Review
DE Clinical trials; Sarcopenia; Public health; Preventative health care; Frailty
ID quality-of-life; lower-extremity function; muscle strength; older-adults; skeletal-muscle; gait-speed; physical performance; body-composition; functional impairment; age-discrimination
AB Sarcopenia is an age-related muscle condition which is frequently a precursor of frailty, mobility disability and premature death. It has a high prevalence in older populations and presents a considerable social and economic burden. Potential treatments are under development but, as yet, no guidelines support regulatory studies for new drugs to manage sarcopenia. The objective of this position paper is therefore to suggest a set of potential endpoints and target population definitions to stimulate debate and progress within the medico-scientific and regulatory communities. A multidisciplinary expert working group was hosted by the European Society for Clinical and Economic Aspects of Osteoporosis and Osteoarthritis, which reviewed and discussed the recent literature from a perspective of clinical experience and guideline development. Relevant parallels were drawn from the development of definition of osteoporosis as a disease and clinical assessment of pharmaceutical treatments for that indication. A case-finding decision tree is briefly reviewed with a discussion of recent prevalence estimations of different relevant threshold values. The selection criteria for patients in regulatory studies are discussed according to the aims of the investigation (sarcopenia prevention or treatment) and the stage of project development. The possible endpoints of such studies are reviewed and a plea is made for the establishment of a core outcome set to be used in all clinical trials of sarcopenia. The current lack of guidelines for the assessment of new therapeutic treatments for sarcopenia could potentially hinder the delivery of effective medicines to patients at risk.

TI Simvastatin Effect on Calcium and Silicon Plasma Levels in Postmenopausal Women with Osteoarthritis
SO BIOLOGICAL TRACE ELEMENT RESEARCH
LA English
DT Article
DE Osteoarthritis; Postmenopausal women; Simvastatin; Plasma bioelements; HPLC
ID bone-mineral density; osteoporosis; progression; statins; health
AB Postmenopausal women more often suffered from knee osteoarthritis and its pathogenesis still remains unclear. Calcium and silicon are significant elements involved in bone and joint metabolism, especially in older people. Cardiovascular diseases are common worldwide and simvastatin is the most prescribed drug in such population of patients. The purpose of this study was to evaluate the effect of simvastatin administration on calcium and silicon concentration in the plasma of postmenopausal women with osteoarthritis. Sixty postmenopausal mild hypercholesterolemic women (mean age 61.4 years, range 54-68) were enrolled. Thirty patients received simvastatin (20 or 40 mg/day) for at least 1 year before being enrolled (simvastatin "+" group). Control group consists of remaining 30 women (simvastatin "-aEuroegroup). Silicon and calcium concentrations were measured spectrophotometrically. Plasma simvastatin level was determined 3 h after the drug administration using HPLC-UV-Vis. Calcium but not silicon level was significantly lower in patients receiving simvastatin in comparison with non-statin group (1.91 +/- A 0.32 vs. 2.33 +/- A 0.19 mmol/l, $p < 0.05$). A weak but significant positive correlation between plasma silicon and simvastatin levels ($r = 0.3$, $p < 0.05$) was observed; this may be due to the fact that simvastatin contains silicon dioxide as an inactive ingredient. The mean simvastatin concentration was 9.02 ng/ml. All hypotheses were verified at the significance level of $p < 0.05$. A statistically significant decrease in the plasma calcium concentration of postmenopausal women, treated with simvastatin suggests that simvastatin may play a role in calcium metabolism in postmenopausal women with osteoarthritis. Positive correlation of simvastatin concentration with silicon level in the plasma suggests that both might prompt the positive effect of osteoarthritis treatment.

TI Resistance Training as a Tool for Preventing and Treating Musculoskeletal Disorders
SO SPORTS MEDICINE
LA English
DT Review
ID low-back-pain; bone-mineral density; aging skeletal-muscle;

rheumatoid-arthritis; knee osteoarthritis; physical-activity; body-composition; older-adults; postmenopausal women; risk-factors
AB The aging process is characterized by several physiological, morphological, and psychological alterations that result in a decreased functional and health status throughout the life span. Among these alterations, the loss of muscle mass and strength (sarcopenia) is receiving increased attention because of its association with innumerous age-related disorders, including (but not limited to) osteoporosis, osteoarthritis, low back pain, risk of fall, and disability. Regular participation in resistance training programs can minimize the musculoskeletal alterations that occur during aging, and may contribute to the health and well-being of the older population. Compelling evidence suggest that regular practice of resistance exercise may prevent and control the development of several musculoskeletal chronic diseases. Moreover, resistance training may also improve physical fitness, function, and independence in older people with musculoskeletal disorders, which may result in improved quality of the years lived. In summary, regular participation in resistance training programs plays an important role in aging and may be a preventive and therapeutic tool for several musculoskeletal disorders.

TI Weekly injection of teriparatide for bone ingrowth after cementless total knee arthroplasty
SO JOURNAL OF ORTHOPAEDIC SURGERY
LA English
DT Article
DE arthroplasty, replacement, knee; bone density; teriparatide
ID x-ray absorptiometry; mineral density; proximal tibia; trabecular bone; follow-up; microstructural analysis; primary osteoporosis; computed-tomography; fracture; hydroxyapatite
AB Purpose. To compare bone mineral density (BMD) in patients with or without weekly injection of teriparatide to promote bone ingrowth after cementless total knee arthroplasty (TKA). Methods. Records of 8 men and 32 women (mean age, 75.6 years) who underwent cementless TKA for medial knee osteoarthritis with (n=20) or without (n=20) once-weekly subcutaneous/hypodermic injection of teriparatide for 48 weeks were reviewed. BMD and bone volume/total volume (BV/TV) of the bone-prosthesis interface of the proximal tibia in 6 regions of interest (ROI) were assessed at 3, 6, 9, and 12 months using multi-detector computed tomography. Results. Patients with or without weekly injection of teriparatide after cementless TKA were comparable in terms of baseline characteristics and pre- and post-operative knee range of motion and Knee Society knee and function scores. In ROI 1 (medial), ROI 3 (anteromedial), and ROI 4 (posteromedial), the BV/TV increased throughout the postoperative period in patients with weekly injection of teriparatide and declined after 6 months in patients without weekly injection of teriparatide. These 3 ROIs of the 2 groups differed significantly only in BMD at 6, 9, and 12 months. In ROI 2 (lateral), ROI 5 (anterolateral), and ROI 6 (posterolateral), both BV/TV and BMD showed a

decreasing trend, and these 3 ROIs of the 2 groups did not differ significantly. Conclusion. Weekly injection of, teriparatide after cementless TKA promoted bone ingrowth mostly in the medial aspect of the bone-prosthesis interface.

TI How Hand Osteoarthritis, Comorbidity, and Pain Interact to Determine Functional Limitation in Older People: Observations From the European Project on OSteoArthritis Study
SO ARTHRITIS & RHEUMATOLOGY
LA English
DT Article
ID physical function; burden; instruments; depression; prevalence; anxiety; impact; index
AB ObjectiveTo examine the role of comorbidity and pain in the associations of hand osteoarthritis (OA) with self-reported and performance-based physical function in a general population of elderly persons. MethodsWe studied data from 2,942 participants ages 65-85 years in the European Project on OSteoArthritis, a collaborative observational study of 6 European cohorts (from Germany, Italy, The Netherlands, Spain, Sweden, and the UK). Outcome measures included self-reported physical function of the hands measured by the AUStralian/CANadian Osteoarthritis Hand Index (AUSCAN) for hand OA physical function subscale and performance-based grip strength measured using a strain gauge dynamometer. ResultsComorbidity was not a confounder in the association of hand OA with self-reported and performance-based functional limitations, while the role of pain as a mediator was confirmed. Anxiety, depression, stroke, and osteoporosis were associated with AUSCAN scores reflecting more impairment. Depression and osteoporosis were associated with less grip strength. ConclusionAlthough comorbidity was decidedly and independently associated with hand functional limitation, it had no effect on the relationship of hand OA with physical function.

Hand OA was found to be associated with both self-reported and performance-based physical function impairment; the association was found to be partially mediated by pain, which reduced its impact.

TI Relation between phalangeal bone mineral density and radiographic knee osteoarthritis: a cross-sectional study
SO BMC MUSCULOSKELETAL DISORDERS
LA English
DT Article
DE Osteoarthritis; Knee; Phalangeal; Bone mineral density; Kellgren-Lawrence grade
ID body-mass index; total hip; postmenopausal women; risk-factors; follow-up; osteoporosis; absorptiometry; epidemiology; association; hand
AB Background: Major reports have suggested that bone mineral density (BMD) is higher in patients with osteoarthritis (OA), while other studies do not agree. Our aim was to examine the cross-sectional association between phalangeal BMD and radiographic knee OA. Methods: A total of 2855 participants were included in this study. Radiographic knee OA was defined as Kellgren-Lawrence (K-L) Grade >= 2 in at least one leg. BMD scans of the middle phalanges of the second, third and fourth digits of the nondominant hand were performed with a compact radiographic absorptiometry system (Alara MetriScan (R)). A multivariable logistic analysis model was applied to test the relation between phalangeal BMD with radiographic knee OA, the presence of knee osteophytes (OSTs), and knee joint space narrowing (JSN) after adjusting for a number of potential confounding factors. Results: The multivariable-adjusted odds ratios with 95 % confidence intervals [ORs (95 % CI)] of radiographic knee OA across phalangeal BMDs were 1.08 (95 % CI 0.89-1.32) and 0.62 (95 % CI 0.45-0.86), respectively. The P for trend was 0.09. For the female population, the multivariable-adjusted ORs (95 % CI) of

radiographic knee OA across phalangeal BMD were 1.01 (95 % CI 0.73-1.37) and 0.58 (95 % CI 0.38 - 0.87), respectively. The P for trend was 0.02. This positive finding, however, did not exist in the male subgroup. There was a significantly lower prevalence of OST in the osteoporosis (OP) group than in the normal group (OR = 0.59, 95 % CI 0.40-0.88; P for trend was 0.01). In contrast, the prevalence of JSN was significantly higher in the osteopenia group (OR = 1.22, 95 % CI 1.00-1.48) and the OP group (OR = 1.35, 95 % CI 1.00-1.84) than in the normal group. The P for trend was 0.02. Conclusions: This study observed lower odds for the presence of radiographic knee OA and OST in OP patients than in normal subjects. The prevalence of JSN was higher in the osteopenia and OP groups than in normal subjects.

DT Review
DE bone; osteoarthritis; osteoporosis
ID high bone mass; population-based cohort; knee osteoarthritis; mineral density; trabecular bone; hand osteoarthritis; fracture risk; all-cause; association; women
AB Purpose of reviewOsteoporosis and osteoarthritis are different diseases, with differences in risk factors, bone mineral density (BMD), BMI, phenotype, morbidity and mortality. We review new data on the role of bone metabolism in osteoporosis and osteoarthritis.Recent findingsThe insights in the common convergent and divergent risk factors between osteoarthritis and osteoporosis have resulted in new findings on the role of BMD, BMI, falls, genetics and epigenetics in the pathophysiology of both diseases and on the increased fracture risk in osteoporosis and osteoarthritis. The relation between BMD, BMI and fracture risk in osteoarthritis is dependent on the stage, definition and location of the osteoarthritis and method of BMD measurement. It has been suggested that osteoarthritis should be further specified in terms of bone involvement.SummaryThese new findings open the way to better understand the bone subtypes of osteoarthritis (osteoporotic, bone forming and erosive) and the common and different ways bone is involved in osteoporosis and osteoarthritis. Much can be expected from further prospective studies, when taking into account the heterogeneous nature of both osteoporosis and osteoarthritis.

TI Integrative Analysis of Genomics and Transcriptome Data to Identify Potential Functional Genes of BMDs in Females
SO JOURNAL OF BONE AND MINERAL RESEARCH
LA English
DT Article
DE OSTEOPOROSIS; BMD; SYSTEM GENETICS; HOMER1
ID coexpression network analysis; wide association data; missing heritability; susceptibility genes; glutamate receptors; bone-resorption; chinese women; osteoporosis; osteoarthritis; identification
AB Osteoporosis is known to be highly heritable. However, to date, the findings from more than 20 genorne wide association studies (GWASs) have explained less than 6% of genetic risks. Studies suggest that the missing heritability data may be because of joint effects among genes. To identify novel heritability for osteoporosis, we performed a system-level study on bone mineral density (BMD) by weighted gene coexpression network analysis (WGCNA), using the largest

GWAS data set for BMD in the field, Genetic Factors for Osteoporosis Consortium (GEFOS-2), and a transcriptomic gene expression data set generated from transiliac bone biopsies in women. A weighted gene coexpression network was generated for 1574 genes with GWAS nominal evidence of association (p <= 0.05) based on dissimilarity measurement on the expression data. Twelve distinct gene modules were identified, and four modules showed nominally significant associations with BMD (p 0.05), but only one module, the yellow module, demonstrated a good correlation between module membership (MM) and gene significance (GS), suggesting that the yellow module serves any important biological role in bone regulation. Interestingly, through characterization of module content and topology, the yellow module was found to be significantly enriched with contractile fiber part (GO:044449), which is widely ecognized as having a close relationship between muscle and bone. Furthermore, detailed subrnodule analyses of important candidate genes (HOMER1, SPTBN1) by all edges within the yellow module implied significant enrichment of functional connections between bone and cytoskeletal protein binding. Our study yielded novel information from system genetics analyses of GWAS data jointly with transcriptomic data. The findings highlighted a module and several genes in the model as playing important roles in the regulation of bone mass in females, which may yield novel insights into the;genetic;basis of osteoporosis. TI Patterns of Non-adherence to Supplementation with Calcium and Vitamin D in Persistent Postmenopausal Women Are Similar at Start and 1Year Later: A Qualitative Longitudinal Study
SO FRONTIERS IN PHARMACOLOGY
LA English
DT Article
DE medication adherence; patient adherence; longitudinal studies; medication event monitoring system (MEMS); drug holidays; osteoporosis; calcium supplementation; electronic monitoring
ID self-reported adherence; antiretroviral therapy; drug-therapy; osteoporosis; medication; metaanalysis; time; questionnaires; combination; rates
AB Background: Osteoporosis is a chronic disease and adherence can fluctuate over time. Therefore, longer observation is necessary to investigate the stability of patients' adherence. The study aim was to compare the overall adherence (OA) to supplementation with the fixed combination of calcium and vitamin D (Ca/D) in postmenopausal women at baseline and after 1 year, and to evaluate the fluctuation of the OA in individual months. Furthermore, we studied whether adherence is influenced by signing of informed consent and routine medical check-up. Methods: This was a longitudinal, observational study. The data were obtained from the Osteocenter of University Hospital in Hradec Kralove, Czech Republic. Adherence was measured using electronic bottles type Medication Events Monitoring System (MEMS). The study was carried out in two 3-month periods; the baseline in 2013 (signing of informed consent while medical check-up) and the follow-up (medical check-up) in 2014. The adherence and adherence-related outcomes were studied in patients who had initiated osteoporosis treatment and were persistent. Results: 21 (49%) out of 43 patients who avoided drug dispenser and were persistent both at baseline and at follow-up, completed the study and were included. Median age was 76. Evaluating the whole 3-month periods, the OA did not differ significantly at baseline and at follow-up, the OA was 71 and 68%, respectively. However, the adherence in month 1 at baseline was significantly higher than the adherence in month 2 at baseline ($p < 0.001$) and also than the adherence in month 1 at follow-up ($p = 0.010$). Analysing the study period without

month 1, a stable adherence was observed in 48% of patients. About 33% of doses were omitted at baseline and 34% at follow-up. As many as 71% of the patients took drug holidays at baseline, and 76% at follow-up. Conclusion: The OA was insufficient, around 70% both at baseline and at follow-up. One half of the patients showed a stable adherence. The patterns of non-adherence were very similar at follow-up. Signing of the informed consent seems to act as bias more than regular medical check-up.

TI Impairment in the activities of daily living in older adults with and without osteoporosis, osteoarthritis and chronic back pain: a secondary analysis of population-based health survey data
SO BMC MUSCULOSKELETAL DISORDERS
LA English
DT Article
DE Activities of daily living; Population-based study; Occupational therapy
ID depressive symptoms; arthritis; people; disability
AB Background: Independence in performing activities of daily living (ADLs) is a central aspect of functioning. Older adults frequently experience impairments and limitations in functioning in various life areas. The aim of this survey was to explore the limitations in the ADLs in older adults in a population-based survey in Austria. Method: A population-based cross-sectional study in 3097 subjects aged >= 65 years who were included in the Austrian health interview survey was performed. Descriptive statistics were used to calculate frequencies of problems in the ADLs. A principal component analysis was applied to analyze the main dimensions of 19 ADL items. Binary logistic regression models were used with the ADL dimensions as the dependent variables and osteoarthritis, chronic back pain, osteoporosis, sex, education level, anxiety or depression, age and pain intensity as independent variables. Results: People with musculoskeletal conditions were significantly more often affected by ADL problems than people without these diseases. The ADL domain which caused problems in the highest proportion of people was "doing heavy housework" (43.9 %). It was followed by the ADL domains "bending or kneeling down" (39.3 %), "climbing stairs up and down without walking aids" (23.1 %), and "walking 500 m without walking aids" (22.8 %). The principal components analysis revealed four dimensions of ADLs: (1) intense "heavy burden" ADLs, (2) basic instrumental ADLs, (3) basic ADLs and (3) hand-focused ADLs. The proportion of subjects who had problems with the respective dimensions was 58.2, 29.2, 23.0, and 9.2 %. Anxiety/depression (greatest effect), followed by the chronic musculoskeletal disease itself, female sex, higher age and pain intensity were significant predictors of ADL problems. Conclusion: This population-based survey indicates that older people have considerable ADL problems. More attention should be paid to the high impact of pain intensity, anxiety and depression on ADLs.

TI Correlation of cartilage metabolic markers & antioxidants with the severity of knee osteoarthritis
SO INDIAN JOURNAL OF MEDICAL RESEARCH
LA English
DT Article
DE Antioxidants; cartilage metabolic markers; osteoarthritis; osteogenic protein-1
ID osteogenic protein-1; arthritis
AB Osteoarthritis is characterized by the degeneration of articular cartilage. Cartilage metabolic markers have been explored as possible markers for

osteoarthritis, and osteogenic protein-1 (OP-1) has emerged out to play a major role in cartilage repair. Oxidative stress has been implicated as a mediator of cartilage damage in patients with osteoarthritis. The aim of this study was to correlate the cartilage metabolic markers and antioxidants with the severity of knee osteoarthritis.

TI Effect of Teriparatide on Bone Formation in the Human Femoral Neck
SO JOURNAL OF CLINICAL ENDOCRINOLOGY & METABOLISM
LA English
DT Article

ID randomized controlled-trial; parathyroid-hormone 1-34; postmenopausal osteoporosis; hip fracture; vertebral fractures; zoledronic acid; cancellous bone; women; alendronate; histomorphometry
AB Purpose: Teriparatide (TPTD) improves bone mass and microstructure resulting in reduced risk of vertebral and nonvertebral fractures. However, hip bone mineral density improvements are modest and there are no data confirming that TPTD reduces hip fracture risk. To study the effects of TPTD on the proximal femur, we performed a double-blind trial of TPTD vs placebo (PBO) in patients with osteoarthritis from whom femoral neck (FN) samples were obtained at total hip replacement (THR) surgery. Methods: Participants were randomly assigned to receive TPTD or PBO for an average of 40 days before THR. Double tetracycline labeling was initiated 21 days prior to THR to allow histomorphometric assessment of bone formation. During the THR, an intact sample of the FN was procured, fixed, and sectioned transversely. Serum levels of bone turnover markers were measured at baseline and during the THR. Standard histomorphometric parameters were measured and calculated on four bone envelopes (cancellous, endocortical, intracortical, and periosteal). The primary outcome measure was bone formation rate/bone surface (BFR/BS). Results: Forty individuals were enrolled (25 women, mean age, 71.5 +/- 8.0 y and 15 men, mean age, 68.9 +/- 7.7 y). In cancellous and endocortical envelopes, BFR/BS was 100% higher in the TPTD vs PBO group ($P < .05$). Bone turnover markers measured at the time of THR correlated with BFR/BS. Conclusion: TPTD stimulates bone formation rapidly in cancellous and endocortical envelopes of the FN. Our findings provide a mechanistic basis for TPTD-mediated improvement in FN bone mass and ultimately hip strength. This study is the first demonstration of the effect of any osteoporosis medication on osteoblast activity in the human proximal femur.

TI Clinical trials of new drugs for the treatment of rheumatoid arthritis: focus on early disease
SO ANNALS OF THE RHEUMATIC DISEASES
LA English
DT Article
ID american-college; double-blind; rheumatology/european league; receptor inhibition; remission; tocilizumab; criteria; multicenter; monotherapy; definition
AB The European Society for Clinical and Economic Aspects of Osteoporosis, Osteoarthritis and Musculoskeletal Diseases convened a task force of experts in rheumatoid arthritis (RA) and clinical trial methodology to comment on the new draft 'Guideline on clinical investigation of medicinal products for the treatment of RA' released by the European Medicines Agency (EMA). Special emphasis was placed by the group on the development of new drugs for the treatment of early RA. In the absence of a clear definition of early RA, it was suggested that clinical investigations in this condition were conducted in disease-modifying antirheumatic drugs naive patients with no more than 1 year disease duration. The expert group recommended using an appropriate improvement in disease activity (American College of Rheumatology (ACR) or Simplified/Clinical Disease Activity Index (SDAI/CDAI) response criteria) or low disease activity (by any score) as primary endpoints, with ACR/European League Against Rheumatism remission as a secondary endpoint. Finally, as compelling evidence showed that the Disease Acrivity Score using 28-joint counts (DAS28) might not provide a reliable definition of remission, or sometimes even low disease activity, the group suggested replacing DAS28 as a measurement instrument to evaluate disease activity in RA clinical trials. Proposed alternatives included SDAI, CDAI and Boolean criteria.

TI The determination of apoptosis rates on articular cartilages of ovariectomized rats with and without alendronate treatment
SO HISTOLOGY AND HISTOPATHOLOGY
LA English
DT Article
DE Alendronate; Apoptosis; Articular cartilage; Osteoarthritis; Rat
ID subchondral bone loss; chondrocyte apoptosis; intraarticular injection; cell-death; osteoarthritis; model; degeneration; expression; fractures; osteoporosis
AB Osteoporosis (OP) is a major health problem characterized by compromised bone strength. Osteoarthritis (OA) is a joint disease that progresses slowly and is characterized by breakdown of the cartilage matrix. Alendronate (ALN), a nitrogen-containing bisphosphonate (BIS), inhibits bone loss and increases bone mineralization, and has been used clinically for the treatment of OP. It is still controversial whether BIS is effective in inhibiting the progression of OA. Chondrocyte apoptosis has been described in both human and experimentally induced OA models. In our study we aimed to detect whether ALN could protect articular cartilage from degeneration and reduce apoptosis rates in experimentally OA induced rats. For this rats were ovariectomized (ovex), nine weeks after operation rats were injected 30 mu g/kg/week ALN subcutaneously for six weeks. After six weeks articular cartilages were obtained. We did Safranin O staining and Mankin and Pritzker scorings to evaluate degeneration and investigated the expressions of p53, cleaved caspase 3, Poly ADP-ribose (PAR), Poly ADP-ribose polymerase 1 (PARP 1), and applied TUNEL technique to determine apoptotis rates. We found a significant decrease in glycosaminoglycan (GAG) amount and increased apoptosis which indicates damage on articular cartilages of ovex rats. GAG amount was higher and apoptosis rate was lower on articular cartilages of

ALN treated ovex rats compared to the ovex group. In contrary to studies showing that early ALN treatment has a protective effect, our study shows late ALN treatment has a chondroprotective effect on articular cartilage since we treated rats nine weeks after ovariectomy.

TI Osteoprotegerin deficiency leads to deformation of the articular cartilage in femoral head
SO JOURNAL OF MOLECULAR HISTOLOGY
LA English
DT Article
DE OPG; Osteoarthritis; Degenerative joint disease; Femoral head; Articular cartilage
ID endochondral ossification; osteoarthritis; bone; disease; mice; opg; calcification;

osteoporosis; chondrocytes; targets
AB Osteoarthritis (OA) was a degenerative joint disease characterized by articular cartilage degradation and extensive remodeling of the subchondral bone. Multiple lines of evidence indicated that Osteoprotegerin (OPG), a member of TNF receptor superfamily that was expressed in the chondrocytes of articular cartilage and adjacent locations in the physiological setting, was involved in maintaining integrity of articular cartilage. OPG could prevent subchondral bone from resorption, and also protect cartilage from degradation. In this study, we used Osteoprotegerin-knockout mice (Opg-KO mice) to find out the role of OPG in articular cartilage. We examined articular cartilage in the femoral head of Opg-KO mice began in early adulthood using modern molecular and imaging methods. We found cartilage changes starting from adulthood and progressively with age, reminiscent of pathological changes in OA. Deficiency of OPG caused thinned articular cartilage and extensive remodeling of the subchondral bone in femoral head in comparison with wild-type mice (WT mice). Also, the articular cartilage of femoral head expressed significantly less of Aggrecan, Col-II and Col-X, but more Col-I and Matrix Metalloproteinases-13 (Mmp-13) than WT mice both at gene and protein level. Moreover, increased chondrocyte apoptosis and decreased chondrocyte proliferation were observed in femoral head of Opg-KO mice compared to WT mice. These data suggested that OPG played an important role in maintaining the homeostasis of articular cartilage of femoral head.

TI Lumbar spondylosis, lumbar spinal stenosis, knee pain, back muscle strength are associated with the locomotive syndrome: Rural population study in Japan
SO JOURNAL OF ORTHOPAEDIC SCIENCE
LA English
DT Article
ID quality-of-life; facet joint osteoarthritis; diagnostic support tool; postmenopausal osteoporosis; height loss; vertebral fractures; paraspinal muscles;

disc degeneration; mobility; deformity
AB Objectives: To comprehensively investigate the clinical and physical factors associating with locomotive syndrome (Loc-S); the locomotorium-disability for daily life. Methods: 647 volunteers participated (247 males, 400 females, Age: 58.4 +/- 11.0, BMI: 22.5 +/- 3.3). Three self-assessment questionnaires were administered: 1) "25-question Geriatric Locomotive Function Scale" (GELS-25) for evaluating Loc-S (GLFS-25 >= 16 defined as Loc-S); 2) "diagnostic support tool for LSS" (LSS-DST) for evaluating the prevalence of lumbar spinal stenosis (LSS); 3) Knee injury and Osteoarthritis Outcome Score (KOOS). Plain radiographs of the bilateral knees and lumbar spine were evaluated, and the severity of lumbar spondylosis (LS) and knee osteoarthritis (KOA) defined by Kellgren-Lawrence grade. Bone status was evaluated by using the osteo-sono assessment index (OSI) at the calcaneus. Isometric muscle strength of trunk and leg (Nm/kg, both extension and flexion) were evaluated. Linear regression analysis was performed to elucidate the factors concerned with GFLS-25 including age, sex, and BMI. Results: Thirty-nine subjects (6.0%, 13 males, 26 females) were defined as having Loc-S. Single regression model showed that age, height, BMI, skeletal muscle mass, OSI, LSS, KOOS, the severity of LS and KOA, and trunk- and leg-muscle strength were correlated with the degree of GLFS-25. Stepwise multiple regression model showed that sex, height, LSS, KOOS, the severity of LS, and back muscle strength were significantly correlated with that of GLFS-25. Conclusion: In this cross-sectional study, pain status associated with LSS and knee joint, structural severity for LS, and back muscle strength primarily affected the degree of GFLS-25. For managing Loc-S, we must pay more intensive attention to these factors. (C) 2016 The Japanese Orthopaedic Association. Published by Elsevier B.V. All rights reserved.

DT Review
DE Sclerostin; Wnt/beta-catenin signalling; osteoarthritis
ID bone morphogenetic protein; knee osteoarthritis; serum sclerostin; subchondral bone; cartilage degradation; postmenopausal osteoporosis; therapeutic target; signaling pathway; physical-activity; rabbit model
AB Osteoarthritis (OA), a debilitating degenerative joint disease which is greatly influenced by alterations in the local mechanical loading environment in the joint. The exact aetiology of OA remains unknown, but loss of articular cartilage, subchondral sclerosis, and bone remodeling has been known to play important roles in OA development. Wnt/beta-catenin signaling has a substantial role in bone

and cartilage homeostasis in the adult skeleton, and has been implicated in the process of cartilage degradation and subchondral remodeling in OA. Sclerostin (SOST), secreted mainly by osteocytes and downregulated by mechanical loading, is a potent inhibitor of Wnt signaling and a regulator of bone metabolism. Thus, by studying the expression of sclerostin and the Wnt pathway, it is possible to investigate the role of the osteocyte in bone remodeling in human musculoskeletal disease, such as OA. However few of literatures have reported about the relation between Sclerostin and OA. In this review we have tried to summarize the current knowledge on the effect of Sclerostin and to explore the potential role of Sclerostin during the process of OA. A better understanding of the relationship between Sclerostin and cartilage/subchondral in both physiological and pathological conditions may lead to development of more effective strategies for treating OA patients.

TI A Comparative Study to Determine Functional and Clinical Outcome Differences Between Patients Receiving Outpatient Direct Physical Therapy Versus Home Physical Therapy Followed by Outpatient Physical Therapy After Total Knee Arthroplasty
SO ORTHOPAEDIC NURSING
LA English
DT Article
ID total hip; joint replacement; rehabilitation; osteoarthritis; performance; population; exercise; obesity; motion; range
AB BACKGROUND: Rehabilitation outcomes for patients with total knee arthroplasty (TKA) after hospital discharge are not well understood. PURPOSE: The purpose of this retrospective cohort study was to describe outpatient physical therapy (PT) after TKA and compare short-term (2 months) functional and clinical outcomes of patients following TKA who were discharged from the hospital to home and received (a) outpatient PT immediately (OP) or (b) home health PT before outpatient PT (HH). METHODS: The medical records of 109 men and women postoperative TKA discharged home were abstracted for the 6-minute walk test (6MWT), Knee Osteoarthritis and Outcome Score (KOOS), and knee range of motion (ROM) preoperatively and after discharge from all postoperative PT. Patients received outpatient clinic-based PT immediately after discharge from the hospital (OP) (n = 87) or home health PT before continued rehabilitation in an outpatient setting (HH) (n = 22). RESULTS: Despite demographic differences between OP and HH preoperatively, adjusted models revealed no signifi cant differences among KOOS, 6MWT, or knee ROM between OP and HH upon completion of postoperative PT. Patients in OP completed PT on average 20 days sooner (p = .0007), although the amount of time in outpatient PT (p = .55) and the number of outpatient PT visits (p = .68) were similar between groups. CONCLUSION: Gains in function were achieved by patients in OP and HH independent of the postoperative PT setting, although OP achieved gains sooner.

ID nonhuman-primates; calorie restriction; pulmonary acariasis; monkeys; lesions; endometriosis; atherosclerosis; neoplasia; prostate; system
AB The rhesus macaque (Macaca mulatta) is one of the most extensively used nonhuman primate models for human diseases. This article presents a literature review focusing on major organ systems and age-associated conditions in humans and primates, combined with information from the Wisconsin National Primate Research Center Electronic Health Record database to highlight and contrast age-associated lesions in geriatric rhesus macaques with younger cohorts. Rhesus macaques are excellent models for age-associated conditions, including diabetes, osteoarthritis, endometriosis, visual accommodation, hypertension, osteoporosis, and amyloidosis. Adenocarcinoma of the large intestine (ileocecocolic junction, cecum, and colon) is the most common spontaneous neoplasm in the rhesus macaque. A combination of cross-sectional and longitudinal studies is required to truly define mechanisms of maturation, aging, and the pathology of age-associated conditions in macaques and thus humans. The rhesus macaque is and will continue to be an appropriate and valuable model for investigation of the mechanisms and treatment of age-associated diseases.

TI Association of COL1A1 polymorphism with subchondral bone degeneration of the temporomandibular joint
SO INTERNATIONAL JOURNAL OF ORAL AND MAXILLOFACIAL SURGERY
LA English
DT Article
DE temporomandibular joint; osteoarthritis; subchondral bone; COL1A1; polymorphism; susceptibility
ID upstream regulatory region; mineral density; diagnostic-criteria; osteoarthritis; osteoporosis; collagens; disorders; severity; genetics; promoter
AB The G/T polymorphism of the COL1A1 gene exhibits a clinically significant influence on bone remodelling, leading to a predisposition to degenerative diseases. The enhancement of bone turnover and further loss of bone mass are thought to be the primary pathological changes in the early degenerative course of temporomandibular joint osteoarthritis (TMJ OA), with the appearance of low density lesions. Thus, it was hypothesized that this polymorphism may also affect this type of bone lesion in TMJ OA. A total of 130 TMJ OA patients with low density lesions (cortical bone erosion, condylar head resorption, cyst-like lesion) and 186 healthy individuals were recruited. DNA samples were extracted from buccal mucosa swabs; genotyping was performed by high-resolution melting assay. The distribution of genotypes in these groups was compared using a multivariate logistic regression model. No significant differences in the distributions of TT and TG genotypes were observed between the groups ($P > 0.05$). Significance was detected for GG homozygous carriers ($P = 0.043$); this genotype might be a risk factor for this type of low-density lesion (odds ratio 1.643, 95% confidence interval 1.016-2.658). This study indicates that the GG genotype might be a risk factor for

low-density lesions in the TMJ.

TI Local bone quality affects the outcome of prosthetic total knee arthroplasty
SO JOURNAL OF ORTHOPAEDIC RESEARCH
LA English
DT Article
DE micro-computed tomography; bone mineral density; osteoarthritis; osteoporosis; implants
ID posterior tibial slope; marrow edema pattern; mineral density; total hip; strength; flexion; microstructure; fractures; migration; failure
AB Osteoporosis and osteoarthritis commonly coexist in the elderly. In patients undergoing prosthetic total knee arthroplasty (TKA), the bone quality around the knee joint may affect the safety of prosthetic implantation and consequently satisfaction with the surgical outcome. We recruited 50 postmenopausal women undergoing TKA for primary osteoarthritis; 43 completed the study protocol. The bone quality parameters of the operated knee, including bone mineral density assessed using dual-energy X-ray absorptiometry and microarchitecture variables assessed using micro-computed tomography, were determined. Surgical outcomes were assessed according to immediate (<1week) postoperative pain quantified using the visual analog scale and knee function quantified using the Knee Injury and Osteoarthritis Outcome Score (KOOS) at 2 and 6months postoperatively. The influence of bone quality parameters on surgical outcomes was analyzed using simple and multiple regression analyses. Volumetric bone mineral density (R-2=0.187-0.234, p<0.01), the structural model index (R-2=0.103-0.181, p<0.05), and trabecular separation (R-2=0.289-0.424, p<0.05) were significantly associated with postoperative pain and improvement according to the KOOS. In conclusion, local bone quality, including mineral content and microarchitecture, affects the surgical outcome of TKA. (c) 2015 Orthopaedic Research Society. Published by Wiley Periodicals, Inc. TI Role of Thyroid Hormones in Skeletal Development and Bone Maintenance
SO ENDOCRINE REVIEWS
LA English
DT Review
ID type-2 iodothyronine deiodinase; growth-factor-i; stimulated osteocalcin synthesis; alkaline-phosphatase activity; dominant-negative mutation; activated protein-kinase; osteoblastic cell-line; l-thyroxine treatment; receptor-beta gene; thyrotropin-suppressive therapy
AB The skeleton is an exquisitely sensitive and archetypal T-3-target tissue that demonstrates the critical role for thyroid hormones during development, linear growth, and adult bone turnover and maintenance. Thyrotoxicosis is an established cause of secondary osteoporosis, and abnormal thyroid hormone signaling has recently been identified as a novel risk factor for osteoarthritis. Skeletal phenotypes in genetically modified mice have faithfully reproduced genetic disorders in humans, revealing the complex physiological relationship between centrally regulated thyroid status and the peripheral actions of thyroid hormones. Studies in mutant mice also established the paradigm that T-3 exerts anabolic actions during growth and catabolic effects on adult bone. Thus, the skeleton represents an ideal physiological system in which to characterize thyroid hormone transport, metabolism, and action during development and adulthood and in response to injury. Future analysis of T-3 action in individual skeletal cell lineages will provide new insights into cell-specific molecular mechanisms and may ultimately identify novel therapeutic targets for chronic degenerative diseases such as osteoporosis and osteoarthritis. This review provides a comprehensive analysis of the current state of the art.

