TI Increased bone resorption that outpaces increased bone formation: An important pathology of rapidly destructive coxarthrosis
SO JOURNAL OF ORTHOPAEDIC RESEARCH
LA English
DT Article
DE homocysteine; rapidly destructive coxarthrosis; total P1NP; TRACP-5b
ID collagen c-telopeptide; total hip-arthroplasty; early mri findings; osteoarthritis;

quality; prevalence; serum
AB Rapid joint destruction caused by rapidly destructive coxarthrosis (RDC) can increase surgical complexity and intraoperative blood loss. This single-center retrospective study investigates osteoporosis-related biomarkers for early RDC diagnosis and explores new treatment targets. We included 398 hip joints from patients who underwent total hip arthroplasty, examining medical records for preoperative patient demographics, bone mineral density of the hip and lumbar spine from dual-energy X-ray absorptiometry scans, and osteoporosis-related biomarkers including TRACP-5b, total P1NP, intact parathyroid hormone, and homocysteine. We compared RDC and osteoarthritis (OA) patients, and univariate analysis showed that RDC patients were older ($p < 0.001$) and had lower serum levels of albumin ($p < 0.001$) and higher serum levels of TRACP-5b, total P1NP ($p < 0.001$), and homocysteine ($p = 0.006$). Multivariable analysis showed that the ratio of serum TRACP-5b to total P1NP had a more significant difference in RDC patients than in OA patients ($p = 0.04$). Serum TRACP-5b levels were negatively correlated with the time between RDC onset and blood collection, and Japanese Orthopedic Association pain score. Receiver operating characteristic curve analysis revealed that the ratio of serum TRACP-5b to total P1NP had the highest area under the curve value. This study is the first to demonstrate that the ratio of serum TRACP-5b to total P1NP-increased bone resorption that outpaces increased bone formation-is significantly elevated in patients with RDC and that TRACP-5b is higher in the early stages of RDC. Inhibiting serum levels of TRACP-5b, activated osteoclasts, during early RDC may suppress disease progression.

TI Impact of patient education by nurse case managers on decision making for out-of-pocket anti-osteoporotic pharmaceutical therapy: a single-center retrospective study
SO BMC NURSING
LA English
DT Article
DE Case managers; Osteoporosis; Patient education; Decision making; Out-of-pocket cost
ID hip fracture; care; probability; position; taiwan
AB Background Osteoporosis is a common condition that increases the risk of fracture and mortality. In Taiwan, clinical guidelines recommend pharmaceutical therapy for patients with a T-score of <= - 2.5; however, Taiwan's National Health Insurance (NHI) only covers these medications for those with a history of fragility fractures. This gap in coverage necessitates a discussion of out-of-pocket treatment options. To address this, we provided an integrated care program with patient

education and shared decision-making by nurse case managers specializing in osteoporosis. We evaluated whether education by nurse case managers influences patients with a T-score <= - 2.5, who are not covered by the NHI, to choose out-of-pocket pharmaceutical therapy. Methods We retrospectively reviewed medical records of patients who underwent bone density scanning at our hospital between January 2014 and December 2021. We identified 4,462 patients with a T-score of <= - 2.5 who were ineligible for NHI-covered anti-osteoporotic therapy and analyzed trends in out-of-pocket medication use. Since the integrated care program began in 2018, we evaluated whether education by nurse case managers between 2018 and 2021 influenced patients' decisions to pay out-of-pocket for therapy. After the implementation of the integrated care program, we identified 2,910 patients with a T-score <= -2.5 who were ineligible for NHI-covered anti-osteoporotic therapy. Of these, 640 opted for out-of-pocket treatment, while 2,270 chose conservative care. After a 1:1 propensity score match based on age and sex, logistic regression was used to analyze the impact of nurse case manager education on these decisions. Results Between 2014 and 2021, 888 of the 4,462 patients chose out-of-pocket pharmaceutical therapy. Before the implementation of the integrated care program and patient education by nurse case managers (2014-2017), 16% of the patients opted to pay out-of-pocket for anti-osteoporotic therapy. After the program was implemented (2018-2021), the rate increased significantly to 22% (P < 0.001). A multivariate logistic regression model showed that a history of osteoarthritis (adjusted odds ratio = 1.576; P = 0.009) and education provided by the nurse case managers (adjusted odds ratio = 5.044; P < 0.001) were significantly associated with choosing out-of-pocket therapy. Conclusions Education from nurse case managers significantly increased the likelihood of patients choosing out-of-pocket anti-osteoporotic therapy in our hospital, thereby bridging the gap between clinical guidelines and NHI reimbursement criteria.

TI Polysaccharides to postbiotics: Nurturing bone health via modulating "gut-immune axis"
SO INTERNATIONAL JOURNAL OF BIOLOGICAL MACROMOLECULES
LA English
DT Review
DE Gut microbiome; Gut-associated metabolites; Immune cells; Osteoimmune system; Immunoporosis; Bone pathologies; Polysaccharides; Postbiotics
ID chain fatty-acids; trimethylamine-n-oxide; histone deacetylase inhibitors; sodium-butyrate; bile-acid; microbial metabolites; intestinal-absorption; tryptophan-metabolism; rheumatoid-arthritis; gene identification
AB The increasing prevalence of individuals affected by bone pathologies globally has sparked catastrophic concerns. Ankylosing spondylitis, osteoporosis, rheumatoid arthritis, osteoarthritis, and fractures alone impact an estimated 1.71 billion people worldwide. The gut microbiota plays a crucial role in interacting with the host through the synthesis of a diverse range of metabolites called gut-associated metabolites (GAMs), which originate from external dietary substrates or endogenous host compounds. Many metabolic disorders have been linked to alterations in the gut microbiota's activity and composition. The

development of metabolic illnesses has been linked to certain microbiota-derived metabolites, such as branched-chain amino acids, bile acids, short-chain fatty acids, tryptophan, trimethylamine N-oxide, and indole derivatives. Moreover, the modulation of gut microbiota through biotics (prebiotics, probiotics and postbiotics) presents a promising avenue for therapeutic intervention. Biotics selectively promote the growth of beneficial gut bacteria, thereby enhancing the production of GAMs with potential beneficial effects on bone metabolism. Understanding the intricate interplay between GAMs, and bone-associated genes through molecular informatics holds significant promise for early diagnosis, prognosis, and novel treatment strategies for various bone disorders.

TI Exploring the impact of pathogenic microbiome in orthopedic diseases: machine learning and deep learning approaches
SO FRONTIERS IN CELLULAR AND INFECTION MICROBIOLOGY
LA English
DT Review
DE pathogenic microbiome; orthopedic; machine learning; deep learning; applications; individuation; osteoporosis; arthritis
ID osteoporosis; osteoarthritis
AB Osteoporosis, arthritis, and fractures are examples of orthopedic illnesses that not only significantly impair patients' quality of life but also complicate and raise the expense of therapy. It has been discovered in recent years that the pathophysiology of orthopedic disorders is significantly influenced by the microbiota. By employing machine learning and deep learning techniques to conduct a thorough analysis of the disease-causing microbiome, we can enhance our comprehension of the pathophysiology of many illnesses and expedite the creation of novel treatment approaches. Today's science is undergoing a revolution because to the introduction of machine learning and deep learning technologies, and the field of biomedical research is no exception. The genesis, course, and management of orthopedic disorders are significantly influenced by pathogenic microbes. Orthopedic infection diagnosis and treatment are made more difficult by the lengthy and imprecise nature of traditional microbial detection and characterization techniques. These cutting-edge analytical techniques are offering previously unheard-of insights into the intricate relationships between orthopedic health and pathogenic microbes, opening up previously unimaginable possibilities for illness diagnosis, treatment, and prevention. The goal of biomedical research has always been to improve diagnostic and treatment methods while also gaining a deeper knowledge of the processes behind the onset and development of disease. Although traditional biomedical research methodologies have demonstrated certain limits throughout time, they nevertheless rely heavily on experimental data and expertise. This is the area in which deep learning and machine learning approaches excel. The advancements in machine learning (ML) and deep learning (DL) methodologies have enabled us to examine vast quantities of data and unveil intricate connections between microorganisms and orthopedic disorders. The

importance of ML and DL in detecting, categorizing, and forecasting harmful microorganisms in orthopedic infectious illnesses is reviewed in this work.

TI Links between three chronic and age-related diseases, osteoarthritis, periodontitis, and osteoporosis, in a wild mammal (moose) population
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE Alces alces; Periodontal disease; Arthritis; Chronic diseases; Age -related diseases; Isle Royale
ID sex-differences; prevalence; burden; hip
AB Objective: Osteoarthritis, periodontitis and osteoporosis are chronic, age-related diseases which adversely impact millions of people worldwide. Because these diseases pose a major global public health challenge, there is an urgent need to better understand how these diseases are interrelated. Our objective was to

document the age and sex-specific prevalence of each disease and assess interrelationships among the three diseases in a wild mammal (moose, Alces alces) population. Methods: We examined the bones of moose dying from natural causes and recorded the severity of osteoarthritis (typically observed on the hip and lowest vertebrae), osteoporosis (osteoporotic lesions observed on the skull) and periodontitis (observed on maxilla and mandibles). Results: Periodontitis was associated with a greater prevalence of both severe osteoarthritis and osteoporotic lesions in moose. We found no evidence to suggest that moose with osteoporotic lesions were more or less likely to exhibit signs of osteoarthritis or severe osteoarthritis. The prevalence of osteoarthritis, periodontitis and osteoporotic lesions was greater among males than for females. Conclusions: Our results were consistent with the hypothesis that bacterial pathogens causing periodontitis are a risk factor for osteoarthritis and osteoporosis. They are also consistent with the hypothesis that the inverse association between osteoarthritis and osteoporosis sometimes observed in humans may be influenced by shared risk factors, such as obesity, smoking or alcohol consumption, which are absent in moose. Together these results provide insights about three diseases which are expected to become more prevalent in the future and that cause substantial socio-economic burdens.

TI Glycemic Marker Correlation with Collagen Denaturation and Non-Enzymatic Collagen Cross-Linking in Age-Associated Bone Resistance
SO JOM
LA English
DT Article
ID glycation end-products; human cortical bone; hip fracture; density; osteoarthritis; polymorphism; endproducts; morphology; mortality; toughness
AB The primary clinical indicator of fracture risk among the elderly is low bone mass, yet it accounts for less than half of fractures in individuals over 50 years. Age is recognized to influence bone quality, affecting bone structure and properties. Previous research indicates that age diminishes tissue plasticity and toughness conferred by collagen, suggesting that age-related changes in the collagen environment may contribute to bone fragility. This study explores the relationship between age-related collagen impairment, specifically the accumulation of non-enzymatic collagen cross-linking and molecular collagen denaturation, and bone toughness in middle-aged and older patients (postmenopausal 50-70 years old and senile osteoporosis age > 70 years old). Additionally, it examines the influence of blood glucose and HbA1c levels, as well as body mass index (BMI), on these factors. Despite not finding any differences in fracture toughness between groups, we found a significant correlation between hemoglobin A1c and collagen integrity (collagen denaturation and non-enzymatic cross-linking).

TI The Role of the Gut Microbiome in Orthopedic Surgery-a Narrative Review
SO CURRENT REVIEWS IN MUSCULOSKELETAL MEDICINE
LA English

DT Review
DE Gut microbiome; Dysbiosis; Gut flora; Commensal bacteria; Orthopedic surgery; Osteoarthritis; Osteoporosis; Osteomyelitis; Fracture healing; Degenerative disc disease; Spinal cord injury; Athletics; Probiotic
ID disease; risk
AB Purpose of ReviewThe importance of the gut microbiome has received increasing attention in recent years. New literature has revealed significant associations between gut health and various orthopedic disorders, as well as the potential for interventions targeting the gut microbiome to prevent disease and improve musculoskeletal outcomes. We provide a broad overview of available literature discussing the links between the gut microbiome and pathogenesis and management of orthopedic disorders.Recent FindingsHuman and animal models have characterized the associations between gut microbiome dysregulation and diseases of the joints, spine, nerves, and muscle, as well as the physiology of bone formation and fracture healing. Interventions such as probiotic supplementation and fecal transplant have shown some promise in ameliorating the symptoms or slowing the progression of these disorders.SummaryWe aim to aid discussions regarding optimization of patient outcomes in the field of orthopedic surgery by providing a narrative review of the available evidence-based literature involving gut microbiome dysregulation and its effects on orthopedic disease. In general, we believe that the gut microbiome is a viable target for interventions that can augment current management models and lead to significantly improved outcomes for patients under the care of orthopedic surgeons.

TI Osteoporosis, Osteoarthritis, and Subchondral Insufficiency Fracture: Recent Insights
SO BIOMEDICINES
LA English
DT Review
DE osteoarthritis; osteoporosis; subchondral insufficiency fracture; bone mineral density; osteoporotic fracture
ID bone-mineral density; vitamin-d supplementation; medial femoral condyle; spontaneous osteonecrosis; knee osteoarthritis; strontium ranelate; hip osteoarthritis; cartilage volume; marrow lesions; radiographic osteoarthritis
AB The increased incidence of osteoarthritis (OA), particularly knee and hip OA, and osteoporosis (OP), owing to population aging, have escalated the medical expense burden. Osteoarthritis is more prevalent in older women, and the involvement of subchondral bone fragility spotlights its association with OP. Notably, subchondral insufficiency fracture (SIF) may represent a more pronounced condition of OA pathophysiology. This review summarizes the relationship between OA and OP, incorporating recent insights into SIF. Progressive SIF leads to joint collapse and secondary OA and is associated with OP. Furthermore, the thinning and fragility of subchondral bone in early-stage OA suggest that SIF may be a subtype of OA (osteoporosis-related OA, OPOA) characterized by significant subchondral bone damage. The high bone mineral density observed in OA may be overestimated due to osteophytes and sclerosis and can potentially contribute to OPOA. The incidence of OPOA is expected to increase along with population aging. Therefore, prioritizing OP screening, early interventions for patients with early-stage OA, and fracture prevention measures such as rehabilitation, fracture liaison services, nutritional management, and medication guidance are essential.

TI Classification of osteoarthritic and healthy cartilage using deep learning with Raman spectra
SO SCIENTIFIC REPORTS
LA English
DT Article
DE Raman spectra; Osteoarthritis; Deep learning; Convolutional neural network; Classification
ID convolutional neural-networks; base-line-correction; background subtraction; spectroscopy; recognition; algorithm; disease
AB Raman spectroscopy is a rapid method for analysing the molecular composition of biological material. However, noise contamination in the spectral data necessitates careful pre-processing prior to analysis. Here we propose an end-to-end Convolutional Neural Network to automatically learn an optimal combination of pre-processing strategies, for the classification of Raman spectra of superficial and deep layers of cartilage harvested from 45 Osteoarthritis and 19 Osteoporosis (Healthy controls) patients. Using 6-fold cross-validation, the Multi-Convolutional Neural Network achieves comparable or improved classification accuracy against the best-performing Convolutional Neural Network applied to either the raw or pre-processed spectra. We utilised Integrated Gradients to identify the contributing features (Raman signatures) in the network decision process, showing they are biologically relevant. Using these features, we compared Artificial Neural Networks, Decision Trees and Support Vector Machines for the feature selection task. Results show that training on fewer than 3 and 300 features, respectively, for the disease classification and layer assignment task provide performance comparable to the best-performing CNN-based network applied to the full dataset. Our approach, incorporating multi-channel input and Integrated Gradients, can potentially facilitate the clinical translation of Raman spectroscopy-based diagnosis without the need for laborious manual

pre-processing and feature selection.