AB The European Society for Clinical and Economic Aspects of Osteoporosis and Osteoarthritis (ESCEO) published a treatment algorithm for the management of knee osteoarthritis (OA) in 2014, which provides practical guidance for the

prioritization of interventions. Further analysis of real-world data for OA provides additional evidence in support of pharmacological interventions, in terms of management of OA pain and function, avoidance of adverse events, disease-modifying effects and long-term outcomes, e.g., delay of total joint replacement surgery, and pharmacoeconomic factors such as reduction in healthcare resource utilization. This article provides an updated assessment of the literature for selected interventions in OA, focusing on real-life data, with the aim of providing easy-to-follow advice on how to establish a treatment flow in patients with knee OA in primary care clinical practice, in support of the clinicians' individualized assessment of the patient. In step 1, background maintenance therapy with symptomatic slow-acting drugs for osteoarthritis (SYSADOAs) is recommended, for which high-quality evidence is provided only for the prescription formulations of patented crystalline glucosamine sulfate and chondroitin sulfate. Paracetamol may be added for rescue analgesia only, due to limited efficacy and increasing safety signals. Topical non-steroidal anti-inflammatory drugs (NSAIDs) may provide additional symptomatic treatment with the same degree of efficacy as oral NSAIDs without the systemic safety concerns. Oral NSAIDs maintain a central role in step 2 advanced management of persistent symptoms. However, oral NSAIDs are highly heterogeneous in terms of gastrointestinal and cardiovascular safety profile, and patient stratification with careful treatment selection is advocated to maximize the risk: benefit ratio. Intra-articular hyaluronic acid as a next step provides sustained clinical benefit with effects lasting up to 6 months after a short-course of weekly injections. As a last step before surgery, the slow titration of sustained-release tramadol, a weak opioid, affords sustained analgesia with improved tolerability. (C) 2015 The Authors. TI Serum and bone pentosidine in patients with low impact hip fractures and in patients with advanced osteoarthritis
SO BMC MUSCULOSKELETAL DISORDERS
LA English
DT Article
DE Biomarkers; Osteoarthritis; Osteoporosis; Pentosidine; Proximal femoral fracture
ID glycation end-product; collagen cross-links; rheumatoid-arthritis; femoral-neck; biomechanical property; postmenopausal women; synovial-fluid; bisphosphonate treatment; nonenzymatic glycation; inflammatory markers
AB Background: Femoral neck fractures are a common occurrence in patients suffering from osteoporosis, while intracapsular hip fracture is rare in cases of osteoarthritis of the hip. Previous histomorphometric studies have emphasized the association between bone microarchitecture and the risk of low-impact fractures in osteoarthritis and osteoporosis patients. However, the strength of bone material is also a function of composition of organic bone matrix. In order to compare tissue material properties in these two clinical conditions, serum and bone pentosidine, a non-enzymatic collagen crosslinking element, was measured in patients who suffered a low-impact fracture, and in patients with advanced osteoarthritis. Methods: The patient population consisted of 70 patients who underwent hemiarthroplasty surgery for a femoral neck fracture, and 41 patients with advanced hip joint osteoarthritis without a history of low-impact fracture, who were indicated for total hip joint replacement. Pentosidine content was analyzed in bone samples and in serum obtained from fracture and osteoarthritis patients using high performance liquid chromatography. Results: Serum and bone concentrations of pentosidine were higher in subjects with hip fractures compared with osteoarthritis

after adjustment for age, sex, weight, serum creatinine, and diabetes. A significant positive correlation was found between bone and serum pentosidine in fractured cases. A comparable relationship was also demonstrated for pentosidine levels in serum and bone relative to differentiation of fracture and osteoarthritis cases. Conclusions: Serum pentosidine can be considered a potential biomarker for identification of subjects with impaired bone quality and bone strength.

ID anterior cruciate ligament; bone-mineral density; female athlete triad; menstrual-cycle; risk-factors; injury risk; knee injury; acl reconstruction; primary

immunolocalization; neuromuscular control
AB Over the last 40years there has been a significant increase in the number of female athletes, as well as a rise in musculoskeletal injuries observed in women. There is sufficient evidence from past medical research identifying various musculoskeletal injuries and conditions that more commonly affect women, such as osteoarthritis, osteoporosis, stress fractures, and anterior cruciate ligament tears. Several women's sports medicine and musculoskeletal health programs have been developed throughout the United States in an attempt to provide more tailored care to the female athlete. The goal of a comprehensive approach to women's musculoskeletal health is to create an interdisciplinary team to facilitate treatment for a variety of injuries and related conditions. This manuscript outlines the musculoskeletal conditions that commonly affect women and highlights the various etiologies of these sex disparities. We discuss the role of interdisciplinary women's musculoskeletal health and sports medicine programs, and define the potential benefits of such an approach. Future studies should focus on assessing the outcomes of multidisciplinary women's sports medicine programs as current literature in this area is lacking.

TI Tai Chi for Chronic Pain Conditions: A Systematic Review and Meta-analysis of Randomized Controlled Trials
SO SCIENTIFIC REPORTS
LA English
DT Article
ID quality-of-life; knee osteoarthritis; physical function; older-adults; balance; pilot; women; exercise; health; gait
AB Several studies reported that Tai Chi showed potential effects for chronic pain, but its role remains controversial. This review assessed the evidence regarding the effects of Tai Chi for chronic pain conditions. 18 randomized controlled trials were included in our review. The aggregated results have indicated that Tai Chi showed positive evidence on immediate relief of chronic pain from osteoarthritis (standardized mean difference [SMD], -0.54; 95% confidence intervals [CI], -0.77 to -0.30; P < 0.05). The valid duration of Tai Chi practice for osteoarthritis may be more than 5 weeks. And there were some beneficial evidences regarding the effects of Tai Chi on immediate relief of chronic pain from low back pain (SMD, -0.81; 95% CI, -1.11 to -0.52; P < 0.05) and osteoporosis (SMD, -0.83; 95% CI, -1.37 to -0.28; P = 0.003). Therefore, clinicians may consider Tai Chi as a viable complementary and alternative medicine for chronic pain conditions.

TI Pharmacodynamics and pharmacokinetics of oral salmon calcitonin in the treatment of osteoporosis
SO EXPERT OPINION ON DRUG METABOLISM & TOXICOLOGY
LA English
DT Review
DE 5-CNAC; bone mineral density; calcitonin; Eudragit; fracture; osteoporosis; treatment
ID painful diabetic-neuropathy; alpha-amino-acids; postmenopausal women; nasal spray; bone mass; recombinant calcitonin; knee osteoarthritis; parathyroid-hormone; controlled-trial; hip fracture
AB Introduction: Salmon calcitonin (sCT) has been used for the treatment of postmenopausal osteoporosis for over 30 years. It is available in injectable and intranasal formulations. Two oral formulations have recently been developed. Areas covered: The basis for oral sCT's bioavailability rests with a carrier molecule (8-(N-2-hydroxy-5-chloro-benzoyl)-amino-caprylic acid) or an acid-resistant enteric coating (Eudragit (R) polymer containing citric acid). With these formulations, sCT is resistant to gastric acid, and thus becomes available for absorption at the higher pH of the small intestine. Even though the changes in bone mineral density and bone turnover markers are greater with oral compared to nasal sCT, it shows only minor effects on these surrogate markers. Expert opinion: Oral sCT is attractive in concept as it is would be more convenient to patients than other routes of administration. While there may be other advantages to the oral formulation such as improving bone mineral density to a greater extent than nasal CT, anti-fracture efficacy has not been shown in a recent major clinical trial. Together with the possibility of an association between the drug and cancer and the availability of antiresorptive drug classes that are clearly more efficacious than sCT, successful development of oral sCT as a treatment for postmenopausal osteoporosis is uncertain.

TI A comprehensive fracture prevention strategy in older adults: The European union geriatric medicine society (EUGMS) statement
SO EUROPEAN GERIATRIC MEDICINE
LA English
DT Article
DE Falls; Fragility fracture; Older people; Prevention; Position statement
ID bone-mineral density; fall prevention; hip-fracture; postmenopausal women; cost-effectiveness; zoledronic acid; risk-factors; pharmacological-treatments; strontium ranelate; liaison service
AB Prevention of fragility fractures in older people has become a public health priority, although the most appropriate and cost-effective strategy remains unclear. In the present statement, the Interest group on falls and fracture prevention of the European union geriatric medicine society (EUGMS), in collaboration with the International association of gerontology and geriatrics for the European region (IAGG-ER), the European union of medical specialists (EUMS), the Fragility fracture network (FFN), the International osteoporosis foundation (IOF) - European society for clinical and economic aspects of osteoporosis and osteoarthritis (ECCEO), outlines its views on the main points in the current debate in relation to the

primary and secondary prevention of falls, the diagnosis and treatment of bone fragility, and the place of combined falls and fracture liaison services for fracture prevention in older people. (C) 2016 Published by Elsevier Masson SAS.

AB A Summary This review provides a critical analysis of currently available approaches to increase bone mass, structure and strength through drug therapy and of possible direct intra-osseous interventions for the management of patients at imminent risk of hip fracture. Purpose Osteoporotic hip fractures represent a particularly high burden in morbidity-, mortality- and health care-related costs. There are challenges and unmet needs in the early prevention of hip fractures, opening the perspective of new developments for the management of osteoporotic patients at imminent and/or at very high risk of hip fracture. Amongst them, preventive surgical intervention needs to be considered. Methods A European Society for Clinical and Economic Aspects of Osteoporosis, Osteoarthritis and Musculoskeletal Diseases (ESCEO)/International Osteoporosis Foundation (IOF) working group reviewed the presently available intervention modalities including preventive surgical options for hip fragility. This paper represents a summary of the discussions. Results Prevention of hip fracture is currently based on regular physical activity; prevention of falls; correction of nutritional deficiencies, including vitamin D repletion; and pharmacological intervention. However, efficacy of these various measures to reduce hip fractures is at most 50% and may need months or years before becoming effective. To face the challenges of early prevention of hip fractures for osteoporotic patients at imminent and/or at very high risk of hip fracture, preventive surgical intervention needs further investigation. Conclusion Preventive surgical intervention needs to be appraised for osteoporotic patients at imminent and/or at very high risk of hip fracture.

TI Falls in older adults with cancer: a systematic review of prevalence, injurious falls, and impact on cancer treatment
SO SUPPORTIVE CARE IN CANCER
LA English
DT Review
DE Falls; Systematic review; Geriatric oncology; Cancer treatment
ID risk-factors; prostate-cancer; cognitive impairment; geriatric syndrm; community; people; predictors; hospitals; care; osteoporosis

AB The purpose of this systematic review was to update and expand the existing systematic review with the aim to answer the following questions: (1) How often do older adults (OA)s with cancer fall? (2) What are the predictors of falls in OA with cancer? (3) What is the rate of injurious falls and predictors of injurious falls in OA with cancer? (4) What are the circumstances and outcomes of falls in this population? (5) How do falls in cancer patients affect subsequent cancer treatment? Medline, Pubmed, Embase, and CINAHL were searched. Eligible studies included clinical trials, cross-sectional, cohort, case-control, and qualitative studies in which the entire sample or a sub-group of the sample were OA aged 60 and above, had cancer, in which falls were examined as a primary or secondary outcome and published in English. Twenty-seven studies met our inclusion criteria with most involving the outpatient setting. Fall rates and injurious fall rates varied widely. Consistent predictors of falls were prior falls among outpatients and cognitive impairment among inpatients. There were no data on impact of falls on cancer treatment. Data on circumstances of falls were limited. Falls and fall-related injuries are common in older cancer patients. However, little is known about circumstances of falls and impact of falls on cancer treatment. Many known fall predictors in community-dwelling OA have not been explored in oncology. More research is needed to address gaps in these areas.

AB A common manifestation of age-related bone loss and resultant osteoporosis are fractures of the hip. Age-related osteoporosis is thought to be determined by a number of intrinsic factors including genetics, hormonal changes, changes in levels of oxidative stress, or an inflammatory status associated with the aging process. The aim of this study was to investigate gene expression and bone architecture in bone samples derived from elderly osteoporotic women with hip fractures (OP) in comparison to bone samples from age matched women with osteoarthritis of the hip (OA). Femoral heads and adjacent neck tissue were collected from 10 women with low-trauma hip fractures (mean age 83 +/- 6) and consecutive surgical hip replacement. Ten bone samples from patients undergoing hip replacement due to osteoarthritis (mean age 80 +/- 5) served as controls. One half of each bone sample was subjected to gene expression analysis. The second half of each bone sample was analyzed by microcomputed tomography. From each half, samples from four different regions, the central and subcortical region of the femoral head and neck, were analyzed. We could show a significantly decreased expression of the osteoblast related genes RUNX2, Osterix, Sclerostin, WNT10B, and Osteocalcin, a significantly increased ratio of RANKL to Osteoprotegerin, and a significantly increased expression of the enzymes superoxide dismutase 2 (SOD2) and glutathione peroxidase GPX3, and of the inflammatory cytokine IL6 in bone samples from hip fracture patients compared to controls. Major microstructural changes in OP bone were seen in the neck and were characterized by a significant decrease of bone volume, trabecular number, and connectivity density and a significant increase of trabecular separation. In conclusion, our data give evidence for a decreased expression of osteoblast related genes and increased expression of osteoclast related genes. Furthermore, increased expression of SOD2 and GPX3 suggest increased antioxidative activity in bone samples from elderly osteoporotic women with hip fractures. (C) 2015 Elsevier Inc. TI The Lineage Specification of Mesenchymal Stem Cells Is Directed by the Rate of Fluid Shear Stress
SO JOURNAL OF CELLULAR PHYSIOLOGY
LA English
DT Article
ID marrow stromal cells; chondrogenic differentiation; matrix elasticity; gene-expression; mc3t3-e1 cells; nitric-oxide; bone-cells; ca2+; substrate; pressure
AB The effective regulation of fluid shear stress (FSS) on the lineage specification of mesenchymal stem cells (MSCs) remains to be addressed. We hypothesized that when MSCs are recruited to musculoskeletal system following stimulation, their differentiation into osteogenic or chondrogenic cells is directed by the rate of FSS (SS) through modulation of the mechanosensitive, cation-selective channels (MSCCs), intracellular calcium levels, and F-actin. To this end, MSCs were exposed to laminar FSS linearly increased from 0 to 10dyn/cm(2) in 0, 2, or 20min and maintained at 10dyn/cm(2) for a total of 20min (termed as SS 0-0, 0-2, and 0-20, respectively, representing more physiological (0-0) and non-physiological (0-2 and 0-20) SS treatments). Our results showed 0-0 facilitated MSC differentiation towards chondrogenic and not osteogenic phenotype, by promoting moderate intracellular calcium concentration ([Ca2+](i)) increase from the calcium channels with the exception of MSCCs or intracellular calcium stores, and F-actin organization. In contrast, 0-2 promoted MSCs towards osteogenic and not chondrogenic phenotype, by inducing significant [Ca2+](i) increase mainly from the MSCCs, and F-actin assembly. However, 0-20 elicited the modest osteogenic and chondrogenic phenotypes, as it induced the lowest [Ca2+](i) increase mainly from MSCCs, and F-actin assembly. Our results suggest that compared to the more physiological SS, the non-physiological SS favors [Ca2+](i) influx from MSCCs. An appropriate non-physiological SS (0-2) even elicits a large [Ca2+](i) influx from the

MSCCs that reverses the lineage specification of MSCs, providing validation for the high mechanosensitivity of MSCs and guidance for training osteoporosis and osteoarthritis patients. J. Cell. Physiol. 231: 1752-1760, 2016. (c) 2015 Wiley Periodicals, Inc.

TI Cementless Total Hip Arthroplasty in Primary Myelofibrosis - a Case Report
SO ACTA CHIRURGIAE ORTHOPAEDICAE ET TRAUMATOLOGIAE CECHOSLOVACA
LA English
DT Article
DE hip; primary myelofibrosis; cementless; THA; total hip replacement
AB There is a great deal of data available, in part contradictory, on the best fixation technique to use for total hip arthroplasty (THA) in hip osteoarthritis. Both the cementless and the cemented versions offer excellent long-term outcomes if the respective technique is applied correctly. However, as far as we know, no recommendation has been made regarding cemented vs. cementless THA in primary myelofibrosis. The case described here concerns a very active 76-year-old patient with primary myelofibrosis. This is a rare hematological disease. It develops from clonal hematopoiesis with impaired blood formation and progressive bone marrow fibrosis. An MRI scan of the patients pelvis showed a marked spotted change over all of the imaged bone. Ultimately, in preoperative planning we decided in favor of a proven cementless implant (Allofit Alloclassic cup and the CLS Spotorno stem from Zimmer). Complication-free osseous integration of the cementless implants was observed. Histologic analysis of the bone showed a focally sclerotically altered bone structure. Neither osteoporosis nor osteopenia were found. In our opinion, taking into account all other indication criteria, there is no reason not to perform a cementless THA implantation in the presence of primary myelofibrosis.

TI Omics analysis of human bone to identify genes and molecular networks regulating skeletal remodeling in health and disease
SO BONE
LA English
DT Review
DE Omics; Osteoporosis; Osteoarthritis; Review; Bone biopsy; Transcriptomics; Epigenetics
ID endogenous cushings-syndrome; peripheral-blood leukocytes; messenger-rna; dna methylation; osteoporotic fractures; subchondral bone; trabecular bone; expression; tissue; osteoarthritis
AB The skeleton is a metabolically active organ throughout life where specific bone cell activity and paracrine/endocrine factors regulate its morphogenesis and remodeling. In recent years, an increasing number of reports have used multi-omics technologies to characterize subsets of bone biological molecular networks. The skeleton is affected by primary and secondary disease, lifestyle and many drugs. Therefore, to obtain relevant and reliable data from well characterized patient and control cohorts are vital. Here we provide a brief overview of omics studies performed on human bone, of which our own studies performed on trans-iliacal bone biopsies from postmenopausal women with osteoporosis (OP) and healthy controls are among the first and largest. Most other studies have been performed on smaller groups of patients, undergoing hip replacement for osteoarthritis (OA) or fracture, and without healthy controls. The major findings emerging from the combined studies are: 1. Unstressed and stressed bone show profoundly different gene expression reflecting differences in bone turnover and remodeling and 2. Omics analyses comparing healthy/OP and control/OA cohorts reveal characteristic changes in transcriptomics, epigenomics (DNA methylation), proteomics and metabolomics. These studies, together with genome-wide association studies, in vitro observations and transgenic animal models have identified a number of genes and gene products that act via Wnt and other signaling systems and are highly associated to bone density and fracture. Future challenge is to understand the functional interactions between bone-related molecular networks and their significance in OP and OA pathogenesis, and also how the genomic architecture is affected in health and disease. TI Heavy metals accumulation affects bone microarchitecture in osteoporotic patients
SO ENVIRONMENTAL TOXICOLOGY
LA English
DT Article
DE heavy metals; osteoporosis; osteoarthrosis; bone health; environmental pollution
ID mineral density; environmental exposure; cadmium exposure; ros 17/2.8; lead; population; resorption; health; copper; women
AB Bone metabolism is affected by mechanical, genetic, and environmental factors and plays a major role in osteoporosis. Nevertheless, the influence of environmental pollution on the occurrence of osteoporosis is still unclear and controversial. In this context, heavy metals are the most important pollutants capable to affect bone mass. The aim of this study was to investigate whether heavy metals accumulation in bone tissues could be related to the altered bone metabolism and architecture of osteoporotic patients. To this end, we analyzed 25 bone head biopsies osteoporotic patients and 25 bone head biopsies of osteoarthritic patients. Moreover we enrolled 15 patients underwent hip arthroplasty for high-energy hip fracture or osteonecrosis of the femoral head as a control group. Bone head biopsies were studied by BioQuant-osteo software, scanning electron microscopy and Energy Dispersive X-ray microanalysis. We found a prevalence of lead, cadmium and chromium accumulation in osteoporotic patients. Noteworthy, high levels of sclerostin, detected by immunohistochemistry, correlate with the accumulation of heavy metal found in the bone of osteoporotic patients, suggesting a molecular link between heavy metal accumulation and bone metabolism impairment. In conclusion, the presence of heavy metals into bone shed new light on the comprehension of the pathogenesis of osteoporosis since these elements could play a non redundant role in the development of osteoporosis at cellular/molecular and epigenetic level. Nevertheless, in vivo and in vitro studies need to better elucidate the molecular mechanism in which heavy metals can participate to osteoporosis. (c) 2016 Wiley Periodicals, Inc. TI The roles and perspectives of microRNAs as biomarkers for intervertebral disc degeneration
SO JOURNAL OF TISSUE ENGINEERING AND REGENERATIVE MEDICINE
LA English
DT Review
DE intervertebral disc degeneration; microRNA; biomarker; NP cell apoptosis; NP cell proliferation; ECM metabolism
ID nucleus pulposus cells; fas-mediated apoptosis; circulating micrornas; rheumatoid-arthritis; up-regulation; tnf-alpha; expression; cancer; mir-21; degradation
AB MicroRNAs (miRNAs) are highly conserved molecules that regulate protein levels post-transcriptionally. Aberrant miRNA expression presents in various musculoskeletal disorders, such as osteoporosis, osteoarthritis and rheumatoid arthritis. The expression levels of miRNAs are characterized by endogenous properties and tissue specificity. This raises the possibility that miRNAs could serve as useful clinical biomarkers in the diagnosis of certain diseases. Intervertebral disc

degeneration (IDD) is one of the major causes of back pain, and a process characterized by a cascade of molecular, cellular, biochemical and structural changes. The presence of dysregulated miRNA expression in patients with disc degeneration diseases indicates that miRNAs may play a vital role in the pathogenesis of IDD. Here, we provide an introduction of the roles of miRNAs in the process of IDD, and the prospective application of miRNAs as biomarkers for IDD. Copyright (c) 2017 John Wiley & Sons, Ltd.

TI The contribution of musculoskeletal disorders in multimorbidity: Implications for practice and policy
SO BEST PRACTICE & RESEARCH IN CLINICAL RHEUMATOLOGY
LA English
DT Article
DE Multimorbidity; Co-morbidity; Musculoskeletal; Arthritis; Osteoarthritis; Osteoporosis; Back pain; Management; Prevalence; Policy
ID health-care utilization; quality-of-life; knee osteoarthritis; risk-factors; rheumatoid-arthritis; physical-activity; back-pain; work-loss; prevalence; impact
AB People frequently live for many years with multiple chronic conditions (multimorbidity) that impair health outcomes and are expensive to manage. Multimorbidity has been shown to reduce quality of life and increase mortality. People with multimorbidity also rely more heavily on health and care services and have poorer work outcomes. Musculoskeletal disorders (MSDs) are ubiquitous in multimorbidity because of their high prevalence, shared risk factors, and shared pathogenic processes amongst other long-term conditions. Additionally, these conditions significantly contribute to the total impact of multimorbidity, having been shown to reduce quality of life, increase work disability, and increase treatment burden and healthcare costs. For people living with multimorbidity, MSDs could impair the ability to cope and maintain health and independence, leading to precipitous physical and social decline. Recognition, by health professionals, policymakers, non-profit organisations, and research funders, of the impact of musculoskeletal health in multimorbidity is essential when planning support for people living with multimorbidity. DE bone targeting drugs; osteoporosis; metabolic skeletal dysplasia; bisphosphonates; nanoparticles
ID stem-cells; adipogenic differentiation; rheumatoid-arthritis; tissue regeneration; plga nanoparticles; delivery-system; bisphosphonates; morquio; interference; oligopeptide

AB The skeletal system, comprising bones, ligaments, cartilage and their connective tissues, is critical for the structure and support of the body. Diseases that affect the skeletal system can be difficult to treat, mainly because of the avascular cartilage region. Targeting drugs to the site of action can not only increase efficacy but also reduce toxicity. Bone-targeting drugs are designed with either of two general targeting moieties, aimed at the entire skeletal system or a specific cell type. Most bone-targeting drugs utilize an affinity to hydroxyapatite, a major component of the bone matrix that includes a high concentration of positively-charged Ca2+. The strategies for designing such targeting moieties can involve synthetic and/or biological components including negatively-charged amino acid peptides or bisphosphonates. Efficient delivery of bone-specific drugs provides significant impact in the treatment of skeletal related disorders including infectious diseases (osteoarthritis, osteomyelitis, etc.), osteoporosis, and metabolic skeletal dysplasia. Despite recent advances, however, both delivering the drug to its target without losing activity and avoiding adverse local effects remain a challenge. In this review, we investigate the current development of bone-targeting moieties, their efficacy and limitations, and discuss future directions for the development of these specific targeted treatments.

TI Quantitative regional and sub-regional analysis of femoral and tibial subchondral bone mineral density (sBMD) using computed tomography (CT): comparison of non-osteoarthritic (OA) and severe OA knees
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE Osteoarthritis (OA); Subchondral bone; Computed tomography (CT); Quantitative; Bone mineral density
ID cartilage thickness; radiographic osteoarthritis; disease progression; joint; alignment; osteoporosis; compartment; adduction; walking; loads
AB Objective: This study aimed to compare subchondral bone mineral density (sBMD) between non-radiographic osteoarthritic (OA) and medial femorotibial OA knees, using computed tomography (CT). Design: CT exams from 16 non-radiographic OA (KL grade < 2) and 16 severe medial OA (KL grade >= 3) knees (average age of 61.7 +/- 3 and 62.2 +/- 5 years old respectively, 50% male in each group), were retrospectively analyzed. CT exams were segmented and 3D maps of sBMD based on the CT number in the most superficial 3 mm of femoral and tibial subchondral bone were computed. Average sBMD and medial-to-lateral sBMD ratios were calculated for total load-bearing regions and for sub-regions of interest in the femur and tibia. Results: The analysis of total load-bearing regions did not reveal any significant difference between groups, except for the lateral tibia, where OA knees had lower sBMD. Sub-regional analysis unveiled differences with some sub-regions of the femur and tibia presenting significantly lower (in the lateral compartment) or higher (in the medial compartment) sBMD in OA knees compared to non-OA knees. The M/L sBMD ratios were significantly higher for OA knees compared to non-OA knees for all regions and sub-regions, except for the internal sub-regions. Conclusions: sBMD locally differs between non-OA and OA knees, in agreement with prior knowledge on biomechanics. CT proved to be a valuable tool for 3D analysis of femoral and tibial sBMD, which can be used in future studies to describe the chronology of sBMD alterations and improve our understanding of the role of subchondral bone in knee OA. TI Bisphosphonate Use and the Risk of Undergoing Total Knee Arthroplasty in Osteoporotic Patients with Osteoarthritis A Nationwide Cohort Study in Taiwan
SO JOURNAL OF BONE AND JOINT SURGERY-AMERICAN VOLUME
LA English
DT Article
ID oral bisphosphonates; randomized-trial; fracture risk; bone; alendronate; adherence; risedronate; progression; symptoms; survival
AB Background: The use of bisphosphonates has been reported to have potential beneficial effects on knee osteoarthritis, but existing studies have limitations. The purpose of this study was to examine the association of bisphosphonate use with the risk of undergoing total knee arthroplasty and with the consumption of pain medication among osteoporotic patients with knee osteoarthritis. Methods: We

identified patients who were newly diagnosed with knee osteoarthritis among a cohort of patients with osteoporosis from 2009 to 2012 in the National Health Insurance Research Database in Taiwan. We further categorized these patients into 2 groups: those who were treated with bisphosphonates (bisphosphonate users) and those who were not treated with any antiosteoporosis drug (nonusers). Bisphosphonate treatment adherence was calculated by the medication possession ratio (MPR) as the proportion of days of bisphosphonate treatment within a fixed duration; an MPR of >= 80% was considered high adherence. The primary and secondary outcomes of interest were undergoing total knee arthroplasty and the use of pain medication, respectively. Analyses using Cox proportional hazard models with propensity-score adjustment were performed to estimate the association between bisphosphonate use and the risk of undergoing total knee arthroplasty. The incremental change in the mean accumulated defined daily doses of pain medications among both bisphosphonate users and nonusers was calculated. Results: We identified 16,276 bisphosphonate users and 123,791 nonusers of any anti-osteoporosis drug among the patients with osteoporosis who were newly diagnosed with osteoarthritis. Bisphosphonate use was significantly associated with a decreased risk of total knee arthroplasty (adjusted hazard ratio [HR], 0.76; 95% confidence interval [CI], 0.69 to 0.83; p < 0.001). In patients with a follow-up period of >= 24 months and an MPR of >= 80%, the effect size was significantly greater (adjusted HR, 0.66; p = 0.048). Over the 5 years of follow-up, we found a significantly greater decrease in the use of pain medication among bisphosphonate users than among nonusers (p < 0.001; Chow test). Conclusions: Among patients with osteoporosis and osteoarthritis, bisphosphonate use was associated with a significantly lower risk of total knee arthroplasty, especially in patients with high adherence and longer treatment duration. A lower consumption of pain medication was also found for bisphosphonate users among the patients with osteoporosis and osteoarthritis.

TI Development of nanomaterials for bone-targeted drug delivery
SO DRUG DISCOVERY TODAY
LA English
DT Review
ID mesoporous silica nanoparticles; endoplasmic-reticulum stress; bioactive glass nanoparticles; nonviral gene delivery; of-the-art; gold nanoparticles; in-vitro; osteoclast differentiation; multifunctional nanoparticles; morphogenetic protein-2
AB Bone is one of the major organs of the human body; it supports and protects other organs, produces blood cells, stores minerals, and regulates hormones. Therefore, disorders in bone can cause serious morbidity, complications, or mortality of patients. However, despite the significant occurrence of bone diseases, such as osteoarthritis (OA), osteoporosis (OP), non-union bone defects, bone cancer, and myeloma-related bone disease, their effective treatments remain a challenge. In this review, we highlight recent progress in the development of nanotechnology-based drug delivery for bone treatment, based on its improved delivery efficiency and safety. We summarize the most commonly used nanomaterials for bone drug delivery. We then discuss the targeting strategies of these nanomaterials to the diseased sites of bone tissue. We also highlight nanotechnology-based drug delivery to bone cells and subcellular organelles. We envision that nanotechnology-based drug delivery will serve as a powerful tool for developing treatments for currently incurable bone diseases.

TI Degenerative inter-vertebral disc disease osteochondrosis intervertebralis in Europe: prevalence, geographic variation and radiological correlates in men and women aged 50 and over
SO RHEUMATOLOGY
LA English
DT Article
DE intervertebral disc; degenerative disease; population-based; multi-centre prevalence study; plane radiology; Kellgren-Lawrence grading; bone mineral density (BMD); reproducibility study; osteochondrosis intervertebralis; age range 50 plus years
ID facet joint osteoarthritis; low-back-pain; bone-density; osteoporotic fractures; osteo-arthrosis; lumbar spine; population; association; deformity; evos

AB Objectives. To assess the prevalences across Europe of radiological indices of degenerative inter-vertebral disc disease (DDD); and to quantify their associations with, age, sex, physical anthropometry, areal BMD (aBMD) and change in aBMD with time. Methods. In the population-based European Prospective Osteoporosis Study, 27 age-stratified samples of men and women from across the continent aged 50+ years had standardized lateral radiographs of the lumbar and thoracic spine to evaluate the severity of DDD, using the Kellgren-Lawrence (KL) scale. Measurements of anterior, mid-body and posterior vertebral heights on all assessed vertebrae from T4 to L4 were used to generate indices of end-plate curvature. Results. Images from 10 132 participants (56% female, mean age 63.9 years) passed quality checks. Overall, 47% of men and women had DDD grade 3 or more in the lumbar spine and 36% in both thoracic and lumbar spine. Risk ratios for DDD grades 3 and 4, adjusted for age and anthropometric determinants, varied across a three-fold range between centres, yet prevalences were highly correlated in men and women. DDD was associated with flattened, non-ovoid inter-vertebral disc spaces. KL grade 4 and loss of inter-vertebral disc space were associated with higher spine aBMD. Conclusion. KL grades 3 and 4 are often used clinically to categorize radiological DDD. Highly variable European prevalences of radiologically defined DDD grades 3+ along with the large effects of age may have growing and geographically unequal health and economic impacts as the population ages. These data encourage further studies of potential genetic and environmental causes.

TI Bone-targeting parathyroid hormone conjugates outperform unmodified PTH in the anabolic treatment of osteoporosis in rats
SO DRUG DELIVERY AND TRANSLATIONAL RESEARCH

DT Article
DE PTH; Bone drug delivery; Anabolic therapy; Osteoporosis; Micro-CT
ID postmenopausal women; ovariectomized rats; mineral crystals; strontium; mass;

receptors; model; osteoarthritis; teriparatide; alendronate
AB Synthetic parathyroid hoinione (PTH) is clinically indicated for the treatment of osteoporosis, through its anabolic effects on parathyroid hormone receptors (PTHRs), located on osteoblast cells. However, the bioavailability of PTH for hone cells is restricted by the short half-life of PTH and the widespread distribution of PTHRs in non-skeletal tissues. To impart affinity for mineralized hone surfaces, bisphosphonate (BP)-mediated PTH analogues were synthesized, characterized, and evaluated in vitro and in vivo. The successful synthesis of PTH-PEG-BP was identified on MALDI-ToF mass spectra; bone-targeting potential was evaluated by hydroxyapatite binding test; and receptor bioactivity was assessed in UMR-106 (rat osteosarcoma) cells that constitutively express PTHRs. Therapeutic efficacy was evaluated using ovariectomized rats that remained untreated for 8 weeks to allow development of osteopenia. Those rats then received daily subcutaneous injections of PTH-PEG-BP, thiol-BP vehicle, or unmodified PTH, and compared to sham-operated healthy rats at 0, 4, 8, 12, and 16 weeks. In vivo micro-CT was conducted on the proximal tibial metaphysis to measure microstnictural hone parameters, and new bone formation was detected using dynamic labeling. Bone strength was assessed using three-point bending mechanical testing. Our study determined that PTH-PEG-BP conjugates significantly enhanced PTH targeting to the hone matrix while retaining full PTH bioactivity. Moreover, PTH-PEG-BP conjugates significantly increased trabecular bone quality, anabolic bone forma lion, and improved bone strength over systemically administered PTH alone. We highlight the promise of a novel class of bone-targeting anabolic compound for the treatment of osteoporosis and related bone disorders.

TI Age-Related Diseases and Clinical and Public Health implications for the 85 Years Old and Over Population
SO FRONTIERS IN PUBLIC HEALTH
LA English
DT Review
DE oldest-old; medical decision-making; public policy; aging; longevity
ID all-cause mortality; physical function; womens health; hearing-loss; young-old; adults; prevalence; services; disability; atherosclerosis
AB By 2050, the American 85 years old and over population will triple. Clinicians and the public health community need to develop a culture of sensitivity to the needs of this population and its subgroups. Sensory changes, cognitive changes, and weakness may be subtle or may be severe in the heterogeneous population of people over age 85. Falls, cardiovascular disease, and difficulty with activities of daily living are common but not universal. This paper reviews relevant changes of normal aging, diseases, and syndromes common in people over age 85, cognitive and psychological changes, social and environmental changes, and then reviews common discussions which clinicians routinely have with these patients and their families. Some hearing and vision loss are a part of normal aging as is decline in immune function. Cardiovascular disease and osteoporosis and dementia are common chronic conditions at age 85. Osteoarthritis, diabetes, and related mobility disability will increase in prevalence as the population ages and becomes more overweight. These population changes have considerable public health importance. Caregiver support, services in the home, assistive technologies, and promotion of home exercise programs as well as consideration of transportation and housing policies are recommended. For clinicians, judicious prescribing and ordering of tests includes a consideration of life expectancy, lag time to benefit, and patient goals. Furthermore, healthy behaviors starting in early childhood can optimize quality of life among the oldest-old.

TI The impact of musculoskeletal diseases on mortality-comparison with internal diseases: A 15-year longitudinal study
SO JOURNAL OF ORTHOPAEDIC SCIENCE
LA English
DT Article
ID follow-up; obesity; hypertension; smoking; risk; osteoarthritis; prevalence; health; cohort; death
AB Background: Aging is associated with an increased incidence of diabetes (DM), hypertension (HT), hyperlipidemia (HL), as well as musculoskeletal disorders, such as osteoarthritis (OA) and osteoporosis (OP). However, the impact of musculoskeletal disorders on mortality remains unclear. This study investigated the risk of mortality if having knee OA or OP. Methods: 601 participants (mean age 67.8 +/- 5.3 years) who underwent musculoskeletal check-ups in Yakumo town were enrolled in this study, 248 were males and 353 were females. The following parameters were assessed: age, sex, body mass index, smoking habit, alcohol drinking habit, physical exercise habit, knee OA, OP, HT, DM and HL. Kaplan-Meier survival curves for smoking, drinking and physical exercise habits, knee OA, OP, HT, DM and HL were prepared, and the log-rank test was performed. Furthermore, the Cox hazard model was used for multivariate analysis of all variables. Results: Knee OA, OP, HT, and DM were associated with a significantly higher mortality rate. Cox regression analysis results showed a hazard ratio of 1.972 for OA (95% CI: 1.356-2.867), 1.965 for DM (1.146-3.368), 1.706 for smoking habits (1.141-2.552), and 1.614 for OP (1.126-2.313). Cardiovascular diseases were the most common causes of death. Conclusions: Smoking, knee OA, OP and DM were all associated with increased risk of mortality. Knee OA had a high hazard ratio, comparable to that of DM. These findings suggest that interventions against smoking, knee OA, OP and DM may reduce the risk of mortality. TI Subchondral bone sclerosis and cancellous bone loss following OA induction depend on the underlying bone phenotype
SO JOINT BONE SPINE
LA English
DT Article

DE Osteoarthritis; Osteoporosis; Subchondral bone sclerosis; Cancellous bone loss
ID articular-cartilage; str/ort mice; alendronate treatment; knee osteoarthritis; mouse; osteoporosis; resorption; turnover; plate; model
AB Objectives: Osteoarthritis (OA) is increasingly considered a disease of the whole joint, yet the interplay between the articular cartilage and the subchondral bone remains obscure. We here set out to investigate the impact of bone mass on the progression of surgically induced knee OA in the mouse. Methods: OA was induced in the right knees of female C57BL/6 (low bone mass) and STR/ort (high bone mass) mice via anterior cruciate ligament transection and destabilization of the medial meniscus. At 36 weeks of age, left and right knee joints were histologically compared for cartilage degeneration and via microCT analysis for subchondral bone plate thickness. In addition, femora were analyzed for bone mass at diaphysis and distal meta-and epiphysis. Results: The severity of cartilage deterioration did not differ under high and low bone mass conditions. However, the extent of bone sclerosis differed and was proportional to the baseline subchondral bone plate thickness. Moreover, the cancellous bone loss following OA progression was inversely related to the bone mass: high bone mass restricted the loss to the epiphysis, whereas low bone mass allowed for a more widespread loss extending into the metaphysis. Conclusions: Our results suggest that cartilage degeneration is independent of the underlying bone mass. In contrast, subchondral bone remodeling associated with OA progression seem to correlate with the initial bone mass and suggest an enhanced crosstalk between the deteriorating cartilage and the subchondral bone under low bone mass conditions. TI Efficacy of acupuncture in pain management of chronic diseases of bone and joint: a review of literature
SO INTERNATIONAL JOURNAL OF CLINICAL AND EXPERIMENTAL MEDICINE
LA English
DT Review
DE Acupuncture; osteoarthritis; rheumatoid arthritis; osteoporosis; pain; anti-inflammatory agents
ID randomized controlled-trial; severe knee osteoarthritis; carpal-tunnel-syndrome; low-back-pain; rheumatoid-arthritis; hyaluronic-acid; pharmacological-treatment; supervised exercise; convergent neurons; adjunctive therapy
AB Acupuncture is in use in China for several millennia as a procedure believed to restore altered energy balance of the body due to any disease through insertion of needles at specific points called energy channels. The use of acupuncture in various types of musculoskeletal pain is on the rise. The analgesic action of acupuncture is mediated by local production of endogenous opioid peptides (EOP) and modulation of nociceptor function. Several high quality randomized clinical trials (RCT) have generally concluded that acupuncture is effective in relieving back pain compared with no treatment and comparable to usual care for back pain. Several high quality studies found significant pain reduction in patients with osteoarthritis of knee although lack of analgesic effect of acupuncture in this disease setting has also been reported. High quality studies on the effect of acupuncture in

rheumatoid arthritis (RA) are lacking. When two well-designed (double-blind, randomized and placebo-controlled) studies with RA patients were considered, one found significantly improved tender joint and pain by traditional acupuncture but the other failed to find any effect of acupuncture over placebo. In case of gouty arthritis, a systematic meta-analysis found significant efficacy of acupuncture treatment in decreasing blood uric acid and improving the overall quality of life. Effect of acupuncture on post-menopausal osteoporosis remains understudied. Results from preclinical studies in gonadectomised rats suggests bone conserving effect of acupuncture; however, efficacy trials in postmenopausal osteoporotic patients are not yet available. The goal of the review was to comprehensively discuss the scientific basis of acupuncture in alleviating chronic pain arising from bone and joint diseases.

TI Aliskiren has chondroprotective efficacy in a rat model of osteoarthritis through suppression of the local renin-angiotensin system
SO MOLECULAR MEDICINE REPORTS
LA English
DT Article
DE aliskiren; osteoarthritis; renin-angiotensin system; chondroprotective efficacy
ID articular-cartilage; gene-expression; knee osteoarthritis; bone-resorption; joint injury; inhibition; differentiation; osteoporosis; chondrocytes; cells
AB The local renin-angiotensin system (RAS) has been reported to have an important role in the pathogenesis and progression of metabolic bone diseases, including osteoarthritis (OA). Aliskiren is the first in a new class of orally effective direct renin inhibitors and is approved for the treatment of hypertension in humans. However, its efficacy in patients with OA is unknown. A rat model of OA was induced to investigate the potential efficacy of aliskiren. Effects of aliskiren on the cartilage structure were detected by safranin O staining and its effects on the widths of the proliferation zone and hypertrophic zone (HZ) of chondrocytes were analyzed by Masson's staining. Tartate-resistant acid phosphatase staining was used to evaluate the effects of aliskiren on osteoclasts in the chondrocytes. Relative histological analyses were performed. Additionally, the expression levels of factors associated with osteoclast differentiation (receptor activator of nuclear factor.B ligand and osteoprotegerin), articular cartilage destruction [tumor necrosis factor-alpha (TNF-alpha) and matrix metalloproteinase 9] and osteoblast differentiation [runt related transcription factor 2 (Runx2)], along with RAS components (renin, renin-receptor, angiotensin type 1 receptor (AT1R), AT2R, angiotensin converting enzyme (ACE) and angiotensin II (Ang II)] were detected in samples from the proximal tibias. Aliskiren did not fully suppress the inflammatory

reaction in OA model animals and had marginal regulatory effects on biochemical bone markers induced by OA. However, aliskiren attenuated cartilage destruction, abnormal cartilage cellularity and the expansion of the HZ of chondrocytes, and significantly attenuated the expression of interleukin-1, TNF-alpha, Runx2 and procollagen type I N-terminal propeptide. These chondroprotective properties were accompanied by reductions in the levels of RAS components (renin, Ang II, ACE and AT1R), indicating that aliskiren exerts multiple effects of on bone formation, osteoblast differentiation and articular cartilage protection via the RAS. OA activates the local bone RAS, inhibits bone formation and stimulates bone resorption. Aliskiren, a renin inhibitor, demonstrated chondroprotective efficacy in a rat model of OA through suppression of the local RAS.

TI In vitro cystein protease inhibitory activity of selected Indian antimalarial plants
SO INDIAN JOURNAL OF TRADITIONAL KNOWLEDGE
LA English
DT Article
DE Nyctanthes arbor- tristis; Falcipain; Cysteine protease inhibitor; Papain inhibition; Malaria
AB In this study few plants having antimalarial activity (leaves of Nyctanthes arbor-tristis L., Caesalpinia crista L., Ailanthus excelsa Roxb., Bauhinia variegate L., seed of Balanites aegyptiaca Delile, entire plant of Enicostema littorale Blume, fruits of Momordica charantia L.) were screened for cystein protease inhibitory activity. Cysteine protease inhibitory activity was done by papain inhibition assay. Water and methanol extracts of all selected plants were screened for in vitro enzyme inhibition assay. Percentage inhibition of papain was measured and IC50 for all the extracts were calculated. Comparative study of above selected medicinal plants methanolic and water extract showed the maximum inhibition in leaves of N. arbor-tristis, 87.8051 %, IC50 - 13.03 mu g/ml and 85.6189 %, IC50 - 16.54 mu g/ml, respectively. The present study has provided scientific validity to leaves of N. arbor-tristis against cysteine protease inhibition activity and it is concluded that protease inhibitor of N. arbor-tristis-leaves are an indicator of wide range of pharmacological activities such as anticancer, antimalarial, osteoarthritis,

osteoporosis, etc., isolation of cysteine protease inhibitors may provide a lead compound for development of novel therapeutic agents in the above areas.

TI Associations between chronic comorbidity and exacerbation risk in primary care patients with COPD
SO RESPIRATORY RESEARCH
LA English
DT Article
ID obstructive pulmonary-disease; health-status; retrospective cohort; prevalence; index; management; mortality; outcm
AB Background: COPD often coexists with chronic conditions that may influence disease prognosis. We investigated associations between chronic (co) morbidities and exacerbations in primary care COPD patients. Method: Retrospective cohort study based on 2012-2013 electronic health records from 179 Dutch general

practices. Comorbidities from patients with physician-diagnosed COPD were categorized according to International Classification of Primary Care (ICPC) codes. Chi-squared tests, uni-and multivariable logistic, and Cox regression analyses were used to study associations with exacerbations, defined as oral corticosteroid prescriptions. Results: Fourteen thousand six hundred three patients with COPD could be studied (mean age 67 (SD 12) years, 53% male) for two years. At baseline 12,826 (88%) suffered from >= 1 comorbidities, 3263 (22%) from >= 5. The most prevalent comorbidities were hypertension (35%), coronary heart disease (19%), and osteoarthritis (18%). Several comorbidities showed statistically significant associations with frequent (i.e., >= 2/year) exacerbations: heart failure (odds ratio [OR], 95% confidence interval: 1.72; 1.38-2.14), blindness & low vision (OR 1.46; 1.21-1.75), pulmonary cancer (OR 1.85; 1.28-2.67), depression 1.48; 1.14-1.91), prostate disorders (OR 1.50; 1.13-1.98), asthma (OR 1.36; 1.11-1.70), osteoporosis (OR 1.41; 1.11-1.80), diabetes (OR 0.80; 0.66-0.97), dyspepsia (OR 1.25; 1.03-1.50), and peripheral vascular disease (OR 1.20; 1.00-1.45). From all comorbidity categories, having another chronic respiratory disease beside COPD showed the highest risk for developing a new exacerbation (Cox hazard ratio 1.26; 1.17-1.36). Conclusion: Chronic comorbidities are highly prevalent in primary care COPD patients. Several chronic comorbidities were associated with having frequent exacerbations and increased exacerbation risk.

TI Exercise and Sports Science Australia (ESSA) position statement on exercise prescription for the prevention and management of osteoporosis
SO JOURNAL OF SCIENCE AND MEDICINE IN SPORT
LA English
DT Review
DE Ageing; Balance; Bone; Exercise guidelines; Falls; Fracture prevention; Muscle; Osteopenia; Physical activity
ID bone-mineral density; randomized controlled-trial; provides lifelong benefits; high-impact exercise; postmenopausal women; physical-activity; older-adults; resistance exercise; falls prevention; vitamin-d
AB Objectives: Osteoporotic fractures are associated with substantial morbidity and mortality. Although exercise has long been recommended for the prevention and management of osteoporosis, existing guidelines are often non-specific and do not account for individual differences in bone health, fracture risk and functional

capacity. The aim of the current position statement is to provide health practitioners with specific, evidence-based guidelines for safe and effective exercise prescription for the prevention or management of osteoporosis, accommodating a range of potential comorbidities. Design: Position statement. Methods: Interpretation and application of research reports describing the effects of exercise interventions for the prevention and management of low bone mass, osteoporosis and osteoporotic fracture. Results: Evidence from animal and human trials indicates that bone responds positively to impact activities and high intensity progressive resistance training. Furthermore, the optimisation of muscle strength, balance and mobility minimises the risk of falls (and thereby fracture), which is particularly relevant for individuals with limited functional capacity and/or a very high risk of osteoporotic fracture. It is important that all exercise programs be accompanied by sufficient calcium and vitamin D, and address issues of comorbidity and safety. For example, loaded spine flexion is not recommended, and impact activities may require modification in the presence of osteoarthritis or frailty. Conclusions: Specific guidelines for safe and effective exercise for bone health are presented. Individual exercise prescription must take into account existing bone health status, co-morbidities, and functional or clinical risk factors for falls and fracture. AB The treatment of adult osteonecrosis of the femoral head (ONFH), with 8.12 million patients in China, remains a challenge to surgeons. To standardize and improve the efficacy of the treatment of ONFH, Chinese specialists updated the experts' suggestions in March 2015, and an experts' consensus was given to provide a current basis for the diagnosis, treatment and evaluation of ONFH. The current guideline provides recommendations for ONFH with respect to epidemiology, etiology, diagnostic criteria, differential diagnosis, staging, treatment, as well as rehabilitation. Risk factors of non-traumatic ONFH include corticosteroid use, alcohol abuse, dysbarism, sickle cell disease and autoimmune disease and others, but the etiology remains unclear. The Association Research Circulation Osseous (ARCO) staging system, including plain radiograph, magnetic

resonance imaging, radionuclide examination, and histological findings, is frequently used in staging ONFH. A staging and classification system was proposed by Chinese scholars in recent years. The major differential diagnoses include mid-late term osteoarthritis, transient osteoporosis, and subchondral insufficiency fracture. Management alternatives for ONFH consist of non-operative treatment and operative treatment. Core decompression is currently the most common procedure used in the early stages of ONFH. Vascularized bone grafting is the recommended treatment for ARCO early stage III ONFH. This guideline gives a brief account of principles for selection of treatment for ONFH, and stage, classification, volume of necrosis, joint function, age of the patient, patient occupation, and other factors should be taken into consideration.

TI Relation between osteoporosis and radiographic and clinical signs of osteoarthritis/arthrosis in the temporomandibular joint: a population-based, cross-sectional study in an older Swedish population
SO GERODONTOLOGY
LA English
DT Article
DE epidemiology; osteoarthritis; osteoporosis; temporomandibular joint
ID research diagnostic-criteria; disorders rdc/tmd; reliability; gothenburg
AB Objective: The aim was to elucidate the relation between osteoporosis and osteoarthritis/arthrosis (OA) in the temporomandibular joint (TMJ). Background: General epidemiological data support the hypothesis that osteoporosis and OA are inversely correlated but is not conclusively investigated in the TMJ. Materials and methods: A group of 114 representative elderly women and men, randomised from a comprehensive population study in Gothenburg, Sweden, had bone mineral density established with whole-body, dual-energy X-ray absorptiometry (DXA) as part of a health survey. In addition, dental examinations were performed, including panoramic radiographs exposed as an overview of the TMJ's and jaws. In 88 of the 80-year-old participants (48 women and 40 men), a clinical orofacial examination according to the RDC/TMD system was performed. Results: A diagnosis of osteopenia/osteoporosis was found in 36% of the 114, with a statistically different greater proportion of women. Condylar alterations evaluated from panoramic radiographs were observed in 34%, with no significant gender difference. No significant differences were found in the proportion of individuals with osteopenia/osteoporosis and any condylar radiographic alteration or not. Forty-one of the clinically examined subjects, 47%, fulfilled the criteria for an RDC/TMD diagnosis with no gender difference. All participants graded the orofacial pain as low chronic pain. An opening capacity of <40 mm denoted a higher risk of having pain in the temporomandibular system. No association was found between clinical diagnosis of RDC/TMD and osteopenia/osteoporosis. Conclusion: The

prevalence of osteopenia/osteoporosis appears not to be of importance for radiological or clinical findings of OA in the TMJ.

AB With the advent of aging, the morbidity rates of such diseases as osteoarthritis, rheumatoid arthritis, and osteoporosis has witnessed a significant increase. As a common rattan drug, sinomenine (SIN) has been widely applied for the treatment of various arthritic diseases in traditional Chinese medicine (TCM) clinics. Given that SIN has been reported to inhibit the expression of Prostaglandin E2 (PGE2) in several types of cells, in this study, the influence of SIN treatment on PGE2 expression in mesenchymal stem cells (MSCs), thereby changing the osteoprotegerin (OPG) receptor/activator for the nuclear factor-kappa B ligand (RANKL) ratio, was investigated. Our results showed that, when compared with the untreated cells, treatment with 0.25 mM SIN can down-regulate the mRNA and protein expression levels of the Prostaglandin E synthase 3 (PTGES3) or PGE2 and RANKL, while the OPG was up-regulated. After being cultured with SIN treated MSC-conditioned medium (stMSC-CM), the amount of TRAP-positive multinucleated osteoclasts differentiated from RAW264.7 cells was reduced. Also, the expression levels of specific markers for active osteoclasts were decreased when incubated with stMSC-CM. Moreover, these changes were able to be recovered when the exogenous RANKL was added to the MSC-CM culture. This indicates that the increased OPG/RANKL ratio can reduce the osteoclastogenesis of RAW264.7 cells. Our results demonstrated that SIN has an inhibitory effect on osteoclast differentiation through mechanisms involving the inhibition of the

PGE2-induced OPG/RANKL ratio. SIN can also serve as a proinflammatory mediator to regulate the MSC immunosuppressive effects. Our findings suggest that SIN can be useful for the treatment of bone diseases associated with over-activity of osteoclasts. (C) 2017 Elsevier Masson SAS. All rights reserved.

TI Rottinger approach with dual-mobility cup to improve functional recovery in hip osteoarthritis patients: biomechanical and clinical follow-up
SO INTERNATIONAL ORTHOPAEDICS
LA English
DT Article
DE Arthroplasty; Gait analysis; Hip; Osteoarthritis; Minimal invasive surgery; Postural balance
ID prevent dislocation; arthroplasty; replacement; gait; anterior; surgery; score
AB Purpose We assumed that the combination of dual-mobility total hip arthroplasty (THA) using the minimally-invasive Rottinger anterolateral approach could guarantee hip stability with faster functional recovery. We objectively analyzed functional improvement after dual-mobility THA by quantitative gait analysis. Methods We compared the results achieved following two different surgical approaches: Rottinger's versus Moore's approach (posterolateral approach). We included 70 patients in an open prospective single-centre study: 38 by Rottinger's approach (age = 67yo) and 32 by Moores's approach (age = 68yo). Clinical and biomechanical analysis (kinematic and kinetic parameters of the hip) were conducted at the pre-operative period and at six months post-op Results We found a significant improvement in all clinical scores and all biomechanical parameters but no difference was found between the two approaches. However, the study showed marked clinical, biomechanical and functional improvements for patients treated with dual-mobility THA for osteoarthritis without complete hip recovery compared with a control group. Conclusions The combination of the Rottinger approach with a dual-mobility cup remains a valid choice for primary THA without functional advantage at midterm.

TI Hyperuricemia, Cardiovascular Profile, and Comorbidity in Older Men and Women: The Pro. VA Study
SO REJUVENATION RESEARCH
LA English
DT Article
DE cardiovascular disease; comorbidity; elderly; epidemiology; hyperuricemia; uric acid
ID serum uric-acid; us general-population; metabolic syndrome; risk-factor; gout; prevalence; management; disease; recommendations; hypertension
AB Hyperuricemia (HU) is growing worldwide and associates with several medical conditions in the elderly. However, data about older people and possible gender differences are sparse. The aim of this study was to compare HU prevalence rates and association with relevant medical disorders in elderly subjects of both sexes. Pro. V.A. is a survey of 3099 individuals aged 65+, focusing on chronic diseases and disability. Uric acid (UA) levels were dichotomized using 6.0 mg/dL (females) and 7.0 mg/dL (males), and multivariate logistic regression models were used to estimate odds ratios (ORs) between HU and single comorbidity. HU prevalence was 21.5% in females and 15.8% in males. HU was associated with most anthropometric and laboratory variables in women, but not in men. After adjustment for age, body mass index, and renal function, HU was independently associated with the presence of cardiovascular diseases in both sexes. In women, HU was associated with hand osteoarthritis (OR = 1.52; 95% CI: 1.12-2.08) and edentulism (OR = 1.31; 95% CI: 1.01-1.71), while resulted protective for osteoporosis (OR = 0.69; 95% CI: 0.53-0.91). In men, HU was significantly related with knee osteoarthritis (OR = 1.72; 95% CI: 1.06-2.79) and chronic obstructive pulmonary disease (OR = 1.60; 95% CI: 1.04-2.45). The presence of >= 4 comorbidities was a stronger determinant of HU in men (OR = 2.54; 95% CI: 1.21-5.37) than in women (ns). Patterns of age-dependent UA increase are markedly different in men and women. HU

prevalence is substantial and its association with other diseases is gender specific, connoting a peculiar clinical profile.

TI Effect of progressive high-impact exercise on femoral neck structural strength in postmenopausal women with mild knee osteoarthritis: a 12-month RCT
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE Cartilage; Exercise; Menopause; RCT
ID bone-mineral density; physical performance; articular-cartilage; hip; fracture; therapy; risk; intensity; mass; mri
AB It is uncertain whether subjects with mild knee osteoarthritis, and who may be at risk of osteoporosis, can exercise safely with the aim of improving hip bone strength. This RCT showed that participating in a high-impact exercise program improved femoral neck strength without any detrimental effects on knee cartilage composition. No previous studies have examined whether high-impact exercise can improve bone strength and articular cartilage quality in subjects with mild knee osteoarthritis. In this 12-month RCT, we assessed the effects of progressive high-impact exercise on femoral neck structural strength and biochemical composition of knee cartilage in postmenopausal women. Eighty postmenopausal women with mild knee radiographic osteoarthritis were randomly assigned into the exercise (n = 40) or control (n = 40) group. Femoral neck structural strength was assessed with dual-energy X-ray absorptiometry. The knee cartilage region exposed to exercise loading was measured by the quantitative MRI techniques of T2 mapping and delayed gadolinium-enhanced MRI of cartilage (dGEMRIC). Also, an accelerometer-based body movement monitor was used to evaluate the total physical activity loading on the changes of femoral neck strength in all participants. Training effects on the outcome variables were estimated by the bootstrap analysis of covariance. A significant between-group difference in femoral neck bending strength in favor of the trainees was observed after the 12-month intervention (4.4%, $p < 0.01$). The change in femoral neck bending strength remained significant after adjusting for baseline value, age, height, and body mass (4.0%, $p = 0.020$). In all participants, the change in bending strength was associated with the total physical activity loading ($r = 0.29$, $p = 0.012$). The exercise participation had no effect on knee cartilage composition. The high-impact training increased femoral neck strength without having any harmful effect on knee cartilage in women with mild knee osteoarthritis. These findings imply that progressive high-impact exercise is a feasible method in seeking to prevent hip fractures in postmenopausal women whose articular cartilage may also be frail.

ID bone-mineral density; prevalent vertebral fractures; iscd official positions; hip axis length; older us adults; osteoporotic fractures; white women; t-score; proximal femur; task-force
AB Bone mineral density (BMD) measurement by dual-energy X-ray absorptiometry (DXA) is the most commonly used method to assess fracture risk. DXA utilizes two different energy X-rays to calculate BMD and, by comparison to a young normative

database, the T-score. In 1994, the World Health Organization defined osteoporosis based on T-score, changing the paradigm of the field and forever placing DXA measurements in the center of osteoporosis diagnosis. Since then, many large studies have demonstrated the predictive value of BMD by DXA-for every standard deviation decline in BMD, there is a relative risk of 1.5-2.5 for fracture. This predictive ability is similar to how blood pressure can predict myocardial infarction. Limitations of DXA are also important to consider. While BMD by DXA can identify those at risk, there is a significant overlap in the BMD of patients who will and will not fracture. Special considerations are also needed in men and ethnic minority groups. These groups may have different bone size, thus affecting the normative range of BMD, and/or distinct bone structure that affect the association between BMD and fractures. Finally, BMD can be affected by positioning errors or artifacts, including osteoarthritis, fracture, and jewelry. Of course, DXA has tremendous strengths as well-namely its wide availability, its low radiation exposure, and a large body of evidence that relate DXA measurements to fracture risk. For these reasons, DXA remains the cornerstone of fracture assessment now and for the foreseeable future.

TI Effects of bisphosphonates on mandibular condyle of ovariectomized osteoporotic rats using micro-ct and histomorphometric analysis
SO JOURNAL OF ORAL PATHOLOGY & MEDICINE
LA English
DT Article
DE bisphosphonate-induced osteonecrosis of the jaws; collagen; mandibular condyle; osteoporosis; ovariectomy
ID subchondral bone; cartilage; estrogen; osteoarthritis; alendronate; growth; joint; beta; degeneration; turnover
AB ObjectiveTo evaluate microarchitectural changes in condylar cartilage and associated subchondral bone after bisphosphonates treatment using an ovariectomized (OVX) osteoporosis rat model. MethodsThirty six-month-old female Sprague-Dawley rats were randomly divided into sham, OVX, and risedronate (RIS)-treated groups. Both OVX and RIS groups received bilateral ovariectomy. OVX group was treated subcutaneously with saline, whereas RIS group received risedronate treatment (2.4 g/kg) subcutaneously for 3 months. At the end of 3 months, animals were sacrificed and the entire condyles were harvested for micro-CT and histological analyses. Immunohistochemistry (IHC) was performed to assess the expression of type I/II collagen protein by semiquantitative imaging analysis. ResultsMicro-CT analysis showed OVX group had significant condylar subchondral bone loss compared to sham as shown by significant decrease in bone volume fraction ($P = 0.028$), trabecular thickness ($P = 0.041$), and significant increase in trabecular spacing ($P = 0.003$). In RIS group, partial inhibition of OVX-induced bone loss was detected. HE staining showed proliferative layer of condylar cartilage reduced, while hypertrophic chondrocyte layer increased significantly in RIS group compared to sham and OVX groups. IHC showed reduced expression of Col I in both the OVX and RIS groups, whereas expression of Col II was reduced in the OVX group but increased in the RIS group. ConclusionOur findings suggest that systemic bisphosphonate treatment influences the structure and ossification of condylar cartilage and it has a dual action on condyle in a postmenopausal osteoporosis rat model which raises the concerns for the potential side effects of BPs on condyle to elder patients.

TI Do whole body vibration exercises affect lower limbs neuromuscular activity in populations with a medical condition? A systematic review
SO RESTORATIVE NEUROLOGY AND NEUROSCIENCE
LA English
DT Review
DE Electromyography; muscle; whole body vibration; rehabilitation
ID quality-of-life; muscle strength; blood-flow; knee osteoarthritis; skeletal-muscle; motor function; chronic stroke; elderly-women; intervention; osteoporosis
AB Background: The use of surface electromyography (sEMG) to evaluate muscle activation when executing whole body vibration exercises (WBVE) in studies provide neuromuscular findings, in healthy and diseased populations. Objectives: Perform a systematic review of the effects of WBVE by sEMG of lower limbs in non-healthy populations. Methods: The search using the defined keywords was performed in PubMed, PEDRo and EMBASE databases by three independent researchers. Applying the PRISMA statement several studies were selected according to eligibility criteria and organized for the review. Full papers were included if they described effects of WBVE for the treatment of illnesses, evaluated by sEMG of lower limbs independently on the year of the publication; in comparison or associated with other treatment and evaluation techniques. Results: Seven publications were selected; two in spinal cord injury patients, one in Friedreich's ataxia patients, three in stroke patients and one study in breast cancer survivors. Reported effects of WBV in were muscle activation by sEMG and also on strength, blood flow and exercise resistance; even in paretic limbs. Conclusion: By the use of sEMG it was verified that WBVE elicits muscle activation in diseased population. These results may lead to the definition of exercise protocols to maintain or increase muscular activation. However, due to the heterogeneity of methods among studies, there is currently no consensus on the sEMG signal processing. These strategies might also induce effects on muscle strength, balance and flexibility in these and other illnesses.

TI Osteoarthritis of the hip joint in elderly patients is most commonly atrophic, with low parameters of acetabular dysplasia and possible involvement of osteoporosis
SO ARCHIVES OF OSTEOPOROSIS
LA English
DT Article
DE Osteoarthritis; Osteoporosis; Acetabular dysplasia; Aging
ID subchondral bone; alendronate treatment; knee osteoarthritis; increased risk; white women; cartilage; patterns; microarchitecture; pathogenesis; damage
AB A Summary As elderly patients with hip osteoarthritis aged, acetabular dysplasia

parameters decreased (Sharp's angle, acetabular roof obliquity angle, and acetabular head index) and the incidence of the atrophic type increased. Vertebral body fracture was more frequent in the atrophic type, suggesting the involvement of osteoporosis at the onset of hip osteoarthritis. Introduction Osteoarthritis (OA) is associated with increased bone formation at a local site. However, excessive bone resorption has also been found to occur in the early stages of OA. Osteoporosis may be involved in the onset of OA in elderly patients. We conducted a cross-sectional radiographic study of patients with hip OA and examined the association between age and factors of acetabular dysplasia (Sharp's angle, acetabular roof obliquity angle, and acetabular head index) as well as the osteoblastic response to determine the potential involvement of osteoporosis. Methods This study included 366 patients (58 men, 308 women) who had undergone total hip arthroplasty for the diagnosis of hip OA. We measured the parameters of acetabular dysplasia using preoperative frontal X-ray images and evaluated each patient according to Bombelli classification of OA (hypertrophic, normotrophic, or atrophic type). Results As the patients aged, the parameters of acetabular dysplasia decreased. The incidence of the atrophic type of OA was significantly higher in older patients. Vertebral body fractures were more frequent in the atrophic type than in the other types. Additionally, the index of acetabular dysplasia was lower in the atrophic type. By contrast, the hypertrophic type was present in relatively younger patients and was associated with an increased index of acetabular dysplasia. Conclusion In elderly patients with hip OA, the parameters of acetabular dysplasia decreased and the incidence of the atrophic type increased as the patients aged. The frequency of vertebral body fracture was high in patients with the atrophic type, suggesting the involvement of osteoporosis in the onset of hip OA.

TI Overweight in patients with chronic obstructive pulmonary disease needs more attention: a cross-sectional study in general practice
SO NPJ PRIMARY CARE RESPIRATORY MEDICINE
LA English
DT Article
ID body-mass index; prognostic value; copd; obesity; prevalence
AB Guidelines for management of chronic obstructive pulmonary disease (COPD) primarily focus on the prevention of weight loss, while overweight and obesity are highly prevalent in patients with milder stages of COPD. This cross-sectional study examines the association of overweight and obesity with the prevalence of comorbid disorders and prescribed medication for obstructive airway disease, in patients with mild to moderate COPD. Data were used from electronic health records of 380 Dutch general practices in 2014. In total, we identified 4938 patients with mild or moderate COPD based on spirometry data, and a recorded body mass index (BMI) of >= 21 kg/m(2). Outcomes in overweight (BMI >= 25 and < 30 kg/m(2)) and obese (BMI >= 30 kg/m(2)) patients with COPD were compared to those with a normal weight (BMI >= 21 and < 25 kg/m(2)), by logistic multilevel analyses. Compared to COPD patients with a normal weight, positive associations were found for diabetes, osteoarthritis, and hypertension, for both overweight (OR: 1.4-1.7) and obese (OR: 2.4-3.8) patients, and for heart failure in obese patients (OR: 2.3). Osteoporosis was less prevalent in overweight (OR: 0.7) and obese (OR: 0.5) patients, and anxiety disorders in obese patients (OR: 0.5). No associations were found for coronary heart disease, stroke, sleep disturbance, depression, and pneumonia. Furthermore, obese patients were in general more often prescribed medication for obstructive airway disease compared to patients with a normal weight. The findings of this study underline the need to increase awareness in general practitioners for excess weight in patients with mild to moderate COPD.

TI Is subchondral bone cyst formation in non-load-bearing region of osteoarthritic knee a vascular problem?
SO MEDICAL HYPOTHESES
LA English
DT Article
ID osteoporosis; angiogenesis
AB Subchondral bone cyst is common in the progressive knee osteoarthritis yet its underlying mechanism remains unclear. In addition to the existing theories such as synovial fluid influx and mechanical contusion, we identified the potential link between vascular pathology and osteoarthritic bone pathologies including cystic lesion formation, particularly in the non-load-bearing region. This new hypothesis for SBC formation in non-load-bearing region for knee, which cannot be explained by the existing theories, will provide us a new angle to understand the pathomechanism and pathophysiology of subchondral bone disturbance in osteoarthritis in addition to the classical biomechanical overloading theories. It might guide us to develop a novel diagnostic and therapeutic approach to treat progressive osteoarthritis via targeting vascular pathology.