AB Objective To elicit expert opinion and gain consensus on specific exercise intervention parameters to minimise hip bone mineral density (BMD) loss following traumatic lower limb amputation. Methods In three Delphi rounds, statements were presented to a panel of 13 experts from six countries. Experts were identified through publications or clinical expertise. Round 1 involved participants rating their agreement with 22 exercise prescription statements regarding BMD loss post amputation using a 5-point Likert scale. Agreement was deemed as 3-4 on the scale (agree/strongly agree). Statements of <50% agreement were excluded. Round 2 repeated remaining statements alongside round 1 feedback. Round 3 allowed reflection on round 2 responses considering group findings and the chance to change or maintain the resp onse. Round 3 statements reaching >= 70% agreement were defined as consensus. Results All 13 experts completed rounds 1, 2 and 3 (100% completion). Round 1 excluded 12 statements and added 1 statement (11 statements for rounds 2-3). Round 3 reached consensus on nine statements to guide future exercise interventions. Experts agreed that exercise interventions should be performed at least 2days per week for a minimum of 6 months, including at least three different resistance exercises at an intensity of 8-12 repetitions. Interventions should include weight-bearing and multiplanar exercises, involve high-impact activities and be supervised initially. Conclusion This expert Delphi process achieved consensus on nine items related to exercise prescription to minimise hip BMD loss following traumatic lower limb amputation. These recommendations should be tested in future interventional trials.

DT Review
DE bone metabolism; oxytocin; BMSC; osteoblast; osteoclast; chondrocyte; estrogen; osteoporosis
ID mesenchymal stem-cells; receptor; differentiation; osteoarthritis; proliferation; expression; female; model; body
AB Oxytocin (OT) is a posterior pituitary hormone that, in addition to its role in regulating childbirth and lactation, also exerts direct regulatory effects on the skeleton through peripheral OT and oxytocin receptor (OTR). Bone marrow mesenchymal stem cells (BMSCs), osteoblasts (OB), osteoclasts (OC), chondrocytes, and adipocytes all express OT and OTR. OT upregulates RUNX2, BMP2, ALP, and OCN, thereby enhancing the activity of BMSCs and promoting their differentiation towards OB rather than adipocytes. OT also directly regulates OPG/RANKL to inhibit adipocyte generation, increase the expression of SOX9 and COMP, and enhance chondrocyte differentiation. OB can secrete OT, exerting influence on the surrounding environment through autocrine and paracrine mechanisms. OT directly increases OC formation through the N kappa B/MAP kinase signaling pathway, inhibits osteoclast proliferation by triggering cytoplasmic Ca2+ release and nitric oxide synthesis, and has a dual regulatory effect on OCs. Under the stimulation of estrogen, OB synthesizes OT, amplifying the biological effects of estrogen and OT. Mediated by estrogen, the OT/OTR forms a feedforward loop with OB. Apart from estrogen, OT also interacts with arginine vasopressin (AVP), prostaglandins (PGE2), leptin, and adiponectin to regulate bone metabolism. This review summarizes recent research on the regulation of bone metabolism by OT and OTR, aiming to provide insights into their clinical applications and further research.

TI Steroids and Malignancy Increase Local Heparanase and Decrease Markers of Osteoblast Activity in Bone Tissue Microcirculation
SO BIOMOLECULES
LA English
DT Article
DE bone; microcirculation; thrombosis; heparanase; steroids; malignancy

ID cancer metastasis; activation; involvement; hemostasis; expression; marrow; cells
AB Bone metastasis and steroids are known to activate the coagulation system and induce osteoporosis, pathological bone fractures, and bone pain. Heparanase is a protein known to enhance the hemostatic system and to promote angiogenesis, metastasis, and inflammation. The objective of the present study was to evaluate the effects of steroids and malignancy on the coagulation factors and osteoblast activity in the bone tissue. The effects of dexacort and malignant medium were evaluated in osteoblasts derived from human bone marrow mesenchymal stem cells and human umbilical vein endothelial cells (HUVECs). The bones of mice treated with dexacort for 1 month were studied. Bone biopsies of ten patients with bone metastasis, ten with steroid-induced avascular necrosis (AVN), and ten with osteoarthritis were compared to ten controls. We found that dexacort and malignant medium significantly increased the heparanase levels in osteoblasts and HUVECs and decreased the levels of alkaline phosphatase (ALKP). Peptide 16AC, derived from heparanase, which interacts with tissue factor (TF), further increased the effect, while peptide 6, which inhibits interactions between heparanase and TF, reversed the effect in these cells. The bone microcirculation of mice treated with dexacort exhibited significantly higher levels of heparanase, TF, TF pathway inhibitor (TFPI), TFPI-2, thrombin, and syndecan-1, but reduced levels of osteocalcin and ALKP. The pathological human bone biopsies' microcirculation exhibited significantly dilated blood vessels and higher levels of heparanase, TF, TFPI, TFPI-2, and fibrin. In summary, steroids and malignancy increased the activation of the coagulation system in the bone microcirculation and reduced the osteoblast activity. Heparanase inhibitors should be further investigated to attenuate bone fractures and pain.

TI General self-efficacy, not musculoskeletal health, was associated with social isolation and loneliness in older adults during the COVID-19 pandemic: findings from the Hertfordshire Cohort Study
SO AGING CLINICAL AND EXPERIMENTAL RESEARCH
LA English
DT Article
DE Social isolation; Loneliness; Self-efficacy; Ageing; COVID-19 pandemic; Musculoskeletal conditions
ID risk-factors; depressive symptoms; mortality; individuals; performance
AB Background Social isolation and loneliness are prevalent among older adults. This study investigated factors influencing worsening social isolation and loneliness in community-dwelling older adults during the COVID-19 pandemic, focusing on musculoskeletal conditions, falls, and fractures. Methods We studied 153 participants from the Hertfordshire Cohort Study. Baseline assessments (2019-20) included osteoporosis, clinical osteoarthritis, fractures after age 45 years, falls in previous year, and lifestyle factors. Self-efficacy was assessed using a shortened General Self-Efficacy Scale. Social isolation was assessed using the 6-item Lubben Social Network Scale. Follow-up (2020-21) assessments included social isolation and loneliness using the 6-item De Jong-Gierveld scale for emotional, social, and overall loneliness. Results Baseline median age was 83.1 years. A history of smoking predicted worsening social isolation ($p = 0.046$). Being married ($p = 0.026$) and higher self-efficacy scores ($p = 0.03$) predicted reduced social isolation at follow-up. Greater alcohol consumption was associated with higher overall loneliness ($p = 0.026$). Being married was related to a 36% (95% CI: 3%, 58%) reduction in emotional loneliness ($p = 0.037$). No musculoskeletal condition was associated with social isolation or loneliness. However, we observed a 22% (14%, 30%; $p < 0.001$) reduction in emotional loneliness and a 12% (4%, 20%; $p = 0.003$) reduction in overall loneliness per unit increase in self-efficacy score. Conclusions No musculoskeletal condition was associated with increased social isolation or loneliness, but longitudinal studies in larger samples are required. Greater self-efficacy was associated with reduced social isolation and reduced loneliness. Interventions promoting self-efficacy in older adults may reduce isolation and loneliness in this age group.

DT Review
DE exosome; extracellular vesicle; bone homeostasis; osteoporosis; osteoarthritis
ID mesenchymal stem-cells; macrophage-derived exosm; extracellular vesicles; osteogenic differentiation; osteoblastic differentiation; osteoarthritis; osteoporosis; cartilage; expression; osteoclastogenesis
AB Bone homeostasis encompasses two interrelated aspects: bone remodeling and cartilage metabolism. Disruption of bone homeostasis can lead to the development of metabolic bone diseases such as osteoporosis and osteoarthritis. The maintenance of bone homeostasis is a complex process that does not solely rely on the functions of the bone tissue itself. In fact, bone tissue is not an isolated entity; it is closely connected to other tissues in the body via exosomes. Within this interconnectivity, exosomes derived from both bone and non-bone cells interfere with each other, forming a complex regulatory network. Therefore, with cell origin as the guiding principle, we have delineated the bone regulatory network of exosomes, elaborated on the specific roles and regulatory mechanisms of exosomes derived from common cell types (cells within the skeletal microenvironment, stem cells from extra-osseous tissues, vascular-derived cells, muscle-derived cells, and neurogenic cells) in bone formation, bone resorption, and cartilage metabolism. We have also discussed the challenges faced in the field of exosome research related to bone homeostasis, unveiled the critical role of exosomes in maintaining bone homeostasis, and proposed that exosomes could serve as highly valuable therapeutic targets for metabolic bone diseases.

DT Review
DE BMAL1; bone development; bone diseases; bone mineralization; bone remodeling; chronotherapy; circadian rhythm; melatonin
ID mesenchymal stem-cells; sympathetic-nervous-system; clock gene-expression; mineral density; osteoblast differentiation; parathyroid-hormone; constant light; melatonin production; peripheral clocks; diurnal-variation
AB Physiological processes within the human body are regulated in approximately 24-h cycles known as circadian rhythms, serving to adapt to environmental changes. Bone rhythms play pivotal roles in bone development, metabolism, mineralization, and remodeling processes. Bone rhythms exhibit cell specificity, and different cells in bone display various expressions of clock genes. Multiple environmental factors, including light, feeding, exercise, and temperature, affect bone diurnal rhythms through the sympathetic nervous system and various hormones. Disruptions in bone diurnal rhythms contribute to the onset of skeletal disorders such as osteoporosis, osteoarthritis and skeletal hypoplasia. Conversely, these bone diseases can be effectively treated when aimed at the circadian clock in bone cells, including the rhythmic expressions of clock genes and drug targets. In this review, we describe the unique circadian rhythms in physiological activities of various bone cells. Then we summarize the factors synchronizing the diurnal

rhythms of bone with the underlying mechanisms. Based on the review, we aim to build an overall understanding of the diurnal rhythms in bone and summarize the new preventive and therapeutic strategies for bone disorders. Bone diurnal rhythms exhibit cell specificity, and different cells in bone display various expressions of clock genes. Multiple environmental factors, including light, feeding, exercise, and temperature, affect bone rhythms through the sympathetic nervous system and various hormones. Disruptions in circadian rhythms contribute to the onset of skeletal disorders such as osteoporosis, osteoarthritis and skeletal hypoplasia. Conversely, these bone diseases can be effectively treated when aimed at the circadian rhythms.image

TI The glucocorticoid receptor in skeletal health and disease: insights from targeted knockout mice
SO JOURNAL OF ENDOCRINOLOGY
LA English
DT Review
DE glucocorticoid receptor; glucocorticoids; knockout mice; skeletal disease; skeletal development; bone loss; fracture; arthritis
ID 11-beta-hydroxysteroid dehydrogenase type-1; suppress bone-formation; osteoblast differentiation; transgenic disruption; mature osteoblasts; binding; arthritis; therapy; mechanisms; expression
AB Glucocorticoids are steroid hormones, secreted by the adrenals to regulate a range of metabolic, immunologic, and homeostatic functions. Due to their potent anti-inflammatory effects, synthetic glucocorticoids are widely used to treat inflammatory disorders. However, their use especially at high doses and over the long-term is associated with several unwanted side effects that compromises their intended use (e.g. glucocorticoid-induced osteoporosis and/or diabetes, myopathy, and skin atrophy). Both endogenous and synthetic glucocorticoids exert their effects through the glucocorticoid receptor, a transcription factor present in nearly all nucleated cells. Glucocorticoid receptor knockout mouse models have proved to be valuable tools in understanding how glucocorticoids contribute to skeletal health and disease. These models, described in this review, have helped to establish that the effects of glucocorticoids on the skeleton are multifaceted, cell specific and concentration dependent. Intriguingly, while endogenous glucocorticoids are essential for bone formation, high-dose exogenous glucocorticoids may induce bone loss. Additionally, the actions of endogenous glucocorticoids vary greatly depending on the disease microenvironment. For example, endogenous glucocorticoids have predominately beneficial anti-inflammatory effects in rheumatoid arthritis, but detrimental actions in osteoarthritis by driving cartilage loss and abnormal bone formation. Studies in tissue-specific knockout models provide important insights that will aid the development of new glucocorticoid therapeutics that can specifically target certain cell types to minimise unwanted effects from current glucocorticoid therapy.

DT Review
DE Musculoskeletal disorders; Tissue engineering; Regenerative medicine; Bone; Muscle
ID mesenchymal stem-cells; growth-factors; satellite cells; in-vitro; scaffold; differentiation; proliferation; promotes; osteoarthritis; stimulation
AB The musculoskeletal system, which is vital for movement, support, and protection, can be impaired by disorders such as osteoporosis, osteoarthritis, and muscular dystrophy. This review focuses on the advances in tissue engineering and regenerative medicine, specifically aimed at alleviating these disorders. It explores the roles of cell therapy, particularly Mesenchymal Stem Cells (MSCs) and Adipose-Derived Stem Cells (ADSCs), biomaterials, and biomolecules/external stimulations in fostering bone and muscle regeneration. The current research underscores the potential of MSCs and ADSCs despite the persistent challenges of cell scarcity, inconsistent outcomes, and safety concerns. Moreover, integrating exogenous materials such as scaffolds and external stimuli like electrical stimulation and growth factors shows promise in enhancing musculoskeletal regeneration. This review emphasizes the need for comprehensive studies and adopting innovative techniques together to refine and advance these multi-therapeutic strategies, ultimately benefiting patients with musculoskeletal disorders.

TI Traditional Chinese Rehabilitation Exercise (TCRE) for Myofascial Pain: Current Evidence and Further Challenges
SO JOURNAL OF PAIN RESEARCH
LA English
DT Article
DE traditional Chinese rehabilitation exercise; pain; myofascial chain; rehabilitation
ID quality-of-life; low-back-pain; knee osteoarthritis; primary osteoporosis; wuqinxi exercise; trigger points; tai chi; qigong; covid-19; stroke
AB Myofascial as a holistic structure emphasizes a holistic approach to intervention and treatment of fascial-related disorders such as neck pain (NP), low back pain (LBP), and knee pain. There are currently adverse effects of medication for diseases related to myofascial. Traditional Chinese rehabilitation exercise (TCRE) is a practical approach to traditional Chinese medicine and is a valuable option for intervening in myofascial-related pain. This article found some research evidence for Baduanjin, Wuqinxi, and Yijinjing in clinical studies of myofascial chain-related

pain. The article summarizes the current evidence and finds that TCRE can enhance limb movement function through breathing and slow movements, increase joint movement and flexibility, and reduce joint pathology and stress-induced pain. As for future directions, focus on TCRE in improving the health of older adults and treating longCOVID syndrome, and integrate robotic and TCRE training to frame safe and effective exercise models. Relevant studies have already been registered in the Clinical Trials Registry, and some clinical study protocols have been published. TCRE can be an alternative nonpharmacological rehabilitation therapy to alleviate chronic rheumatic pain symptoms and augment public health management.