TI Impact of lumbar syndesmophyte on bone health as assessed by bone density (BMD) and bone texture (TBS) in men with axial spondyloarthritis
SO JOINT BONE SPINE
LA English
DT Article
DE Spondyloarthritis; Syndesmophytes; TBS; Spine BMD
ID ankylosing-spondylitis; mineral density; vertebral fractures; score tbs; osteoporotic fractures; radiographic damage; caucasian women; spine; microarchitecture; progression
AB Introduction: Patients with spondyloarthritis (SpA) have an elevated incidence of osteoporosis and are at increased risk of pathological vertebral fracture. Evaluation of bone density by dual energy X-ray absorptiometry (DXA) has its limits in fracture prediction, already known in this population. One hypothesis is that the presence of lumbar syndesmophyte could overestimate the spine bone mineral density

(BMD). Trabecular bone score (TBS) is a new texture measurement correlated with bone microarchitecture. Previous studies have shown that TBS is mildly impacted by osteoarthritis and thus could be a predictor of fracture better than spine BMD. We aimed to evaluate a male population of SpA with BMD and TBS measurement and see the impact of lumbar syndesmophytes. Method: Two cohorts of SpA male patients (Lausanne, Sofia) with SpA disease, clinical and bone parameters (femoral neck and total spine BMD + spine TBS) were merged. We compared BMD and TBS results regarding to the presence/absence of syndesmophytes. Results: Our study concerned 51 men [29 with lumbar syndesmophytes (L1 to L4,>= 1), 22 without], fulfilling the European Spondyloarthropathy Study Group (ESSG) and the Assessment of SpondyloArthritis international Society (ASAS) criteria. Mean age was 52.18 years old (no difference between the 2 groups) and mean body mass index (BMI) 27.47 kg/m(2) (29.12 +/- 0.67 with and 25.30 +/- 0.81 without, A=0.0006). For the overall population mean BMD T-score at the spine was 0.55 +/- 1.54, mean BMD T-score at the femoral neck 1.20 +/- 0.95 and mean lumbar spine TBS was 1.26 +/- 0.13. Regarding to the presence or the absence of syndesmophytes, mean spine BMD T-score was 0.07 +/- 1.63 and 1.18 +/- 1.16 (A=0.009 and 0.250 before and after adjustment for BMI), mean femoral neck BMD T-score was 1.37 +/- 0.93 and 0.97 +/- 0.94 (A=0.14 and 0.03 before and after adjustment for BMI) and mean TBS was 1.21 +/- 0.12 and 1.33 +/- 0.11 (A=0.001 and 0.06 before and after adjustment for BMI) respectively for SpA men with and without syndesmophytes. Conclusion: Our results showed that SpA men with and without syndesmophytes have lower results compared to the normal population regarding hip BMD, spine TBS and spine BMD except for men with syndesmophytes who have a normal BMD spine T-score. These results suggest that TBS is not influenced by the syndesmophytes in opposite to spine BMD and could be measured in this population in addition to the neck BMD to assess the bone fragility. AB Clustering analysis can identify subgroups of patients based on similarities of traits. From data on 10,775 subjects, we document nine patient clusters of different fracture risks. Differences emerged after age 60 and treatment compliance differed by hip and lumbar spine bone mineral density profiles. The purposes of this study were to establish and quantify patient clusters of high, average and low fracture risk using an unsupervised machine learning algorithm. Regional and national Danish patient data on dual-energy X-ray absorptiometry (DXA) scans, medication reimbursement, primary healthcare sector use and comorbidity of female subjects

were combined. Standardized variable means, Euclidean distances and Ward's D2 method of hierarchical agglomerative clustering (HAC), were used to form the clustering object. K number of clusters was selected with the lowest cluster containing less than 250 subjects. Clusters were identified as high, average or low fracture risk based on bone mineral density (BMD) characteristics. Cluster-based descriptive statistics and relative Z-scores for variable means were computed. Ten thousand seven hundred seventy-five women were included in this study. Nine (k = 9) clusters were identified. Four clusters (n = 2886) were identified based on low to very low BMD with differences in comorbidity, anthropometrics and future bisphosphonate compliance. Two clusters of younger subjects (n = 1058, mean ages 30 and 51 years) were identified as low fracture risk with high to very high BMD. A mean age of 60 years was the earliest that allowed for separation of high-risk clusters. DXA scan results could identify high-risk subjects with different antiresorptive treatment compliance levels based on similarities and differences in lumbar spine and hip region BMD. Unsupervised HAC presents a novel technology to improve patient characteristics in bone disease beyond traditional T-score-based diagnosis. Technological and validation limitations need to be overcome to improve its use in internal medicine. Current DXA scan indication guidelines could be further improved by clustering algorithms.

TI Whole-body vibration of mice induces progressive degeneration of intervertebral discs associated with increased expression of Il-1β and multiple matrix degrading enzymes
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE Whole-body vibration; Intervertebral disc; Disc degeneration; Bone; Inflammation; Spine
ID low-back-pain; randomized controlled-trial; magnitude mechanical signals; placebo-controlled trial; high-frequency; bone-density; in-vivo; postmenopausal women; lumbar spine; rat
AB Objective: Whole-body vibration (WBV) is a popular fitness trend based on claims of increased muscle mass, weight loss and reduced joint pain. Following its original implementation as a treatment to increase bone mass in patients with osteoporosis, WBV has been incorporated into clinical practice for musculoskeletal disorders, including back pain. However, our recent studies revealed damaging effects of WBV on joint health in a murine model. In this report, we examined potential mechanisms underlying disc degeneration following exposure of mice to WBV. Methods: Ten-week-old male mice were exposed to WBV (45 Hz, 0.3 g peak acceleration, 30 min/day, 5 days/week) for 4 weeks, 8 weeks, or 4 weeks WBV followed by 4 weeks recovery. Micro-computed tomography (micro-CT), histological, and gene expression analyses were used to assess the effects of WBV on spinal tissues. Results: Exposure of mice to 4 or 8 weeks of WBV did not alter total body composition or induce significant changes in vertebral bone density. On the other hand, WBV-induced intervertebral disc (IVD) degeneration, associated with decreased disc height and degenerative changes in the annulus fibrosus (AF) that did not recover within 4 weeks after cessation of WBV. Gene expression analysis showed that WBV for 8 weeks induced expression of Mmp3, Mmp13, and Adamts5 in IVD tissues, changes preceded by increased expression of Il-1 beta. Conclusions: Progressive IVD degeneration induced by WBV was associated with increased expression of Il-1 beta within the IVD that preceded Mmp and Adamts gene induction. Moreover, WBV-induced IVD degeneration is not reversed following cessation of vibration. (C) 2017 Osteoarthritis Research Society International. Published by Elsevier Ltd. All rights reserved.

TI Age-related Changes in Bone Marrow Mesenchymal Stromal Cells: A Potential

Impact on Osteoporosis and Osteoarthritis Development
SO CELL TRANSPLANTATION
LA English
DT Article
DE aging; bone marrow (BM); mesenchymal stromal cells (MSCs); in vitro; in vivo
ID stem-cells; progenitor cells; osteogenic differentiation; adipocyte differentiation; postmenopausal women; subchondral bone; aging mechanisms; life-span; senescence; osteoblast
AB Aging at the cellular level is a complex process resulting from accumulation of various damages leading to functional impairment and a reduced quality of life at the level of the organism. With a rise in the elderly population, the worldwide incidence of osteoporosis (OP) and osteoarthritis (OA) has increased in the past few decades. A decline in the number and "fitness" of mesenchymal stromal cells (MSCs) in the bone marrow (BM) niche has been suggested as one of the factors contributing to bone abnormalities in OP and OA. It is well recognized that MSCs in vitro acquire culture-induced aging features such as gradual telomere shortening, increased numbers of senescent cells, and reduced resistance to oxidative stress as a result of serial population doublings. In contrast, there is only limited evidence that human BM-MSCs "age" similarly in vivo. This review compares the various aspects of in vitro and in vivo MSC aging and suggests how our current knowledge on rejuvenating cultured MSCs could be applied to develop future strategies to target altered bone formation processes in OP and OA.

TI Pharmaceutical-grade Chondroitin sulfate is as effective as celecoxib and superior to placebo in symptomatic knee osteoarthritis: the ChONdroitin versus CElecoxib versus Placebo Trial (CONCEPT)
SO ANNALS OF THE RHEUMATIC DISEASES
LA English
DT Article
ID patient reported outcm; european-society; economic-aspects; double-blind; hip osteoarthritis; clinical-trial; task-force; recommendations; osteoporosis; management
AB Objectives Chondroitin sulfate 800 mg/day (CS) pharmaceutical-grade in the management of symptomatic knee osteoarthritis consistent with the European Medicines Agency guideline. Methods A prospective, randomised, 6-month, 3-arm, double-blind, double-dummy, placebo and celecoxib (200 mg/day)-controlled trial assessing changes in pain on a Visual Analogue Scale (VAS) and in the Lequesne Index (LI) as coprimary endpoints. Minimal-Clinically Important Improvement (MCII), Patient-Acceptable Symptoms State (PASS) were used as secondary endpoints. Results 604 patients (knee osteoarthritis) diagnosed according to American College of Rheumalogy (ACR) criteria, recruited in five European countries and followed for 182 days. CS and celecoxib showed a greater significant reduction in pain and LI than placebo. In the intention-to-treat (ITT) population, pain reduction in VAS at day 182 in the CS group (-42.6 mm) and in celecoxib group (-39.5 mm) was significantly greater than the placebo group (-33.3 mm) (p=0.001 for CS and p=0.009 for celecoxib), while no difference observed between CS and celecoxib. Similar trend for the LI, as reduction in this metric in the CS group (-4.7) and celecoxib group (-4.6) was significantly greater than the placebo group (-3.7) (p=0.023 for CS and p=0.015 for celecoxib), no difference was observed between CS and celecoxib. Both secondary endpoints (MCII and PASS) at day 182 improved significantly in the CS and celecoxib groups. All treatments demonstrated excellent safety profiles. Conclusion A 800 mg/day

pharmaceutical-grade CS is superior to placebo and similar to celecoxib in reducing pain and improving function over 6 months in symptomatic knee osteoarthritis (OA) patients. This formulation of CS should be considered a first-line treatment in the medical management of knee OA.

TI A highly sensitive electrochemical biosensor based on AuNP-modified gold electrodes for selective determination of serum levels of crosslaps
SO 3 BIOTECH
LA English
DT Article
DE CTX; Biosensor; Bone turnover marker; Electrochemistry; Crosslaps
ID antibody-based sensors; i collagen; degradation-products; c-telopeptide; nanoparticles; osteoporosis; markers; urine; ctx; osteoarthritis
AB This article explains a step-wise protocol to develop an electrochemical sensor to quantify serum levels of C-telopeptide (CTX) crosslinks also known as crosslaps in a matter of minutes and with high level of accuracy. The technique needs only one-step (incubation) and can thus be used for point of care screening. Due to the

excellent electrical properties of the as-prepared immunosensor, CTX levels were successfully measured from 1 to 1000 pg/mL. This is while the normal reference of the marker is 50-450 pg/mL, suggesting that the sensor can acceptably detect CTX. The results also showed a good correlation with ECLIA in measuring serum levels of CTX.

TI Is bone density associated with intervertebral disc pressure in healthy and degenerated discs?
SO JOURNAL OF BIOMECHANICS

LA English
DT Article
DE Disc degeneration; Vertebra; Endplate; Intervertebral disc; Nucleus pulposus; Annulus fibrosus; Glycosaminoglycan; Disc space narrowing; Computed tomography
ID vertebral body; lumbar disc; postmenopausal women; proteoglycan content; spine; age; fracture; osteoarthritis; osteoporosis; architecture
AB The coupling of the intervertebral disc (IVD) and vertebra as a biomechanical unit suggests that changes in the distribution of pressure within the 1VD (intradiscal pressure, IDP) as a result of disc degeneration can influence the distribution of bone density within the vertebra, and vice versa. The goal of this study was to assess the correspondence between IDP and bone density in the adjacent vertebrae, with emphasis on how this correspondence differs between healthy and degenerated IVDs. Bone density of the endplates and subchondral bone in regions adjacent to the anterior and posterior annulus fibrosus (aAF and pAF, respectively) and nucleus pulposus (NP) was measured via quantitative computed tomography (QCT) in 61 spine segments (T7-9,19-11,110-12: 71 +/- 14 years). IDP was measured in the aAF, NP, and pAF regions in 26 of the spine segments (68 16 years) while they were tested in flexed (5) or erect postures. Disc degeneration was assessed by multiple grading schemes. No correlation was found between bone density and IDP in either posture ($p > 0.104$). Regional variations in 1DP and, to a greater extent bone density, were found to change with advancing degeneration: both IDP ($p = 0.045$) and bone density ($p = 0.024$) decreased in the NP region relative to the aAF region. The finding of only a modest correspondence between degeneration-associated changes in IDP and bone density may arise from complexity in how IDP relates to mechanical force transmission through the endplate and from limitations of the available IVD grading schemes in estimating the mechanical behavior of the IVD. DT Article
ID research diagnostic-criteria; internal derangement; bone changes; dimension; joint; radiographs; osteoarthrosis; osteoporosis; reliability; morphology
AB Objectives. The aim of this study was to evaluate changes in the trabecular structure of the mandibular condyle in patients with temporomandibular disorders (TMDs) using fractal analysis. Study Design. A total of 100 patients ages 18 to 73 years were clinically assessed using the Diagnostic Criteria for Temporomandibular Disorders. The control group was age-and sex-matched with the patient group. Panoramic radiographs were obtained using a Kodak 8000 digital device with 73 kVp and 5 mA fixed parameters. The degree of degeneration in the mandibular condyles was calculated. Regions of interest (84 X 84 pixels) were selected within the cortical boundary of the mandibular condyle, and the fractal dimension (FD) was calculated using ImageJ version 1.48. Results. Radiographic degenerative changes were more frequently present and more severe in the patient group ($P < .001$). The mean value of FD was 1.22 +/- 0.06 in the patient group and 1.25 +/- 0.06 in the control group ($P = .001$). A significant decrease in FD was observed ($P = .001$) in the left temporomandibular joints of the patient group, whereas a nonsignificant decrease in FD was observed in the right temporomandibular joints ($P = .073$) as degenerative changes increased. Conclusions. Lower FD values were associated with more severe degenerative changes in the patient group. The trabecular structure of condyles in patients with TMD exhibited decreased complexity when erosive and sclerotic changes were evident. As a result, fractal analysis enhanced the use of panoramic radiography in detecting degenerative changes in patients with TMD. (Oral Surg Oral Med Oral Pathol Oral Radiol 2017;123: 382-391)

TI Radiographic measurements of the hip joint and their associations with hip pain in Japanese men and women: the Research on Osteoarthritis/osteoporosis Against Disability (ROAD) study
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE Osteoarthritis; Acetabular dysplasia; Prevalence; Pain; Cross-sectional
ID acetabular dysplasia; progression; prevalence; osteoarthrosis; arthroplasty; definitions; rotterdam; space; knee
AB Objective: To investigate radiographic measurements of the hip joint and their associations with hip pain, and the prevalence of acetabular dysplasia defined by radiographic measurements of the hip joint in Japanese men and women using the large-scale population-based cohort of the Research on Osteoarthritis/osteoporosis Against Disability (ROAD) study. Methods: From the

baseline survey of the ROAD study (cross-sectional study), 2963 participants (1040 men, 1923 women; mean age, 70.2 years) were analyzed. All participants underwent radiographic examinations of both hips using an anteroposterior view under weight-bearing. Minimum joint space width (mJSW), central-edge (CE) angle, acetabular depth-to-width ratio (ADR), and acetabular head index (AHI) were measured. Associations between these radiographic measurements and hip pain were assessed by calculating odds ratios (ORs) using multivariable logistic-regression analysis. Acetabular dysplasia was defined as a CE angle < 20 degrees. Results: Mean radiographic measurements of the hip joint for men were: mJSW, 3.8 mm; CE angle, 30.6 degrees; ADR, 262.1 per 1000; and AHI, 81.4%. For women, these values were: mJSW, 3.4 mm; CE angle, 29.9 degrees; ADR, 262.7 per 1000; and AHI, 81.2%. Associations were seen between hip pain and each of mJSW, CE angle, ADR, and AHI (OR 4.52, 95% confidence interval 3.45-5.97; 1.14, 1.11-1.18; 1.31, 1.24-1.40; and 1.15, 1.12-1.18, respectively). Acetabular dysplasia showed an overall prevalence of 13.9%, and was significantly more prevalent in women than in men (P = 0.012). C onclusion: The present study of radiographic measurements of the hip joint showed that mJSW, CE angle, ADR, and AHI were associated with hip pain. TI Vitamin D supplementation in the prevention and management of major chronic diseases not related to mineral homeostasis in adults: research for evidence and a scientific statement from the European society for clinical and economic aspects of osteoporosis and osteoarthritis (ESCEO)
SO ENDOCRINE
LA English
DT Article
DE Cholecalciferol; Cancer; Diabetes; Mortality; Cardiovascular diseases; Autoimmune diseases
ID serum 25-hydroxyvitamin d; systemic-lupus-erythematosus; multiple-sclerosis activity; parathyroid-hormone levels; different monthly regimens; placebo-controlled trial; all-cause mortality; beta-cell function; d-binding protein; blood-pressure
AB Introduction Optimal vitamin D status promotes skeletal health and is recommended with specific treatment in individuals at high risk for fragility fractures. A growing body of literature has provided indirect and some direct evidence for possible extraskeletal vitamin D-related effects. Purpose and Methods Members of the European Society for Clinical and Economic Aspects of Osteoporosis and Osteoarthritis have reviewed the main evidence for possible proven benefits of vitamin D supplementation in adults at risk of or with overt chronic extra-skeletal diseases, providing recommendations and guidelines for future studies in this field. Results and conclusions Robust mechanistic evidence is available from in vitro studies and in vivo animal studies, usually employing cholecalciferol, calcidiol or calcitriol in pharmacologic rather than physiologic doses. Although many cross-sectional and prospective association studies in humans have shown that low 25-hydroxyvitamin D levels (i.e., < 50 nmol/L) are consistently associated with chronic diseases, further strengthened by a dose-response relationship, several meta-analyses of clinical trials have shown contradictory results. Overall, large randomized controlled trials with sufficient doses of vitamin D are missing, and available small to moderate-size trials often included people with baseline levels of serum 25-hydroxyvitamin D levels > 50 nmol/L, did not simultaneously assess multiple outcomes, and did not report overall safety (e.g., falls). Thus, no recommendations can be made to date for the use of vitamin D supplementation in general, parental compounds, or non-hypercalcemic vitamin D analogs in the prevention and treatment of extra-skeletal chronic diseases. Moreover, attainment of serum 25-hydroxyvitamin D levels well above the threshold desired for bone health cannot be recommended based on current evidence, since safety has yet to be confirmed. Finally, the promising findings from mechanistic studies, large cohort studies, and small clinical trials obtained for autoimmune diseases (including type 1 diabetes, multiple sclerosis, and systemic lupus erythematosus), cardiovascular disorders, and overall reduction in mortality require further confirmation.

TI How clinical practitioners assess frailty in their daily practice: an international survey
SO AGING CLINICAL AND EXPERIMENTAL RESEARCH
LA English
DT Article
DE Frailty; Survey; Clinical practice; Standardisation
ID screening tool; health; definition; phenotype; consensus; questionnaire; population; sarcopenia; indicator
AB Introduction Various operational definitions have been proposed to assess the frailty condition among older individuals. Our objective was to assess how practitioners measure the geriatric syndrome of frailty in their daily routine. Methods An online survey was sent to national geriatric societies affiliated to the European Union Geriatric Medicine Society (EUGMS) and to members of the European Society for Clinical and Economic Aspects of Osteoporosis, Osteoarthritis and Musculoskeletal Diseases (ESCEO). Results A total of 388 clinicians from 44 countries answered to the survey. Most of them were medical doctors (93%), and their primary field of practice was geriatrics (83%). Two hundred and five clinicians (52.8%) always assessed frailty in their daily practice, 38.1% reported to "sometimes" measure it, and 9.1% never assess it. A substantial proportion of clinicians (64.9%) diagnose frailty using more than one instrument. The most widely used tool was the gait speed test, adopted by 43.8% of the clinicians, followed by clinical frailty scale (34.3%), the SPPB test (30.2%), the frailty phenotype (26.8%) and the frailty index (16.8%). Conclusion A variety of tools is used to assess frailty of older patients in clinical practice highlighting the need for standardisation and guidelines.

TI Multiple Roles of Angiopoietin-Like 4 in Osteolytic Disease
SO FRONTIERS IN ENDOCRINOLOGY
LA English
DT Review
DE angiopoietin-like 4; bone resorption; cartilage degradation; angiogenesis; inflammation; rheumatoid arthritis
ID hypoxia-inducible factor; giant-cell tumor; gene-expression; vascular-permeability; bone-resorption; osteoclast differentiation; articular-cartilage; lipoprotein-lipase; protein; angiogenesis
AB Hypoxia and the hypoxia-inducible factor (HIF) transcription factor drive pathological bone loss in conditions including rheumatoid arthritis (RA), osteoarthritis, osteoporosis, primary bone tumours, and bone metastatic cancer. There is therefore considerable interest in determining the function(s) of HIF-induced genes in these pathologies. Angiopoietin-like 4 (ANGPTL4) is an adipose-derived, HIF-1 alpha- and PPAR gamma-induced gene that was originally discovered as an endocrine and autocrine/paracrine regulator of lipid metabolism. Given the inverse relationship between bone adiposity and fracture risk, ANGPTL4 might be considered a good candidate for mediating the downstream effects of HIF-1 alpha relevant to osteolytic disease. This review will consider the possible roles of ANGPTL4 in regulation of osteoclast-mediated bone resorption, cartilage degradation, angiogenesis, and inflammation, focusing on results obtained in the study of RA. Possible roles in other musculoskeletal pathologies will also be

discussed. This will highlight ANGPTL4 as a regulator of multiple disease processes, which could represent a novel therapeutic target in osteolytic musculoskeletal disease.

TI PTH [1-34] induced differentiation and mineralization of mandibular condylar cartilage
SO SCIENTIFIC REPORTS
LA English
DT Article
ID parathyroid-hormone; subchondral bone; articular-cartilage; i collagen; osteoarthritis; intermittent; cells; chondrocytes; phosphatase; progression
AB Intermittent Parathyroid Hormone (I-PTH) is the only FDA approved anabolic drug therapy available for the treatment of osteoporosis in males and

postmenopausal females. The effects of I-PTH on the chondrogenic lineage of the mandibular condylar cartilage (MCC) are not well understood. To investigate the role of I-PTH on the MCC and subchondral bone, we carried out our studies using 4 to 5 week old triple transgenic mice (Col1a1XCol2a1XCol10a1). The experimental group was injected with PTH (80 mu g/kg) daily for 2 weeks, while control group was injected with saline. Our histology showed that the I-PTH treatment led to an increased number of cells expressing Col1a1, Col2a1 and Col10a1. Additionally, there was an increase in cellular proliferation, increased proteoglycan distribution, increased cartilage thickness, increased TRAP activity, and mineralization. Immunohistochemical staining showed increased expression of pSMAD158 and VEGF in the MCC and subchondral bone. Furthermore our microCT data showed that I-PTH treatment led to an increased bone volume fraction, tissue density and trabecular thickness, with a decrease in trabecular spacing. Morphometric measurements showed increased mandibular length and condyle head length following I-PTH treatment. In conclusion, our study suggests that I-PTH plays a critical role in cellular proliferation, proteoglycan distribution, and mineralization of the MCC.

TI EQ-5D studies in musculoskeletal and connective tissue diseases in eight Central and Eastern European countries: a systematic literature review and meta-analysis
SO RHEUMATOLOGY INTERNATIONAL
LA English
DT Review
DE EQ-5D; Musculoskeletal diseases; Central and Eastern Europe; Patient reported outcomes; Health-related quality of life; Meta-analysis
ID quality-of-life; low-back-pain; rheumatoid-arthritis; ankylosing-spondylitis; health-status; single-blind; osteoporotic fractures; psoriatic-arthritis; utility; osteoarthritis
AB EQ-5D is becoming the preferred instrument to measure health-state utilities involved in health technology assessment. The objective of this study is to assess the state of EQ-5D research in musculoskeletal disorders in 8 Central and Eastern European countries and to provide a meta-analysis of EQ-5D index scores. Original research articles published in any language between Jan 2000 and Sept 2016 were included, if they reported any EQ-5D outcome from at least two musculoskeletal patients from Austria, Bulgaria, the Czech Republic, Hungary, Poland, Romania, Slovakia, or Slovenia. Risk of bias was assessed with the Cochrane Collaboration's tool. Twenty-nine articles (5992 patients) were included on rheumatoid arthritis (n = 7), osteoporosis (n = 5), chronic pain (n = 5), osteoarthritis (n = 4), ankylosing spondylitis (n = 2), psoriatic arthritis (n = 2), total hip replacement (n = 2), and scleroderma (n = 2). Low back pain was under-represented, while studies in neck pain, systemic lupus erythematosus, gout, and childhood disorders were lacking. EQ-5D index scores were reported in 24 studies, while the version of the instrument and the value-set was not specified in 41% and 46% of the articles, respectively. Meta-analysis was performed on 24 disease states involving 6876 observation points. Intervention effect was reported in 22 subgroups, out of which risk of bias was low in 41%. This review provides recommendations to improve reporting standards of EQ-5D results and highlights potential areas for future research. Coordinated research in conditions with greatest public health impact as well as a development of a regional value-set could provide locally relevant health-state utilities that are transferable among countries within the region.

TI Dietary magnesium intake and fracture risk: data from a large prospective study
SO BRITISH JOURNAL OF NUTRITION
LA English
DT Article
DE Magnesium; Fractures; Osteoporosis; Epidemiology
ID bone; metaanalysis; women; inflammation; performance; patterns; calcium; disease; people; cohort
AB Research considering the relationship between dietary Mg and osteoporosis as well as fractures are sparse and conflicting. We therefore aimed to investigate Mg intake and the onset of fractures in a large cohort of American men and women involved in the Osteoarthritis Initiative over a follow-up period of 8 years. Dietary Mg intake (including that derived from supplementation) was evaluated through a FFQ at baseline and categorised using sex-specific quintiles (Q); osteoporotic fractures were evaluated through self-reported history. Overall, 3765 participants (1577 men; 2071 women) with a mean age of 60.6 (sd 9.1) years were included. During follow-up, 560 individuals (198 men and 368 women) developed a new fracture. After adjusting for fourteen potential confounders at baseline and taking those with lower Mg intake as reference (Q1). men (hazard ratio (HR) 0.47; 95 % CI 0.21, 1.00, P = 0.05) and women (HR 0.38; 95 % CI 0.17, 0.82, P = 0.01) in the highest quintile reported a significantly lower risk for fracture. Women meeting the recommended Mg intake were at a 27 % decreased risk for future fractures. In conclusion, higher dietary Mg intake has a protective effect on future osteoporotic fractures, especially in women with a high risk for knee osteoarthritis. Those women meeting the recommended Mg intake appear to be at a lower risk for fractures.

TI Do vitamin D levels affect the clinical prognoses of patients with knee osteoarthritis?
SO JOURNAL OF BACK AND MUSCULOSKELETAL REHABILITATION
LA English
DT Article
DE Knee osteoarthritis; vitamin D deficiency; quality of life
ID serum-levels; d deficiency; cartilage
AB OBJECTIVE: Although vitamin D deficiency has been associated with

osteoporosis, as well as fractures, in elderly men and women, the role of vitamin D deficiency in the pathogenesis of osteoarthritis (OA) remains controversial. In this study, we aimed to investigate the effects of vitamin D deficiency on the functional status and disease prognosis of patients with knee osteoarthritis. PATIENTS AND METHODS: Our study comprised 100 patients that met the American College of Rheumatology criteria for a diagnosis of knee osteoarthritis. Each patient underwent knee radiography, the results of which were graded according to Kellgren and Lawrence radiographic grading scale; those that met the diagnostic criteria were included in the study. The visual analog scale (VAS), Nottingham Health Profile (NHP), Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) and Lequesne Knee Osteoarthritis Index were used to assess patients' pain, function and quality of life. Complete blood counts, sedimentation rates and serum C-reactive protein, rheumatoid factor, alanine aminotransferase, aspartate aminotransferase, alkaline phosphatase, sodium, potassium, calcium, phosphorus, parathyroid and thyroid hormone levels were routinely recorded for each patient. Vitamin D levels were analyzed in winter (between November and February) using high performance liquid chromatography. RESULTS: Patients were divided into two groups, Group 1 and Group 2, according to the presence or absence of vitamin D deficiency. The groups did not differ significantly in terms of age, disease duration, sex distribution, presence of osteoporosis or radiographic stage of knee osteoarthritis ($p = 0.793$, 0.092, 0.250, 0.835 and 0.257, respectively). However, the NHP pain, physical activity, fatigue, social isolation, and emotional reactions subsets, WOMAC pain and physical function subsets and total score, Lequesne knee osteoarthritis index, and patient/physician VAS scores were significantly higher in Group 1 than in Group 2 ($p < 0.05$). CONCLUSIONS: Our study therefore suggests that vitamin D deficiency exacerbates pain, dysfunction and a poorer quality of life in patients with knee osteoarthritis. Further longer-term studies are needed to investigate the effects of vitamin D deficiency on OA-related symptoms.

TI One-stage bilateral implantation of a calcar-guided short-stem in total hip arthroplasty Minimally invasive modified anterolateral approach in supine position
SO OPERATIVE ORTHOPADIE UND TRAUMATOLOGIE
LA English
DT Article
DE Arthroplasty, replacement, hip; Prostheses and implants; Minimally invasive surgical procedures; Round-the-corner; Optimys
ID replacement; mortality
AB One-stage bilateral, muscle-preserving, calcar-guided implantation technique through the modified minimally invasive anterolateral approach in supine position. Bilateral primary/secondary osteoarthritis of the hip; bilateral femoral head necrosis; ASA I-III. ASA IV; severe osteoporosis, other factors jeopardizing stable anchorage of cementless, calcar-guided short-stem; infection. Supine position. Skin incision. Opening of fascia; blunt dissection, pushing gluteal muscles dorsally with the index finger. Capsulectomy. Individual osteotomy according to preoperative plan to determine short-stem position. Remove femoral head. Prepare acetabulum. Position cup. Femoral preparation with the curved opening awl. Spare greater trochanter and gluteal muscles. Insert trial rasps in ascending sizes with "round-the-corner" technique. Select offset version, then trial reposition with intraoperative radiograph and implantation of the definitive implant. Wound closure. Consultation with the anesthesiologist to confirm a stable patient. Same procedure on contralateral hip. Mobilization on day 1 with immediate full weight bearing. Remove wound drains and urinary catheter (only female patients) on day 2. Intensive protocol of physiotherapy and rehabilitation. Thrombosis prophylaxis. Rehabilitation from day 7. Almost 500 patients have undergone surgery since 2010. First consecutive 54 patients (108 hips) prospectively evaluated. After 2 years, Harris Hip Score was 98.8; satisfaction on visual analogue scale was 9.9. Low peri- and

postoperative complication rates; no implant revisions. The muscle-sparing approach and the special "round-the-corner" technique in one-stage bilateral procedure leads to rapid mobilization and rehabilitation with excellent early clinical results and high satisfaction rates.

TI The relationship of bone properties using high resolution peripheral quantitative computed tomography to radiographic components of hip osteoarthritis
SO OSTEOARTHRITIS AND CARTILAGE

LA English
DT Article
DE Osteoarthritis; Bone microarchitecture; Epidemiology; Osteoporosis; Cortical; Trabecular
ID mineral density; fractures; risk; mass; men
AB Objective: Positive associations between radiographic osteoarthritis (OA) and areal bone mineral density (BMD) have been demonstrated and appear strongest when bony features of OA are considered. To date, these associations have not been assessed using HRpQCT. Design: A total of 318 participants (170 men and 148 women), aged 72.1-81.4 years from a non-selected cohort, underwent HRpQCT of the distal radius and tibia along with hip radiography. Differences in bone microarchitecture were assessed between those with and without osteophytes, sclerosis or joint space narrowing (JSN) in either hip. Results: Men with osteophytes alone had significantly higher radial trabecular volumetric BMD (Tb.vBMD) and radial and tibial trabecular thickness (Tb.Th). Men with both sclerosis and osteophytes had significantly higher cortical volumetric BMD (Ct.vBMD) and cortical thickness (Ct.Th) at the distal tibia than those with osteophytes alone ($P < 0.05$). These relationships were maintained after adjustment for age and Body Mass Index (BMI), and were not replicated in women. Bone microarchitecture did not differ significantly in those with JSN from those without it in men or women. Conclusions: Our findings suggest higher Tb.vBMD and Tb.Th in men with osteophytosis but higher tibial Ct.vBMD and Ct.Th in men with hip joint sclerosis. These results do however require replication in other cohorts. (C) 2017 Osteoarthritis Research Society International. Published by Elsevier Ltd. All rights reserved.

TI Spectrum of paediatric rheumatic diseases in Nigeria
SO PEDIATRIC RHEUMATOLOGY
LA English
DT Article
DE Paediatric rheumatic disease; Nigeria; Juvenile idiopathic arthritis; Juvenile systemic lupus erythematosus
ID systemic-lupus-erythematosus; united-states; east-africa; populations; prevalence
AB Background: Paediatric rheumatology service in Sub-Sahara African is virtually not available as there is a shortage of paediatric rheumatologists and other rheumatology health professionals. We aim to describe the clinical spectrum and

the frequencies of paediatric rheumatic diseases (PRDs) in Lagos State University Teaching Hospital (LASUTH), Lagos, Nigeria. Methods: This is a retrospective review of patients with PRDs seen over a five year period (March 2010 to February 2016) at the rheumatology clinic and children ward of LASUTH. We reviewed the folders of 57 patients from our records. The demographics, baseline laboratory features, clinical diagnosis, treatment patterns and patient outcomes were extracted and analyzed. Clinical and laboratory characteristics between patients with Juvenile idiopathic arthritis (JIA) and patients with juvenile connective tissue diseases (JCTD) were compared using Fisher's exact test. Results: Fifty seven patients were studied with a female to male ratio of 3 to 1 (Female: 43; M: 14). The mean age at presentation in years was 14 +/- 4.4 years (range: 1.5-22 years). The mean duration of symptoms before diagnosis was 18.4 +/- .9 months (range: 2-60 months). The diagnostic types of PRDs included 28(49.1%) cases of JIA. These were made up of 14 cases of polyarticular JIA, nine cases of oligoarticular JIA and 5 cases of systemic onset JIA. Others were 18 (24.6%) cases of juvenile systemic lupus erythematosus (JSLE), 3 (5.3%) cases of joint hypermobility syndrome, 2 (3.5%) cases of juvenile systemic sclerosis, 2 (3.5%) cases of fibromyalgia, 2 (3.5%) cases of plantar fasciitis, 1 (1.6%) case of juvenile dermatomyositis (JDM), 1 (1.6%) case of juvenile polymyositis-systemic lupus erythematosus (PM-SLE) overlap, 1 (1.6%) case of secondary bilateral knee osteoarthritis from Blount disease, 1 (1.6%) case of secondary osteoporosis from childhood leukemia and 1 (1.6%) case of Osgood-Schlatter's disease. Constitutional symptoms and extra-articular diseases were significantly more frequent among JCTD cases than among the JIA cases (Constitutional symptoms: 100% vs 83.3%, p = 0.003; extra-articular disease: 100% vs 10.7%, p = 0.001). The percentage mortality in this study was 10.5% while 20 (35.1%) of the patients were lost to clinic follow up. Conclusion: The pattern of PRDs observed in this study is similar to that described in South African and North American series but it differs from patterns reported in Asian series. Although hitherto largely unrecognized, PRDs may constitute a substantial cause of morbidity and mortality in black Africans.