TI Femoral Component Design Is Associated With the Risk of Periprosthetic Femur Fracture After Cementless THA in Patients 65 Years or Older
SO CLINICAL ORTHOPAEDICS AND RELATED RESEARCH
LA English
DT Article

ID total hip-arthroplasty; collar; stems
AB Background Periprosthetic femur fracture is a known complication after THA. The associated risk of cementless femoral component design for periprosthetic femur fracture in a registry population of patients older than 65 years has yet to be clearly identified. Questions/purposes(1) Is femoral stem geometry associated with the risk of periprosthetic femur fracture after cementless THA? (2) Is the presence or absence of a collar on cementless femoral implant designs associated with the risk of periprosthetic femur fracture after THA? Methods We analyzed American Joint Replacement Registry data from 2012 to March 2020. Unique to this registry is the high use of cementless femoral stems in patients 65 years and older. We identified 266,040 primary cementless THAs during the study period in patients with a diagnosis of osteoarthritis and surgeries linked to supplemental Centers for Medicare and Medicaid data where available. Patient demographics, procedure dates, and reoperation for periprosthetic femur fracture with revision or open reduction and internal fixation were recorded. The main analysis was performed comparing the Kheir and Chen classification: 42% (112,231 of 266,040) were single-wedge, 22% (57,758 of 266,040) were double-wedge, and 24% (62,983 of 266,040) were gradual taper/metadiaphyseal-filling cementless femoral components, which yielded a total of 232,972 primary cementless THAs. An additional analysis compared cementless stems with collars (20% [47,376 of 232,972]) with those with collarless designs (80% [185,596 of 232,972]). A Cox proportional hazard regression analysis with the competing risk of death was used to evaluate the association of design and fracture risk while adjusting for potential confounders. Results After controlling for the potentially confounding variables of age, sex, geographic region, osteoporosis or osteopenia diagnosis, hospital volume, and the competing risk of death, we found that compared with gradual taper/metadiaphyseal-filling stems, single-wedge designs were associated with a greater risk of periprosthetic femur fracture (HR 2.9 [95% confidence interval (CI) 2.2 to 3.9]; p < 0. 001). Compared with gradual taper/metadiaphyseal-filling stems, double-wedge designs showed an increased risk of periprosthetic femur fracture (HR 3.0 [95% CI 2.2 to 4.0]; p < 0. 001). Collarless stems showed an increased risk of periprosthetic fracture compared with collared stems (HR 7.8 [95% CI 4.1 to 15]; p < 0. 001). Conclusion If cementless femoral fixation is used for THA in patients 65 years or older, surgeons should consider using gradual taper/metadiaphyseal-filling and collared stem designs because they are associated with a lower risk of periprosthetic femur fracture. Future investigations should compare gradual taper/metadiaphyseal-filling and collared cementless designs with cemented fixation in this population.

TI Exposure to per- and polyfluoroalkyl substances and bone health: a systematic review and meta-analysis
SO INTERNATIONAL JOURNAL OF ENVIRONMENTAL HEALTH RESEARCH
LA English
DT Review
DE Per- and polyfluoroalkyl substances; bone mineral density; bone mineral content; fracture; osteoporosis
ID perfluorooctane sulfonate; perfluoroalkyl substances; mineral density; us population; association; nhanes; osteoarthritis
AB Perfluoroalkyl substances (PFAS) as a large group of synthetic compounds widely contaminated the environment and lead to health problems. However, the correlation between PFAS exposure, bone health parameters and osteoporosis

remains controversial. Therefore, we conducted a systematic review and meta-analysis of published literature to evaluate the effects of PFAS on human bone health. All observational studies were collected up to 2 December 2023. A total of 2096 articles were retrieved. Of these, 21 articles investigated the association between PFAS exposure and human bone health. However, only 10 studies were included in the final meta-analysis. Doubling of serum perfluorooctanoic acid (PFOA) (beta = -0.11, 95% confidence interval (CI): -0.18, -0.05) and perfluorooctane sulfonic acid (PFOS) (beta = -0.06, 95% CI: -0.11, -0.01) levels showed significant negative correlations with total body less head bone mineral density (TBLH-BMD). Subgrouping showed that only perfluorohexane sulfonate (PFHxS) (odds ratio [OR] = 1.37, 95% CI: 1.12, 1.68) was correlated with osteoporosis.

TI Prediction of the Molecular Mechanism of Corni Fructus-Epimedii Folium-Rehmanniae Radix Praeparata in the Treatment of Postmenopausal Osteoporosis based on Network Pharmacology and Molecular Docking
SO CURRENT COMPUTER-AIDED DRUG DESIGN
LA English
DT Article
DE Corni fructus; epimedii folium; rehmanniae radix praeparata; data mining; network pharmacology; postmenopausal osteoporosis
ID growth-factor receptor; osteoclast differentiation; thyroid-hormone; bone-formation; big data; akt1; transactivation; osteoarthritis; osteogenesis; association
AB Introduction: In this study, core drugs of clinical postmenopausal osteoporosis were retrieved using data mining, the drug molecular action target was predicted through network pharmacology, the key nodes of interaction were identified by combining postmenopausal osteoporosis-related targets, and the pharmacological mechanism of Traditional Chinese Medicine (TCM) against postmenopausal osteoporosis and other action mechanisms was explored.Methods: TCMISS V2.5 was used to collect TCM prescriptions of postmenopausal osteoporosis from databases, including Zhiwang, Wanfang, PubMed, etc., for selecting the highest confidence drugs. TCMSP and SwissTargetPrediction databases were selected to screen the main active ingredients of the highest confidence drugs and their targets. Relevant targets for postmenopausal osteoporosis were retrieved from GeneCards and GEO databases, PPI network diagrams construction and selection of core nodes in the network, GO and KEGG enrichment analysis, and molecular docking validation.Results: Correlation analysis identified core drug pairs as 'Corni

Fructus-Epimedii Folium-Rehmanniae Radix Praeparata' (SZY-YYH-SDH). After TCMSP co-screening and de-weighting, 36 major active ingredients and 305 potential targets were selected. PPI network graph was built from the 153 disease targets and 24 TCM disease intersection targets obtained. GO, KEGG enrichment results showed that the intersectional targets were enriched in the PI3K-Akt signalling pathway, etc. The target organs were mainly distributed in the thyroid, liver, CD33+_Myeloid, etc. Molecular docking results showed that the core active ingredients of the 'SZY-YYH-SDH' were able to bind to the pair core nodes and PTEN and EGFR.Conclusion: The results showed that 'SZY-YYH-SDH' can provide the basis for clinical application and treat postmenopausal osteoporosis through multi-component, multi-pathway, and multi-target effects.

TI The role of bDMARDs in the prevention and treatment of inflammatory-related comorbidities in Psoriatic Arthritis
SO EXPERT OPINION ON BIOLOGICAL THERAPY
LA English
DT Review
DE Psoriatic arthritis; bDMARDs; comorbidities; obesity; metabolic syndrome; depression; osteoporosis; NASH
ID platelet-rich plasma; position statement; knee arthroplasty; total hip; society; osteoarthritis; management; recommendations; rheumatology; replacement
AB IntroductionPsoriatic arthritis (PsA) is an immune-inflammatory disease that affects both joints and entheses, and with diverse extra-articular manifestations (psoriasis, inflammatory bowel disease (IBD), and uveitis). A wide range of comorbid conditions, including cardiovascular diseases, obesity, metabolic syndrome (MetS), nonalcoholic fatty liver disease (NAFLD), mental health disorders (depression/anxiety), and osteoporosis are highly prevalent in course of PsA.Biological DMARDs (bDMARD), including TNF-inhibitors (TNFi), Interleukin (IL-17i) and IL-23i represent the cornerstone of the management of active disease. The use of these therapies obviously requires considering comorbidities presence, safety aspects and contraindications.IntroductionPsoriatic arthritis (PsA) is an immune-inflammatory disease that affects both joints and entheses, and with diverse extra-articular manifestations (psoriasis, inflammatory bowel disease (IBD), and uveitis). A wide range of comorbid conditions, including cardiovascular diseases, obesity, metabolic syndrome (MetS), nonalcoholic fatty liver disease (NAFLD), mental health disorders (depression/anxiety), and osteoporosis are highly prevalent in course of PsA.Biological DMARDs (bDMARD), including TNF-inhibitors

(TNFi), Interleukin (IL-17i) and IL-23i represent the cornerstone of the management of active disease. The use of these therapies obviously requires considering comorbidities presence, safety aspects and contraindications.Areas coveredThe aim of this review is to describe the inflammatory mechanisms behind PsA comorbidities, and the role of bDMARDs in the prevention and treatment of these conditions in course of PsA.Expert opinionTailoring therapeutic strategies to the individual characteristics of each PsA patient can be an effective approach to manage comorbidities, maximizing the efficacy of bDMARDs, and reducing the incidence of AEs. Identifying targets within disease pathways can guide research into therapeutics that address both PsA and comorbidities simultaneously, but more studies are advocated for clarifying the potential prevention and management of bDMARDs used for PsA.

TI Mechanism exploration of Osteoking in the treatment of lumbar disc herniation based on network pharmacology and molecular docking
SO JOURNAL OF ORTHOPAEDIC SURGERY AND RESEARCH
LA English
DT Article
DE Osteoking; Lumbar disc herniation; Network pharmacology; Molecular docking
ID human intervertebral disc; nucleus pulposus; tnf-alpha; cells; expression; injection
AB ObjectiveLumbar disc herniation (LDH) is a common spinal surgical disease. Low back and leg pain caused by LDH is the main factor leading to functional disability, which has caused a serious burden to patients and society. Osteoking can delay the progression of osteoporosis and osteoarthritis, and even has a significant effect on the prevention of deep vein thrombosis after fracture surgery. In recent years, it has been gradually used in the treatment of LDH and has received significant results. However, the underlying mechanism remains unclear. The aim of this study was to predict the mechanism of Osteoking in the treatment of LDH through network pharmacology and verify it by molecular docking method.MethodsThe TCMSP database was used to collect the relevant active components and targets of Osteoking, while the GeneCards, OMIM and DisGeNET databases were utilized to collect the relevant disease targets of LDH. The Venny 2.1.0 software was employed to obtain the intersecting gene targets of Osteoking and LDH. PPI network construction and core target selection were performed using Cytoscape 3.9.0 software. The Metascape database was used for GO and KEGG enrichment analysis of the relevant targets. Finally, molecular docking was conducted using AutoDock software.ResultsThe study identified 116 potential targets and 26 core targets for the treatment of LDH with Osteoking. Pathways in cancer, Alzheimer's disease, microRNAs in cancer and the IL-17 signalling pathway were among the main involved signalling pathways. Molecular docking results demonstrated that the key targets AKT1, IL-6, ALB, TNF and IL-1 beta exhibited relatively stable binding activities with the main active components of Osteoking.ConclusionsOsteoking can alleviate the symptoms of lumbar disc herniation through the modulation of multiple targets and signalling pathways.

TI Knowledge, Attitudes, and Practices of Patients with Knee Osteoarthritis Regarding Osteoporosis and Its Prevention: A Cross-Sectional Study in China
SO INTERNATIONAL JOURNAL OF GENERAL MEDICINE
LA English
DT Article
DE osteoarthritis of the knee; osteoporosis; disease prevention; surveys and questionnaires; health knowledge; attitudes; practice
ID management; diagnosis; fractures; women; hip
AB Background: Older age and female sex are risk factors for osteoarthritis and

osteoporosis (OP). This study evaluated the knowledge, attitudes, and practices of patients with knee osteoarthritis (KOA) in China regarding OP and its prevention. This cross-sectional, questionnaire-based study enrolled patients with KOA at four grade-A tertiary hospitals in Shandong Province between 1st September and 20th November 2022. Methods: The administered questionnaire contained 55 items across four dimensions (demographic information, knowledge, attitude, and practice). Logistic regression analyses were performed to identify factors associated with an overall questionnaire score >= 70% of the maximum possible score. SPSS 26.0 was used for the analyses; P<0.05 was considered significant. Results: The analysis included 434 participants (261 females). The median knowledge, attitude, and practice scores were 7 (interquartile range: 5-10) (possible range, 0-17 points), 44 (interquartile range: 42-49) (possible range, 11-55 points), and 43 (interquartile range: 38- 47) (possible range, 13-65 points), respectively. Multivariable logistic regression indicated that female sex (odds ratio [OR], 2.421; 95% confidence interval [95% CI] 1.558-3.762; P<0.001), age 56-65 years-old (OR, 4.222; 95% CI, 1.763-10.109; P=0.001 vs <= 55 years-old), age >65 years-old (OR, 4.358; 95% CI, 1.863-10.195; P=0.001 vs <= 55 years-old), middle/high/technical secondary school education (OR, 1.853; 95% CI, 1.002-3.428; P=0.049 vs primary school or below), and having KOA for 4-5 years (OR, 2.682; 95% CI, 1.412-5.094; P=0.003 vs <= 3 years) were independently associated with a high KAP score. Conclusion: There is room for improvement in the knowledge and practices of patients with osteoarthritis in China regarding OP. The findings of this study may facilitate the design and implementation of education programs to increase awareness about OP prevention among patients with KOA.

TI Effect of Bone Marrow Stromal Cells Derived miR-26b on Chondrocytes of Osteoporosis Rats
SO ANNALS OF CLINICAL AND LABORATORY SCIENCE
LA English
DT Article
DE mir-26b; sirt2; osteoporosis
ID mesenchymal stem-cells; osteogenic differentiation; microrna expression; management; prevention; endocrine; diagnosis; sirtuins
AB Objective. Osteoporosis is a common bone disease. miR-26b regulates OA-induced osteogenesis and induces osteoporosis. miR-26b is elevated in bone marrow stromal cells (BMSCs) during bone formation; however, we haven't fully revealed whether it is directly involved in this process, which was the aim of this study. Methods. An oophorectomized rat model of osteoporosis was used. BMSCs were detected by electron microscopy of exosomes, and mir-26b levels were detected by RT-PCR. The correlation between mir-26b and sirt2 was detected by bioinformatics and luciferase activity analysis. Bone microstructure and cartilage moisture content were also measured. The proliferation ability of mir-26b and sirt2 on chondrocytes was detected by cell viability test and flow cytometry. Results. Western blotting further proved that the surface markers of isolated granular exosomes were positive for CD63 and CD81. Further analysis showed that exosomes' diameters ranged from 50 to 150 nm. Mir-26b is elevated in BMSC, and its mimics can promote proliferation. Luciferase showed that mir-26b targets sirt2 and the effect of elevated mir-26b on chondrocytes was completely reversed by silencing sirt2. The proliferation ability of C28/12 chondrocytes in Mir MICs group was lower than other two groups, while that in Mir inhibition group had stronger proliferation ability than in the Mir NC group. mir-26b was highly expressed in BMSC, indicating that mir-26b comes from secretion of BMSC. Conclusion. Mir-26 is highly expressed in OP. mir-26b can therefore target sirt2 to promote proliferation and inhibit apoptosis of OP chondrocytes. It may offer a possibility of a treatment of OP in the future.

TI Protective Effects of Phellodendron Species on Bone Health: A Novel Perspective on Their Potentials in Treating Osteoporosis and Osteoarthritis
SO CHINESE JOURNAL OF INTEGRATIVE MEDICINE
LA English
DT Review
DE Phellodendron species; bone health; osteoporosis; osteoarthritis; review
ID metabolism; berberine; palmatine; mice
AB Phellodendron (PN) species, traditionally used in Chinese medicine for centuries, hold promise as a potential treatment for osteoporosis (OP) and osteoarthritis (OA) due to their bioactive compounds. The bioactive compounds, including berberine and palmatine, exhibit anti-inflammatory, antioxidant, and bone-protective properties, contributing to their potential therapeutic benefits in promoting bone health and preventing bone loss. However, challenges such as the need for standardized preparation and dosing, limited clinical studies, and potential interactions with other medications hinder their clinical use. Nonetheless, the rich history of PN species in Chinese medicine provides a promising foundation for future investigation into their potential as alternative treatments for OP and OA. Further research is needed to fully understand the underlying mechanisms of action and explore the clinical implications of PN for bone health.

DT Review
DE PET; Metabolic imaging; Quantitative imaging; Musculoskeletal
ID early-stage osteoarthritis; regional bone metabolism; rheumatoid-arthritis; fluoride pet; joint infection; lumbar spine; f-18-fluoride; pet/mri; knee; localization
AB Musculoskeletal (MSK) disorders are associated with large impacts on patient's pain and quality of life. Conventional morphological imaging of tissue structure is limited in its ability to detect pain generators, early MSK disease, and rapidly assess treatment efficacy. Positron emission tomography (PET), which offers unique capabilities to evaluate molecular and metabolic processes, can provide novel information about early pathophysiologic changes that occur before structural or

even microstructural changes can be detected. This sensitivity not only makes it a powerful tool for detection and characterization of disease, but also a tool able to rapidly assess the efficacy of therapies. These benefits have garnered more attention to PET imaging of MSK disorders in recent years. In this narrative review, we discuss several applications of multimodal PET imaging in non-oncologic MSK diseases including arthritis, osteoporosis, and sources of pain and inflammation. We also describe technical considerations and recent advancements in technology and radiotracers as well as areas of emerging interest for future applications of multimodal PET imaging of MSK conditions. Overall, we present evidence that the incorporation of PET through multimodal imaging offers an exciting addition to the field of MSK radiology and will likely prove valuable in the transition to an era of precision medicine.

TI Temporomandibular Joint Discectomy in Patients With Disc Displacement: Assessment of Osteoarthritis at 10-and 30-Year Follow-Up
SO JOURNAL OF ORAL REHABILITATION
LA English
DT Article
DE DC-TMD; discectomy; follow-up; osteoarthritis; radiography; temporomandibular joint
ID long-term evaluation; chronic closed lock; internal derangement; surgical-treatment; diagnostic-criteria; clicking
AB Background: Few >= 10-year follow-up studies of temporomandibular joint (TMJ) discectomy without replacement in patients with disc displacement (DD) analyse the relationship between the surgery and osteoarthritis (OA) exist. Objectives: To radiologically evaluate bony joint changes and OA development 10 and 30 years after TMJ discectomy as well as 30-year clinical outcome. Methods: Twenty-two discectomy patients at the University of Oslo, Norway, with records confirming initial TMJ diagnosis and attendance of 10-year radiological follow-up were evaluated and eligible for 30-year follow-up. Primary variables: discectomy

and CT-/CBCT-diagnosed OA at follow-ups. Secondary variables: perioperative TMJ diagnoses and remodelling at follow-up. Unoperated TMJs (Unop-TMJs) in unilaterally operated patients were controls. Statistical association and correlation analyses were performed for the 10-year follow-up (significance level $p < 0.05$). Results: Twenty-two patients attended the 10-year follow-up (mean follow-up 11 years) with 27 operated TMJs (Op-TMJs) and 17 Unop-TMJs. OA perioperatively was associated with DD without reduction ($p = 0.001$) and additional disc abnormalities ($p = 0.016$). Although statistically non-significant, the number of TMJs with OA had increased at 10-year follow-up ($p = 0.114$, Op-TMJs: 14 to 20 joints; Unop-TMJs: 2 to 5 joints). Remodelling was correlated with discectomy ($p = 0.003$) and to OA ($p = 0.006$). Nine patients attended the 30-year follow-up (mean follow-up 32 years, 11 Op-TMJs). All TMJs with OA at 30-year follow-up had OA at 10-year follow-up. Mean maximal interincisal opening was 39 mm. No DC-TMD-diagnosed arthralgia was found. Conclusion: Osteoarthritis developed similarly between Op- and Unop-TMJs. Only remodelling, not OA, was correlated to the surgery. The clinical results were still favourable at final follow-up.

TI Flap-Based Lower Extremity Reconstruction in the Elderly-Is It Safe and Does Age Impact Ambulation?
SO MICROSURGERY
LA English
DT Article
DE ambulation; free flap; local flap; lower extremity; outcomes
ID quality-of-life; microsurgical reconstruction; lower leg; amputation; thickness; mortality; defects; older
AB Introduction: Lower extremity (LE) reconstruction in the elderly population presents a multifaceted challenge, primarily due to age-related degenerative changes, comorbidities, and functional decline. Elderly individuals often encounter conditions such as osteoarthritis, osteoporosis, and cardiovascular and peripheral artery disease (PAD), which can severely compromise the structural integrity and function of the lower limbs. As such, we aim to assess postoperative complications and functional recovery following LE reconstruction in elderly patients. Methods: Patients >= 18 years who underwent post-traumatic LE reconstruction with flap reconstruction at a Level 1 trauma center between 2007 and 2022 were included. Patient demographics, flap/wound characteristics, complications, and ambulation for the elderly (>= 60 years old) and the control (< 60 years old) cohorts were recorded. The primary outcome was final ambulation status, modeled with logistic regression. Secondary outcomes included postoperative complications. Results: The mean ages of the control (n = 374) and elderly (n = 49) groups were 37.4 +/- 12.6 and 65.8 +/- 5.1 years, respectively. Elderly patients more frequently required amputation after flap surgery (p = 0.002). There was no significant difference between the two cohorts in preoperative ambulation status (p = 0.053). Postoperatively, 22.4% of elderly patients were independently ambulatory at final follow-up, compared to 49.5% of patients < 60. Of the elderly, 14.3% could ambulate with an assistance device (cane, walker, etc.), compared to 26.5% in the control group. A wheelchair was required for 46.9% of elderly patients, significantly higher than the 22.7% of those < 60 years of age (p < 0.001). Multivariate regression confirmed an association between older age and nonambulatory final status (p = 0.033). Conclusion: LE reconstruction can likely be performed safely in patients 60 years of age or older. However, older age is independently associated with significantly worse postoperative ambulation. Preoperative assessment, including gait and muscle strength, and early initiation of postoperative rehabilitation can potentially improve ambulation in elderly individuals undergoing LE reconstruction.

TI The current insights of mitochondrial hormesis in the occurrence and treatment of bone and cartilage degeneration
SO BIOLOGICAL RESEARCH
LA English
DT Review
DE Mitochondrial hormesis; Senescence; Osteoarthritis; Intervertebral disc degeneration; Osteoporosis
ID intervertebral disc; oxidative stress; osteoarthritis implications; cellular senescence; kinase-activity; life-span; mitohormesis; ros; promotes; exercise
AB It is widely acknowledged that aging, mitochondrial dysfunction, and cellular phenotypic abnormalities are intricately associated with the degeneration of bone and cartilage. Consequently, gaining a comprehensive understanding of the regulatory patterns governing mitochondrial function and its underlying mechanisms holds promise for mitigating the progression of osteoarthritis, intervertebral disc degeneration, and osteoporosis. Mitochondrial hormesis, referred to as mitohormesis, represents a cellular adaptive stress response mechanism wherein mitochondria restore homeostasis and augment resistance capabilities against stimuli by generating reactive oxygen species (ROS), orchestrating unfolded protein reactions (UPRmt), inducing mitochondrial-derived peptides (MDP), instigating mitochondrial dynamic changes, and activating mitophagy, all prompted by low doses of stressors. The varying nature, intensity, and duration of stimulus sources elicit divergent degrees of mitochondrial stress responses, subsequently activating one or more signaling pathways to initiate mitohormesis. This review focuses specifically on the effector molecules and regulatory networks associated with mitohormesis, while also scrutinizing extant mechanisms of mitochondrial dysfunction contributing to bone and cartilage degeneration through oxidative stress damage. Additionally, it underscores the potential of mechanical stimulation, intermittent dietary restrictions, hypoxic preconditioning, and low-dose toxic compounds to trigger mitohormesis, thereby alleviating bone and cartilage degeneration.

TI Long-term results after medial patellotibial ligament reconstruction for the treatment of patellofemoral instability
SO ARCHIVES OF ORTHOPAEDIC AND TRAUMA SURGERY
LA English
DT Article
DE MPTL reconstruction; Patellar dislocation; Patellar instability; Knee reconstructive surgery
ID primary patellar dislocation; mpfl reconstruction; clinical-outcm; follow-up; children
AB Purpose To evaluate long-term clinical outcomes and redislocation rate after medial patellotibial ligament reconstruction. Materials and methods A total of 26 knees with mean age 26.3 +/- 10.6 years (25 patients, 7 males and 18 females) treated for patellar instability (at least two objective dislocations) with medialization of the patellar tendon medial third were evaluated with an intermediate clinical follow-up (FU) at a mean of 6.5 +/- 2.1 years and with a final telephone interview follow-up at mean of 15.6 +/- 2.5 years (11.4-20.1). Western Ontario and MacMaster Universities Osteoarthritis Index (WOMAC), Kujala, Visual Analog Scale (VAS) for pain and Tegner activity scores were used. Information about further redislocation and knee surgery was also collected. Results All the clinical scores had a significant improvement compared to preoperative status (WOMAC pre-op 55.9 +/- 27.2 vs. WOMAC final FU 80.8 +/- 22.2; KUJALA pre-op 41.0 +/- 24.0 vs. KUJALA final FU 77.2 +/- 24.1; VAS pre-op 6.0 +/- 3.1 vs. VAS final FU 3.44 +/- 2.35; TEGNER pre-op 2.1 +/- 2.0 vs. TEGNER final FU 3.6 +/- 1.8; $p < 0.001$), and the outcomes remained stable at the final follow-up compared to the intermediate follow-up ($p > 0.05$). A total of 4 knees had at least one redislocation at the final follow-up, while 3 knees underwent total knee replacement surgery. The redislocation-survival rate at 5 years is 92%, meanwhile is 84% at 10 and 15 years. Conclusions MPTL reconstruction produced good clinical results and a survival rate of 84% at a mean of 16 years follow-up and could be considered as associated procedure in case of patellofemoral instability. Level of evidenceLevel IV.

TI Prevention of obstetric anal sphincter injuries with perineal support and lateral episiotomy: A historical cohort study
SO ACTA OBSTETRICIA ET GYNECOLOGICA SCANDINAVICA
LA English
DT Article
DE delivery mode; episiotomy; fetal position; OASIS; parity
ID operative vaginal delivery; fetal head position; risk-factors; mediolateral episiotomy; routine; reduce; tears
AB IntroductionThere are many risk factors for obstetric anal sphincter injury (OASIS) and the interaction between these risk factors is complex and understudied. The many observational studies that have shown a reduction of OASIS rates after implementation of perineal support have short follow-up time. We aimed to study the effect of integration of active perineal support and lateral episiotomy on OASIS rates over a 15-year period and to study interactions between risk factors known before delivery.Material and methodsWe performed a historical cohort study over the periods 1999-2006 and 2007-2021 at Stavanger University Hospital, Norway. The main outcome was OASIS rates. Women without a previous cesarean section and a live singleton fetus in cephalic presentation at term were eligible. The department implemented in 2007 the Finnish concept of active perineal protection, which includes support of perineum, control of fetal expulsion, good communication with the mother and observation of perineal stretching. The practice of mediolateral episiotomy was replaced with lateral episiotomy when indicated. We analyzed the OASIS rates in groups with and without episiotomy stratified for delivery mode, fetal position at delivery and for parity, and adjusted for possible confounders (maternal age, gestational age, oxytocin augmentation and epidural analgesia).ResultsWe observed a long-lasting reduction in OASIS rates from 4.9% to 1.9% and an increase in episiotomy rates from 14.4% to 21.8%. Lateral episiotomy was associated with lower OASIS rates in nulliparous women with instrumental vaginal deliveries and occiput anterior (OA) position; 3.4% versus 10.1% (OR 0.31; 95% CI: 0.24-0.40) and 6.1 versus 13.9% (OR 0.40; 95% CI: 0.19-0.82) in women with occiput posterior (OP) position. Lateral episiotomy was also associated with lower OASIS rates in nulliparous women with spontaneous deliveries and OA position; 2.1% versus 3.2% (OR 0.62; 95% CI: 0.49-0.80). The possible confounders had little confounding effects on the risk of OASIS in groups with and without episiotomy.ConclusionsWe observed a long-lasting reduction in OASIS rates after implementation of preventive procedures. Lateral episiotomy was associated with lower OASIS rates in nulliparous women with an instrumental delivery. Special attention should be paid to deliveries with persistent OP position. Obstetric anal sphincter injuries rates during the study period differentiated in accordance with the Robson ten-group classification system. Blue line represents Robson ten-group classification system group 1, green line group 2, brown line

TI Multiple applications of metal-organic frameworks (MOFs) in the treatment of orthopedic diseases
SO FRONTIERS IN BIOENGINEERING AND BIOTECHNOLOGY
LA English
DT Review
DE metal-organic frameworks; MOFs; tumor; osteoporosis; osteoarthritis
ID delivery; osteoarthritis; nanoparticles; hydroxyapatite; osteosarcoma; hif-2-alpha; osteogenesis; prevalence; stability; chemistry
AB Pharmacologic treatment of orthopedic diseases is a common challenge for clinical orthopedic surgeons, and as an important step in the stepwise treatment of orthopedic diseases, it is often difficult to achieve satisfactory results with existing pharmacologic treatments. Therefore, it is increasingly important to find new ways to effectively improve the treatment pattern of orthopedic diseases as well as to enhance the therapeutic efficacy. It has been found that metal-organic frameworks (MOFs) possess the advantages of high specific surface area, high porosity, chemical stability, tunability of structure and biocompatibility. Therefore, MOFs are expected to improve the conventional traditional treatment modality for bone diseases. This manuscript reviewed the applications of MOFs in the treatment of common clinical bone diseases and look forward to its future development.

TI Sphingolipid-Induced Bone Regulation and Its Emerging Role in Dysfunction Due to Disease and Infection

SO INTERNATIONAL JOURNAL OF MOLECULAR SCIENCES
LA English
DT Review
DE sphingolipids; bone; infection; disease; osteoporosis
ID mesenchymal stem-cells; necrosis-factor-alpha; staphylococcus-aureus infections; sphingosine 1-phosphate levels; collagen-induced arthritis; neutral sphingomyelinase 2; novo ceramide synthesis; acid sphingomyelinase; pseudomonas-aeruginosa; induced apoptosis
AB The human skeleton is a metabolically active system that is constantly regenerating via the tightly regulated and highly coordinated processes of bone resorption and formation. Emerging evidence reveals fascinating new insights into the role of sphingolipids, including sphingomyelin, sphingosine, ceramide, and sphingosine-1-phosphate, in bone homeostasis. Sphingolipids are a major class of highly bioactive lipids able to activate distinct protein targets including, lipases, phosphatases, and kinases, thereby conferring distinct cellular functions beyond energy metabolism. Lipids are known to contribute to the progression of chronic inflammation, and notably, an increase in bone marrow adiposity parallel to elevated bone loss is observed in most pathological bone conditions, including aging, rheumatoid arthritis, osteoarthritis, and osteomyelitis. Of the numerous classes of lipids that form, sphingolipids are considered among the most deleterious. This review highlights the important primary role of sphingolipids in bone homeostasis and how dysregulation of these bioactive metabolites appears central to many chronic bone-related diseases. Further, their contribution to the invasion, virulence, and colonization of both viral and bacterial host cell infections is also discussed. Many unmet clinical needs remain, and data to date suggest the future use of sphingolipid-targeted therapy to regulate bone dysfunction due to a variety of diseases or infection are highly promising. However, deciphering the biochemical and molecular mechanisms of this diverse and extremely complex sphingolipidome, both in terms of bone health and disease, is considered the next frontier in the field.

DT Article
DE bone microarchitecture; fracture risk assessment; osteoporosis; osteoarthritis; high-resolution peripheral quantitative computed tomography
ID in-vivo assessment; trabecular bone score; fracture risk-assessment; 2nd-generation hr-pqct; distal radius; cortical bone; subject motion; mass measurements; mineral density; microarchitecture
AB Twenty years have passed since the introduction of high-resolution peripheral quantitative computed tomography (HR-pQCT) to assess human bone microarchitecture. During that time, the technique has emerged as an important research tool used by clinicians and scientists to learn about the pathophysiology of bone adaptation in the context of osteoporosis and many other bone-affected conditions. Its rich three-dimensional data is well suited for precise longitudinal monitoring of bone microarchitecture and associated patient-specific estimated bone strength. However, uptake of HR-pQCT as a clinical diagnostic tool has been limited, in part due to challenges such as availability, regulatory approvals, and demonstrated cost effectiveness. New research suggests fracture risk assessment using HR-pQCT is comparable with current standards based on traditional bone densitometry, but its contribution to clinical care is best suited to two areas: (1) leveraging microarchitectural information to assist in treatment decisions for the large subset of patients who lie in the so-called gray zone by current fracture risk assessment, and (2) longitudinal monitoring that establishes highly refined trajectories of bone adaptation and can inform decisions to initiate treatment, monitor treatment effects, and inform cessation.