TI Menopause as a potential cause for higher prevalence of low back pain in women than in age-matched men
SO JOURNAL OF ORTHOPAEDIC TRANSLATION
LA English
DT Article
DE epidemiology; intervertebral disc degeneration; low back pain; oestrogen; physiological sex difference
ID estrogen-replacement therapy; lumbar disc degeneration; elderly chinese men; hormone-therapy; risk-factors; general-population; sex-differences; association; osteoarthritis; fractures
AB Female sex hormones play an important role in the aetiology and pathophysiology of a variety of musculoskeletal degenerative diseases. Postmenopausal women show accelerated disc degeneration due to relative oestrogen deficiency, resulting in narrower intervertebral disc space in women than age-matched men, increased prevalence of spondylolisthesis, and increased prevalence of facet joint osteoarthritis. Postmenopausal women also show higher osteoporosis related spine fracture rate, particularly at the thoracic-lumbar junction site. I propose the concept that low back pain (LBP) is more prevalent in postmenopausal women than age-matched men and is associated with the physiological changes caused by the relatively lower level of sex hormones after menopause in women. Considering hormone replacement treatment (HRT)'s consistent efficacy reported with menopause-associated osteoarthritis, an in-depth understanding of the role of the gonadal hormones in LBP modulation warrants further study. HRT initiated at early postmenopausal phase may be protective for recurring LBP. If this is the case, further cost-benefit analysis should be performed for optimal HRT regimen in cases of women with high risk of recurring severe LBP.

TI Suppression of human arthritis synovial fibroblasts inflammation using dexamethasone-carbon nanotubes via increasing caveolin-dependent endocytosis and recovering mitochondrial membrane potential
SO INTERNATIONAL JOURNAL OF NANOMEDICINE
LA English
DT Article
DE carbon nanotubes; polyethylene-glycol; dexamethasone; arthritis; fibroblast-like synoviocytes; caveolin-dependent endocytosis
ID rheumatoid-arthritis; oxidative stress; delivery; tnf; synoviocytes; nanoparticle; pathogenesis; cytokines; micelles; hypoxia
AB Dexamethasone (DEX), a non-particulate glucocorticoid (GC) to inhibit anti-inflammatory response, has been widely used for the treatment of various diseases such as arthritis, cancer, asthma, chronic obstructive pulmonary disease, cerebral edema, and multiple sclerosis. However, prolonged and/or high-dose GC therapy can cause various serious adverse effects (adrenal insufficiency, hyperglycemia, Cushing's syndrome, osteoporosis, Charcot arthropathy, etc). In this study, developed DEX-carbon nanotube (CNT) conjugates improved intracellular drug delivery via increased caveolin-dependent endocytosis and ultimately suppressed the expression of major pro-inflammatory cytokines in tumor necrosis factor-alpha (TNF-alpha)stimulated human fibroblast-like synoviocytes (FLS) at low drug concentrations. Specifically, DEX on polyethylene-glycol (PEG)-coated CNTs induced caveolin uptake, recovered mitochondrial disruption, and inhibited reactive oxygen species production by targeting mitochondria that was released from the early endosome in TNF-alpha-stimulated FLS. The obtained results clearly demonstrated that DEX-PEG-coated CNTs significantly inhibited the inflammation by FLS in rheumatoid arthritis (RA) by achieving greater drug uptake and efficient intracellular drug release from the endosome, thus suggesting a mechanism of

effective low-dose GC therapy to treat inflammatory diseases, including RA and osteoarthritis.

TI Relationships between fish and otolith size of nine deep-sea fishes from the Andaman and Nicobar waters, North Indian Ocean
SO JOURNAL OF APPLIED ICHTHYOLOGY
LA English
DT Article
ID weight-length relationships; eastern arabian sea; age-determination; stock discrimination; primary productivity; growth increments; back-calculation; predator-prey; persian-gulf; western bay
AB The study presents for the first time the otolith morphology of nine species of deep-sea fishes. This study was based on sampling carried out on-board FORV Sagar Sampada (Cruise No 349) during March-April 2016, along the continental margin of the Andaman and Nicobar Islands in the Bay of Bengal using high speed demersal trawl. Unbroken (complete) otoliths from Polymixia fusca Kotthaus, 1970, Neoepinnula orientalis (Gilchrist & von Bonde 1924), Chlorophthalmus nigromarginatus (Kamohara, 1953), Cubiceps baxteri (McCulloch, 1923), Bembrops caudimacula (Steindachner, 1876), Neoscopelus microchir (Matsubara, 1943), Ostracoberyx dorygenis Fowler, 1934, Synagrops japonicus (Doderlein, 1883), and Bathyclupea hoskynii Alcock 1891) were used for this study. Length-weight

relationships (LWR) and the regression between otolith size (width, weight, area and perimeter) and fish length (TL) of nine deep-sea Fishes were considered. Numerical relationships derived from the relationship between otolith size and the fish can be used as predictors to estimate the prey size as well as to understand trophic relations and food web dynamics of these hitherto unexamined deep-sea ichthyofauna. LWR showed negative allometric otolith growth in five species; four species showed positive allometric growth. Otolith size to fish size (TL) relation is explained by a simple linear regression considering otolith width (OW), otolith weight (OWe), otolith area (OA) and otolith perimeter (OP). Stronger r(2) values (>.76) indicate robustness, except for Cubiceps baxteri (r(2)=.65), and give better estimates for the TL of the fish.

TI OSTEOPOROSIS IN BRAZILIAN PATIENTS AWAITING KNEE ARTHROPLASTY
SO ACTA ORTOPEDICA BRASILEIRA
LA English
DT Article
DE Osteoporosis; Climacteric; Arthroplasty
ID total hip-arthroplasty; risk-factors; osteoarthritis; validation; women
AB Objective: The primary objective of this study was to determine the prevalence of osteoporosis and osteopenia prior to total knee arthroplasty (TKA) in female patients. As a secondary objective, we evaluated the incidence of hip fractures, types of drugs to treat osteoporosis and serum vitamin D levels. Method: This is a transversal, descriptive and observational study which evaluated 60 women above age 55 prior to total knee replacement. Results: Mean patient age was 71.4 years. Osteoporosis was present in 16.7% of the sample and osteopenia in 15%. In the patients with osteoporosis, femur fracture (20%) was most frequent. Most of the group with osteopenia did not take any medication to treat this condition (55.6%), while most patients with osteoporosis took alendronate (30%) and 30% did not take any medication. Conclusion: The female population awaiting total knee replacement should be considered at risk for osteoporosis, confirming recent findings in the literature.

TI Effect of strontium ranelate on pain behavior in an experimental model of osteoarthritis
SO BRAZILIAN JOURNAL OF MEDICAL AND BIOLOGICAL RESEARCH
LA English
DT Article
DE Osteoarthritis; Strontium ranelate; Pain; Treatment; Prophylaxis
ID postmenopausal women; vertebral fracture; risk; mechanism; bone; knee
AB Strontium ranelate (SrRan) is a drug usually prescribed to treat osteoporosis, with proven effects of decreasing the risk of fractures and an indication of reducing the progression of osteoarthritis (OA). This study aimed to investigate the effects of SrRan as either a prophylactic or a treatment drug, using an OA rat model to assess pain behavior. A monoiodoacetate (MIA)-induced knee joint OA model in Wistar rats was used. Thirty Wistar rats (both sexes, 60 days old) were distributed in five groups of 6 rats each: the control group, that received no intervention; a prophylactic group, that received oral administration of 25 mg . kg(-1) . day(-1) of SrRan for 28 days before induction of OA; a group treated with 25 mg . kg(-1) . day(-1) of SrRan for 28 days after OA induction; a group treated with 50 mg . kg(-1) . day(-1) during 28 days after OA induction; and a group that received oral saline for 28 days after induction. The assessment of pain behavior was performed considering articular incapacitation (weight-bearing test), mechanical hyperalgesia (Randall Selitto test) and motor activity (rotarod test), on days 0, 7, 14, 21, and 28. This experiment did not yield a significant difference when comparing the group that received SrRan prophylactically with the groups treated with 25 or 50 mg . kg(-1) . day(-1) and the group that received oral saline. Thus, SrRan did not provide analgesia in either treated rats or as a prophylactic drug with the tested doses. Higher doses should be tested further to achieve possible significant results.

TI Mass spectrometry imaging: a novel technology in rheumatology
SO NATURE REVIEWS RHEUMATOLOGY
LA English
DT Review
ID ablation electrospray-ionization; paraffin-embedded tissue; maldi-ms; proteomic analysis; mouse-brain; tof-sims; in-vivo; atmospheric-pressure; bone mineralization; spatial-resolution
AB Mass spectrometry imaging (MSI) is used to determine the relative abundance and spatial distribution of biomolecules such as peptides, proteins, lipids and other organic compounds in tissue sections by their molecular masses. This technique provides a sensitive and label-free approach for high-resolution imaging, and is currently used in an increasing number of biomedical applications such as biomarker discovery, tissue classification and drug monitoring. Owing to technological advances in the past 5 years in diverse MSI strategies, this technology is expected to become a standard tool in clinical practice and provides information complementary to that obtained using existing methods. Given that MSI is able to extract mass-spectral signatures from pathological tissue samples, this technique provides a novel platform to study joint-related tissues affected by rheumatic diseases. In rheumatology, MSI has been performed on articular cartilage, synovium and bone to increase the understanding of articular destruction and to characterize diagnostic and prognostic biomarkers for osteoarthritis, rheumatoid arthritis and osteoporosis. In this Review, we provide an overview of MSI technology and of the studies in which joint tissues have been analysed by use of this methodology. This approach might increase knowledge of rheumatic pathologies and ultimately prompt the development of targeted strategies for their management.

TI Identification and management of patients at increased risk of osteoporotic fracture: outcomes of an ESCEO expert consensus meeting
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Review
DE Fracture risk; Healthcare burden; Management; Osteoporosis; Secondary prevention; Treatment gap
ID postmenopausal women; hip fracture; vertebral fractures; nonvertebral fractures; strontium ranelate; united-kingdom; abaloparatide; teriparatide; probability; health
AB Osteoporosis represents a significant and increasing healthcare burden in Europe, but most patients at increased risk of fracture do not receive medication, resulting in a large treatment gap. Identification of patients who are at particularly high risk will help clinicians target appropriate treatment more precisely and cost-effectively, and should be the focus of future research. The purpose of the study was to review data on the identification and treatment of patients with osteoporosis at increased risk of fracture. A working group convened by the European Society for Clinical and Economic Aspects of Osteoporosis and Osteoarthritis met to review current data on the epidemiology and burden of osteoporosis and the patterns of medical management throughout Europe. In Europe in 2010, the cost of managing osteoporosis was estimated at a,notsign37 billion and notably the costs of treatment and long-term care of patients with fractures were considerably higher than the costs for pharmacological prevention. Despite the availability of effective treatments, the uptake of osteoporosis therapy is low and declining, in particular for secondary fracture prevention where the risk of a subsequent fracture following a first fracture is high. Consequently, there is a significant treatment gap between those who would benefit from treatment and those who receive it, which urgently needs to be addressed so that the burden of disease can be reduced. Implementation of global fracture prevention strategies is a critical need. Future research should focus on identifying specific risk factors for imminent fractures, periods of high fracture risk, patients who are at increased risk of fracture and therapies that are most suited to such high-risk patients and optimal implementation strategies in primary, secondary and tertiary care.

DT Article
DE Osteoporosis; Osteoarthritis; Transglutaminase 2; Cartilage; Bone remodeling
ID femoral-neck fracture; articular-cartilage; extracellular-matrix; knee osteoarthritis; subchondral bone; cross-linking; endochondral ossification; messenger-rna; hip; cells
AB Osteoporosis (OP) and osteoarthritis (OA) are the most common joint diseases, with a high incidence in the elderly population. OP is characterized by trabecular bone remodeling and reabsorption, whereas articular cartilage and subchondral bone remodeling are major features of OA. Although classically considered as independent or even conflicting processes, clinical coexistence of OP and OA was recently described. Transglutaminase 2 (TG2) expression is considered a biomarker of OA, but its role in osteoporotic bone remodeling is still uncertain. We investigated TG2 and bone biological markers (Osteocalcin, Osteopontin, and Sclerostin) in osteoporotic and osteoarthritic osteocartilagineous tissue (n = 54) and human chondrocyte cultures in vitro by immunohistochemistry, immunofluorescence and RT-PCR. Histomorphometric evaluation of bone trabecular remodeling was also performed. In cartilage, TG2 expression was faint in control and OP and significantly less than in OA and OP + OA chondrocytes; the opposite was found for Osteocalcin, whereas Osteopontin and Sclerostin expression was similar. In the subchondral trabecular bone, osteocytes/osteoblasts TG2 expression was slight and similar comparing control, OP, OA, and OP + OA group, whereas Osteocalcin and Osteopontin expression was lower in OP compared to control, OA and OP + OA. Increased TG2 and reduced Osteocalcin expression were maintained in human osteoarthritic chondrocytes in vitro. Histomorphometric analysis confirmed reduced trabecular bone mass in OP and OP + OA compared with OA patients. TG2 represented a suitable biomarker of osteoarthritic chondrocyte activation, whereas osteocalcin and osteopontin characterized osteoporotic osteocyte/osteoblast changes; differences were lost in OP + OA patients, suggesting careful consideration when coexistence of the two diseases occurs.

TI PAIN AND FRAILTY IN ELDERLY FEMALES WITH OSTEOPOROSIS
SO TURKISH JOURNAL OF GERIATRICS-TURK GERIATRI DERGISI
LA English
DT Article
DE Aged; Female; Frail Elderly; Geriatrics; Osteoporosis; Pain
ID quality-of-life; older-adults; rheumatoid-arthritis; back-pain; osteoarthritis; prevalence; population; fracture; knee
AB Introduction: Most adults who live to an advanced age become frail. Although not a disease, frailty is a combination of age-related changes and associated medical problems. This descriptive study aimed to determine the pain level and frailty status of elderly females with osteoporosis. Materials and Method: The present study sample consisted of 105 elderly females with osteoporosis who were admitted to the geriatric outpatient units of two university hospitals. Data were collected using the questionnaire prepared by the author on the basis of a literature review, the Geriatric Pain Scale and the Edmonton Frail Scale. Data were analysed using descriptive statistics, the Mann-Whitney U test, the Kruskal-Wallis H test and correlation analysis. Results: In total, 6.7% of the elderly females with osteoporosis reported a slight level of pain, 67.3% reported mild pain and 26% reported severe pain. Edmonton Frail Scale mean scores indicated that 16.3% of the subjects had moderate frailty and that 44.2% had severe frailty. Elderly females with osteoporosis who were sad and depressed during the past seven days due to pain were found to be more fragile ($p<0.05$). In addition, weight loss, depressive symptoms and urinary incontinence were related to frailty ($p<0.05$). A poor positive significant relationship was found between the mean scores of the Geriatric Pain Scale and the Edmonton Frail Scale. Conclusion: Nurses and people involved in health care should assess the frailty status of elderly females with osteoporosis, particularly those reporting pain, and be aware of the characteristics, possible symptoms and affecting factors.

TI Radiologic and Clinical Features of Misdiagnosed Idiopathic Osteonecrosis of the Femoral Head

SO ORTHOPEDICS
LA English
DT Article
ID distinguishing transient osteoporosis; advanced hip osteoarthritis; bone-marrow edema; avascular necrosis; nontraumatic osteonecrosis; mri findings; osteotomy; histopathology; fracture; cells
AB Idiopathic osteonecrosis of the femoral head (ONFH) can be correctly diagnosed in accordance with the established criteria. However, some general orthopedic physicians have misdiagnosed patients as having ONFH. The goal of this study was to clarify the radiologic and clinical features of misdiagnosed patients. This study included 50 patients who were referred to the authors' hospital by general physicians with a diagnosis of ONFH. The correct diagnosis was made based on the Japanese Investigation Committee diagnostic criteria for ONFH. Demographic data were compared between patients with and without ONFH. Of the 50 patients, 24 were diagnosed with other diseases: 10 with osteoarthritis, 7 with transient osteoporosis of the femoral head, 4 with rapidly destructive coxopathy, and 3 with subchondral insufficiency fracture. Seventeen patients who did not have ONFH had magnetic resonance imaging findings that showed a bone marrow edema pattern at the femoral head. The mean age of 62.9 years among patients without ONFH was significantly higher than that of 45.2 years among patients with ONFH. There were 18 female patients in the non-ONFH group and 5 female patients in the ONFH group. Bilateral disease was found in 1 patient in the non-ONFH group and 17 patients in the ONFH group. No patients in the non-ONFH group had a history of systemic steroid administration compared with 11 patients in the ONFH group. Clinical features associated with the non-ONFH group were female sex, older age, unilateral disease, and no history of systemic steroid administration. For patients with these features, the diagnosis of ONFH should be made carefully.

TI Efficacy of Alendronate for the Prevention of Bone Loss in Calcar Region Following Total Hip Arthroplasty

SO JOURNAL OF ARTHROPLASTY
LA English
DT Article
DE alendronate; alfacalcidol; total hip arthroplasty; stress shielding; bone mineral density
ID mineral density; femoral components; proximal femur; stem; dimensions; implant; dxa
AB Background: Bone mineral density (BMD) loss around femoral implants, particularly in the proximal femur, is a common outcome after total hip arthroplasty. Previous studies reported the prevention of postsurgical decrease in BMD with the use of osteoporosis drug therapy. This randomized study evaluated the efficacy of alendronate and alfacalcidol for preserving BMD over a long-term follow-up. Methods: Sixty consecutive patients with hip osteoarthritis who had undergone primary cementless total hip arthroplasty were randomly assigned to an alendronate (n = 20), alfacalcidol (n = 18), or control (n = 22) group. Periprosthetic BMD was measured using dual-energy X-ray absorptiometry at 1 week, 1 year, and the current follow-up (minimum 9 years after surgery). Changes in BMD are reported as mean percentages relative to the values at 1 week (baseline reference). Results: All groups showed a significant decrease in the BMD of the calcar at the current follow-up compared to the values at both 1 week and 1 year postoperatively (P < .001). The BMD values were significantly higher in the alendronate group than in the alfacalcidol and control groups (P < .05). The BMD values at the current follow-up were 76% +/- 30% (alendronate group), 64% +/- 22% (alfacalcidol group), and 59% +/- 22% (control group) of the baseline values. Conclusion: Our findings demonstrate the efficacy of early administration of alendronate for the prevention of bone loss in the calcar region. (C) 2017 Elsevier Inc. All rights reserved.

TI Influences of osteoarthritis and osteoporosis on the electrical properties of human bones as in vivo electrets produced due to Wolff's law
SO BIO-MEDICAL MATERIALS AND ENGINEERING
LA English
DT Article
DE Electrical property; human bone; electrical polarization; osteoarthritis; osteoporosis; proximal femur
ID hydroxyapatite; polarization
AB We characterized the electrical properties of living bone obtained from patients who had undergone total hip arthroplasty (THA) or hemiarthroplasty by means of analysis of the electrically polarized and nonpolarized bone specimens, and we discussed the role of an organic and inorganic matrix of human bone in bone piezoelectricity. We used human femoral neck bone that was harvested during THA for advanced osteoarthritis of the hip joint (OA group) and hemiarthroplasty for femoral neck fracture (FNF group). The specimens were scanned to evaluate the cancellous bone structures using micro-computed tomography, and we quantified the carbonic acid by attenuated total reflection (ATR) spectra to estimate carbonate apatite. The stored electrical charge in the electrically polarized and nonpolarized bone specimens were calculated using thermally stimulated depolarized current (TSDC) measurements. Each TSDC curve in the groups had peaks at 100 degrees C, 300 degrees C and 500 degrees C, which may be attributed to collagen, carbonate apatite and hydroxyapatite, respectively. It is suggested that organic substances are more effectively electrically polarized than apatite minerals by the polarization at room temperature and that the stored charge in living bone may be affected not only by total bone mass but also by bone quality, including 3-dimensional structure and structural component.

TI TGF β1 gene polymorphisms correlate with the susceptibility of osteoarthritis
SO INTERNATIONAL JOURNAL OF CLINICAL AND EXPERIMENTAL PATHOLOGY
LA English
DT Article
DE Transforming growth factor beta 1; polymorphism; osteoarthritis
ID risk-factors; tgf-beta; disease; association; bone; hip; age; osteoporosis; arthritis; impact
AB Purpose: We investigated the potential role of transforming growth factor beta 1 (TGF beta 1) gene polymorphisms (rs1800470 and rs1800469) in the occurrence of osteoarthritis (OA). Methods: Genotypes of TGF beta 1 gene polymorphisms (rs1800470 and 1800469) were genotyped by TaqMan method in 111 OA patients and 129 healthy controls. The representativeness of case and control was inspected by Hardy-Weinberg equilibrium (HWE). Genotype and allele distribution differences between case and control groups were calculated by Chi-square test. Odds ratios (ORs) and their corresponding 95% confidence intervals (95% CIs) were utilized to emerge the relative risk of OA. Results: Genotype distributions of the two TGF beta 1 gene polymorphisms were according to HWE examination. TT genotype of rs1800470 was significantly associated with the occurrence of OA (P=0.046, OR=2.093, 95% CI=1.009-4.340). For rs1800469, both TT genotype and T allele had significant association with the susceptibility of OA (P=0.000, OR=3.650, 95% CI=1.759-7.575; P=0.000, OR=1.957, 95% CI=1.360-2.817). Conclusion: TT genotype of rs1800470, TT genotype and T allele of rs1800469 were increased the risk of OA. We conjectured that the polymorphisms of TGF beta 1 gene might increase the individual susceptible of OA.

TI Rheumatoid Arthritis Masquerading as Fibromyalgia
SO JCPSP-JOURNAL OF THE COLLEGE OF PHYSICIANS AND SURGEONS PAKISTAN
LA English
DT Article
DE Musculoskeletal ultrasound; Rheumatoid arthritis; Fibromyalgia
AB Symptoms of inflammatory arthritis such as rheumatoid arthritis (RA) can overlap with fibromyalgia syndrome (FMS). Moreover, FMS and RA can coexist. Hence, the diagnosis of low intensity, antibody-negative RA may present a challenge. Here, we present the case of a middle-aged woman thought to have FMS, osteoarthritis and osteoporosis for 4 years prior to being diagnosed as seronegative RA on musculoskeletal ultrasound (MSKUS). Targeted therapy with etanercept led to a complete clinical response and normalization of previously elevated C-reactive protein. We conclude that MSKUS is a sensitive tool for distinguishing low-intensity inflammatory arthritis from FMS with important clinical consequences.

TI A scoping review of the public health impact of vitamin D-fortified dairy products for fracture prevention
SO ARCHIVES OF OSTEOPOROSIS
LA English
DT Review
DE Cost-effectiveness; Dairy products; Fractures; Nutrition; Osteoporosis; Public health
ID cost-effectiveness; european-society; economic-aspects; intervention thresholds; calcium supplementation; postmenopausal women; osteoporosis; osteoarthritis; management; consensus
AB Purpose Dairy products are rich in nutrients that positively influence bone health and hence fracture risk, and have therefore been recommended and used for fracture prevention. To help decision makers to efficiently allocate scare resources, it is further important to assess the public health and economic impact of any health intervention. In recent years, several studies have been conducted to estimate the public health and/or economic impact of dairy products but no overview is currently available. This article aims therefore to summarize evidence and review articles that estimated the public health and/or economic impact of

vitamin D-fortified dairy products for fracture prevention. Methods A literature review was conducted using PubMed to identify original studies that assessed the public health and/or economic impact of dairy products (or of calcium/vitamin D supplementation) for fracture prevention up to January 15, 2017. Results Seven articles were identified. Different strategies were used by the authors to model the economic/public health impact of dairy products. The four studies assessing the public health impact of dairy products revealed a substantial benefit in terms of fracture prevented, life years, disability-adjusted life years and/or quality-adjusted life years gained. Studies assessing the cost-effectiveness revealed that the use of dairy products is generally cost-effective in the general population aged above 70 years, and from the age of 60 years in populations at high risk of fractures. Conclusion This systematic review suggests that the use of dairy products could substantially reduce the burden of osteoporotic fractures and seem to be an economically beneficial strategy.

TI Arthroscopic Lateral Retinacular Release and Modified Elmslie-Trillat Operation Improve Severe Isolated Lateral Patello-Femoral Osteoarthritis
SO JOURNAL OF KNEE SURGERY
LA English
DT Article
DE arthroscopy; patello-femoral OA; Elmslie-Trillat operation
ID tibial tubercle osteotomy; recurrent patellar instability; subchondral bone; articular-cartilage; contact pressure; proximal tibia; in-vitro; osteoporosis; malalignment; progression
AB To evaluate whether arthroscopic lateral retinacular release and the modified Elmslie-Trillat operation improve osteoarthritis (OA) progression and clinical outcomes in patients with severe isolated lateral patello-femoral OA. Nine women (11 knees) and one man (one knee) with isolated late-stage lateral patello-femoral OA underwent surgery. The severity of patello-femoral OA was recorded using the Merchant method, while the level of pain and anterior knee function were scored using the visual analogue scale (VAS) and Kujala knee scores, respectively. The articular cartilage was graded under arthroscopy using the Outerbridge classification. All of the patients underwent the modified Elmslie-Trillat operation after arthroscopic surgery, including lateral retinacular release. Ten patients (12 knees) had a mean 6.45 +/- 0.80 mm of medial transfer, 6.02 +/- 0.80 mm of anterior transfer of the tibial tubercle, and follow-up of 67.0 months. The mean VAS and Kujala knee scores improved from 8 +/- 0.17 preoperatively to 2.33 +/- 0.33 on the last follow-up and from 43.08 +/- 2.09 to 68.83 +/- 2.59, respectively (both $p < 0.001$). Postoperatively, all had improved subchondral bone remodeling, including cyst resolution, density and trabeculae normalization, and subchondral smoothing in the patello-femoral compartment. The patello-femoral joint space and patellar thickness increased from 0.39 +/- 0.16 mm to 1.77 +/- 0.18 mm and from 18.28 +/- 0.67 mm to 19.60 +/- 0.69 mm, respectively ($p < 0.001$ and $p = 0.005$). Treatment of severe isolated lateral patello-femoral OA using arthroscopic

lateral retinacular release and the modified Elmslie-Trillat operation can improve pain relief, functional outcomes, and subchondral bone remodeling, and also restore the patello-femoral joint space and patellar thickness. Prompt transfer of the tibial tubercle seems to reverse the progress of OA radiographically.

ID musculoskeletal pain; neuropathic pain; sensitization; impact; epidemiology; mechanisms; people; mri; comorbidity; diagnosis
AB The objective of this study was to investigate the associations of knee structural abnormalities with different patterns of pain. A total of 891 participants (average age 63 years; range 50 to 80 years) participated in this study. Presence of pain at the neck, back, hands, shoulders, hips, knees, and feet was assessed by questionnaire. Participants were categorized as having no pain at any site (no pain), pain only at the knee (KP), pain at other sites but not the knee (OP), and pain at the knee and other sites (KOP). T1-weighted or T2-weighted MRI of the right knee was performed to measure cartilage defects, bone marrow lesions (BMLs), and effusion-synovitis. Osteophytes and joint space narrowing were assessed by X-ray. KP, KOP, and OP were, respectively, present in 3, 43, and 42% of the participants. In multivariable analyses, KOP was associated with the presence of cartilage defects, BMLs, and osteophytes (OR 3.57 (95% CI 1.78 to 7.14), 2.37 (1.27 to 4.43), and 2.87

(1.10 to 7.51), respectively) in those with radiographic knee OA. KP was also associated with presence of these structural abnormalities as well as effusion-synovitis, and these associations were much stronger. The associations between structural abnormalities and KOP were weaker than those with KP in those with radiographic knee OA. This suggests that mechanisms mediating the association between structural pathology, localized, and generalized pain may be different, and central sensitization is possibly involved in generalized pain. Pain at other sites needs to be considered in the management and treatment of OA-related pain.

TI Sclerostin expression and functions beyond the osteocyte
SO BONE
LA English
DT Article
DE Sclerostin; Wnt; Osteoarthritis; Ankylosing spondylitis; Rheumatoid arthritis
ID van-buchem-disease; bone-formation; serum sclerostin; prostate-cancer; ankylosing-spondylitis; postmenopausal women; cell proliferation; multiple-myeloma; sost expression; bmp antagonist
AB Sclerostin, the product of the SOSTgene, is a secreted inhibitor of Wnt signaling that is produced by osteocytes to regulate bone formation. While it is often considered an osteocyte-specific protein, SOST expression has been reported in numerous other cell types, including hypertrophic chondrocytes and cementocytes. Of interest, SOST/sclerostin expression is altered in certain pathogenic conditions, including osteoarthritis and rheumatic joint disease, and it is unclear whether sclerostin plays a protective role or whether sclerostin may mediate disease pathogenesis. Therefore, as anti-sclerostin antibodies are being developed for the treatment of osteoporosis, it is important to understand the functions of sclerostin beyond the regulation of bone formation. TI Knee subchondral bone perfusion and its relationship to marrow fat and trabeculation on multi-parametric MRI and micro-CT in experimental CKD
SO SCIENTIFIC REPORTS
LA English
DT Article
ID chronic kidney-disease; quantitative-analysis; vascular axis; osteoarthritis; model; osteoporosis; images; quantification; progression; lesions
AB The pathogenesis of chronic kidney disease (CKD) is multifactorial. In the

progression of CKD arthropathy, arteriosclerosis may alter the knee subchondral bone marrow by altering blood flow through the bone vasculature. Herein, multi-parametric MRI assessment, including dynamic contrast enhanced magnetic resonance imaging (DCE-MRI), magnetic resonance spectroscopy (MRS), MRIT2*, contrast enhanced MR angiography (CE-MRA), and micro-CT were applied in a rodent nephrectomy model to: 1) investigate the blood perfusion of subchondral bone marrow and its relationship to fat water content and trabeculation pattern in CKD and 2) demonstrate the feasibility of using multi-parametric MRI parameters as imaging biomarkers to evaluate the disease's progression. Two groups of rats in our study underwent either 1) no intervention or 2) 5/6 nephrectomy. We found that in the CKD group, perfusion amplitude A and elimination constant k(ei) values were significantly decreased, and vascular permeability k(ep) was significantly increased. MRS showed that fat fraction (FF) was significantly lower, water fraction (WF) was significantly higher in the CKD group. Micro-CT showed a significant loss of trabecular bone. Knee subchondral bone marrow perfusion deficiency in experimental CKD may be associated with decreased fat content, increased water content, and sparse trabeculation.

ID dna methylation; subchondral bone; osteoporosis; bmp-2; stimulation; mechanisms; cartilage; skeletal; regions; lineage
AB Insufficient activity of the bone-forming osteoblasts leads to low bone mass and predisposes to fragility fractures. The functional capacity of human mesenchymal stem cells (hMSCs), the precursors of osteoblasts, may be compromised in elderly individuals, in relation with the epigenetic changes associated with aging. However, the role of hMSCs in the pathogenesis of osteoporosis is still unclear. Therefore, we aimed to characterize the genome-wide methylation and gene expression signatures and the differentiation capacity of hMSCs from patients with hip fractures. We obtained hMSCs from the femoral heads of women undergoing hip replacement due to hip fractures and controls with hip osteoarthritis. DNA methylation was explored with the Infinium 450K bead array. Transcriptome analysis was done by RNA sequencing. The genomic analyses revealed that most differentially methylated loci were situated in genomic regions with enhancer activity, distant from gene bodies and promoters. These regions were associated with differentially expressed genes enriched in pathways related to hMSC growth and osteoblast differentiation. hMSCs from patients with fractures showed enhanced proliferation and upregulation of the osteogenic drivers RUNX2/OSX. Also, they showed some signs of accelerated methylation aging. When cultured in osteogenic medium, hMSCs from patients with fractures showed an impaired differentiation capacity, with reduced alkaline phosphatase activity and poor accumulation of a mineralized matrix. Our results point to 2 areas of potential interest for discovering new therapeutic targets for low bone mass disorders and bone regeneration: the mechanisms stimulating MSCs proliferation after fracture and those impairing their terminal differentiation.

DT Article
ID osteoblastic differentiation; bone-resorption; mc3t3-e1 cells; c-fos; osteoporosis; activation; mineralization; pathways; receptor; system
AB The medicinal properties of functionally active organosulfur compounds have received great attention for applications in treating various diseases. Thiacremonone (2,4-dihydroxy-2,5-dimethyl-thiophene-3-one, THIA) is a novel organosulfur compound generated from high-temperature-high-pressure-treated garlic and has been reported to display pharmacological effects against various diseases. However, the role of THIA in bone resorbing cells was not reported. Herein, we have examined the pharmacological properties of THIA on osteoclast differentiation in primary cultured bone marrow macrophages (BMMs). Our results showed that THIA suppressed receptor activator of NF-kappa B ligand (RANKL)-induced gene expression (c-Fos and NF-ATc1) for osteoclast differentiation under no cytotoxicity condition. In addition, THIA significantly inhibited TRAP positive multinucleated osteoclasts and F-actin ring formation during RANKL-mediated osteoclastogenesis. However, in primary cultured calvarial pre-osteoblasts, THIA did not influence the cytotoxicity and osteoblast differentiation, as assessed from the alkaline phosphatase (ALP) activity and mineralized nodule formation. Our findings have suggested that THIA can be considered as a potential agent for the therapeutics of bone diseases such as osteoporosis, alveolar bone resorption, and osteoarthritis.

DT Article
DE Magnolia officinalis; 4-O-methylhonokiol; Osteoblast; Osteoclast; RANKL
ID osteoblastic differentiation; mc3t3-e1 cells; c-fos; osteoporosis; activation; receptor; mineralization; resorption; pathways; system
AB Magnolol, honokiol, and obovatol are well known bioactive constituents of the bark of Magnolia officinalis and have been reported to have beneficial effects in various diseases. We recently isolated a novel active compound,

4-O-methylhonokiol (4-O-MH) from the ethanol extract of M. officinalis, which was previously reported to have pharmacological effects including anti-inflammatory, anti-oxidative, and anti-aging activities. Here, we examined the pharmacological properties of 4-O-MH on osteoblast (bone-forming cells) and osteoclast (bone-resorbing cells) differentiation, and its underlying signaling pathways in primary cultured pre-osteoblasts and bone marrow macrophages. Our results showed that 4-O-MH did not affect cell viability in pre-osteoblasts and did not influence osteoblast differentiation and mineralized nodule formation, as assessed by alkaline phosphatase activity and Alizarin red staining. However, 4-O-MH significantly inhibited TRAP-positive multinuclear osteoclasts and F-actin ring formation during Receptor activator of NF-kappa B ligand (RANKL)-mediated osteoclastogenesis without cytotoxicity. In addition, 4-O-MH suppressed RANKL-induced critical factors (c-Fos, NF-ATc1, TRAP, and ITB3) for osteoclast differentiation and function. Furthermore, RANKL-mediated signaling, including ERK1/2, AKT, and NF-kB pathways was attenuated by 4-O-MH. Taken together, 4-O-MH has an inhibitory role in RANKL-mediated osteoclastogenesis but not osteoblast differentiation, and our findings also suggest that 4-O-MH is a potential therapeutic agent for bone-destructive diseases such as osteoporosis, alveolar bone resorption, and osteoarthritis.