TI Prediction of Multiple Degenerative Diseases Based on DNA Methylation in a Co-Physiology Mechanisms Perspective
SO INTERNATIONAL JOURNAL OF MOLECULAR SCIENCES
LA English
DT Article
DE DNA methylation; epigenetic clock; degenerative diseases; deep learning
ID biomarker
AB Degenerative diseases oftentimes occur within the continuous process of aging, and the corresponding clinical manifestations may be neurodegeneration, neoplastic diseases, or various human complex diseases. DNA methylation provides the opportunity to explore aging and degenerative diseases as epigenetic traits. It

has already been applied to age prediction and disease diagnosis. It has been shown that various degenerative diseases share co-physiology mechanisms with each other, clues of which may be gained from studying the aging process. Here, we endeavor to predict the risk of degenerative diseases in an aging-relevant comorbid mechanism perspective. Firstly, an epigenetic clock method was implemented based on a multi-scale convolutional neural network, and a Shapley feature attribution analysis was applied to discover the aging-related CpG sites. Then, these sites were further screened to a smaller subset composed of 196 sites by using biomics analysis according to their biological functions and mechanisms. Finally, we constructed a multilayer perceptron (MLP)-based degenerative disease risk prediction model, Mlp-DDR, which was well trained and tested to accurately classify nine degenerative diseases. Recent studies also suggest that DNA methylation plays a significant role in conditions like osteoporosis and osteoarthritis, broadening the potential applications of our model. This approach significantly advances the ability to understand degenerative diseases and represents a substantial shift from traditional diagnostic methods. Despite the promising results, limitations regarding model complexity and dataset diversity suggest directions for future research, including the development of tissue-specific epigenetic clocks and the inclusion of a wider range of diseases.

DT Review
DE Bone tissue engineering; Nanotechnology; 3D printing technology; Bioactive scaffold
ID calcium-phosphate ceramics; silver nanoparticles; tricalcium phosphate; in-vitro; scaffolds; proliferation; biomaterials; regeneration; fabrication; design
AB With the graying of the world's population, the morbidity of age-related chronic degenerative bone diseases, such as osteoporosis and osteoarthritis, is increasing yearly, leading to an increased risk of bone defects, while current treatment methods face many problems, such as shortage of grafts and an incomplete repair. Therefore, bone tissue engineering offers an alternative solution for regenerating and repairing bone tissues by constructing bioactive scaffolds with porous structures that provide mechanical support to damaged bone tissue while promoting angiogenesis and cell adhesion, proliferation, and activity. 3D printing technology has become the primary scaffold manufacturing method due to its ability to precisely control the internal pore structure and complex spatial shape of bone scaffolds. In contrast, the fast development of nanotechnology has provided more possibilities for the internal structure and biological function of scaffolds. This review focuses on the application of 3D printing technology in bone tissue engineering and nanotechnology in the field of bone tissue regeneration and repair, and explores the prospects for the integration of the two technologies.

TI Holistic vibrational spectromics assessment of human cartilage for osteoarthritis diagnosis
SO BIOMEDICAL OPTICS EXPRESS
LA English
DT Article
ID articular-cartilage; raman-spectroscopy; nir spectroscopy; disease

AB Osteoarthritis (OA) is the most common degenerative joint disease, presented as wearing down of articular cartilage and resulting in pain and limited mobility for 1 in 10 adults in the UK [Osteoarthr. Cartil. 28(6), 792 (2020)]. There is an unmet need for patient friendly paradigms for clinical assessment that do not use ionizing radiation (CT), exogenous contrast enhancing dyes (MRI), and biopsy. Hence, techniques that use non-destructive, near- and shortwave infrared light (NIR, SWIR) may be ideal for providing label-free, deep tissue interrogation. This study demonstrates multimodal "spectromics", low-level abstraction data fusion of non-destructive NIR Raman scattering spectroscopy and NIR-SWIR absorption spectroscopy, providing an enhanced, interpretable "fingerprint" for diagnosis of OA in human cartilage. This is proposed as method level innovation applicable to both arthro- or endoscopic (minimally invasive) or potential exoscopic (non-invasive) optical approaches. Samples were excised from femoral heads post hip arthroplasty from OA patients (n =13) and age-matched control (osteoporosis) patients (n = 14). Under multivariate statistical analysis and supervised machine learning, tissue was classified to high precision: 100% segregation of tissue classes (using 10 principal components), and a classification accuracy of 95% (control) and 80% (OA), using the combined vibrational data. There was a marked performance improvement (5 to 6-fold for multivariate analysis) using the spectromics fingerprint compared to results obtained from solely Raman or NIR-SWIR data. Furthermore, clinically relevant tissue components were identified through discriminatory spectral features - spectromics biomarkers - allowing interpretable feedback from the enhanced fingerprint. In summary, spectromics provides comprehensive information for early OA detection and disease stratification, imperative for effective intervention in treating the degenerative onset disease for an aging demographic. This novel and elegant approach for data fusion is compatible with various NIR-SWIR optical devices that will allow deep non-destructive penetration.

TI Relationship between DXA measured systemic bone mineral density and subchondral bone cysts in postmenopausal female patients with knee osteoarthritis: a cross-sectional study
SO BMC MUSCULOSKELETAL DISORDERS
LA English
DT Article
DE Bone mineral density; Osteoarthritis; Subchondral bone cyst; Vitamin D
ID synovial-fluid macrophages; vitamin-d; resorption; hip; 1,25-dihydroxyvitamin-d3; association; progression; prevalence; expression; cartilage
AB BackgroundIndividuals with high systemic bone mineral density (BMD) may have an increased risk of incident knee osteoarthritis (OA). Besides that, radiographic osteophytes are strongly associated with BMD. Because of these

reasons, the aim of the study was to investigate the possible association between radiological subchondral bone cyst (SBC) grade and systemic BMD and vitamin D status in the postmenopausal female patients with knee OA in a crosss-sectional study.MethodsThis study included of 48 osteoporosis treatment-free postmenopausal patients diagnosed with symptomatic medial compartment knee OA. BMD analysis was performed using dual-energy X-ray absorptiometry (DXA) and serum vitamin D levels were measured after recording patients' findings. Each knee was scanned using computed tomography (CT), and categorical SBC scores were graded for the medial and lateral tibiofemoral (TF) and patellofemoral (PF) compartments and further calculated as compartmental total, total TF and grand total of both TF compartments. SBC scores were analysed with correlation analysis.ResultsThe patient population was characterized by radiographic joint space narrowing, obesity and low vitamin D status. Median medial total and grand total TF SBC scores were significantly different between the patient groups according to the Kellgren-Lawrence (KL) radiographic grading ($p = 0.006$ and $p = 0.007$, respectively). There were no correlations between femoral BMD values and SBC scores. However, positive correlations were detected significantly between L1 - 4 DXA values and TF SBC scores, but not with PF SBC scores ($p = 0.005$ for the correlation between L1 - 4 BMD and medial compartments total TF SBC score, $p = 0.021$ for the correlation between L1 - 4 BMD and grand total TF SBC score). No significant correlations were found with Vitamin D levels.ConclusionsDevelopment of TF OA high-grade SBCs may be linked to systemic bone mass as represented by trabecular bone-rich lumbar vertebrae. The relationship might point to the importance of bone stiffness as an acting factor in knee OA possibly with mechanical energy transfer to the joint.

TI Exploring the pharmacological mechanism of Xianlingubao against diabetic osteoporosis based on network pharmacology and molecular docking: An observational study
SO MEDICINE

LA English
DT Article
DE diabetes mellitus; drug repurposing; osteoporosis; pharmacology; traditional Chinese medicine
ID bone-mineral density; differentiation; adipocytes; quercetin; osteoblast; pathways; resource
AB Xianlinggubao formula (XLGB), is a traditional Chinese compound Medicine that has been extensively used in osteoarthritis and aseptic osteonecrosis, but its curative effect on diabetic osteoporosis (DOP) and its pharmacological mechanisms remains not clear. The aim of the present study was to investigate the possible mechanism of drug repurposing of XLGB in DOP therapy. We acquired XLGB active compounds from the traditional Chinese medicine systems pharmacology and traditional Chinese medicines integrated databases and discovered potential targets for these compounds by conducting target fishing using the traditional Chinese medicine systems pharmacology and Swiss Target Prediction databases. Gene Cards and Online Mendelian Inheritance in Man (R) database were used to identify the DOP targets. Overlapping related targets between XLGB and DOP was selected to build a protein-protein interaction network. Next, the Metascape database was utilized to enrich the Gene Ontology and Kyoto Encyclopedia of Genes and Genomes pathways. In addition, Auto-Dock Vina software was used to verify drug and target binding. In total, 48 hub targets were obtained as the candidate targets responsible for DOP therapy. The anti-DOP effect mediated by XLGB was primarily centralized on the advanced glycation end products (AGEs)-receptor for AGE signaling pathway in diabetic complications and osteoclast differentiation. In addition, AKT serine/threonine kinase 1, tumor necrosis factor, Interleukin-6, vascular endothelial growth factor A and peroxisome proliferator activated receptor gamma, which were considered as potential therapeutic targets. Furthermore, molecular docking results confirm the credibility of the predicted therapeutic targets. This study elucidates that XLGB may through regulating AGEs formation and osteoclast differentiation as well as angiogenesis and adipogenesis against DOP. And this study provides new promising points to find the exact regulatory mechanisms of XLGB mediated anti-DOP effect.

TI Biological Activities of Deer Antler-Derived Peptides on Human Chondrocyte and Bone Metabolism
SO PHARMACEUTICALS
LA English
DT Article
DE chondrocyte; deer antler; Guilu erxian jiao; kyotorphin; osteoblast; osteoclast differentiation
ID expression; rankl; kyotorphin; cells; calcium; culture; brain
AB Orally administered "tortoiseshell and deer antler gelatin" is a common traditional medicine for patients with osteoporosis or osteoarthritis. From the pepsin-digested gelatin, we previously isolated and identified the osteoblast-stimulating pentapeptide, TSKYR. Its trypsin digestion products include the dipeptide YR, enhancing calcium ion uptake, and tripeptide TSK, resulting in remarkable 30- and 50-fold increases in mineralized nodule area and density in human osteoblast cells. These peptides were chemically synthesized in this study. The composition of deer antler preparations comprises not only proteins and peptides but also a significant quantity of metal ion salts. By analyzing osteoblast growth in the presence of peptide YR and various metal ions, we observed a

synergistic effect of calcium and strontium on the effects of YR. Those peptides could also stimulate the growth of C2C12 skeletal muscle cells and human chondrocytes, increasing collagen and glycosaminoglycan content in a three-dimensional environment. The maintenance of bone homeostasis relies on a balance between osteoclasts and osteoblasts. Deer antler peptides were observed to inhibit osteoclast differentiation, as evidenced by ROS generation, tartrate-resistant acid phosphatase (TRACP) activity assays, and gene expression in RAW264.7 cells. In summary, our findings provide a deep understanding of the efficacy of this folk medicine.

TI Imaging Review of Different Subchondral Insufficiency Fractures
SO JOURNAL OF COMPUTER ASSISTED TOMOGRAPHY
LA English
DT Article
DE subchondral fractures; joint arthropathy; osteoarthritis
ID bone-marrow edema; dual-energy ct; osteochondritis-dissecans; transient osteoporosis; mri
AB Subchondral fractures are a common cause of joint pain that may ultimately lead to articular collapse and the need for arthroplasty. This type of fracture has been reported at multiple joints throughout the body. While clinical and radiographic resolution can be achieved, progressive bone collapse can occur and lead to a variety of complications. Understanding the pertinent imaging findings can aid in the early evaluation of subchondral fractures and in the prevention of their associated complications.

DT Review
DE microRNA; osteoarthritis; OA; osteoarthrosis; miRNA; pathophysiology
ID affects chondrocyte proliferation; risk-factors; knee osteoarthritis; articular-cartilage; double-blind; tnf-alpha; expression; targets; pathogenesis; diagnosis
AB Worldwide, osteoarthritis (OA) is the most common cause of joint pain in older people. Many factors contribute to osteoarthritis' development and progression, including secondary osteoarthritis' underlying causes. It is important to note that osteoarthritis affects all four tissues: cartilage, bone, joint capsule, and articular apparatus. An increasingly prominent area of research in osteoarthritis regulation is microRNAs (miRNAs), a small, single-stranded RNA molecule that controls gene expression in eukaryotes. We aimed to assess and summarize current knowledge about the mechanisms of the action of miRNAs and their clinical significance. Osteoarthritis (OA) is affected by the interaction between miRNAs and inflammatory processes, as well as cartilage metabolism. MiRNAs also influence cartilage cell apoptosis, contributing to the degradation of the cartilage in OA. Studies have shown that miRNAs may have both an inhibitory and promoting effect on osteoporosis progression through their influence on molecular mechanisms. By identifying these regulators, targeted treatments for osteoarthritis may be developed. In addition, microRNA may also serve as a biomarker for osteoarthritis. By using these biomarkers, the disease could be detected faster, and early intervention can be instituted to prevent mobility loss and slow deterioration.

TI RANKL blockade for erosive hand osteoarthritis: a randomized placebo-controlled phase 2a trial
SO NATURE MEDICINE
LA English
DT Article
ID interphalangeal finger joints; radiographic progression; postmenopausal women; denosumab treatment; general-population; pain; prevalence; index

AB Erosive hand osteoarthritis (OA) is a prevalent and disabling disease with limited treatment options. Here we present the results of a monocentric, placebo-controlled, double-blind, randomized phase 2a clinical trial with denosumab, a receptor activator of nuclear factor-kappa B ligand inhibitor, evaluating the effects on structure modification in erosive hand OA. Patients were randomized to 48 weeks treatment with denosumab 60 mg every 3 months (n = 51, 41 females) or placebo (n = 49, 37 females). The primary (radiographic) endpoint was the change in the total Ghent University Scoring System (GUSS) at week 24, where positive changes correspond to remodeling and negative changes to erosive progression. Secondary endpoints were the change in the GUSS at week 48 and the number of new erosive joints at week 48 by the anatomical phase scoring system. Baseline mean GUSS (standard deviation) of target joints was 155.9 (69.3) in the denosumab group and 158.7 (46.8) in the placebo group. The primary endpoint was met with an estimated difference between groups of 8.9 (95% confidence interval (CI) 1.0 to 16.9; P = 0.024) at week 24. This effect was confirmed at week 48 (baseline adjusted GUSS (standard error of the mean) denosumab and placebo were 163.5 (2.9) and 149.2 (3.9), respectively; with an estimated difference between groups of 14.3 (95% CI 4.6 to 24.0; P = 0.003)). At patient level, more new erosive joints were developed in the placebo group compared with denosumab at week 48 (odds ratio 0.24 (95% CI 0.08 to 0.72); P = 0.009). More adverse events occurred in the placebo group (125 events in 44 patients (90%)) compared with the denosumab group (97 events in 41 patients (80%)). These results demonstrate that denosumab has structure modifying effects in erosive hand OA by inducing remodeling and preventing new erosive joints. EU Clinical Trials Register identifier 2015-003223-53. Denosumab, a receptor activator of nuclear factor-kappa B ligand inhibitor, previously developed for osteoporosis, was shown to be effective at inducing structural modification in patients with erosive hand osteoarthritis after 24 weeks.