TI THE CURRENT ISSUES ON OSTEOPOROSIS AMONG MALE SAUDI ARABIANS
SO JOURNAL OF MENS HEALTH
LA English
DT Article
ID bone-mineral density; glucocorticoid-induced osteoporosis; hip fracture; vertebral fractures; older men; prevalence; prevention; women; risk; population
AB Background and Objectives Osteoporosis was reported to be common among the Saudi Arabian population. In the last decade there have been no reports related to the male osteoporosis in Saudi Arabian citizens. The objective of this study was to find the hospital-based prevalence of male osteoporosis and the associated diseases. Methodology This is a retrospective study between January 2014 and December 2016 in which all patients who were referred for DEXA (Dual Energy X-ray Absorptiometry) scan to the radiology department of the King Fahd Hospital of the University, AlKhobar were included. Patient's demographic data were collected from the medical records. Patients who were younger than 50 and those

who had a fragility fracture were excluded from the analysis. From the Picture Archiving and Communication System (PACS, Siemens AG, Erlangen, Germany) the readings of the DEXA were collected. Associated diseases of the patients were also extracted from the QuadruMed Data Base. The data was entered in the database and analyzed using SPSS Inc. version 19 and p value of <0.05 was considered significant. Results Four hundred and fifty-five patients had a DEXA scan during the study period. Three hundred and seventy-one (81.5%) were >= 50 years. The average was 65.33 +/- 9.85 years (range 50-97). On the basis of Spinal T score, 222 (59.8%) were osteoporotic with the Spinal T score of <-3.58 +/- 0.88, while, with Hip T score 120 (32.3%) were osteoporotic with T score of <-3.24 +/- 0.59. Thirty-six (9.7%) had a normal DEXA of spine and 74(19.9%) of patients had normal DEXA when the Hip T score was taken into consideration. Patients could be divided into 4 groups based on their diseases; they were on treatment for cardiac disease 106 (28.5%), Diabetes mellitus 95 (25.7%), osteoarthritis 141 (38%) and respiratory disease 29 (7.8%). Based on the Spinal T score osteoporosis was observed in 61/106 (57.5%) patients with cardiac disease, 62/95 (65.3%) in diabetics, in osteoarthritis 83/141 (58.9%) and 16/29 (55.1%) in patients with respiratory system diseases. Majority of the patients had vitamin D3 analysis and were most of the patients were in the deficiency range. From 222 (59.83%) patients who were diagnosed to have osteoporosis only 108 (48.64%) were on appropriate treatment for osteoporosis. Conclusion This study finds that the prevalence of osteoporosis in Saudi Arabian males is higher than in the western world and has increased in the last decade. The authors believe a more determined effort is needed to lower the screening age for osteoporosis and report the observations. This will allow a consensus to be reached regarding the frequency of osteoporosis in Saudi Arabian males and implement appropriate measures to limit its growth.

SO CURRENT RHEUMATOLOGY REPORTS
LA English
DT Article
DE Microbiome; Osteoarthritis; Osteoporosis; Bone; Inflammation
ID gut microbiota; inflammation; mice; osteoarthritis; arthritis; increases; intestine; severity; obesity; growth
AB Purpose of Review Changes in the constituents and activity of the microbiome have been associated with a number of conditions linked to bone and joint disease.

This review concentrates on ways in which the microbiome is known to influence osteoarthritis and osteoporosis. Recent Findings Animal studies have demonstrated that changes in the microbiome can mediate the effects of obesity on cartilage degeneration. Additionally, the microbiome influences the amount of the bone (bone quantity), as well as bone tissue material properties (bone quality). Early clinical findings support the effects of the microbiome on osteoporosis and osteoarthritis. Summary Although animal studies implicate the microbiome in the development of bone and joint disease, available results are limited and can be conflicting. Further investigation of the mechanisms linking from changes in the microbiome to alterations in the bones and joints are necessary.

TI MicroRNA-221 is involved in the regulation of osteoporosis through regulates RUNX2 protein expression and osteoblast differentiation
SO AMERICAN JOURNAL OF TRANSLATIONAL RESEARCH
LA English
DT Article
DE Osteoporosis; osteoblast; osteogenic differentiation; microRNA-221; RUNX2
ID mesenchymal stem-cells; osteogenic differentiation; bone-development; pathway; cancer; pathogenesis; chondrocyte; activation; mir-221; mirnas
AB Introduction: MicroRNAs (miRNAs) has emerged as important factors in osteogenesis and chondrogenesis. This study aimed to determine whether miR-221 is involved in the regulation of osteoporosis and its underlying mechanism.

Methods: Total RNA was extracted from fresh femoral neck trabecular bone from women undergoing hip replacement due to either osteoporotic fracture (OP group, n = 12) or osteoarthritis in the absence of osteoporosis (Control group, n = 12). Gene expression was quantified using TaqMan quantitative RT-PCR assays and protein production was determined by western blot analysis. The role of miR-221 in osteoblast differentiation was identified by gain or loss function experiment. MiRNA targets were identified using bioinformatics and luciferase reporter assay. Results: MiR-221 was down-regulated in the osteoporotic samples compared with non-osteoporotic controls, and decreased in a C2C12 cell model of osteogenic differentiation. Overexpression of miR-221 resulted in a decrease in the osteogenic potential, as indicated by the reduced expression levels of key osteoblast markers, including osteocalcin (OC), alkaline phosphatase (ALP) and collagen, type I, a 1 (COL1A1), whereas inhibition of miR-221 promoted the activity of OC, ALP and COL1A1. Then bioinformatic analysis identified potential target sites of the miR-221 located in the 3' untranslated regions of RUNX2. Western blot analysis demonstrated that miR-221 inhibited RUNX2 gene expression. Furthermore, dual-luciferase reporter assays confirmed that RUNX2 was a direct target of miR-221. Rescue experiments showed that overexpression of RUNX2 significantly attenuated the effect of miR-221 on osteoblast markers providing strong evidence that miR-221 mediated the osteoblast differentiation by targeting RUNX2. Conclusions: Taken together, these data implied that miR-221 played an important part in osteoporosis through regulating RUNX2 expression and osteoblast differentiation.

TI Non-guideline-recommended prescribing of proton pump inhibitors in the general population
SO CURRENT MEDICAL RESEARCH AND OPINION
LA English
DT Article
DE Guideline adherence; health services; prescriptions; proton pump inhibitors
ID inappropriate prescription; hospitalized-patients; predictors; patterns; overuse
AB Objectives: To determine the magnitude of non-guideline-recommended prescribing (NGRP) of proton pump inhibitors (PPIs) in the general population, its associated factors and expense. Methods: We undertook a cross-sectional observational study in three community pharmacies in a Spanish region in 2013 involving a total of 302 patients with a prescription for PPIs. The main variable was the NGRP of PPIs. Secondary variables were: gender, age, antidepressants, osteoporosis, osteoarthritis, prescription cost per month and total number of chronic diseases. The cost associated with NGRP was calculated. To evaluate the associated factors, a multivariate binary logistic regression model was constructed and the adjusted odds ratios (OR) were obtained. Results: NGRP was observed in 192 cases (63.6%). The average cost associated with NGRP per prescription was 3.24 euros per month. The factors significantly associated with NGRP (p<. 05) were: antidepressants (OR = 2.66, p =.001), osteoporosis (OR = 3.53, p =.001), osteoarthritis (OR = 3.57, p<. 001) and number of chronic diseases (OR = 0.73, p =.003). Conclusion: A novel approach was used to quantify the NGRP of PPIs in a

Spanish community, as well as the associated economic costs. Qualitative studies are needed to better understand the causes of NGRP of PPIs. This analysis will aid in designing interventions to minimize this problem. Limitations: Qualitative studies are needed to better understand the attitude of health professionals when prescribing PPIs.

TI The role of calcium supplementation in healthy musculoskeletal ageing
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Review
DE Calcium supplementation; Fracture reduction; Myocardial infarction; Vitamin D supplementation
ID vitamin-d supplementation; bone-mineral density; calcium/vitamin-d supplementation; coronary-artery calcification; placebo-controlled trial; cardiovascular-disease; postmenopausal women; serum-calcium; older women; myocardial-infarction
AB The place of calcium supplementation, with or without concomitant vitamin D supplementation, has been much debated in terms of both efficacy and safety. There have been numerous trials and meta-analyses of supplementation for

fracture reduction, and associations with risk of myocardial infarction have been suggested in recent years. In this report, the product of an expert consensus meeting of the European Society for Clinical and Economic Aspects of Osteoporosis, Osteoarthritis and Musculoskeletal Diseases (ESCEO) and the International Foundation for Osteoporosis (IOF), we review the evidence for the value of calcium supplementation, with or without vitamin D supplementation, for healthy musculoskeletal ageing. We conclude that (1) calcium and vitamin D supplementation leads to a modest reduction in fracture risk, although population-level intervention has not been shown to be an effective public health strategy; (2) supplementation with calcium alone for fracture reduction is not supported by the literature; (3) side effects of calcium supplementation include renal stones and gastrointestinal symptoms; (4) vitamin D supplementation, rather than calcium supplementation, may reduce falls risk; and (5) assertions of increased cardiovascular risk consequent to calcium supplementation are not convincingly supported by current evidence. In conclusion, we recommend, on the basis of the current evidence, that calcium supplementation, with concomitant vitamin D supplementation, is supported for patients at high risk of calcium and vitamin D insufficiency, and in those who are receiving treatment for osteoporosis.

TI Piezoelectric material - A promising approach for bone and cartilage regeneration
SO MEDICAL HYPOTHESES
LA English
DT Article
DE Piezoelectricity; Bone regeneration; Cartilage regeneration; Tissue engineering
ID mesenchymal stem-cells; articular-cartilage; growth-factors; morphogenetic proteins; calcium; microfracture; defects; matrix; repair; differentiation
AB Bone and cartilage are major weight-bearing connective tissues in human and possesses utmost vulnerability for degeneration. The potential causes are mechanical trauma, cancer and disease condition like osteoarthritis and osteoporosis, etc. The regeneration/repair is a challenging, since their complex structures and activities. Current treatment options comprise of auto graft, allograft, artificial bone sub-stituent, autologous chondrocyte implantation, mosaicplasty, marrow stimulation and tissue engineering. Were incompetent to overcome the problem like abandoned growth factor degradation, indistinct growth factor dose and lack of integrity and mechanical properties in regenerated tissues. Present, paper focuses on the novel hypothesis for regeneration of bone and cartilage by using piezoelectric smart property of scaffold material. (c) 2017 Elsevier Ltd. All rights reserved.

TI Bone Mineral Density is Lower in Patients with Severe Knee Osteoarthritis and Attrition
SO CALCIFIED TISSUE INTERNATIONAL
LA English
DT Article
DE Osteoarthritis; Bone mineral density; Biomarkers; Attrition; Knee arthroplasty; Bone turnover markers
ID total hip-arthroplasty; vitamin-d status; biochemical markers; general-population; 2-year rsa; osteoporosis; epidemiology; prevalence; women; replacement
AB Bone quality is probably important for the survival of knee arthroplasty (KA), but little is known about systemic bone mineral density and bone turnover in patients prior to KA surgery. The aim of this study was to explore the prevalence of osteoporosis and bone turnover in relation to knee osteoarthritis (OA) grade in patients scheduled for KA surgery. Prospective preoperative evaluation of 450 patients (259 females) prior to KA between 2014 and 2016 with standing knee radiography, Dual-energy X-ray absorptiometry (DXA), biomarkers for bone turnover (CTX, P1NP), and vitamin D. Grading of knee OA was done with the Altman Atlas and Kellgren Lawrence (KL). Adjustments for age and BMI were made. The mean age was 67.9 years (range 39-94), and mean BMI was 28.8 (SD 4.8). The prevalence of osteoporosis was 9.6% (CI 95% 7.2; 12.7), while the proportion of patients with osteopenia was 36.0%. T score was similar between KL OA grade 3 and 4 ($p = 0.06$); however, T score was lower ($p = 0.02$) with the worst knee OA grade (attrition). The median serum Vitamin D level was 78.5 nmol/L (range 10-196), and there was no association between serum vitamin D and the grade of OA ($p > 0.88$). P1NP was significantly higher in KL grade 4 compared to KL grade 3 ($p = 0.03$), but there was no association between KL grade and CTX ($p = 0.21$). 10% had osteoporosis, which is similar to the age-matched background population. Bone mineral density was lower with severe knee osteoarthritis (attrition), and P1NP was higher with worse osteoarthritis grading.

TI Metal Artifact Reduction for Orthopedic Implants (O-MAR): Usefulness in CT Evaluation of Reverse Total Shoulder Arthroplasty
SO AMERICAN JOURNAL OF ROENTGENOLOGY
LA English
DT Article
DE arthroplasty; CT; metal artifact; prosthesis; shoulder
ID density; osteoarthritis; osteoporosis; strength; tool
AB OBJECTIVE. The objective of this study is to evaluate the effect of the metal artifact reduction algorithm for orthopedic implants (O-MAR) on CT image quality for patients with reverse total shoulder arthroplasty (RTSA), with emphasis placed on the evaluation of bone in the vicinity of prostheses. MATERIALS AND METHODS. Sixty-five patients who underwent CT scanning after RTSA were enrolled in the study. Two radiologists analyzed the images reconstructed with filtered back projection (FBP) with or without O-MAR processing. Images were evaluated to determine the degree of streaking artifacts, the confidence in depicting various structures around the prosthesis, and the presence of pseudolesions. The mean CT number and SD of the selected ROIs placed in the greater tuberosity, glenoid bone, and deltoid muscle were recorded. For measurements from the greater tuberosity and glenoid bone, the frequency with which the measurement met the typical CT number of bone was calculated. RESULTS. O-MAR images showed less metal streak artifact and noise and provided better visualization of the axillary neurovascular bundle compared with FBP images, with a statistically significant difference ($p < 0.001$ for all). FBP images were found to be statistically significantly better than O-MAR images, offering better visualization of bone cortex, bone trabeculae, and the bone-prosthesis interface ($p < 0.001$ for all). Scapular pseudonotching was observed on 4.6% of FBP images and 36.9% of O-MAR images. The pseudocemented appearance was noted on 47.7% of O-MAR images but was not seen on FBP images. CONCLUSION. The use of O-MAR improved CT image quality for patients with RTSA in the aspect of metal artifact reduction and soft-tissue profile. However, O-MAR tends to degrade depiction of the bone trabeculae and

bone cortex and generate new artifacts, including a pseudocemented appearance and scapular pseudonotching.

TI BMP-7 ameliorates cobalt alloy particle-induced inflammation by suppressing Th17 responses

SO APMIS
LA English
DT Article
DE OP-1; Th17; total joint arthroplasty
ID periprosthetic osteolysis; autoimmune arthritis; cells; macrophages; wear; hip; metal; replacements; activate
AB Metal wear debris has been shown to activate an aseptic osteolytic process that causes failure in total joint arthroplasty (TJA). This osteolysis is characterized by a proinflammatory, self-propagating immune response involving primarily macrophages, dendritic cells, and activated osteoclasts, as well as T cells and B cells. The human bone morphogenic protein (BMP)-7, on the other hand, was shown to promote osteoblast survival, and reversed the downregulation of anabolic Smad proteins and Runx2 following cobalt injury. Therefore, we investigated the effect and mechanism of BMP-7 on the proinflammatory immune responses in osteoarthritis patients with previous TJA. Cobalt-treated monocytes/macrophages presented significantly elevated levels of interleukin 6 (IL-6) and tumor necrosis factor (TNF), both of which were suppressed by the addition of exogenous BMP-7. In patients with TJA, the serum BMP-7 level was inversely associated with the level of IL-6 and TNF secreted by monocytes/macrophages. Cobalt-treated monocytes/macrophages effectively supported Th17 inflammation, by an IL-6-dependent but not TNF-dependent mechanism. BMP-7, however, significantly suppressed cobalt-induced Th17 inflammation. In patients with TJA, the risk of osteolysis development was positively associated with the frequency of Th17 cells and negatively associated with the level of BMP-7. Together, these results demonstrated that BMP-7 could serve as a therapeutic agent in treating patients with metal wear debris-induced inflammation.

TI Correlation between age-related serum follicle stimulating hormone levels and osteoarthritis in postmenopausal women
SO BIOMEDICAL RESEARCH-INDIA
LA English
DT Article
DE FSH; Osteoarthritis; Menopause
ID bone turnover; fsh; osteoporosis; association; markers; risk; men
AB Objective: To study the changes of age-related serum Follicle Stimulating Hormone (FSH) level and Xray of knee joint and the relationship between FSH and postmenopausal knee osteoarthritis in postmenopausal women. Methods: 248 postmenopausal women aged over 50 y were randomly selected from Shandong Provincial Hospital affiliated with Shandong University after excluding patients with related diseases and medication history that affected bone metabolism and the that long-term used bone metabolism drugs. The levels of serum FSH, Luteinizing Hormone (LH) and Estradiol (E2) were measured by radioimmunoassay, and knee joint by X-ray. The changes of serum FSH, LH, E2 with age were analysed. The difference of FSH level between patients with postmenopausal osteoarthritis and control group was compared. Results: The serum FSH and LH levels increased with age, reaching a peak around 60 y old, and then decreased with age. Serum E2 levels decreased with age after menopause. Serum FSH and LH levels in patients with knee osteoarthritis were significantly higher than those in the control group ($P<0.05$), while E2 was significantly lower ($P<0.05$). Conclusion: This work shows the changes of FSH, LH and E2 in the postmenopausal women and indicates that FSH level may have an effect on the development of osteoarthritis.

TI A Comparison of Four-Year Health Outcomes following Combat Amputation and Limb Salvage
SO PLOS ONE
LA English
DT Article
ID injury severity score; military; iraq; afghanistan; trauma; prevalence; veterans
AB Little research has described the long-term health outcomes of patients who had combatrelated amputations or leg-threatening injuries. We conducted retrospective analysis of Department of Defense and Department of Veterans Affairs health data for lower extremity combat-injured patients with (1) unilateral amputation within 90 days postinjury (early amputation, n = 440), (2) unilateral amputation more than 90 days postinjury (late amputation, n = 78), or (3) leg-threatening injuries without amputation (limb salvage, n = 107). Patient medical records were analyzed for four years postinjury. After adjusting for group differences, early amputation was generally associated with a lower or similar prevalence for adverse physical and psychological diagnoses (e. g., pain, osteoarthritis, posttraumatic stress disorder) versus late amputation and/or limb salvage. By contrast, early amputation was associated with an increased likelihood of osteoporosis during the first year postinjury. The prevalence of posttraumatic stress disorder increased for all patient groups over four years postinjury,

particularly in the second year. The different clinical outcomes among combat extremity injured patients treated with early amputation, late amputation, or limb salvage highlight their different healthcare requirements. These findings can inform and optimize the specific treatment pathways that address the physical and psychological healthcare needs of such patients over time.

TI Incident acute pseudogout and prior bisphosphonate use: Matched case-control study in the UK-Clinical Practice Research Datalink
SO MEDICINE
LA English
DT Article
DE acute pseudogout; bisphosphonates; calcium pyrophosphate crystal deposition; case-control study; primary care
ID practice research database; american-society; vascular events; task-force; bone; chondrocalcinosis; risk; gout; osteoarthritis; epidemiology
AB Oral bisphosphonates are the most commonly used drugs to treat

postmenopausal osteoporosis. Acute pseudogout is anecdotally reported to occur following bisphosphonate initiation but empirical data are lacking. We investigated whether treatment with oral bisphosphonates is a risk factor for incident acute pseudogout. A matched case-control study was undertaken using data from the UK-Clinical Practice Research Datalink. Adults who consulted for incident acute pseudogout between 1987 and 2012 were each matched for gender, age at pseudogout diagnosis, and general practice to up to 4 control subjects without pseudogout. The exposure of interest was a prescription for an oral bisphosphonate issued within the 60-day period prior to the date of incident acute pseudogout. Associations between incident acute pseudogout and prior bisphosphonate prescription were examined using conditional logistic regression, adjusting for hyperparathyroidism, osteoarthritis, rheumatoid arthritis, hemochromatosis, hypophosphatasia, and prescriptions for diuretics and oral corticosteroids. Two thousand eleven acute pseudogout cases were compared with 8013 matched controls without acute pseudogout (mean age [standard deviation] 72 years [14]; 52% male). One hundred twenty-three cases (6.1%) had received an oral bisphosphonate prescription in the 60-day exposure period compared with 305 controls (3.8%) (adjusted incidence rate ratio [IRR] 1.33; 95% confidence interval [CI] 1.05-1.69). This association was stronger in females (adjusted IRR 1.49; 95% CI 1.15-1.94) and was nonsignificant in males (0.83; 0.48-1.44). Incident acute pseudogout was associated with prescription of an oral bisphosphonate in the preceding 60 days. Prescribers should be aware of acute pseudogout as a possible side effect of bisphosphonate treatment. Further research is needed to explore the risks conferred by different bisphosphonates and the mechanism underlying this association.

TI The inferomedial femoral neck is compromised by age but not disease: Fracture toughness and the multifactorial mechanisms comprising reference point microindentation
SO JOURNAL OF THE MECHANICAL BEHAVIOR OF BIOMEDICAL MATERIALS
LA English
DT Article
DE Bone quality; Femoral Neck; Fracture Toughness; Reference point indentation; Osteoporosis; Osteoarthritis
ID human cortical bone; in-vivo; indentation fracture; subchondral bone; mineral density; hard tissue; osteoarthritis; nanoindentation; osteoporosis; damage
AB The influence of ageing on the fracture mechanics of cortical bone tissue is well documented, though little is known about if and how related material properties are further affected in two of the most prominent musculoskeletal diseases, osteoporosis and osteoarthritis (OA). The femoral neck, in close proximity to the most pertinent osteoporotic fracture site and near the hip joint affected by osteoarthritis, is a site of particular interest for investigation. We have recently shown that Reference Point micro-Indentation (RPI) detects differences between cortical bone from the femoral neck of healthy, osteoporotic fractured and osteoarthritic hip replacement patients. RPI is a new technique with potential for in vivo bone quality assessment. However, interpretation of RPI results is limited because the specific changes in bone properties with pathology are not well understood and, further, because it is not conclusive what properties are being assessed by RPI. Here, we investigate whether the differences previously detected between healthy and diseased cortical bone from the femoral neck might reflect changes in fracture toughness. Together with this, we investigate which additional properties are reflected in RPI measures. RPI (using the Biodent device) and fracture toughness tests were conducted on samples from the inferomedial neck of bone resected from donors with: OA (41 samples from 15 donors), osteoporosis (48 samples from 14 donors) and non age-matched cadaveric controls (37 samples from 10 donoros) with no history of bone disease. Further, a subset of indented samples were imaged using micro-computed tomography (3 osteoporotic and 4 control samples each from different donors) as well as fluorescence microscopy in combination with serial sectioning after basic fuchsin staining (7 osteoporotic and 5 control samples from 5 osteoporotic and 5 control donors). In this study, the bulk indentation and fracture resistance properties of the inferomedial femoral neck in osteoporotic fracture, severe OA and control bone were comparable ($p > 0.05$ for fracture properties and < 10% difference for indentation) but fracture toughness reduced with advancing age (7.0% per decade, $r = 0.36$, $p = 0.029$). Further, RPI properties (in particular, the indentation distance increase, IDI) showed partial correlation with fracture toughness ($r = -0.40$, $p = 0.023$) or derived elastic modulus

(r = -0.40, p = 0.023). Multimodal indent imaging revealed evidence of toughening mechanisms (i.e. crack deflection, bridging and microcracking), elastoplastic response (in terms of the non-conical imprint shape and presence of pile-up) and correlation of RPI with damage extent (up to r = 0.79, p = 0.034) and indent size (up to r = 0.82, p < 0.001). Therefore, crack resistance, deformation resistance and, additionally, micro-structure (porosity: r = 0.93, p = 0.002 as well as pore proximity: r = -0.55, p = 0.027 for correlation with IDI) are all contributory to RPI. Consequently, it becomes clear that RPI measures represent a multitude of properties, various aspects of bone quality, but are not necessarily strongly correlated to a single mechanical property. In addition, osteoporosis or osteoarthritis do not seem to further influence fracture toughness of the inferomedial femoral neck beyond natural ageing. Since bone is highly heterogeneous, whether this finding can be extended to the whole femoral neck or whether it also holds true for other femoral neck quadrants or other material properties remains to be shown.

AB Objective: To assess the differential features of marrow adiposity between osteoarthritis (OA) and osteoporosis (OP) in postmenopausal women using water/fat MRI. Methods: This cross-sectional study included 97 postmenopausal women (OA [n = 25], OA + osteopenia [n = 27], OA + OP [n = 23], and OP groups [n = 22]). Water/fat MRI, dual-energy x-ray absorptiometry and biochemical analysis were performed to assess vertebral marrow fat fraction, bone mineral density, and bone biomarkers, respectively. Harris Hip Score was recorded to evaluate hip function. Results: There were significant differences in marrow fat content among the OA, OA + osteopenia, and OA + OP groups, between OP and OA participants with normal bone mass or osteopenia (all $P < 0.05$); no significant difference was observed between OA + OP and OP groups. Serum levels of leptin and beta-Crosslaps in OA with normal bone mass and osteopenic OA groups were higher than in OP group. Marrow fat fraction was inversely correlated with Harris Hip Score ($r = -0.371$, $P = 0.013$), bone mineral density ($r = -0.554$, $P = 0.009$) and leptin levels ($r = -0.610$, $P < 0.001$). In multivariate regression analysis, marrow fat fraction was found to have a consistent and unchanged inverse association with leptin levels (S beta = -0.311, $P = 0.002$) and bone mineral density (S beta = -0.265, $P = 0.006$) after adjusting for age, years since menopause, and body mass index. Conclusions: Postmenopausal OA with OP have a phenotype with higher marrow adiposity. OA and OP could coexist, for the presence of a specific subgroup of OA with increased marrow fat accumulation and high risk of developing OP.

ID fragility fractures; italy extension; osteoporosis; regulator
AB Background: Sarcopenia, osteoporosis and osteoarthritis are the most frequent musculoskeletal disorders affecting older people. The main aim of this study was to test the hypothesis that the balance between BMPs and myostatin pathways regulates the age-related muscle degeneration in OP and OA patients. To this end, we investigated the relationship among the expression of BMP-2/4-7, myostatin and phosphorylated Smads1-5-8 and the muscle quality, evaluated in term of fibers atrophy and satellite cells activity. Methods: In this retrospective study, we collected 123 biopsies of vastus lateralis: 48 biopsies from patients who underwent hip arthroplasty for subcapital fractures of the femur (OP), 55 biopsies from patients who underwent hip arthroplasty for osteoarthritis (OA) and 20 biopsies from patients who underwent hip arthroplasty for high-energy hip fractures (CTRL). Muscle biopsies were fixed in 4% paraformaldehyde and paraffin embedded. Serial sections were used for morphometrical and immunohistochemical analysis (BMP/2/4-7, myostatin, Smads1-5-8, Pax7 and myogenin). In addition, 1 mm(3) of muscle tissue of each patient was embedded in epon for ultrastructural study. Results: Morphometric data indicated an increase of the number of atrophic fibers in OP patients compare to OA. In line with these data, we found an high regenerative potential in muscle tissues of OA patients due to the significant amount of both Pax7 and myogenin positive satellite cells detected in OA group. In addition, our data showed the decrease of BMP2/4 and -7 expression in OP patients compared to both OA group and CTRL. Conversely, OP patients were characterized by high levels of myostatin expression. A different expression profile

was also found for phosphorylated Smad1-5-8 between OP and OA patients. In particular, OP patients showed a low number of positive phosphorylated Smad1-5-8 nuclei. Conclusion: The identification of molecular pathways involved in the pathogenesis of sarcopenia open new prospective for the development of drugs able to prevent/treat the muscle impairment that occur in elderly. Results here reported, highlighting the role of BMPs and myostatin pathways in physio-pathogenesis of human sarcopenia, allow us to propose human recombinant BMP-2/7 and anti-myostatin antibodies as a possible therapeutic option for the sarcopenia.

AB Frailty is a consequence of advanced aging, where the frailty phenotype tries to capture overall decline in health. Frailty involves multiple physiological systems that are intrinsically interrelated and with highly complex interactions. Frailty is closely linked to musculoskeletal health; musculoskeletal functioning is a key component in quantifying frailty, while at the same time, frailty is associated with the most common age-related musculoskeletal conditions: osteoporosis, fractures, falls, osteoarthritis, and spinal conditions. Beyond that, frailty includes additional physical domains such as nutrition and energy, psychological, and social factors. Despite its recognized role in aging health, there is still a lack of consensus on a core set of variables and how to best define clinically relevant thresholds. This would be of utmost importance for additional use to evaluate many aspects associated with musculoskeletal health, progression and personalized interventions, and rehabilitation. TI Impact of comorbid conditions in COPD patients on health care resource utilization and costs in a predominantly Medicare population
SO INTERNATIONAL JOURNAL OF CHRONIC OBSTRUCTIVE PULMONARY DISEASE
LA English
DT Article
DE COPD; comorbidities; utilization; cost; database; Medicare
ID obstructive pulmonary-disease; economic burden; united-states; depression; prevalence; anxiety
AB Background: Patients with chronic obstructive pulmonary disease (COPD) often have multiple underlying comorbidities, which may lead to increased health care resource utilization (HCRU) and costs. Objective: To describe the comorbidity profiles of COPD patients and examine the associations between the presence of comorbidities and HCRU or health care costs. Methods: A retrospective cohort study utilizing data from a large US national health plan with a predominantly Medicare population was conducted. COPD patients aged 40-89 years and continuously enrolled for 12 months prior to and 24 months after the first COPD diagnosis during the period of January 01, 2009, through December 31, 2010, were selected. Eleven comorbidities of interest were identified 12 months prior through 12 months after COPD diagnosis. All-cause and COPD-related hospitalizations and costs were assessed 24 months after diagnosis, and the associations with comorbidities were determined using multivariate statistical models. Results: Ninety-two percent of 52,643 COPD patients identified had at least one of the 11 comorbidities. Congestive heart failure (CHF), coronary artery disease, and cerebrovascular disease (CVA) had the strongest associations with all-cause

hospitalizations (mean ratio: 1.56, 1.32, and 1.30, respectively; P<0.0001); other comorbidities examined had moderate associations. CHF, anxiety, and sleep apnea had the strongest associations with COPD-related hospitalizations (mean ratio: 2.01, 1.32, and 1.21, respectively; P<0.0001); other comorbidities examined (except chronic kidney disease [CKD], obesity, and osteoarthritis) had moderate associations. All comorbidities assessed (except obesity and CKD) were associated with higher all-cause costs (mean ratio range: 1.07-1.54, P<0.0001). CHF, sleep apnea, anxiety, and osteoporosis were associated with higher COPD-related costs (mean ratio range: 1.08-1.67, P<0.0001), while CVA, CKD, obesity, osteoarthritis, and type 2 diabetes were associated with lower COPD-related costs. Conclusion: This study confirms that specific comorbidities among COPD patients add significant burden with higher HCRU and costs compared to patients without these comorbidities. Payers may use this information to develop tailored therapeutic interventions for improved management of patients with specific comorbidities.

TI Real-life effectiveness of spa therapy in rheumatic and musculoskeletal diseases: a retrospective study of 819 patients
SO INTERNATIONAL JOURNAL OF BIOMETEOROLOGY
LA English
DT Article
DE Spa therapy; Balneotherapy; Rheumatic diseases; Musculoskeletal disorders
ID low-back-pain; randomized controlled-trial; quality-of-life; fibromyalgia impact questionnaire; shoulder disability questionnaire; health-assessment questionnaire; 4-week rehabilitation program; chronic neck pain; mud-bath therapy; knee osteoarthritis
AB The objective of this study is to determine the use and efficacy of spa therapy in patients with a wide spectrum of rheumatic and musculoskeletal diseases under real-life clinical practice circumstances. In this retrospective observational study at the Medical Ecology and Hydroclimatology Department of Istanbul Faculty of Medicine, the records of all adult patients with rheumatic and musculoskeletal diseases who were prescribed a spa therapy in various health resorts in Turkey between 2002 and 2012 were analyzed. Patients sojourned to and stayed at a health resort and followed a usual 2-week course of spa therapy. The patients were examined within a week before and after the spa therapy at the department by the physicians and outcome measures were pain intensity (visual analog scale, VAS), patient's general evaluation (VAS), physician's general evaluation (VAS), Health Assessment Questionnaire (HAQ), Lequesne's Functional Index (LFI), Western Ontario and McMaster Universities Index (WOMAC), Waddell Index (WI), Neck Pain and Disability Scale (NPDS), Shoulder Disability Questionnaire (SDQ), Fibromyalgia Impact Questionnaire (FIQ), and Beck's Depression Inventory (BDI). In total, 819 patients were included in the analysis. The diagnoses were 536 osteoarthritis; 115 fibromyalgia; 50 lumbar disc herniation; 34 cervical disc herniation; 23 nonspecific low back pain; 22 ankylosing spondylitis; 16 rheumatoid arthritis; 9 rotator cuff tendinitis; and 14 other conditions/diseases including scoliosis, stenosing flexor tenosynovitis, congenital hip dislocation in adult, Beh double dagger et's disease, de Quervain tendinopathy, psoriatic arthritis, osteoporosis, fracture rehabilitation, and diffuse idiopathic skeletal hyperostosis. Statistically significant decrease in pain scores was found in all patients except hip osteoarthritis ($p = 0.063$) and rheumatoid arthritis ($p = 0.134$) subgroups; and statistically significant

improvement in function in all patients except hip osteoarthritis (p = 0.068), rheumatoid arthritis (p = 0.111), and rotator cuff tendinitis (p = 0.078) subgroups. In daily clinical practice, spa therapy is prescribed and practiced mainly for osteoarthritis, then fibromyalgia, lumbar/cervical disc herniation, and nonspecific low back pain; and less for ankylosing spondylitis, rheumatoid arthritis, and rotator cuff tendinitis. The study results suggest that real-life spa therapy may be effective in a variety of rheumatic and musculoskeletal diseases by improving pain and function.

TI Beneficial Effects and Toxicity Studies of Xian-ling-gu-bao on Bone Metabolism in Ovariectomized Rats
SO FRONTIERS IN PHARMACOLOGY
LA English
DT Article
DE XLGB; ovariectomized rats; osteoporosis; toxicity test; OPG/RANKL
ID osteoporosis; zebrafish; mice; mass
AB Xian-ling-gu-bao (XLGB) is a well-known patented traditional Chinese prescription widely used to treat osteoporosis, osteoarthritis, aseptic bone necrosis, or climacteric syndrome. However, recent reports have suggested that XLGB may cause liver injury in humans. In the present study, we aimed to evaluate the efficacy of XLGB in the prevention of osteoporosis in the zebrafish and ovariectomized (OVX) rats, both of which have been used as osteoporosis models. The safety of XLGB after long-term administration to OVX rats was also assessed. OVX rats were administered by oral gavage 270 mg/kg (recommended daily dose), 1350 mg/kg, and 1800 mg/kg of XLGB for 26 weeks. Bone mineral density, relative bone surface to bone volume, relative bone volume to total volume, trabecular number, mean trabecular thickness, and mean trabecular spacing in OVX rats were examined at the end of the 26-week dosing period. Additionally, OPG and RANKL expression in the femur were determined by western blot and immunohistochemical staining. To evaluate the safety of XLGB, body weight, hematology, serum biochemistry markers related to toxicology, and organ histopathology were determined in each group of OVX rats. Conversely, the zebrafish was treated with prednisolone to induce osteoporosis in the embryo. Disodium etidronate was used as a treatment control. XLGB was shown to be effective in preventing osteoporosis in both the OVX rats and the prednisolone-treated zebrafish. Similarly, XLGB increased OPG protein and decreased RANKL protein in OVX rats. Interestingly, no obvious toxicity was observed in the heart, liver, kidney, small intestine, or stomach at dosages of up to

1800 mg/kg after treating the OVX rats for 26 weeks. XLGB was shown to be very effective in treating osteoporosis in OVX rats. No obvious toxicity or adverse effects developed in OVX rats at dosages up to 1800 mg/kg, which is equivalent to six times the daily-recommended dose. Therefore, XLGB should be considered a good option for the treatment of post-menopausal osteoporosis.

TI Multimorbidity in Middle-Aged Adults with Cerebral Palsy
SO AMERICAN JOURNAL OF MEDICINE
LA English
DT Article
DE Cerebral palsy; Diabetes; Hypertension; Multimorbidity; Obesity; Osteoporosis
ID older-adults; musculoskeletal; mobility; health; risk; sex
AB OBJECTIVE: Individuals with cerebral palsy have less lean body mass, greater relative adiposity, and lower fitness and physical activity participation, and yet the prevalence of age-related multimorbidity in this population has yet to be established. The study objective was to examine the prevalence of lifestyle-related chronic conditions and multimorbidity in a sample of middle-aged adults with cerebral palsy. METHODS: A clinic-based sample of middle-aged adults with cerebral palsy was examined using Electronic Medical Records Search Engine software. Our cohort included 435 individuals aged 40 to 60 years, with an International Classification of Diseases, Clinical Modification, 9th and 10th Revisions Diagnosis Code for cerebral palsy. Prevalence of 12 chronic conditions was evaluated, including existing diagnoses or historical record of osteopenia/osteoporosis, myocardial infarction, stroke, coronary artery disease, impaired glucose tolerance/type 2 diabetes, other cardiovascular conditions, rheumatoid arthritis, osteoarthritis, asthma, emphysema, prehypertension/hypertension, and hyperlipidemia. Multivariate logistic models were used to estimate multimorbidity (ie, >= 2 chronic conditions), adjusting for age, sex, smoking status, obesity, and Gross Motor Function Classification System (GMFCS). RESULTS: There were 137 unique multimorbidity combinations. Multimorbidity was significantly more prevalent among obese versus nonobese individuals for both GMFCS I-III (75.8% vs 53.6%) and GMFCS IV-V (79.0% vs 64.2%), but was also significantly higher in nonobese individuals with GMFCS IV-V (64.2%) compared with nonobese individuals with GMFCS I-III (53.6%). Both the obesity status (odds ratio, 2.20; 95% confidence interval, 1.32-2.79) and the GMFCS IV-V category (odds ratio, 1.81; 95% confidence interval, 1.32-3.68) were independently associated with multimorbidity. CONCLUSIONS: Middle-aged adults with cerebral palsy have high estimates of multimorbidity; both obesity and higher GMFCS levels are independently associated with greater risk. (C) 2017 Elsevier Inc. TI Vitamin D status correction in Saudi Arabia: an experts' consensus under the auspices of the European Society for Clinical and Economic Aspects of Osteoporosis, Osteoarthritis, and Musculoskeletal Diseases (ESCEO)
SO ARCHIVES OF OSTEOPOROSIS
LA English
DT Article
DE Vitamin D; Saudi Arabia; ESCEO; Recommendations; Consensus
ID 25-hydroxyvitamin d concentrations; d deficiency; d supplementation; middle-east; recommendations; population; management; women; risk; prevention
AB Background Vitamin D deficiency is common in the Middle East and in Saudi Arabia, in particular. While several international recommendations on the management of vitamin D deficiency have been documented and practiced globally, these recommendations should be adapted to the conditions of the Middle Eastern region. To address this challenge, the Prince Mutaib Chair for Biomarkers of Osteoporosis (PMCO) in King Saud University (KSU), Riyadh, KSA,

together with local experts and in cooperation with the European Society for Clinical and Economic Aspects of Osteoporosis and Osteoarthritis (ESCEO), organized a panel that formulated unified recommendations in the diagnosis and treatment of vitamin D deficiency in the region. Methods The selection of local and international experts commenced during the 2nd International Vitamin D Symposium conducted in Riyadh, Saudi Arabia, last January 20-21, 2016. Reviews of the most recent literature were done, and face-to-face meetings were conducted for revisions and final recommendations. Results: Vitamin D sufficiency is defined as circulating serum 25(OH) D >= 50 nmol (>= 20 ng/ml) for the general population and vitamin D adequacy as serum 25(OH) D >75 nmol/L l (>30 ng/ml) for the frail and osteoporotic elderly. Despite overwhelming prevalence of vitamin D deficiency, universal screening is not recommended. Recommendations for the general population, children, pregnant/lactating women, postmenopausal women, the elderly, and those with subsequent metabolic diseases were provided. Results Vitamin D sufficiency is defined as circulating serum 25(OH) D >= 50 nmol (>= 20 ng/ml) for the general population and vitamin D adequacy as serum 25(OH) D > 75 nmol/L l (>30 ng/ml) for the frail and osteoporotic elderly. Despite overwhelming prevalence of vitamin D deficiency, universal screening is not recommended. Recommendations for the general population, children, pregnant/lactating women, post-menopausal women, the elderly, and those with subsequent metabolic diseases were provided. Conclusion Vitamin D supplementation/correction is advised in all persons whose serum 25(OH) D falls below 50 nmol/l (20 ng/ml), and achieving a target of 75 nmol/l (30 ng/ml) is particularly suited for frail, osteoporotic, and older patients. Conducting well-designed clinical trials in the region that will address economic implications and investigations on the treatment persistence and compliance to vitamin D treatment in the region are encouraged.

TI Calcium Pyrophosphate Deposition Disease and Associated Medical Comorbidities: A National Cross-Sectional Study of US Veterans
SO ARTHRITIS CARE & RESEARCH
LA English
DT Article
ID dihydrate crystal deposition; monosodium urate crystals; proton pump inhibitors; rheumatoid-arthritis; synovial-fluid; articular chondrocalcinosis;

prevalence; osteoarthritis; hypomagnesemia; calcification
AB ObjectiveCalcium pyrophosphate deposition disease (CPDD) is a common cause of acute and chronic arthritis, yet there are few large epidemiologic studies of CPDD. We sought to characterize CPDD in the national Veterans Affairs (VA) population. MethodsUsing data from the Department of VA Corporate Data Warehouse, patients with International Classification of Diseases, Ninth Revision, codes for CPDD seen at any VA medical center from 2010 through 2014 were matched by age and sex with control patients without CPDD. We used multivariate analysis to compare the prevalence and odds ratios (ORs) of various comorbidities, substance use, medication exposures, and arthroplasties among patients with and without CPDD. ResultsWe identified 25,157 patients with CPDD, yielding a point prevalence of 5.2 per 1,000. The meanSD age was 68.1 +/- 12.3 years, and 95% were male. The strongest positive associations with CPDD were hyperparathyroidism (OR 3.35 [95% confidence interval (95% CI) 2.96-3.79]), gout (OR 2.82 [95% CI 2.69-2.95]), osteoarthritis (OR 2.26 [95% CI 2.15-2.37]), rheumatoid arthritis (OR 1.88 [95% CI 1.74-2.03]), and hemochromatosis (OR 1.87 [95% CI 1.57-2.24]). Positive associations were also seen with higher odds for osteoporosis (OR 1.26 [95% CI 1.16-1.36]), hypomagnesemia (OR 1.23 [95% CI 1.16-1.30]), chronic kidney disease (OR 1.12 [95% CI 1.07-1.18]), and calcium supplementation (OR 1.15 [95% CI 1.06-1.24). Negative associations were seen with proton-pump inhibitors (OR 0.58 [95% CI 0.55-0.60]) and loop diuretics (OR 0.80 [95% CI 0.76-0.84]). ConclusionUsing a large national data set, we confirmed known associations with CPDD, provided support for positive associations with rheumatoid arthritis, hypomagnesemia, and osteoporosis, and suggested potential novel negative associations with commonly used medications.

TI The role of mineral elements and other chemical compounds used in balneology: data from double-blind randomized clinical trials
SO INTERNATIONAL JOURNAL OF BIOMETEOROLOGY
LA English
DT Review
DE Spa therapy; Balneotherapy; Peloid therapy; Mud therapy; Double blind trial; Review

ID mud-bath therapy; low-back-pain; bilateral knee osteoarthritis; radon spa therapy; follow-up; rheumatoid-arthritis; single-blind; thermal water; pack therapy; hand osteoarthritis
AB The aims of this study were to conduct a systematic literature review on balneotherapy about the specific therapeutic role of mineral elements and other chemical compounds of mineral waters and derivate peloids/muds and to discuss the study methods used to evaluate it (in musculoskeletal conditions). We searched Medline by PubMed using the following key words: "spa therapy" "balneotherapy" "mud" "peloid" "mud pack Therapy" in combination with "randomized controlled trial" "double blind trial." We also reviewed the reference list of articles retrieved by the Medline search. We selected the double-blind randomized clinical trials that assessed the effects of mineral water or mud treatments compared to tap water, attenuated peloid/mud therapy or similar treatments without the specific minerals or chemical compounds of the treatment group ("non-mineral"). We evaluated the internal validity and the quality of the statistical analysis of these trials. The final selection comprised 27 double-blind randomized clinical trials, 20 related to rheumatology. A total of 1118 patients with rheumatological and other musculoskeletal diseases were evaluated in these studies: 552 of knee osteoarthritis, 47 of hand osteoarthritis, 147 chronic low back pain, 308 of reumathoid arthritis, and 64 of osteoporosis; 293 of these participants were assigned to the experimental groups of knee osteoarthritis, 24 in hand osteoarthritis, 82 of low back pain, 152 with reumathoid arthritis, and 32 with osteoporosis. They were treated with mineral water baths and/or mud/peloid (with or without other forms of treatment, like physical therapy, exerciseaEuro broken vertical bar). The rest were allocated to the control groups; they received mainly tap water and/or "non-mineral" mud/peloid treatments. Mineral water or mud treatments had better and longer improvements in pain, function, quality of life, clinical parameters, and others in some rheumatologic diseases (knee and hand osteoarthritis, chronic low back pain, rheumatoid arthritis, and osteoporosis) compared to baseline and non-mineral similar treatments. Internal validity and other limitations of the study's methodology impede causal relation of spa therapy on these improvements. Randomized clinical trials are very heterogeneous. Double-blind randomized clinical trials seem to be the key for studying the role of mineral elements and other chemical compounds, observing enough consistency to demonstrate better and longer improvements for mineral waters or derivate compared to tap water; but due to heterogeneity and gaps on study protocol and methodology, existing research is not sufficiently strong to draw firm conclusions. Well-designed studies in larger patients' population are needed to establish the role of minerals and other chemical compounds in spa therapy.

TI Trapeziumectomy and Mini Tightrope stabilization of the first metacarpal for thumb carpometacarpal osteoarthritis : a prospective case series
SO ACTA ORTHOPAEDICA BELGICA
LA English
DT Article
DE First carpometacarpal joint; Mini Tightrope; Trapezium; Osteoarthritis; Trapeziumectomy
ID suture-button suspensionplasty; trapeziometacarpal joint osteoarthritis; ligament reconstruction; tendon interposition; implant arthroplasty; follow-up; arthritis; trapeziectomy; allograft; excision
AB Our purpose was to investigate the short-term results of trapeziumectomy and stabilization of the first metacarpal by using the TightRope (c) device, at a maximum follow-up of 1 year post-op. This is a novel method in treating first carpometacarpal joint osteoarthritis and an alternative to the variety of other methods that have been previously reported. We recruited 21 patients and assessed them at regular intervals, comparing pre-operative and postoperative variables. We recorded all complications during the study period. There was a statistically significant improvement in pain, hand grip and tip pinch power and functional outcome scores. Patients were very satisfied at 12 months after surgery. No significant change in thumb opposition was noted. There was subsidence of the first metacarpal at 1 year after surgery. Despite the existence of a significant number of alternative procedures, we feel that the procedure described in this paper has promising short-term results and is safe.

TI Risk factors for post-operative periprosthetic fractures following primary total hip arthroplasty with a proximally coated double-tapered cementless femoral component
SO BONE & JOINT JOURNAL
LA English
DT Article
ID femur fracture; joint registry; stem design; replacement; knee; epidemiology;

osteoporosis; mortality; revision; index
AB Aims The aim of this study was to identify patient-and surgery-related risk factors for sustaining an early periprosthetic fracture following primary total hip arthroplasty (THA) performed using a double-tapered cementless femoral component (Bi-Metric femoral stem; Biomet Inc., Warsaw, Indiana). Patients and Methods A total of 1598 consecutive hips, in 1441 patients receiving primary THA between January 2010 and June 2015, were retrospectively identified. Level of pre-operative osteoarthritis, femoral Dorr type and cortical index were recorded. Varus/valgus placement of the stem and canal fill ratio were recorded post-operatively. Periprosthetic fractures were identified and classified according to the Vancouver classification. Regression analysis was performed to identify risk factors for early periprosthetic fracture. Results The mean follow-up was 713 days (1 to 2058). A total of 48 periprosthetic fractures (3.0%) were identified during the follow-up and median time until fracture was 16 days, (interquartile range 10 to 31.5). Patients with femoral Dorr type C had a 5.2 times increased risk of post-operative periprosthetic fracture compared with type B, while female patients had a near significant two times increased risk over time for post-operative fracture. Conclusion Dorr type C is an independent risk factor for early periprosthetic fracture, following THA using a double tapered cementless stem such as the Bi-Metric. Surgeons should take bone morphology into consideration when planning for primary THA and consider using cemented femoral components in female patients with poor bone quality.

TI Bone fracture nonunion rate decreases with increasing age: A prospective inception cohort study
SO BONE
LA English
DT Article
DE Geriatric fracture; Fragility fracture; Smoking; Osteoporosis; Arthritis; Hypertension
ID older-adults; hip fracture; osteoporotic fracture; risk prediction; pelvic ring; bed rest; mortality; metaanalysis; disability; prevention
AB Background: Fracture nonunion risk is related to severity of injury and type of treatment, yet fracture healing is not fully explained by these factors alone. We hypothesize that patient demographic factors assessable by the clinician at fracture presentation can predict nonunion. Methods: A prospective cohort study design was used to examine similar to 2.5 million Medicare patients nationwide. Patients making fracture claims in the 5% Medicare Standard Analytic Files in 2011 were analyzed; continuous enrollment for 12 months after fracture was required to capture the ICD-9-CM nonunion diagnosis code (733.82) or any procedure codes for nonunion repair. A stepwise regression analysis was used which dropped variables from analysis if they did not contribute sufficient explanatory power. In-sample predictive accuracy was assessed using a receiver operating characteristic (ROC) curve approach, and an out-of-sample comparison was drawn

from the 2012 Medicare 5% SAF files. Results: Overall, 47,437 Medicare patients had 56,492 fractures and 2.5% of fractures were nonunion. Patients with healed fracture (age 75.0 +/- 12.7 SD) were older ($p < 0.0001$) than patients with nonunion (age 69.2 +/- 13.4 SD). The death rate among all Medicare beneficiaries was 4.8% per year, but fracture patients had an age and sex-adjusted death rate of 11.0% ($p < 0.0001$). Patients with fracture in 14 of 18 bones were significantly more likely to die within one year of fracture ($p < 0.0001$). Stepwise regression yielded a predictive nonunion model with 26 significant explanatory variables (all, $p <= 0.003$). Strength of this model was assessed using an area under the curve (AUC) calculation, and out-of-sample AUC = 0.710. Conclusions: A logistic model predicted nonunion with reasonable accuracy (AUC = 0.725). Within the Medicare population, nonunion patients were younger than patients who healed normally. Fracture was associated with increased risk of death within 1 year of fracture ($p < 0.0001$) in 14 different bones, confirming that geriatric fracture is a major public health issue. Comorbidities associated with increased risk of nonunion include past or current smoking, alcoholism, obesity or morbid obesity, osteoarthritis, rheumatoid arthritis, type II diabetes, and/or open fracture (all, multivariate $p < 0.001$). Nonunion prediction requires knowledge of 26 patient variables but predictive accuracy is currently comparable to the Framingham cardiovascular risk prediction. (C) 2016 Bioventus LLC. TI Non-synonymous WNT16 polymorphisms alleles are associated with different osteoarthritis phenotypes
SO RHEUMATOLOGY INTERNATIONAL
LA English
DT Article
DE WNT; Genetic association; Osteoarthritis; Bone; Cartilage; Joints
ID bone-mineral density; knee osteoarthritis; articular-cartilage; hip; prevalence; osteoporosis; pathogenesis; activation; deformity; fracture
AB Hereditary factors have a strong influence on osteoarthritis (OA). The Wnt pathway is involved in bone and cartilage homeostasis. Hence, we hypothesized that allelic variations of WNT16 could influence the OA phenotype. We studied 509 Caucasian patients undergoing joint replacement due to severe primary OA. Radiographs were used to classify the OA as atrophic or hypertrophic. Two nonsynonymous polymorphisms of WNT16 (rs2707466 and rs2908004) were analyzed. The association between the genotypes and the OA phenotype was analyzed by logistic regression and adjusted for age and body mass index. A genotype-phenotype association was found in the sex-stratified analysis. Thus, there was a significant difference in the genotypic frequencies of rs2707466 between hypertrophic and atrophic hip OA in males ($p = 0.003$), with overrepresentation of G alleles in the hypertrophic phenotype (OR 2.08; CI 1.28-3.38). An association in the same direction was observed between these alleles

and the type of knee OA, with G alleles being more common in the hypertrophic than in atrophic knee phenotypes (p = 0.008; OR 1.956, CI 1.19-3.19). Similar associations were found for the rs2908004 SNP, but it only reached statistical significance for knee OA (p = 0.017; OR 0.92, CI 0.86-0.989). This is the first study attempting to explore the association of genetic variants with the OA phenotype. These data suggest the need to consider the OA phenotype in future genetic association studies of OA.

TI Association of Condylar Bone Quality with TMJ Osteoarthritis
SO JOURNAL OF DENTAL RESEARCH
LA English
DT Article
DE mandibular condyle; bone volume; cone beam computed tomography; micro-computed tomography; multivariate analysis; cross-sectional study
ID temporomandibular-joint; computed-tomography; mineral density; risk; osteoporosis; diagnosis; prevalence; morphology; disorders; growth
AB The etiology and treatment of temporomandibular joint (TMJ) osteoarthritis (TMJOA) remain complex and unclear. Based on clinical observations, we hypothesized that low condylar bone quality is significantly correlated with TMJOA and explored this association in a cross-sectional study with human patients. A

total of 254 postmenopausal female participants were included in this study. Radiographic findings from cone beam computed tomography (CBCT) and clinical symptoms were used to classify each TMJ data sample as healthy control (n = 124) or TMJOA (n = 130). Condylar bone mineral density (BMD) (computed tomography Hounsfield unit [CT HU]) and bone volume fraction (BV/TV) were measured and modeled as predictors of healthy control versus TMJOA status in multilevel logistic regression analyses. Both CT HU (adjusted odds ratio [AOR] = 0.9989, interquartile odds ratio [IOR] = 0.4206) and BV/TV (AOR= 0.8096, IOR = 0.1769) were negatively associated with TMJOA (P = 0.049, 0.011, respectively). To assess the diagnostic performance of CT HU and BV/TV for identification of TMJOA, receiver operating characteristic (ROC) curves were plotted. The estimated areas under the curve (AUC) were 0.6622 for BV/TV alone, 0.6074 for CT HU alone, and 0.7136 for CT HU and BV/TV together. The model incorporating CT HU and BV/TV together had a significantly higher AUC than the models using BV/TV alone (P = 0.038) or HU alone (P = 0.021). In conclusion, we found that low condylar bone quality was significantly correlated with TMJOA development and that condylar CT HU and BV/TV can be used together as a potential diagnostic tool for TMJOA. Careful clinical evaluation of the condyle coupled with appropriate radiographic interpretation would thus be critical for the early detection of TMJOA.

TI Pulsed Electromagnetic Field at Different Stages of Knee Osteoarthritis in Rats Induced by Low-Dose Monosodium Iodoacetate: Effect on Subchondral Trabecular Bone Microarchitecture and Cartilage Degradation
SO BIOELECTROMAGNETICS
LA English
DT Article
DE osteoarthritis; pulsed electromagnetic field; subchondral bone; cartilage; X-ray microtomography
ID micro-computed tomography; biochemical markers; in-vitro; stimulation; model; chondrocytes; alendronate; degeneration; osteoporosis; metabolism
AB The aim of the study was to investigate the efficacy of pre-emptive, early, and delayed pulsed electromagnetic field (PEMF) treatment on cartilage and subchondral trabecular bone in knee osteoarthritis (OA) rats induced by low-dose monosodium iodoacetate (MIA). Seventy-five 12-week-old male Sprague-Dawley rats were assigned to five groups: OA (n = 30), pre-emptive PEMF (n - 10), early PEMF (n - 10), delayed PEMF (n - 10), and control (n - 15). Osteoarthritis was induced by injecting 0.2 mg MIA in rat's right knee joint. Control rats received a single sterile saline injection in the right knee. Male rats received pre-emptive (n = 10, day 0-end of week 4), early (n = 10, end of week 4-end of week 8), or delayed (n = 10, end of week 8-end of week 12) PEMF treatment (75 Hz, 1.6 mT). After 4, 8, and 12 weeks, rats were sacrificed at each time point and right knees were harvested. After sacrifice, micro-computed tomography, histology, and biomarker

analyses were performed. We found pre-emptive PEMF treatment preserved subchondral trabecular bone microarchitecture and prevented subchondral bone loss in MIA-induced OA rat model. Early and delayed PEMF treatment maintained subchondral trabeculae. PEMF treatment increased bone and cartilage formation, and decreased bone and cartilage resorption. Pre-emptive and early PEMF treatment had moderate effects on cartilage degradation. Time point of treatment initiation is crucial for treating OA. PEMF might become a potential biophysical treatment modality for osteoarthritis. (C) 2016 Wiley Periodicals, Inc.

TI Epidemiology of the locomotive syndrome: The research on osteoarthritis/osteoporosis against disability study 2005-2015
SO MODERN RHEUMATOLOGY
LA English
DT Review
DE Disability; Locomotive syndrome; Metabolic syndrome; Mild cognitive impairment; Osteoarthritis; Osteoporosis
ID diagnostic-criteria; society
AB Although locomotive organ disorders are major causes of disability and require support, little information is available regarding their epidemiology. Prevalence and co-existence of locomotive organ disorders including knee osteoarthritis (KOA),

lumbar spondylosis (LS), hip osteoarthritis, and osteoporosis have been determined from baseline results of the Research on Osteoarthritis/Osteoporosis Against Disability (ROAD) study. KOA, LS, and hip osteoarthritis overlap in the population, while KOA and LS co-exist in 42.0% of people. Mutual associations between locomotive organ disorders, metabolic syndrome components, and mild cognitive impairment were found using baseline and 3-year follow-up data from the ROAD study. Logistic regression analysis showed that hypertension, impaired glucose tolerance, and mild cognitive impairment increase the risk of KOA. Osteoporosis at L2-4 was significantly influenced by the presence of femoral neck osteoporosis, and vice versa. In turn, excess weight was inversely associated with the occurrence of femoral neck osteoporosis. Finally, data from the 3rd survey (7-year follow-up) were used to calculate the prevalence of the locomotive syndrome using tests proposed by the Japanese Orthopaedic Association for assessing the risk of developing locomotive syndrome. Subsequently, the age-sex prevalence of stage 1 and stage 2 locomotive syndrome was estimated at 69.8% and 25.1%, respectively.

TI The lumbar spine age-related degenerative disease influences the BMD not the TBS: the Osteolaus cohort
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE BMD; Degenerative disease; Lumbar spine; TBS; Vertebral fracture
ID trabecular bone score; mineral density; fracture probability; women; osteoporosis; osteoarthritis; diagnosis; risk; men; prediction
AB We evaluated the influence of degenerative disease and fractured vertebra on lumbar spine bone mineral density (BMD) and trabecular bone score (TBS) in 1500 women aged 50-80 years. TBS was not affected by a degenerative disease. While BMD increases after 62.5 years, TBS continues to decline. TBS should play a leading role in lumbar spine evaluation. After menopause, lumbar spine (LS) BMD and TBS values decrease. Degenerative disease (DD) increases with age and affect LS BMD. The aim of this study was to measure changes in LS BMD and TBS in women 50 to 80 years old, taking into account the impact of fractured vertebrae and DD. LS BMD, TBS, and vertebral fracture assessment were evaluated in the OsteoLaus cohort (1500 women, 50-80 years old). The exams were analyzed following ISCD guidelines to identify vertebrae with fractures or DD (Vex). 1443 women were enrolled: mean age 66.7 +/- 11.7 years, BMI 25.7 +/- 4.4. LS BMD and TBS were weakly correlated (r2 = 0.16). The correlation (Vex excluded) between age and BMD was +0.03, between age and TBS -0.34. According to age group, LS BMD was 1.2 to 3.2% higher before excluding Vex ($p < 0.001$). TBS had an insignificant change of < 1% after excluding Vex. LS BMD (Vex) decreased by 4.6% between 52.5 and 62.5 years, and increased by 2.6% between 62.5 and 77.5 years. TBS (Vex excluded) values decreased steadily with age with an overall loss of 8.99% between 52.5 and 77.5 years. Spine TBS, femoral neck, and total hip BMD gradually decreased with age, reaching one SD between the oldest and youngest group. TBS is not affected

by DD. While BMD increases after 62.5 years, TBS continues to decline. For lumbar spine evaluation, in view of its independence from DD, TBS should play a leading role in the diagnosis in complement to BMD.

TI Raman spectral characteristics of neck and head of femur in low-density lipoprotein receptor gene knockout mice submitted to treadmill aerobic training
SO JOURNAL OF PHOTOCHEMISTRY AND PHOTOBIOLOGY B-BIOLOGY
LA English
DT Article
DE Bone tissue; Hyperlipidemia; Raman spectroscopy; Principal component analysis
ID bone-mineral density; exercise; spectroscopy; health; osteoarthritis; osteoporosis; morphology; strength; rats

AB Hypercholesterolemia is associated with deterioration of bone tissue. Trough Raman spectroscopy, the present study aimed to assess the molecular changes in terms of mineral and organic bone-tissue remodeling in low density lipoprotein receptor gene knockout mice (LDLr - / -) submitted to treadmill aerobic training. In order to evaluate alterations in trabecular bone and cartilage surface, neck and head femoral were assessed into four groups: (CON, n = 7), the 1) animals did not perform any physical activity and had hypercholesterolemia (CON, n = 7); The trained groups where animals underwent a protocols of low, moderate and high training for 8 weeks and 4 times per week on a treadmill with progressive intensities: running speed (8-13 m/min) and time of exercise (20-60 min). These progressive intensities were needed to adjust the working load for the physical training to 2) 30-49% (LOW, n = 7), 3) 50-79% (MOD, n = 7), and 4) 80-100% (HIGH, n = 7) of the maximum running speed. Each group was examined for molecular changes in both bone phases (mineral and organic) using principal components analysis (PCA). All exercised groups showed a significant increase ($p < 0.05$) of bone remodeling in trabecular area and a higher content of proteins (organic content) in cartilage independently of physical activity intensity. Thus, this work demonstrated that physical training could act as a bone-protector factor in hyperlipidemic animal model as well as Raman technique associated with PCA analysis may be feasible methodology for assessment or monitoring of bone at the molecular level.

TI Danish Hip Arthroscopy Registry (DHAR): the outcome of patients with femoroacetabular impingement (FAI)
SO JOURNAL OF HIP PRESERVATION SURGERY
LA English
DT Article
ID osteoarthritis; risk; pain; prevalence; management; scale; joint
AB The Danish Hip Arthroscopy Registry (DHAR) was initiated in January 2012 as a web-based prospective registry. The purpose of this study was to evaluate and report the first registry based outcome data of a national population with radiological and clinical femoroacetabular impingement (FAI) undergoing hip arthroscopic treatment. Our primary hypothesis was that patients undergoing hip arthroscopy would improve significantly in pain, quality of life and sports related outcome measurements in Patient Related Outcome Measures (PROM). Perioperative data and Patient Reported Outcome Measures (PROM) data from DHAR between January 2012 and November 2015 were extracted. Radiological pincer-type FAI was defined as LCE > 35 degrees and cam FAI as alphaangle > 55 degrees. These data were combined with FAI surgical data such as osteochondroplasty and labral repair or resection. PROMs consisting of HAGOS, EQ-5 D, HSAS and NRS pain scores were submitted online by the patients pre-operatively and at 1 and 2-years follow-up. 2054 FAI procedures in 1835 patients were included in this study (219 patients had bilateral procedures performed). HAGOS demonstrated significant improvement in all subscales at follow up. EQ-5 D demonstrated improvement after 1 and 2 years from 0.66 pre-op to 0.78 at 2 years. HSAS improved significantly from 2.5 to 3.3. Pain score data demonstrated improvement in NRS-rest 39 to 17 and NRS Walk 49 to 22 at follow-up. We conclude that patients with FAI undergoing hip arthroscopy experience improvement in pain, quality of life and also in function and sports related outcome measures during the first 2 years after surgery.

TI Role of glucocorticoid-induced leucine zipper (GILZ) in inflammatory bone loss
SO PLOS ONE
LA English
DT Article
ID tumor-necrosis-factor; nf-kappa-b; rheumatoid-arthritis; transgenic mice; factor inhibitors; progenitor cells; synovial-fluid; tnf-alpha; therapy; osteoarthritis
AB TNF-alpha plays a key role in the development of rheumatoid arthritis (RA) and inflammatory bone loss. Unfortunately, treatment of RA with anti-inflammatory glucocorticoids (GCs) also causes bone loss resulting in osteoporosis. Our previous studies showed that overexpression of glucocorticoid-induced leucine zipper (GILZ), a mediator of GC's anti-inflammatory effect, can enhance osteogenic differentiation in vitro and bone acquisition in vivo. To investigate whether GILZ could antagonize TNF-alpha-induced arthritic inflammation and protect bone in mice, we generated a TNF-alpha-GILZ double transgenic mouse line (TNF-GILZ Tg) by crossbreeding a TNF-alpha Tg mouse, which ubiquitously expresses human TNF-alpha, with a GILZ Tg mouse, which expresses mouse GILZ under the control of a 3.6kb rat type I collagen promoter fragment. Results showed that overexpression of GILZ in bone marrow mesenchymal stem/progenitor cells protected mice from TNF-alpha-induced inflammatory bone loss and improved bone integrity (TNF-GILZ double Tg vs. TNF-alpha Tg, n = 12-15). However, mesenchymal cell lineage restricted GILZ expression had limited effects on TNF-alpha-induced arthritic inflammation as indicated by clinical scores and serum levels of inflammatory cytokines and chemokines.

AB Inflammation, an essential tissue response to extrinsic/intrinsic damage, is a very dynamic process in terms of complexity and extension of cellular and metabolic involvement. The aim of the inflammatory response is to eliminate the pathogenic initiator with limited collateral damage of the inflamed tissue, followed by a complex tissue repair to the preinflammation phenotype. Persistent inflammation is a major contributor to the pathogenesis of many musculoskeletal diseases including ageing-related pathologies such as osteoporosis, osteoarthritis, and sarcopaenia. The translational potential of this article: Understanding the mechanisms of inflammation and its resolution is therefore critical for the development of effective regenerative, and therapeutic strategies in orthopaedics.

TI Association between MRI-detected osteophytes and changes in knee structures and pain in older adults: a cohort study
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE Knee osteoarthritis; Magnetic resonance imaging; Osteophytes; Knee pain; Knee structures abnormalities
ID early radiographic osteoarthritis; cartilage volume loss; imaging findings; surface-area; defects; prevalence; features; abnormality; progression; history
AB Objective: To describe cross-sectional and longitudinal associations between magnetic resonance imaging (MRI)-detected osteophytes (OPs) and knee structural abnormalities and knee pain in older adults. Method: A prospective population-based cohort study of 895 participants aged 50-80 years (mean age 62 years, 50% female) was performed. T1-or T2-weighted fat suppressed MRI was used to assess knee OPs, cartilage volume, cartilage defects and bone marrow lesions (BMLs) at baseline and after 2.6 years. Radiographically-detected OPs were scored according to the Osteoarthritis Research Society International (OARSI) atlas. Knee pain was assessed using a self-administered questionnaire at baseline, 2.6 and 5 years later. Results: 85% of participants had MRI-detected OPs at baseline, while 10% of participants had radiographically-detected OPs. Cross-sectionally, higher gardes of MRI-detected OPs in all compartments were significantly, independently and site-specifically associated with higher prevalences of cartilage defects and BMLs, lower cartilage volume and higher prevalence of knee pain. Longitudinally, higher gardes of baseline MRI-detected OPs site-specifically predicted greater risks of any increase in cartilage defects or BMLs, and loss of cartilage volume in medial and lateral tibiofemoral (LTF) and total compartments over 2.6 years in multivariable analyses. These significant associations were similar in those without radiographically-detected OPs. MTF and total OP scores were significantly associated with change in total knee pain over 2.6 and 5 years but these became non-significant after adjustment for cartilage defects and BMLs. Conclusion: MRI-detected knee OPs are common and appear to be clinically relevant to knee structural changes in older adults. (C) 2017 Osteoarthritis Research Society International. TI Calcitonin protects chondrocytes from lipopolysaccharide-induced apoptosis and inflammatory response through MAPK/Wnt/NF-κB pathways
SO MOLECULAR IMMUNOLOGY
LA English
DT Article
DE Calcitonin; Lipopolysaccharide (LPS); Osteoarthritis; Bone morphogenetic protein 2 (BMP-2); MAPE/Wnt/NF-kappa B pathways
ID matrix-metalloproteinase expression; bone morphogenetic protein; c-reactive protein; cartilage degeneration; articular-cartilage; salmon-calcitonin; osteoarthritic cartilage; postmenopausal women; ii degradation; early-stage
AB Calcitonin (CT) is an anti-absorbent, which has long been used for treatment of osteoporosis. However, little information is available about the effects of CT on osteoarthritis (OA). This study was mainly aimed to explore the effects of CT on the treatment of OA, as well as the underlying mechanisms. Chondrocytes were isolated from immature mice and then were incubated with lipopolysaccharide (LPS), CT, small interfering (si) RNA against bone morphogenetic protein (BMP)-2, and/or the inhibitors of MAPK/Wnt/NF-kappa B pathway. Thereafter, cell viability, apoptosis, nitric oxide (NO) and inflammatory factors productions, and expression levels of cartilage synthesis protein key factors, cartilage-derived morphogenetic protein (CDMP) 1, SRY (sex-determining region Y)-box 9 protein (SOX9), and

MAPK/Wnt/NF-kappa B pathways key factors were determined. CT significantly reversed LPS-induced cell viability decrease, apoptosis increase, the inflammatory factors and NO secretion, the abnormally expression of cartilage synthesis proteins and the activation of MAPK/Wnt/NF-kappa B pathways ($P < 0.05$). In addition, we observed that administration of the inhibitors of MAPK/Wnt/NF-kappa B pathways statistically further increased the levels of CDMP1 and SOX9 ($P < 0.05$). Suppression of BMP-2 decreased the levels of CDMP1 and SOX9 and activated MAPK/Wnt/NF-kappa B pathways, and could partially abolish CT-modulated the expression changes in CDMP1 and SOX9, and MAPK/Wnt/NF-kappa B pathways key factors ($P < 0.05$). The results showed that CT protects chondrocytes from LPS-induced apoptosis and inflammatory response by regulating BMP-2 and thus blocking IVIAPK/Wnt/NF-kappa B pathways.