DT Review
DE Immune system; Immunosenescence; Aging; Anti-aging; Age-related diseases
ID alzheimers association guidelines; immune-system; t-cells; posttraumatic osteoarthritis; neuropathologic assessment; streptococcus-pneumoniae; parkinsons-disease; therapeutic target; national institute; senescent cells
AB The immune system is a major regulatory system of the body, that is composed of immune cells, immune organs, and related signaling factors. As an organism ages, observable age-related changes in the function of the immune system accumulate in a process described as 'immune aging. Research has shown that the impact of aging on immunity is detrimental, with various dysregulated responses that affect the function of immune cells at the cellular level. For example, increased aging has been shown to result in the abnormal chemotaxis of neutrophils and decreased phagocytosis of macrophages. Age-related diminished functionality of immune cell types has direct effects on host fitness, leading to poorer responses to vaccination, more inflammation and tissue damage, as well as autoimmune disorders and the inability to control infections. Similarly, age impacts the function of the immune system at the organ level, resulting in decreased hematopoietic function in the bone marrow, a gradual deficiency of catalase in the thymus, and thymic atrophy, resulting in reduced production of related immune cells such as B cells and T cells, further increasing the risk of autoimmune disorders in the elderly. As the immune function of the body weakens, aging cells and inflammatory factors cannot be cleared, resulting in a cycle of increased inflammation that accumulates over time. Cumulatively, the consequences of immune aging increase the likelihood of developing age-related diseases, such as Alzheimer's disease, atherosclerosis, and osteoporosis, among others. Therefore, targeting the age-related changes that occur within cells of the immune system might be an effective anti-aging strategy. In this article, we summarize the relevant literature on immune aging research, focusing on its impact on aging, in hopes of providing new directions for anti-aging research.

DT Article
DE Knee osteoarthritis; Global burden of disease; Joinpoint analysis; Cross-national inequality
ID patient-reported outcm; body-mass index; total hip-arthroplasty; income inequality; global burden; obesity; health; disease; risk; osteoporosis
AB ObjectiveTo describe the disease burden of knee osteoarthritis (KOA) globally, regionally, and in 204 countries by age, sex, and sociodemographic index (SDI) from 1990 to 2019, and to explore cross-national inequalities across SDI.MethodsThe Global Burden of Disease (GBD) 2019 database collected data on KOA worldwide from 1990 to 2019, including prevalence, incidence, years lived with disability (YLDs). The average annual percentage change (AAPC) was used to measure temporal trends. In addition, the inequality slope index and the health concentration index were calculated to quantify the unequal distribution of the burden of KOA across 204 countries worldwide.ResultsIn 2019, the global age-standardized prevalence rate increased by 7.5% compared with 1990, and the age-standardized incidence rate increased by about 6.2%; The age-standardized YLDs rate increased by about 7.8%. In addition to the Republic of Korea and the United States of America, the disease burden of KOA has increased year by year in other countries around the world. The incidence of KOA was highest at ages 50-59, while the prevalence and rates of YLDs were highest at ages 75-84. The burden of KOA was higher in women than in men. Cross-country inequality suggests that the inequality in the burden of KOA between high SDI and low SDI countries becomes greater, and that countries with high SDI bear a disproportionately high burden.ConclusionThe global KOA burden has risen steadily between 1990 and 2019, and cross-national inequality gaps remain large. Targeted measures must therefore be taken to address this inequality and the increasing global KOA disease burden.

TI Chondrocyte-targeted exosome-mediated delivery of Nrf2 alleviates cartilaginous endplate degeneration by modulating mitochondrial fission
SO JOURNAL OF NANOBIOTECHNOLOGY
LA English
DT Article
DE Cartilaginous endplate degeneration; Engineered exosome; Nrf2; Drp1; Mitochondrial fission; Apoptosis
ID inflammation

AB Background Cartilaginous endplate (CEP) degeneration, which is an important contributor to intervertebral disc degeneration (IVDD), is characterized by chondrocyte death. Accumulating evidence has revealed that dynamin-related protein 1 (Drp1)-mediated mitochondrial fission and dysfunction lead to apoptosis during CEP degeneration and IVDD. Exosomes are promising agents for the treatment of many diseases, including osteoporosis, osteosarcoma, osteoarthritis and IVDD. Despite their major success in drug delivery, the full potential of exosomes remains untapped.Materials and methods In vitro and in vivo models of CEP degeneration were established by using lipopolysaccharide (LPS). We designed genetically engineered exosomes (CAP-Nrf2-Exos) expressing chondrocyte-affinity peptide (CAP) on the surface and carrying the antioxidant transcription factor nuclear factor E2-related factor 2 (Nrf2). The affinity between CAP-Nrf2-Exos and CEP was evaluated by in vitro internalization assays and in vivo imaging assays. qRT-PCR, Western blotting and immunofluorescence assays were performed to examine the expression level of Nrf2 and the subcellular localization of Nrf2 and Drp1. Mitochondrial function was measured by the JC-1 probe and MitoSOX Red. Mitochondrial morphology was visualized by MitoTracker staining and transmission electron microscopy (TEM). After subendplate injection of the engineered exosomes, the degree of CEP degeneration and IVDD was validated radiologically and histologically.Results We found that the cargo delivery efficiency of exosomes after cargo packaging was increased by surface modification. CAP-Nrf2-Exos facilitated chondrocyte-targeted delivery of Nrf2 and activated the endogenous antioxidant defence system in CEP cells. The engineered exosomes inhibited Drp1 S616 phosphorylation and mitochondrial translocation, thereby preventing mitochondrial fragmentation and dysfunction. LPS-induced CEP cell apoptosis was alleviated by CAP-Nrf2-Exo treatment. In a rat model of CEP degeneration, the engineered exosomes successfully attenuated CEP degeneration and IVDD and exhibited better repair capacity than natural exosomes.Conclusion Collectively, our findings showed that exosome-mediated chondrocyte-targeted delivery of Nrf2 was an effective strategy for treating CEP degeneration.

TI The osteocytic actions of glucocorticoids on bone mass, mechanical properties, or perilacunar remodeling outcomes are not rescued by PTH(1-34)
SO FRONTIERS IN ENDOCRINOLOGY
LA English

DT Article
DE osteocyte; glucocorticoids; prednisolone; parathyroid hormone (PTH); PTH (1-34); perilacunar canalicular remodeling; osteocytic osteolysis; bone
ID parathyroid-hormone; induced osteoporosis; gene-expression; articular-cartilage; subchondral bone; femoral-head; mice; pth; gender; osteoarthritis
AB Glucocorticoids (GC) and parathyroid hormone (PTH) are widely used therapeutic endocrine hormones where their effects on bone and joint arise from actions on multiple skeletal cell types. In osteocytes, GC and PTH exert opposing effects on perilacunar canalicular remodeling (PLR). Suppressed PLR can impair bone quality and joint homeostasis, including in GC-induced osteonecrosis. However, combined effects of GC and PTH on PLR are unknown. Given the untapped potential to target osteocytes to improve skeletal health, this study sought to test the feasibility of therapeutically mitigating PLR suppression. Focusing on subchondral bone and joint homeostasis, we hypothesize that PTH(1-34), a PLR agonist, could rescue GC-suppressed PLR. The skeletal effects of GC and PTH(1-34), alone or combined, were examined in male and female mice by micro-computed tomography, mechanical testing, histology, and gene expression analysis. For each outcome, females were more responsive to GC and PTH(1-34) than males. GC and PTH(1-34) exerted regional differences, with GC increasing trabecular bone volume but reducing cortical bone thickness, stiffness, and ultimate force. Despite PTH(1-34)'s anabolic effects on trabecular bone, it did not rescue GC's catabolic effects on cortical bone. Likewise, cartilage integrity and subchondral bone apoptosis, tartrate-resistant acid phosphatase (TRAP) activity, and osteocyte lacunocanalicular networks showed no evidence that PTH(1-34) could offset GC-dependent effects. Rather, GC and PTH(1-34) each increased cortical bone gene expression implicated in bone resorption by osteoclasts and osteocytes, including Acp5, Mmp13, Atp6v0d2, Ctsk, differences maintained when GC and PTH(1-34) were combined. Since PTH(1-34) is insufficient to rescue GC's effects on young female mouse bone, future studies are needed to determine if osteocyte PLR suppression, due to GC, aging, or other factors, can be offset by a PLR agonist.

TI Microbiome dysbiosis by antibiotics protects cartilage degradation in OAOP mice
SO JOURNAL OF ENDOCRINOLOGY
LA English
DT Article
DE gut microbiota; osteoarthritis; osteoporosis; LPS
ID nf-kappa-b; gut microbiota; bone mass; osteoarthritis; osteoporosis; model; severity; fracture; density; impact
AB The role of this study was to evaluate the impact of gut microbiota depletion on the progression of osteoarthritis (OA) and osteoporosis (OP). We conducted an experimental mouse model of OA and OP over an 8-week period. The model involved destabilization of the medial meniscus and bilateral ovariectomy (OVX). To deplete the gut microbiota, we administered a course of antibiotics for 8 weeks. The severity of OA was assessed through micro-CT scanning, X-rays, and immunohistochemical staining. Microbiome analysis was performed using PCR of 16S DNA on fecal samples, and the levels of serum lipopolysaccharide, interleukin 6, tumor necrosis factor-alpha (TNF-alpha), osteocalcin, and estrogen were measured using enzyme-linked immunosorbent assay. We found that in comparison to the OVX+OA group, the OVX+OA+ABT group exhibited increased bone mineral density ($P < 0.0001$), bone volume fraction ($P = 0.0051$), and trabecular number ($P = 0.0023$) in the metaphyseal bone. Additionally, cartilage injury and levels of matrix metalloproteinase 13 were reduced in the OVX+OA+ABT group compared to the OVX+OA group. Moreover, the OVX+OA+ABT group demonstrated decreased relative abundance of Bacteroidetes, serum lipopolysaccharide ($P = 0.0005$), TNF-alpha ($P < 0.0001$), CTX-1 ($P = 0.0002$), and increased expression of bone formation markers. These findings were further supported by correlation network analyses. Depletion of gut microbiota was shown to protect against bone loss and cartilage degradation by modulating the composition of the gut microbiota in osteoporosis and osteoarthritis.

TI Ten-Year Incidence of Sarcopenia in a Population-Based Cohort: Results from the Research on Osteoarthritis/Osteoporosis Against Disability Study
SO JOURNAL OF THE AMERICAN MEDICAL DIRECTORS ASSOCIATION
LA English
DT Article
DE Sarcopenia; incidence; cohort study; AWGS 2019
ID asian working group; bioelectrical-impedance analysis; dwelling elderly subjects; skeletal-muscle mass; older men; prevalence; consensus; adults; epidemiology; association
AB Objectives: To investigate the prevalence and incidence rates of sarcopenia in Japanese communitydwelling people according to the criteria of the Asian Working Group for Sarcopenia 2019 recommendations, using a large-scale

population-based cohort over a 10-year follow-up period. Design: Prospective cohort study. Setting and Participants: This study was conducted using data from the Research on Osteoarthritis/ Osteoporosis Against Disability (ROAD) study. In total, 1551 participants (521 men and 1030 women; mean age, 65.8 years) from the second ROAD survey (2008-2-10) were included in this study. Methods: The participants from the second survey were followed-up at 4, 7, and 10 years. Skeletal muscle mass, handgrip strength, and walking speed were assessed. Sarcopenia was defined according to the Asian Working Group for Sarcopenia 2019 criteria. The incidence of sarcopenia was calculated using the person-year method. Cox proportional hazard model was used to assess risk factors for incident sarcopenia. Results: The prevalence of sarcopenia was 8.1% (8.8% in men and 7.7% in women), and the prevalence of severe sarcopenia was 2.9% (2.7% in men and 3.1% in women). The incidence rates of sarcopenia were 17.8 per 1000 and 14.5 per 1000 person-years in men and women, respectively. Additionally, the incidence rates of severe sarcopenia were 6.4 per 1000 and 4.2 per 1000 person-years in men and women, respectively. The significant risk factors for the incidence of sarcopenia were age [+1 year; hazard ratio risk factors for the incidence of severe sarcopenia were age (+1 year; HR, 1.18; 95% CI, 1.14-1.22) and body Conclusions and Implications: The prevalence and incidence rates of sarcopenia in Japan were clarified in (c) 2024 The Author(s). DT Review
DE osteoarthritis; osteoporosis; sarcopenia; cardiovascular diseases; diabetes mellitus; dementia; Parkinson's disease; mental disease
ID knee osteoarthritis; cardiovascular-disease; risk-factors; depressive symptoms; physical function; muscle strength; vitamin-d; inflammation; epidemiology; prevalence
AB Osteoarthritis is the most prevalent age-related degenerative joint disease and a leading cause of pain and disability in aged people. Its etiology is multifaceted, involving factors such as biomechanics, pro-inflammatory mediators, genetics, and metabolism. Beyond its evident impact on joint functionality and the erosion of patients' quality of life, OA exhibits symbiotic relationships with various systemic diseases, giving rise to various complications. This review reveals OA's extensive impact, encompassing osteoporosis, sarcopenia, cardiovascular diseases, diabetes mellitus, neurological disorders, mental health, and even cancer. Shared inflammatory processes, genetic factors, and lifestyle elements link OA to these systemic conditions. Consequently, recognizing these connections and addressing them offers opportunities to enhance patient care and reduce the burden of

associated diseases, emphasizing the need for a holistic approach to managing OA and its complications.

AB Bone metabolism plays a crucial role in maintaining normal bone tissue homeostasis and function. Imbalances between bone formation and resorption can lead to osteoporosis, osteoarthritis, and other bone diseases. The dynamic and complex process of bone remodeling is driven by various factors, including epigenetics. Histone modification, one of the most important and well-studied components of epigenetic regulation, has emerged as a promising area of research in bone metabolism. Different histone proteins and modification sites exert diverse effects on osteogenesis and osteoclastogenesis. In this review, we summarize recent progress in understanding histone modifications in bone metabolism, including specific modification sites and potential regulatory enzymes. Comprehensive knowledge of histone modifications in bone metabolism could reveal new therapeutic targets and treatment strategies for bone diseases. (c) 2024 Published by Elsevier B.V.

TI A clinical application of gait quality patterns in osteoarthritis
SO GAIT & POSTURE
LA English
DT Article
DE Gait Analysis; Smartphone; Primary Health Care; Osteoarthrosis
ID reliability
AB Aim: To investigate whether a smartphone-based gait analysis tool can reliably output gait quality parameters that can be cross-analyzed to establish individual & disease-based changes in gait quality patterns. Methods: A cross-sectional study made up of a 48-patients undergoing disability certification at the "Dr. Jose<acute accent> Castro Villagrana" or the "Dr. David Fragoso Lizalde" Health Centers in Mexico City, Mexico. Their sensorimotor performance was evaluated through an in-house smartphone/IMU based digital tool. Gait was analyzed by means of frequency analysis of the acceleration of the body mass measured at the sternum. A composite gait quality score was determined through principal component analysis based primarily on the explainability and uniformity of gait. Quality independence against demographic variables (age & weight) was tested through

ANCOVA. The association between gait quality and gait parameters was analyzed by using multiple linear regression. Results: A multiple regression model developed with a limited set of gait quality parameters successfully predicted gait smoothness with a 97.05% accuracy with a mean square error of 0.085 between predicted and actual quality scores. The model demonstrates different predictive capacities across disease groups, with Osteoarthrosis + Osteoporosis having the highest R2 at 0.98 ($p < 0.001$) and Coxarthrosis having the lowest explained R2 at 0.79 ($p < 0.001$). Conclusions: The assessment of gait quality, in family medicine, with low-cost digital tools is an area of opportunity yet to be explored. This tool can potentially disrupt the current disability workflow between primary and specialty care to have an objective method of assessing gait within a clinical consult. Individual patient-level benchmarking can give us insights into the patient's disease status, develop practical intervention strategies, and control the cost and quality of medical care by predicting an individualized course of disability or rehabilitation. Further studies are needed to validate digital gait assessments as clinical decision support tools for day-to-day clinical operations. MeSH: Gait Analysis, Smartphone, Primary Health Care, Osteoarthrosis

TI Unlocking the potential of exosomes: a breakthrough in the theranosis of degenerative orthopaedic diseases
SO FRONTIERS IN BIOENGINEERING AND BIOTECHNOLOGY
LA English
DT Review
DE exosomes; osteoarthritis; osteoporosis; intervertebral disc degeneration; treatment
ID mesenchymal stem-cells; suppress cartilage degradation; extracellular vesicles; membrane-vesicles; drug-delivery; disc degeneration; rat model; in-vitro; osteoarthritis; inflammation
AB Degenerative orthopaedic diseases pose a notable worldwide public health issue attributable to the global aging population. Conventional medical approaches, encompassing physical therapy, pharmaceutical interventions, and surgical methods, face obstacles in halting or reversing the degenerative process. In recent times, exosome-based therapy has gained widespread acceptance and popularity as an effective treatment for degenerative orthopaedic diseases. This therapeutic approach holds the potential for "cell-free" tissue regeneration. Exosomes, membranous vesicles resulting from the fusion of intracellular multivesicles with the cell membrane, are released into the extracellular matrix. Addressing challenges such as the rapid elimination of natural exosomes in vivo and the limitation of drug concentration can be effectively achieved through various strategies, including engineering modification, gene overexpression modification, and biomaterial binding. This review provides a concise overview of the source, classification, and preparation methods of exosomes, followed by an in-depth analysis of their functions and potential applications. Furthermore, the review explores various strategies for utilizing exosomes in the treatment of degenerative orthopaedic diseases, encompassing engineering modification, gene overexpression, and biomaterial binding. The primary objective is to provide a fresh viewpoint on the utilization of exosomes in addressing bone degenerative conditions and to support the practical application of exosomes in the theranosis of degenerative orthopaedic diseases.