TI Preventive effects of kudzu root on bone loss and cartilage degradation in

ovariectomized rat
SO AMERICAN JOURNAL OF TRANSLATIONAL RESEARCH
LA English
DT Article
DE Osteoporosis; osteoarthritis; bone absorption; cartilage degradation; kudzu; SERMs
ID hormone replacement therapy; articular-cartilage; postmenopausal women; estrogen; osteoarthritis; management; pathways; turnover; disease; health
AB The clinical utility of Traditional Chinese Medicine (TCM) herbs/roots extracts in osteoporosis (OP) and osteoarthritis (OA) has been described in multiple reports, but there have been few studies of TCM for preventing bone loss and cartilage degradation simultaneously. Six-month-old female Sprague-Dawley rats each were subjected to ovariectomized (OVX) or sham surgery and treated orally once daily with herbal extracts or vehicle. Body weight was recorded weekly, and blood samples were collected from fasting animals at different time points. Biochemical markers of bone resorption and cartilage degradation were analyzed. Changes in bone mineral density and calcium content were determined in the femoral center and femoral telocentric end of rats. Out of 56 TCM herbs/roots extracts, only kudzu root demonstrated consistent joint protective effects. OVX resulted in a marked increase in bone resorption and cartilage degradation, which could be significantly reversed by kudzu after three weeks of treatment. Compared to vehicle, kudzu induced a significant increase in bone mineral density in the femoral center and femoral telocentric end, and calcium content. The results show that kudzu exerts direct effects on articular cartilage in the OVX rat and can effectively prevent the acceleration of cartilage degradation induced by ovariectomy. Moreover, kudzu has demonstrated positive effects on metabolic health (cause a weight reduction) and may represent a possible treatment for OP and OA with high body mass index. Further studies are needed to investigate the potential effects of kudzu root in postmenopausal women.

ID quality-of-life; global burden; rheumatoid-arthritis; chronic disease; psychological distress; systematic analysis; co-morbidity; health-care; prevalence; comorbidity
AB Background: Multiple health conditions are increasingly a problem for adults with musculoskeletal conditions. However, multimorbidity research has focused

primarily on the elderly and those with a limited subset of musculoskeletal disorders. We sought to determine whether associations between multimorbidity and additional burden differ with specific forms of musculoskeletal conditions among working-age adults. Methods: Data were sourced from a nationally representative Australian survey. Specific musculoskeletal conditions examined were osteoarthritis; inflammatory arthritis; other forms of arthritis or arthropathies; musculoskeletal conditions not elsewhere specified; gout; back pain; soft tissue disorders; or osteoporosis. Multimorbidity was defined as the additional presence of one or more of the Australian National Health Priority Area conditions. Burden was assessed by self-reported measures of: (i) self-rated health (ii) musculoskeletal-related healthcare and medicines utilisation and, (iii) general healthcare utilisation. Associations between multimorbidity and additional health or healthcare utilisation burden among working-age adults (aged 18 - 64 years of age) with specific musculoskeletal conditions were estimated using logistic regression, adjusting for confounders. Interaction terms were fitted to identify whether there were specific musculoskeletal conditions where multimorbidity was more strongly associated with poorer health or greater healthcare utilisation than in the remaining musculoskeletal group. Results: Among working-age adults, for each of the specified musculoskeletal conditions, multimorbidity was associated with similar, increased likelihood of additional self-rated health burden and certain types of healthcare utilisation. While there were differences in the relationships between multimorbidity and burden for each of the specific musculoskeletal conditions, no one specific musculoskeletal condition appeared to be consistently associated with greater additional health burden in the presence of multimorbidity across the majority of self-rated health burden and healthcare use measures. Conclusions: For working-age people with any musculoskeletal conditions examined here, multimorbidity increases self-reported health and healthcare utilisation burden. As no one musculoskeletal condition appears consistently worse off in the presence of multimorbidity, there is a need to better understand and identify strategies that acknowledge and address the additional burden of concomitant conditions for working-age adults with a range of musculoskeletal conditions.

DE Menopause; Systemic lupus erythematosus; Osteoarthritis; Rheumatoid arthritis
ID systemic-lupus-erythematosus; hormone-replacement-therapy; bone-mineral density; isolated pulmonary-hypertension; postmenopausal women; risk-factors; ovarian failure; double-blind; radiographic osteoarthritis; estrogen metabolites
AB Menopause occurs naturally in women at about 50 years of age. There is a wealth of data concerning the relationship of menopause to systemic lupus erythematosus, rheumatoid arthritis, and osteoarthritis; there are limited data

concerning other rheumatic diseases. Age at menopause may affect the risk and course of rheumatic diseases. Osteoporosis, an integral part of inflammatory rheumatic diseases, is made worse by menopause. Hormone replacement therapy has been studied; its effects vary depending on the disease and even different manifestations within the same disease. Cyclophosphamide can induce early menopause, but there is underlying decreased ovarian reserve in rheumatic diseases.

DT Review
DE Bone; cartilage; chondrocyte; long noncoding (lnc) RNAs; osteoarthritis; osteoblast; osteosarcoma
ID mesenchymal stem-cells; promotes osteoblast differentiation; potential therapeutic target; wide dna methylation; genome-wide; chondrogenic differentiation; gene-expression; bone-marrow; poor-prognosis; osteogenic differentiation
AB Normal skeletal development requires tight coordination of transcriptional networks, signaling pathways, and biomechanical cues, and many of these pathways are dysregulated in pathological conditions affecting cartilage and bone. Recently, a significant role has been identified for long noncoding RNAs (lncRNAs) in developing and maintaining cellular phenotypes, and improvements in sequencing technologies have led to the identification of thousands of lncRNAs across diverse cell types, including the cells within cartilage and bone. It is clear that lncRNAs play critical roles in regulating gene expression. For example, they can function as epigenetic regulators in the nucleus via chromatin modulation to control gene transcription, or in the cytoplasm, where they can function as scaffolds for protein-binding partners or modulate the activity of other coding and noncoding RNAs. In this review, we discuss the growing list of lncRNAs involved in normal development and/or homeostasis of the skeletal system, the potential mechanisms by which these lncRNAs might function, and recent improvements in the methodologies available to study lncRNA functions in vitro and in vivo. Finally, we address the likely utility of lncRNAs as biomarkers and therapeutic targets for diseases of the skeletal system, including osteoarthritis, osteoporosis, and in cancers of the skeletal system.

TI Correction of vitamin D status by calcidiol: pharmacokinetic profile, safety, and biochemical effects on bone and mineral metabolism of daily and weekly dosage regimens
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE Fracture; Hypovitaminosis D; Osteomalacia; Osteoporosis; Rickets; Vitamin D deficiency
ID randomized controlled-trial; serum 25-hydroxyvitamin d; d supplementation; postmenopausal women; osteoarthritis esceo; oral vitamin-d-3; european-society; economic-aspects; parathyroid-hormone; turnover markers
AB Rationale: Calcidiol can be employed to correct vitamin D deficiency. Main results: Calcidiol administered at daily and weekly regimens over a period of 3 months was able to successfully raise 25-hydroxyvitamin D levels without altering other markers related to bone and mineral metabolism. Significance: Calcidiol supplementation is effective and safe. Introduction The correction of vitamin D status is necessary to maintain an optimal mineral and skeletal homeostasis. Despite cholecalciferol (vitamin D-3) is the most commonly used drug for vitamin D supplementation, the more hydrophilic compound calcidiol (25-hydroxyvitamin D-3) can be employed at daily, weekly, and monthly regimens to reach in the short term the target levels of serum 25-hydroxyvitamin D [25(OH)D]. In the administration of different doses of calcidiol pharmacokinetic study (ADDI-D study), the efficacy and safety of daily and weekly dosages of calcidiol were tested. Methods A total of 87 Caucasian, community-dwelling, postmenopausal women, aged 55 years or older, with vitamin D inadequacy (serum 25(OH)D levels < 30 ng/ml, with mean 25(OH)D below 20 ng/ml, namely 16.5 +/- 7.5 ng/ml) were randomized to receive three different dosages of calcidiol: 20 mu g/day, 40 mu g/day, and 125 mu g/week for 3 months. The attained level of serum 25(OH)D was selected as primary endpoint to assess efficacy, while other parameters of mineral metabolism, (serum calcium, parathyroid hormone, phosphate, FGF23, urinary calcium, and markers of bone turnover) were assessed as secondary endpoints to establish safety. Results In all the three groups, serum 25(OH)D values significantly

and promptly rose and plateaued above the 30 ng/ml threshold remaining within safety interval after 14 days of treatment, with similar efficacy for the similar daily and weekly dose regimens. The different dosages were also equally effective in controlling secondary hyperparathyroidism. No significant changes in calcium and phosphate metabolism and in bone turnover markers were observed for any of the treatments, confirming the safety of this compound. Conclusions The results of this study demonstrate the short- and mid-term efficacy and safety on core parameters of mineral metabolism of different daily or weekly dosages of calcidiol when used to treat vitamin D inadequacy or deficiency in postmenopausal women. Further studies are needed to assess falls as primary outcome of calcidiol supplementation.

TI Do Comorbidities Play a Role in Hand Osteoarthritis Disease Burden? Data from the Hand Osteoarthritis in Secondary Care Cohort
SO JOURNAL OF RHEUMATOLOGY
LA English
DT Article
DE HAND OSTEOARTHRITIS; COMORBIDITY; PATIENT-REPORTED OUTCOMES; DISABILITY; HAND PAIN; QUALITY OF LIFE
ID quality-of-life; knee osteoarthritis; rheumatology criteria; depression scale;

hospital anxiety; clinical-trials; health-status; pain; disability; impact
AB Objective. Because the association and its clinical relevance between comorbidities and primary hand osteoarthritis (OA) disease burden is unclear, we studied this in patients with hand OA from our Hand OSTeoArthritis in Secondary care (HOSTAS) cohort. Methods. Cross-sectional data from the HOSTAS study were used, including consecutive patients with primary hand OA. Nineteen comorbidities were assessed: 18 self-reported (modified Charlson index and osteoporosis) and obesity (body mass index = 30 kg/m(2)). Mean differences were estimated between patients with versus without comorbidities, adjusted for age and sex: for general disease burden [health-related quality of life (HRQOL), Medical Outcomes Study Short Form-36 physical component scale (0-100)] and disease-specific burden [self-reported hand function (0-36), pain (0-20; Australian/Canadian Hand OA Index), and tender joint count (TJC, 0-30)]. Differences above a minimal clinically important improvement/difference were considered clinically relevant. Results. The study included 538 patients (mean age 61 yrs, 86% women, 88% fulfilled American College of Rheumatology classification criteria). Mean (SD) HRQOL, function, pain, and TJC were 44.7 (8), 15.6 (9), 9.3 (4), and 4.8 (5), respectively. Any comorbidity was present in 54% (287/531) of patients and this was unfavorable [adjusted mean difference presence/absence any comorbidity (95% CI): HRQOL-4.4 (-5.8 to-3.0), function 1.9 (0.4-3.3), pain 1.4 (0.6-2.1), TJC 1.3 (0.4-2.2)]. Number of comorbidities and both musculoskeletal (e. g., connective tissue disease) and nonmusculoskeletal comorbidities (e. g., pulmonary and cardiovascular disease) were associated with disease burden. Associations with HRQOL and function were clinically relevant. Conclusion. Comorbidities showed clinically relevant associations with disease burden. Therefore, the role of comorbidities in hand OA should be considered when interpreting disease outcomes and in patient management.

TI Prevalence of Chronic Neck Pain, Low Back Pain, and Knee Pain and Their Related Factors in Community-Dwelling Adults in Iran A Population-based National Study
SO CLINICAL JOURNAL OF PAIN
LA English
DT Article
DE chronic musculoskeletal pain; low back pain; neck pain; knee pain; prevalence; odds ratio
ID chronic musculoskeletal pain; global burden; physical-activity; health-status; risk-factors; disease; osteoarthritis; epidemiology; osteoporosis; country
AB Background: Chronic musculoskeletal pain (CMP) is increasing in prevalence rapidly. Over the past 2 decades low back pain has been ranked globally as the primary cause of years lived with disability. The primary objective of this study was to investigate the prevalence of chronic neck pain (CNP), chronic low back pain (CLBP), and chronic knee pain (CKP) and their related risk factors in the national Iranian population. Methods: We analyzed data obtained through a cross-sectional, population-based survey of 7889 Iranians who were aged between 30 and 70 years. Results: The prevalence of CNP, CLBP, and CKP was 15.34%, 27.18%, and 29.97%, respectively. Female sex, aging, body mass index >= 25, Lur or Arab ethnicity, illiteracy, passive smoking, positive osteoporosis history, and low or high physical

activity levels were risk factors for CLBP, CNP, and CKP after adjustment for potential confounders. For example, in participants with a body mass index >= 30, odds ratios for CNP, CLBP, and CKP adjusted for age, sex, ethnicity, living area, education, employment status, smoking, and physical activity levels were 1.26 (95% confidence interval [CI], 1.04-1.52), 1.37 (95% CI, 1.17-1.59), and 1.64 (95% CI, 1.41-1.91), respectively. Conclusions: This is the first study investigating the prevalence of CNP, CLBP, and CKP in the national population of Iran. It shows some modifiable risk factors for CMP, and suggests that affordable planning for these risk factors can be valuable in preventing CMP globally. However, this is a cross-sectional study and future longitudinal studies in this field are necessary.

TI Effects of low-intensity pulsed electromagnetic fields on bone microarchitecture, mechanical strength and bone turnover in type 2 diabetic db/db mice
SO SCIENTIFIC REPORTS
LA English
DT Article
ID ovariectomy-induced osteoporosis; affects osteoclast formation; hormone replacement therapy; knee osteoarthritis; leptin; transcription; osteogenesis; stimulation; model; gene
AB Type 2 diabetic patients have impaired bone quality, leading to increased fracture risk. Substantial evidence demonstrates that pulsed electromagnetic fields (PEMF) could resist osteopenia/osteoporosis induced by estrogen deficiency and disuse. However, the effects of PEMF on osteopenia/osteoporosis associated with diabetes, especially for more prevalent type 2 diabetes, remain poorly understood. We herein investigated the skeletal effects and mechanisms of PEMF (15 Hz, 20 Gs) on leptin receptor-deficient db/db mice with typical type 2 diabetic symptoms. Our mu CT results showed that 12-week PEMF exposure significantly improved both cancellous and cortical bone microarchitecture in db/db mice. Three-point bending and biomechanical indentation testing demonstrated that PEMF improved whole-bone structural properties and tissue-level material properties in db/db mice. PEMF significantly promoted bone formation in db/db mice evidenced by increased serum osteocalcin and bone mineral apposition rate, whereas PEMF exerted no observable alteration in bone resorption. Real-time PCR showed that PEMF upregulated tibial gene expression of osteoblastogenesis-related of canonical Wnt/beta-catenin signaling but not osteoclastogenesis-related RANKL-RANK signaling in db/db mice. Our findings demonstrate that PEMF improved bone quantity and quality with obvious anabolic activities in db/db mice, and imply that PEMF might become a clinically applicable treatment modality for improving bone quality in type 2 diabetic patients.

TI The combined therapy with chondroitin sulfate plus glucosamine sulfate or chondroitin sulfate plus glucosamine hydrochloride does not improve joint damage in an experimental model of knee osteoarthritis in rabbits
SO EUROPEAN JOURNAL OF PHARMACOLOGY
LA English
DT Article
DE Osteoarthritis; Cartilage damage; Synovial inflammation; Subchondral bone; Chondroitin sulfate; Glucosamine sulfate
ID subchondral bone; articular-cartilage; chronic arthritis; mineral density; osteoporosis; increases; synovitis; inflammation; combination; symptoms
AB Osteoarthritis is the most common chronic joint disorder especially during aging. Although with controversies, glucosamine, both in its forms of sulfate and hydrochloride, and chondroitin sulfate are commonly employed to treat osteoarthritis. Due to the modest improve in the symptoms observed in patients treated with these drugs alone, a formulation combining both agents has been considered. The discrepant results achieved for pain control or structural improvement in osteoarthritis patients has been attributed to the quality of chemical formulations or different bias in clinical studies. The current study has been designed to test the effects of two different combined formulations with adequate pharmaceutical grade of these drugs in osteoarthritic joints, and to explore the underlying mechanisms modulated by both formulations in different osteoarthritis target tissues. Knee osteoarthritis was surgically induced in experimental rabbits. Some animals received the combined therapy (CT) 1, (chondroitin sulfate 1200 mg/day + glucosamine sulfate 1500 mg/day), or the CT2 ((chondroitin sulfate 1200 mg/day + glucosamine hydrochloride 1500 mg/day). Neither CT1 nor CT2 significantly modified the cartilage damage or the synovial inflammation observed in osteoarthritic animals. Treatments were also unable to modify the presence of pro-inflammatory mediators, and the synthesis of metalloproteinases in the cartilage or in the synovium of osteoarthritic animals. Combined therapies did not modify the decrease in the subchondral bone mineral density observed in osteoarthritic rabbits. Therapies of chondroitin sulfate plus glucosamine sulfate or chondroitin sulfate plus glucosamine hydrochloride failed to improve structural damage or to ameliorate the inflammatory profile of joint tissues during experimental osteoarthritis.

TI Strontium ranelate causes osteophytes overgrowth in a model of early phase osteoarthritis
SO BMC MUSCULOSKELETAL DISORDERS
LA English
DT Article
DE Osteoarthritis; Strontium ranelate; Cartilage; Osteophytes; Subchondral bone; Micro-CT
ID cruciate ligament transection; subchondral bone; cartilage degradation; knee osteoarthritis; histological assessments; extracellular-matrix; articular-cartilage; rat model; degeneration; recommendations
AB Background: Osteoarthritis (OA) involves cartilage changes as well as modifications of subchondral bone and synovial tissues. Strontium ranelate (SR), an anti-osteoporosis compound, which is currently in phase III clinical trial for treatment of OA. Evidences suggest that SR preferably deposited in osteophyte, other than in subchondral bone in early phase of OA. This phenomenon raises concern about its utility for OA treatment as a disease-modifying drug. To evaluate the effect of SR on cartilage, subchondral bone mass and subchondral trabecular bone structure in medial meniscectomized (MNX) guinea pigs. Method: Thirty-six 3-month-old male Dunkin Hartley albino guinea pigs received either sham or medial meniscectomy operations. One week after the procedure, meniscectomized animals began 12 weeks of SR (625 mg/kg, daily) treatment by oral gavage for MNX + SR group, or normal saline for MNX + V group. All animals were euthanized 12 weeks later, cartilage degeneration and subchondral bone micro-architecture was analyzed. Results: Both OARSI scores (P = 0.523 for marcoscopic scores, P = 0.297 for histological scores) and Cartilage thickness (P = 0.335) in MNX + SR group were comparable to MNX + V group. However, osteophyte sizes were larger in MNX + SR group (P = 0.014), and collapsed osteophytes in MNX + SR group (7 by 12) were significantly more than in MNX + V group (1 by 12) (P = 0.027), while immunohistochemistry indicates catabolic changes in osteophyte/plateau junction. Micro-CT analysis showed bone mineral density (BMD) (P = 0.001), bone volume fraction (BV/TV) (P = 0.008), trabecular spacing (Tb.Sp) (P = 0.020), trabecular thickness (Tb.Th) (P = 0.012) and structure model index (SMI) (P = 0.005) levels to be significantly higher in the MNX + SR group than in the MNX + V group. Conclusions: SR (625 mg/kg/day) did not protect cartilage from degeneration in MNX guinea pigs but subchondral bone was significantly enhanced. In early phase

OA, SR administration causes osteophyte overgrowth, which may be related to incorporation into mineralizing osteophytes. This adverse effect is important for future studies of SR in OA.

TI TGF-β Family Signaling in Connective Tissue and Skeletal Diseases
SO COLD SPRING HARBOR PERSPECTIVES IN BIOLOGY
LA English
DT Article
ID growth-factor-beta; bone morphogenetic protein; smooth-muscle-cells; camurati-engelmann-disease; van-buchem-disease; medial edge epithelium; transforming growth-factor-beta-1 expression; hereditary hemorrhagic telangiectasia; hyperostosis corticalis generalisata; progressive diaphyseal dysplasia
AB The transforming growth factor beta (TGF-beta) family of signaling molecules, which includes TGF-beta s, activins, inhibins, and numerous bone morphogenetic proteins (BMPs) and growth and differentiation factors (GDFs), has important functions in all cells and tissues, including soft connective tissues and the skeleton. Specific TGF-beta family members play different roles in these tissues, and their activities are often balanced with those of other TGF-beta family members and by interactions with other signaling pathways. Perturbations in TGF-beta family pathways are associated with numerous human diseases with prominent involvement of the skeletal and cardiovascular systems. This review focuses on the role of this family of signaling molecules in the pathologies of connective tissues that manifest in rare genetic syndromes (e.g., syndromic presentations of thoracic aortic aneurysm), as well as in more common disorders (e.g., osteoarthritis and osteoporosis). Many of these diseases are caused by or result in pathological alterations of the complex relationship between the TGF-beta family of signaling mediators and the extracellular matrix in connective tissues.

TI Medication-related problems in individuals with spinal cord injury in a primary care-based clinic
SO JOURNAL OF SPINAL CORD MEDICINE
LA English
DT Article
DE Adverse drug reaction; Drug side effects; Pharmacists; Polypharmacy; Spinal cord injury
AB Objective: To determine the frequency of medical problems, reason for referral/primary complaint, products used, medication-related problems, and polypharmacy in patients with spinal cord injury (SCI) seen at an interprofessional primary care mobility clinic. Design: Retrospective review of medical records of patients with SCI for patient visits between August 2012 and March 2013. Methods: Data were abstracted from medical records of patients with SCI. Results: Of 74

patients who presented to the clinic, 19 had an SCI. Mean age was 46.7 years and 74% were male. Most frequent medical problems were depression/anxiety (37%), osteoporosis/osteopenia (26%), hypertension (21%), dyslipidemia (21%), and osteoarthritis (21%). Most common presenting complaints were pain (23%) and bowel/bladder issues (13%). Most common medication-related problems were untreated conditions (41%), ineffective medications (21%), adverse drug reactions (18%), and under-and over-dosage (each 9%). Patients with SCI most frequently used products to treat pain (68%), constipation (42%), muscle spasm (42%), hypertension (42%), and depression (37%). When including natural health products, vitamins and minerals, polypharmacy was seen in 74% of patients with SCI (63% when limited to prescription and over-the-counter medications). For patients with SCI in whose care a pharmacist collaborated, a mean of 3.2 medication-related problems per patient were identified compared with 1 per patient when the pharmacist was not involved. Conclusion: This study is the first to describe medication use, polypharmacy and medication-related problems in patients with SCI seen at an interprofessional primary care clinic. Use of high-risk medications, polypharmacy, and medication-related problems in patients with SCI suggest the need for collaborative interprofessional care that includes a pharmacist.

TI A topological look at human trabecular bone tissue
SO MATHEMATICAL BIOSCIENCES
LA English
DT Article
DE CW-complex; Euler characteristic; Trabecular bone tissue; Kelvin cell
ID cancellous bone; quantification
AB Bone quality is affected by trabecular architecture at microscopic level. Various abnormalities of bone tissue lead to altered strength and to an increased susceptibility to fracture, such as Osteoporosis and Osteoarthritis, two major health burdens of our society. These are two complex musculoskeletal diseases that mainly concern bone tissue. In the last twenty years, there has been a growing interest in finding an appropriate topological model for the micro-architecture of trabecular bone tissue. In particular, we prove that these models involve general topological spaces. The appropriate notion to deal with is that of CW-complex. (C) 2017 Elsevier Inc. All rights reserved.

DT Article
DE Dog-related injuries; meniscus tear; ulna fracture
AB In this article, we present two middle-aged female patients with ulna fracture or medial meniscal tear resulting from dog-related injuries, which are not common. Both patients mentioned that pain started after their dogs pulled away their collar ropes strongly and suddenly. Both patients had postmenopausal osteoporosis and degenerative osteoarthritis. For this reason, ulna fracture and meniscus tear had developed with low-energy trauma resulting from dog-related injuries.

TI Hip osteoarthritis as a predictor of the fracture pattern in proximal femur fractures
SO INJURY-INTERNATIONAL JOURNAL OF THE CARE OF THE INJURED
LA English

DT Article
DE Hip osteoarthritis; Hip fracture; Intracapsular; Extracapsular
ID bone-mineral density; femoral-neck; risk-factors; postoperative complications; elderly-women; osteoporosis; mortality; outcm; association; cohort
AB Introduction: Several authors have suggested a correlation between the fracture patterns of proximal femur fractures and the degree of hip osteoarthritis (HOA), but the current evidence to support this are insufficient. The aim of our study was to demonstrate whether there is an association between the grade of HOA and fracture pattern observed, in patients presenting with a fragility fracture of the proximal femur. Materials and methods: We contacted a retrospective review of all patients presenting to our institution with fragility fractures involving the proximal femur, between March 2012 and October 2013. Pathological fractures, high-energy injuries and patients with less than one year of follow-up were excluded from further analysis. Admission radiographs and severity of HOA were assessed according to Kellgren and Lawrence scale (minimal: Grades 1-2; severe: Grades 3-4). Fractures were classified according to AO/OTA classification. Results: A total of 1003 patients (725 females; 1003 fractures) met the inclusion criteria, having a mean age of 81.5 (46-106 years). With regards to fracture classification, 417 (41.6%) fractures were classified as extracapsular and 586 (58.4%) as intracapsular. A total of 939 (93.9%) patients presented with minimal HOA, whilst 61 (6.1%) of the patients presented with severe HOA. Of the 61 patients presenting with severe HOA, 42 patients (68.9%) sustained a 31A-interthrocanteric fracture and 19 patients (31.1%) sustained a 31B-intracapsular fracture. Regarding the patients presenting with minimal HOA (832 patients in total), 323 patients (38.8%) sustained 31A-intertrochanteric fracture and 509 patients (61.2%) sustained a 31B-intracapsular fracture. Patients presenting with severe HOA were found to have a statistically significant chance to present with an extracapsular fracture ($p < 0.01$). Conclusions: The degree of HOA is related to the fracture pattern in patients presenting following simple mechanical falls. More specifically, higher grades of HOA are associated with extracapsular fracture patterns, whereas lower grades of HOA are associated with intracapsular fracture patterns. (C) 2017 Elsevier Ltd. TI Increased detection of genetic loci associated with risk predictors of osteoporotic fracture using a pleiotropic cFDR method
SO BONE
LA English
DT Article
DE Osteoporosis; Association; Bone mineral density; Human genetics
ID bone-mineral density; genome-wide association; human height; polymorphisms; metaanalysis; osteoarthritis; determinant; population; disease; protein
AB Although GWAS have been successful in identifying some osteoporosis associated loci, the findings explain only a small fraction of the total genetic variance. In this study we use a recently developed novel pleiotropic conditional false discovery rate (cFDR) method to identify novel genetic loci associated with two risk traits for osteoporotic fracture (the clinical outcome and end result of osteoporosis), Height (HT) and Femoral Neck (FNK) BMD. The cFDR method allows us to improve the detection of associated variants by incorporating any potentially shared genetic mechanisms between the two associated traits. We analyzed the summary statistics from two GWAS meta-analyses for single nucleotide polymorphisms (SNPs) that are associated with HT and FNK BMD. Using the cFDR method, we show enrichment in the identification of SNPs associated with each trait conditioned on their strength of association with the second trait. The findings revealed 18 SNPs that are associated with both HT and FNK BMD, 4 of which had not previously been reported to play a role in bone health. The novel SNPs located at K1F1B and the intergenic region between FERD3L and TWISTNB are noteworthy as these genes may be associated with processes that are functionally important in bone metabolism. By leveraging GWAS results from related phenotypes we identified several novel loci that may contribute to the proportion of variability explained for each trait, although we cannot speculate about these potential contributions to heritability based on this analysis alone. TI Lumbar disc degeneration was not related to spine and hip bone mineral densities in Chinese: facet joint osteoarthritis may confound the association
SO ARCHIVES OF OSTEOPOROSIS
LA English
DT Article
DE Lumbar spine; Bone mineral density; Disc degeneration; Facet joint osteoarthritis
ID osteoporosis; women; densitometry; discography; impact; mass; men; ct
AB A sample of 512 Chinese was studied and we observed that greater disc degeneration on MRI was associated with greater spine DXA BMD. Yet, this association may be confounded by facet joint osteoarthritis. BMD may not be a risk factor for lumbar disc degeneration in Chinese. Purpose Evidence suggested that lumbar vertebral bone and intervertebral disc interact with each other in multiple ways. The current paper aims to determine the association between bone mineral density (BMD) and lumbar disc degeneration using a sample of Chinese. Methods We studied 165 patients with back disorders and 347 general subjects from China. All subjects had lumbar spine magnetic resonance (MR) imaging and dual-energy X-ray absorptiometry (DXA) spine BMD studies, and a subset of general subjects had additional hip BMD measurements. On T2-weighted MR images, Pfirrmann score was used to evaluate the degree of lumbar disc degeneration and facet joint osteoarthritis was assessed as none, slight-moderate, and severe. Regression analyses were used to examine the associations between lumbar and hip BMD and disc degeneration, adjusting for age, gender, body mass index (BMI), lumbar region, and facet joint osteoarthritis. Results Greater facet joint osteoarthritis was associated with greater spine BMD ($P < 0.01$) in both patients and general subjects. For general subjects, greater spine BMD was associated with severe disc degeneration, controlling for age, gender, BMI, and lumbar region. When facet joint osteoarthritis entered the regression model, however, greater spine BMD was associated with greater facet joint osteoarthritis ($P < 0.01$) but not greater disc degeneration ($P > 0.05$). No statistical association was observed between spine BMD and lumbar disc degeneration in patients with back disorders ($P > 0.05$), and between hip BMD and disc degeneration in general subjects ($P > 0.05$). Conclusion

BMD may not be a risk factor for lumbar disc degeneration in Chinese. Facet joint osteoarthritis inflates DXA spine BMD measurements and therefore, may confound the association between spine BMD and disc degeneration.

DT Article
DE Knee osteoarthritis; polymorphism; transforming growth factor-beta 1
ID bone-mineral density; growth-factor-beta-1; women; differentiation; tgf-beta-1;

epidemiology; osteoporosis; expression; aneurysms; receptor
AB Objective To investigate associations between single polymorphisms (SNPs) rs1800469 and rs1982073 in the transforming growth factor-1 gene (TGF-1) and knee osteoarthritis (OA) susceptibility in a Chinese Han population. MethodsTGF-1 rs1800469 and rs1982073 were genotyped in patients with knee OA and age- and sex-matched OA-free controls from a Chinese Han population. The association was further analyzed according to gender and age. Results A total of 765 patients with knee OA and 780 controls were included. CT and CT+CC genotypes of rs1982073, and variant C, were associated with a significantly increased risk of knee OA. Stratification analysis showed that the association between the OA risk and rs1982073 CT heterozygotes compared with TT homozygotes was stronger in females and those aged >65years. In contrast, CT, TT, and CT+TT genotypes of rs1800469 were not significantly associated with the risk of knee OA, even after further stratification analysis for gender and age. Conclusions The TGF-1 rs1982073 T to C change and the variant C genotype may contribute to knee OA risk in the Chinese Han population.

TI Local Variation in Femoral Neck Cortical Bone: In Vitro Measured Bone Mineral Density, Geometry and Mechanical Properties
SO JOURNAL OF CLINICAL DENSITOMETRY
LA English
DT Article
DE Bone mineral density; cortical bone; indentation; mechanical properties; osteoporosis
ID hip fracture; osteoarthritis; osteoporosis; microindentation; recommendations; variability; orientation; women; age
AB Age- and disease (osteoporotic fractured and osteoarthritic tissue)-related changes in the distribution of cortical bone were examined, using a multimodality approach, including measurement of local density, geometry and mechanical properties, where changes in these properties can give rise to instability and increasing probability of fracture. In contrast to the majority of previously reported research, this study also focuses on the characteristic non-circular femoral neck cross-sectional geometry and variation in bone mineral density (BMD) around the femoral neck. Twenty-two osteoarthritic and 7 osteoporotic femoral neck slices, collected from elective and trauma-related arthroplasty, and 16 cadaveric donor tissue controls were tested mechanically using Reference Point Indentation (BioDent (TM), Active Life Technologies, Santa Barbara, CA) and then scanned with in vitro-based radiography intended to replicate the dual-energy X-ray absorptiometry technique. All parameters were measured regionally around the

circumference of the femoral neck, allowing examination of spatial variability within the cortical bone. Fractured tissue was less resistant to indentation in the thinner superolateral segment compared to other segments and other groups. BMD around the fractured femoral necks appeared more consistent than that of nonfractured tissue, where BMD was reduced in the superolateral segment for the other groups. Cortical bone was thin in the superolateral segment for all groups except for the osteoarthritic group, and was thicker in the inferomedial segment for both osteoarthritic and fractured groups, resulting in the largest variation in buckling ratio (ratio of cortical bone diameter to cortical bone thickness) around the femoral neck for the fractured group. With age, healthy controls appeared to have lower inferomedial cortical thickness, whereas no significant differences in Reference Point Indentation measurements and density were observed. The study has highlighted several (both quality- and quantity-related) parameters that may be used to improve prediction of fracture risk.

TI Osteoblast Role in Rheumatic Diseases
SO INTERNATIONAL JOURNAL OF MOLECULAR SCIENCES
LA English
DT Review
DE arthritis; osteoarthritis; osteoblast; osteoporosis; spondyloarthritis
ID necrosis-factor-alpha; subchondral bone osteoblasts; glucocorticoid-induced osteoporosis; ankylosing-spondylitis; beta-catenin; osteoclast differentiation; growth-factor; receptor activator; rank ligand; proinflammatory cytokines
AB Alterations in osteoblast growth, differentiation and activity play a role in the pathogenesis of several rheumatic diseases, such as rheumatoid arthritis, spondyloarthritides, osteoarthritis, and osteoporosis. In fact, in these rheumatic diseases, abnormal activity of Wnt signaling, receptor activator of nuclear factor-kappa B (RANK)-RANK ligand (RANKL)-osteoprotegerin (OPG) signaling, bone morphogenetic proteins (BMPs) pathway and other mechanisms have been described in osteoblasts. This review article is focused on current knowledge on the role of osteoblast dysregulation occurring in rheumatic diseases.