TI Incidence and Progression of Foot Osteoarthritis in a Longitudinal Cohort: The Johnston County Osteoarthritis Project
SO GERONTOLOGY
LA English
DT Article
DE Foot; Osteoarthritis; Pain; Cohort; Epidemiology
ID knee osteoarthritis; outcome score; association; ankle; population; prevalence; epidemiology; arthritis; gout; pain

AB Introduction: The aim of this study was to examine the incidence and progression of foot osteoarthritis (OA), as well as associated factors, in a community-based cohort. Methods: Baseline (2013-2015) and follow-up (2016-2018) foot radiographs were available for 541 participants (71% women, mean age 69 years; 35% black, 53% with obesity). The LaTrobe Foot Atlas was used to examine osteophytes (OPs, score 0-3) and joint space narrowing (JSN, score 0-3) at 5 joint sites. Incident foot radiographic OA (rOA) was a baseline score < 2 OP and JSN in all 5 joints with >= 2 OP or JSN at follow-up in any of the joints. Progression was a worsening OP or JSN score in a joint with baseline foot rOA. At baseline and follow-up, participants reported the presence/ absence of foot symptoms and completed the Foot and Ankle Outcome Score (FAOS) for each foot. Joint-based logistic regression models with generalized estimating equations were used to examine associations (adjusted odds ratio [aOR], 95% confidence interval [CI]) of foot rOA incidence and progression and with covariates. Results: Among 928 feet without baseline rOA, 4% developed incident foot rOA (2% of those developed symptoms). Among 154 feet with baseline foot rOA, 55% had radiographic progression (16% of those had symptoms). Women and those with higher body mass index (BMI) were more likely to have incident foot rOA (aOR [95% CI] = 4.10 [1.22, 13.8] and 1.60 [1.31, 1.97], respectively); history of gout was associated with incidence or progression of foot rOA (2.75 [1.24, 6.07]). BMI was associated with worse scores on all FAOS subscales (aORs range 1.21-1.40). Conclusion: Progression of foot rOA is common but not necessarily related to worsening symptoms. BMI may be a modifiable risk factor for foot OA. (c) 2024 S. Karger AG, Basel

TI Novel Risk Factors for Cervical Facet Joint Degeneration in the Subaxial Cervical Spine: Correlation with Cervical Sagittal Alignment and Bone Mineral Density
SO WORLD NEUROSURGERY
LA English
DT Article
DE Bone mineral density; Disc degeneration; Modic change; Sagittal alignment; Zygapophyseal joint
ID osteoarthritis; osteoporosis; balance
AB Objective: The impact of cervical sagittal alignment on cervical facet joint degeneration (CFD) and the risk factors for CFD in patients with degenerative cervical myelopathy (DCM) were investigated in the current study. Methods: A total of 250 surgical patients with DCM were recruited. The clinical data and radiographical characteristics, including CFD, cervical sagittal balance parameters, Hounsfield unit (HU) values, disc degeneration (DD), and modic change, were collected. The detailed correlation between these characteristics and CFD was analyzed. Characteristics, including CFD, were compared among the various cervical alignment types and different CFD groups. Finally, the risk factors for CFD were revealed via logistic regression. Results: CFD was prevalent in DCM patients. Age, cervical sagittal vertical axis (cSVA), range of motion, T1 slope, thoracic inlet angle, DD, HU value, and modic change correlated with CFD segmentally and globally (P

< 0.05). The lordosis and sigmoid types had a significantly higher CFD prevalence (P < 0.05). Furthermore, the average CFD threshold for the severe CFD group was 1.625 (area under the curve, 0.958). Additionally, 167 patients with average CFD <1.625 and 83 patients with CFD of >= 1.625 were classified into the mild CFD group and severe CFD group, respectively. Finally, multivariate analysis was performed, and age, cSVA, HU value, modic change, and DD were determined to be independent risk factors for CFD. Conclusions: The load distribution tends to shift to a more shear-like pattern in the sigmoid and kyphosis types and in those with a higher cSVA, thereby promoting CFD. Aging, cervical malalignment, low bone mineral density, DD, and modic change were revealed to result in high risks of CFD.

TI A network pharmacological study to unveil the mechanisms of xianlinggubao capsule in the treatment of osteoarthritis and osteoporosis
SO ARCHIVES OF MEDICAL SCIENCE
LA English
DT Article
DE network pharmacology; traditional Chinese medicine; osteoarthritis; osteoporosis; KEGG
ID estrogen-receptor modulator; bone mass; osteoblast; cells; kinase; endometrium; inhibition; pathway; drugs; trial
AB Introduction: Xianlinggubao (XLGB) capsule is a traditional Chinese medicine, which is approved by the Chinese State Food and Drug Administration (CFDA) for osteoarthritis (OA) and osteoporosis (OP). However, as a capsule with complex ingredients, the molecular mechanisms supporting the therapeutic effects have not been explored. Material and methods: A network pharmacology -based approach was conducted to explore the complex interactome among the targets of the XLGB active compounds. Results: The herbs in the capsule contain 41 compounds with 246 high score targets, which cover four known OA targets (PTGS1, PTGS2, PTGER4 and TNF) and six known OP targets (AR, ESR1, PGR, PTGER2, TNFSF11 and VDR) of FDA -approved drugs or drugs undergoing clinical trials. The protein -protein interaction (PPI) network of the 246 targets had six key modules. Among the six modules, neuroactive ligand-receptor interaction, cAMP signaling pathway and calcium signaling pathway are the key pathways, which are all closely associated with the degeneration of joint cartilage and bone formation and resorption. Conclusions: Neuroactive ligand-receptor interaction, cAMP signaling pathway, and calcium signaling pathway might be the critical pathways upon which the capsule

might act. The present study laid down a foundation to understand the molecular mechanisms of the XLGB capsule and also provided fundamental information for better improvement of the drug with the concept "less herbal materials for achieving equal treatment efficacy".

TI MocapMe: DeepLabCut-Enhanced Neural Network for Enhanced Markerless Stability in Sit-to-Stand Motion Capture
SO SENSORS
LA English
DT Article
DE human movement analysis; motion tracking; neural network; markerless pose estimation; sit-to-stand analysis
ID osteoarthritis; predict
AB This study examined the efficacy of an optimized DeepLabCut (DLC) model in motion capture, with a particular focus on the sit-to-stand (STS) movement, which is crucial for assessing the functional capacity in elderly and postoperative patients. This research uniquely compared the performance of this optimized DLC model, which was trained using 'filtered' estimates from the widely used OpenPose (OP) model, thereby emphasizing computational effectiveness, motion-tracking precision, and enhanced stability in data capture. Utilizing a combination of smartphone-captured videos and specifically curated datasets, our methodological approach included data preparation, keypoint annotation, and extensive model training, with an emphasis on the flow of the optimized model. The findings demonstrate the superiority of the optimized DLC model in various aspects. It exhibited not only higher computational efficiency, with reduced processing times, but also greater precision and consistency in motion tracking thanks to the stability brought about by the meticulous selection of the OP data. This precision is vital for developing accurate biomechanical models for clinical interventions. Moreover, this study revealed that the optimized DLC maintained higher average confidence levels across datasets, indicating more reliable and accurate detection capabilities compared with standalone OP. The clinical relevance of these findings is profound. The optimized DLC model's efficiency and enhanced point estimation stability make it an invaluable tool in rehabilitation monitoring and patient assessments,

potentially streamlining clinical workflows. This study suggests future research directions, including integrating the optimized DLC model with virtual reality environments for enhanced patient engagement and leveraging its improved data quality for predictive analytics in healthcare. Overall, the optimized DLC model emerged as a transformative tool for biomechanical analysis and physical rehabilitation, promising to enhance the quality of patient care and healthcare delivery efficiency.

TI Targeting type H vessels in bone-related diseases
SO JOURNAL OF CELLULAR AND MOLECULAR MEDICINE
LA English
DT Review
DE angiogenesis; osteoarthritis; osteogenesis; osteoporosis; type H vessels
ID attenuates osteoarthritis; angiogenesis; regeneration; osteogenesis; metastasis; subtype
AB Blood vessels are essential for bone development and metabolism. Type H vessels in bone, named after their high expression of CD31 and Endomucin (Emcn), have recently been reported to locate mainly in the metaphysis, exhibit different molecular properties and couple osteogenesis and angiogenesis. A strong correlation between type H vessels and bone metabolism is now well-recognized. The crosstalk between type H vessels and osteoprogenitor cells is also involved in bone metabolism-related diseases such as osteoporosis, osteoarthritis, fracture healing and bone defects. Targeting the type H vessel formation may become a new approach for managing a variety of bone diseases. This review highlighted the roles of type H vessels in bone-related diseases and summarized the research attempts to develop targeted intervention, which will help us gain a better understanding of their potential value in clinical application.

TI Investigate the Therapeutic Effect of Ibandronate Sodium on Knee Osteoarthritis Based on TLRs/MyD88/NF-κB Signaling Pathway in Vitro and in Vivo
SO DISCOVERY MEDICINE
LA English
DT Article
DE ibandronate sodium; knee osteoarthritis; TLRs/MyD88/NF-B-K; articular chondrocyte
ID chondrocytes; resveratrol
AB Background: For decades, bisphosphonates have primarily found application in clinical practice for the treatment and pre-vention of bone metastases associated with malignant tumors and various bone metabolic disorders. However, third-generation bisphosphonates like ibandronate have demonstrated significant utility in addressing conditions like osteoporosis (OA) and other bone metabolism-related ailments. Ibandronate, distinguished by its high effectiveness, low toxicity, and ease of administration, has garnered attention for its potential applications in the treatment of rheumatoid arthritis, OA, and orthopedic concerns. In recent years, the utilization of ibandronate sodium in these contexts has sparked considerable interest. Research has pointed to a possible connection between ibandronate and the Toll-like receptors (TLRs), myeloid differentiation factor 88 (MyD88), and nuclear factor -KB (NF -KB) signaling pathway, particularly in the context of inflammation and immunological regulation. Consequently, this study is designed to investigate the therapeutic impact of ibandronate on in vitro and in vivo models of knee osteoarthritis, while also delving into its influence on the TLRs/MyD88/NF-KB pathway. Method: Various dosages of ibandronate sodium, including low (10 g/kg), medium (20 g/kg), and high (30 g/kg), were administered following the establishment of both in vivo and in vitro models of knee osteoarthritis (KOA). Post-intervention, an in-depth quantitative analysis of bone tissue microstructure was conducted. The morphology of articular cartilage tissue was observed in vivo, and the modified Mankin score was subsequently calculated. In the in vitro setting, cartilage was entirely isolated, and mRNA and total protein were extracted to measure the expression levels of TLR4, MyD88, and NF -KB at both the mRNA and protein levels. Furthermore, the study explored the effects of Interleukin-1 beta (IL-1 beta) on cell proliferation, apoptosis, stromal

decomposition enzyme activity, ossification, and the expression of TLR4, MyD88, and NF -KB. Result: In the results of the in vivo experiments, several noteworthy findings emerged. The knee curvature, gait score, Mankin score, pathological knee joint injury degree, cartilage protein loss, and trabecular separation within the model group exhibited significant elevations compared to both the sham operation group and the blank control group ($p < 0.05$). Conversely, bone density, bone volume fraction, and trabecular thickness in the model group displayed lower values in comparison to the sham operation and blank control groups ($p < 0.05$). Following the administration of ibandronate sodium, there was a progressive improvement in these parameters, with the medium and high-dose groups demonstrating the most favorable outcomes ($p < 0.05$). Additionally, the model group exhibited the highest expression levels of TLR4, MyD88, and NF -KB, while the ibandronate sodium intervention group displayed reduced expression levels of these markers, with the high-dose group registering the most significant changes ($p < 0.05$). Turning to the in vitro experiments, it was observed that the cell proliferation capacity and ossification degree of the IL-1 beta-induced group experienced declines, concomitant with an increase in stromal decomposition enzyme activity and cell apoptosis rate ($p < 0.05$). However, post-intervention with ibandronate sodium, all these indicators gradually returned to normal, with the medium-dose group exhibiting the most notable improvements. The expression levels of TLR4, MyD88, and NF -KB in the IL-1 beta-induced group showed an increase, while the expression levels in the ibandronate sodium intervention group displayed a decrease, particularly in the high-dose group ($p < 0.05$). Conclusions: Ibandronate sodium demonstrates a protective effect on articular chondrocytes and exhibits the potential to decelerate the pathological progression of knee osteoarthritis (KOA) in rats. This mechanism is likely achieved through the inhibition of the TLRs/MyD88/NF-KB signaling pathway.

TI A monoallelic variant in CCN2 causes an autosomal dominant spondyloepimetaphyseal dysplasia with low bone mass
SO BONE RESEARCH
LA English
DT Article
ID tissue-growth-factor; monoclonal-antibody; family proteins; signal peptide; in-vitro; gene; mutations; differentiation; expression; ctgf
AB Cellular communication network factor 2 (CCN2) is a secreted extracellular matrix-associated protein, and its aberrantly increased expression has been implicated in a diversity of diseases involving pathological processes of fibrosis, chronic inflammation, or tissue injury, which has promoted the evaluation of CCN2 as therapeutic targets for multiple disorders. However, human phenotypes associated with CCN2 deficiency have remained enigmatic; variants in CCN2 have not yet been associated with a human phenotype. Here, we collected families diagnosed with spondyloepimetaphyseal dysplasia (SEMD), and screened candidate pathogenic genes for families without known genetic causes using next-generation sequencing. We identified a monoallelic variant in signal peptide of CCN2 (NM_001901.2: c.65 G > C [p.Arg22Pro]) as the cause of SEMD in 14 subjects presenting with different degree of short stature, premature osteoarthritis, and osteoporosis. Affected subjects showed decreased serum CCN2 levels. Cell lines harboring the variant displayed decreased amount of CCN2 proteins in culture medium and an increased intracellular retention, indicating impaired protein secretion. And the variant weakened the stimulation effect of CCN2 on osteogenesis of bone marrow mesenchymal stem cells. Zebrafish ccn2a knockout model and osteoblast lineage-specific Ccn2-deficient mice (Ccn2(fl/fl);Prx1(Cre)) partially recapitulated the phenotypes including low bone mass observed in affected subjects. Pathological mechanism implicated in the skeletal abnormality in Ccn2(fl/fl);Prx1(Cre) mice involved decreased bone formation, increased bone resorption, and abnormal growth plate formation. Collectively, our study indicate that monoallelic variants in CCN2 lead to a human inherited skeletal dysplasia, and highlight the critical role of CCN2 in osteogenesis in human.

TI Microbiome's role in musculoskeletal health through the gut-bone axis insights
SO GUT MICROBES
LA English
DT Review
DE Microbiome; musculoskeletal health; gut-bone axis; musculoskeletal disease; bone health
ID vitamin-d; dietary fiber; calcium; supplementation; osteoclastogenesis; inflammation; association; mechanisms; cells
AB The interplay between the human microbiome and the musculoskeletal system represents a burgeoning field of research with profound implications for understanding and treating musculoskeletal disorders. This review articulates the pivotal role of the microbiome in modulating bone health, highlighting the gut-bone axis as a critical nexus for potential therapeutic intervention. Through a meticulous analysis of recent clinical research, we underscore the microbiome's influence on osteoporosis, sarcopenia, osteoarthritis, and rheumatoid arthritis, delineating both the direct and indirect mechanisms by which microbiota could impact musculoskeletal integrity and function. Our investigation reveals novel insights into the microbiota's contribution to bone density regulation, hormone production, immune modulation, and nutrient absorption, laying the groundwork for innovative microbiome-based strategies in musculoskeletal disease management. Significantly, we identify the challenges hindering the translation of research into clinical practice, including the limitations of current microbial sequencing techniques and the need for standardized methodologies in microbiome studies. Furthermore, we highlight promising directions for future research, particularly in the realm of personalized medicine, where the

microbiome's variability offers unique opportunities for tailored treatment approaches. This review sets a new agenda for leveraging gut microbiota in the diagnosis, prevention, and treatment of musculoskeletal conditions, marking a pivotal step toward integrating microbiome science into clinical musculoskeletal care.

TI Repurposing drugs for the treatment of osteoarthritis
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Review
DE Osteoarthritis; Disease modification; DMOAD; Drug repurposing
ID bone-marrow lesions; vitamin-d supplementation; interleukin-1 receptor antagonist; radiographic knee osteoarthritis; cartilage volume; double-blind; structural progression; zoledronic acid; clinical-trial; pain
AB Objective: Currently, no disease-modifying therapies for osteoarthritis (OA) exist, and attempts to identify novel cellular targets have been challenging. Risk factors for OA include advanced age, obesity, and metabolic syndrome. This creates an attractive opportunity to repurpose existing drugs that are used to treat comorbidities commonly encountered in patients with OA, if those drugs possess OA disease modifying properties. Methods: This narrative review incorporates findings from knee or hand OA randomized clinical trials, posthoc clinical trial analyses, prospective cohort studies, and observational data. Results: Drugs used for the treatment of rheumatoid arthritis (methotrexate; TNFa, IL-1, and IL-6 pathway inhibitors; hydroxychloroquine), atopic/allergic disease (anti-histamines), osteoporosis (bisphosphonates and vitamin D), type 2 diabetes (metformin and GLP-1 agonists), and cardiovascular disease (atorvastatin, fish oil, and beta blockers) were reviewed for their potential benefit in OA. This review outlines the successful attributes of repurposed drugs, the challenges in repurposing drugs, and strategies for future clinical trials to support OA drug repurposing. Potential drug candidates for OA may be identified through the use of existing datasets and via collaborations with researchers in other fields to include OA endpoints in future clinical trials. Conclusion: Given the association of OA with several commonly treated comorbidities, drug repurposing is an appealing approach that could provide a favorable benefit-to-risk ratio for chronic OA treatment. TI The burden of rheumatologic disease in Aboriginal and Torres Strait Islander Australians
SO INTERNAL MEDICINE JOURNAL
LA English
DT Review
DE rheumatology; indigenous health; epidemiology
ID systemic-lupus-erythematosus; low-back-pain; gouty-arthritis; indigenous australians; body-composition; high prevalence; people; care; health; impact
AB The objective of this article is to summarise the current knowledge regarding the prevalence of six rheumatological conditions in indigenous Australians - rheumatoid arthritis (RA), osteoarthritis (OA), osteoporosis (OSP), systemic lupus erythematosus (SLE), gout and musculoskeletal (MSK) pain. Online medical literature databases were searched for 'indigenous', 'Aboriginal' and 'Torres Strait Islander', as well as the names of the six conditions. Other included search terms were 'crystal', 'urate', 'arthritis' and 'arthropathy'. No limitations were placed on publication data or language. Forty-five articles examining the prevalence of the six conditions were identified. Based on the published literature, SLE appears to have a higher prevalence, while RA appears to have a lower prevalence in indigenous Australians compared to the non-indigenous community. MSK pain is prevalent, has a significant impact on indigenous people and is perceived as an important area of need. There is a paucity of data regarding these conditions in indigenous Australians. This may be impacted by the uncertainty of case ascertainment by self-report, differences in disease phenotypes and prevalence between the

metropolitan compared to the rural or remote indigenous population, and difficulty with access to healthcare. Further studies in conjunction with local indigenous communities are needed to accurately determine the burden of rheumatological disease in the indigenous population. This will assist with resource and workforce planning to deliver culturally appropriate interventions. Strategies for future clinical work and research include the development and dissemination of culturally safe rheumatology resources, rheumatology training of Aboriginal Health Workers and wider integration of rheumatology clinics into community-controlled Aboriginal Health Services.

TI The effect of the Hippocampus erectus decoction on improving osteoporosis in zebrafish
SO AQUACULTURE REPORTS
LA English
DT Article
DE Osteoporosis; Zebrafish larvae; Seahorse decoction; Prednisolone
ID seahorse hippocampus; induced inhibition; osteoblast; model; expression; osteogenesis; extracts; taurine; peptide; cells
AB The seahorse is a traditional Chinese herbal medicine that has been utilized for the treatment of conditions such as osteoporosis, nonunion fractures, knee osteoarthritis, and herniated lumbar disks. Zebrafish is an excellent animal model to study the effects of herbal preparations on osteogenesis and bone metabolism, and bone biology is highly similar to that of mammals, so it has been used to develop multiple glucocorticoid-induced osteoporosis (GIOP) models. Our study aimed to explore whether the decoction of Hippocampus erectus (DHe) administered in zebrafish larvae promotes bone health under physiological and osteoporotic conditions. In zebrafish larvae, 25 mu M prednisolone solution was successfully used to induce the zebrafish osteoporosis model, which can significantly inhibit the mineralization area and degree of bone mineralization, reduce the activity of alkaline phosphatase, and increase tartrate-resistant acid phosphatase activity. The results showed that 0.3 g/L DHe had a significant improvement effect on osteoporosis in zebrafish by enhancing the mineralization degree and phosphatase activity of zebrafish, while also promoting the expression of genes associated with bone development. It can be considered a good candidate to develop new drugs against osteoporosis.

TI Additional effects of herbal medicine combined with bisphosphonates for primary osteoporosis: a systematic review and meta-analysis
SO FRONTIERS IN PHARMACOLOGY
LA English
DT Review
DE primary osteoporosis; herbal medicines; bisphosphonates; combination therapy; bone mineral density
ID bone-resorption; in-vitro; differentiation; mechanisms; quality; capsule; osteoarthritis; prevention; diagnosis; luteolin
AB Background: Osteoporosis (OP) is a significant medical issue associated with population aging. Recent research on herbal medicines (HMs) for OP has been increasing, with these therapies sometimes used in conjunction with bisphosphonates (BPs), the standard treatment for OP. We conducted a systematic review and meta-analysis to evaluate the effects of combining HMs with BPs on improving bone mineral density (BMD) in patients with primary OP. Methods: We searched nine databases-PubMed, Embase, Cochrane Library, China National Knowledge Infrastructure Wanfang, KISS, Kmbase, Science On, and Oasis-up to 31 August 2023. We selected randomized controlled trials (RCTs) comparing BMD between HMs plus BPs and BPs alone in primary OP. A meta-analysis with BMD as the primary outcome was performed using RevMan version 5.4. Study quality and evidence certainty were assessed through Cochrane's risk of bias2 and GRADE. Results: Out of 43 RCTs involving 4,470 participants (mean age 65.8 +/- 6.6 years), 35 RCTs with 3,693 participants were included in the meta-analysis. The combination of HMs and BPs was found to be more effective in improving BMD

compared to BPs alone, with improvements of 0.10 g/cm(2) at the lumbar spine (33 RCTs, 95% CI: 0.07-0.12, p < 0.001, I-2 = 93%) and 0.08 g/cm(2) at the femoral neck (20 RCTs, 95% CI: 0.05-0.12, p < 0.001, I-2 = 94%), though this result was associated with high heterogeneity, high risk of bias, and very low certainty of evidence. Conclusion: Our data suggest the possibility that combining HMs with BPs may improve BMD in primary OP more effectively than using BPs alone. However, the results should be interpreted with caution due to the high heterogeneity and low quality of the studies included in the review. Therefore, further well-designed RCTs are needed to confirm these findings.

TI MicroRNA-877-5p promotes osteoblast differentiation by targeting EIF4G2 expression
SO JOURNAL OF ORTHOPAEDIC SURGERY AND RESEARCH
LA English
DT Article
DE miR-877-5p; Osteoblast differentiation
ID mc3t3-e1 cells; translation; phosphorylation; osteoarthritis; proliferation; osteoporosis; initiation; migration; model
AB Stimulating bone formation potentially suggests therapeutics for orthopedic diseases including osteoporosis and osteoarthritis. Osteoblasts are key to bone remodeling because they act as the only bone-forming cells. miR-877-5p has a chondrocyte-improving function in osteoarthritis, but its effect on osteoblast differentiation is unknown. Here, miR-877-5p-mediated osteoblast differentiation was studied. Real-time reverse transcriptase-polymerase chain reaction was performed to measure miR-877-5p expression during the osteogenic differentiation of MC3T3-E1 cells. Osteoblast markers, including alkaline phosphatase (ALP), collagen type I a1 chain, and osteopontin, were measured and detected by alizarin red staining and ALP staining. Potential targets of miR-877-5p were predicted from three different algorithms: starBase (http://starbase.sysu.edu.cn/), PITA (http://genie.weizmann.ac.il/pubs/mir07/mir07_data.html), and miRanda (http://www.microrna.org/microrna/home.do). It was further verified by dual luciferase reporter gene assay. The experimental results found that miR-877-5p was upregulated during the osteogenic differentiation of MC3T3-E1 cells. Overexpression of miR-877-5p promoted osteogenic differentiation, which was characterized by increased cell mineralization, ALP activity, and osteogenesis-related gene expression. Knockdown of miR-877-5p produced the opposite result. Dual luciferase reporter gene assay showed that miR-877-5p directly targeted eukaryotic translation initiation factor 4 gamma 2 (EIF4G2). Overexpression of EIF4G2 inhibited osteogenic differentiation and reversed the promoting effect of overexpression of miR-135-5p on osteogenic differentiation. These results indicate that miR-877-5p might have a therapeutic application related to its promotion of bone formation through targeting EIF4G2.

DT Review
ID pulposus cell apoptosis; circular rnas; nuclear export; osteoblast differentiation; dendritic cells; tnf-alpha; expression; cartilage; dicer; mouse
AB Protein-encoding genes only constitute less than 2% of total human genomic sequences, and 98% of genetic information was previously referred to as "junk DNA". Meanwhile, non-coding RNAs (ncRNAs) consist of approximately 60% of the transcriptional output of human cells. Thousands of ncRNAs have been identified in recent decades, and their essential roles in the regulation of gene expression in diverse cellular pathways associated with fundamental cell processes, including proliferation, differentiation, apoptosis, and metabolism, have been extensively investigated. Furthermore, the gene regulation networks they form modulate gene expression in normal development and under pathological conditions. In this review, we integrate current information about the classification, biogenesis, and function of ncRNAs and how these ncRNAs support skeletal development through their regulation of critical genes and signaling pathways in vivo. We also summarize the updated knowledge of ncRNAs involved in common skeletal diseases and disorders, including but not limited to osteoporosis, osteoarthritis, rheumatoid arthritis, scoliosis, and intervertebral disc degeneration, by highlighting their roles established from in vivo, in vitro, and ex vivo studies.

TI Radiofrequency Echographic Multispectrometry (REMS) can Overcome the Effects of Structural Internal Artifacts and Evaluate Bone Fragility Accurately
SO CALCIFIED TISSUE INTERNATIONAL
LA English
DT Article
DE Abdominal aortic calcification; Bone mineral density; Dual-energy X-ray absorptiometry; REMS; Semi-quantitative grading of vertebral fractures
ID abdominal aortic calcification; hip osteoarthritis; mineral density; osteoporosis; prevention; fracture; mass
AB PurposeThis study measured bone mineral density (BMD) in a Japanese population using the novel non-ionizing system using radiofrequency echographic multispectrometry (REMS) and compared the results with those obtained using traditional dual-energy X-ray absorptiometry (DXA). We aimed to identify any discrepancies between measurements obtained using these instruments and identify the influencing factors.MethodsThis cross-sectional study examined patients with osteoporosis treated at a single center from April to August 2023. We examined BMD assessment by DXA and REMS in lumbar spine and proximal femur. Patients were categorized into two groups: those with discrepancies between lumbar spine BMD measured by DXA and REMS, and those without. Semiquantitative evaluation of vertebral fractures and abdominal aortic

calcification scoring were also performed and compared between the two groups, along with various patient characteristics.ResultsA total of 70 patients (88.6% female; mean age 78.39 +/- 9.50 years) undergoing osteoporosis treatment were included in the study. A significant difference was noted between DXA and REMS measurement of BMD and T-scores, with REMS recording consistently lower values. The discrepancy group exhibited a higher incidence of multiple vertebral fractures and increased vascular calcification than the non-discrepancy group. Multivariate analysis indicated that diabetes mellitus, severe vertebral fractures, and increased abdominal aortic calcification scores were significantly associated with discrepancies in lumbar spine T-scores.ConclusionThis study suggests that REMS may offer a more accurate measurement of BMD, overcoming the overestimation of BMD by DXA owing to factors such as vertebral deformities, abdominal aortic calcification, and diabetes mellitus.

TI Mesenchymal stem cell-derived extracellular vesicles: A novel nanoimmunoregulatory tool in musculoskeletal diseases
SO NANO TODAY
LA English

DT Review
DE Mesenchymal stem cell extracellular vesicles; Osteoimmunology; Nanoparticles; Exosomes; Musculoskeletal disorders
ID regulatory t-cells; stromal cells; tnf-alpha; macrophage polarization; rheumatoid-arthritis; vertebral fractures; cartilage repair; bone-resorption; exosm; osteoarthritis
AB The musculoskeletal system involves various cell types that participate in maintaining bone homeostasis, which is crucial for balancing osteogenesis and osteoclastogenesis. Imbalances in bone homeostasis can lead to numerous musculoskeletal disorders, including osteoarthritis (OA) and osteoporosis (OP). In recent years, there has been growing interest in osteoimmunity due to its significant regulatory impact on bone homeostasis. Various cell types, including macrophages, T cells, and B cells, participate in osteoimmunology and regulate bone homeostasis. Currently, extracellular vesicles (EVs) play crucial roles in cell -to -cell communication. In particular, mesenchymal stem cell (MSC) -derived EVs have been reported as potential immunoregulators in certain immune -related diseases. This comprehensive review aims to present recent advancements in the understanding of the immunoregulatory effects of MSC -derived EVs in musculoskeletal diseases. In addition, we discuss the immunoregulatory effects of MSC-EVs on programed cell death in osteoblasts, osteoclasts, and chondrocytes, and the effect of this modulation on bone homeostasis. Moreover, we provide insights into the potential applications of MSC-EVs in the management of prevalent musculoskeletal disorders, including OP, OA, and bone fractures. In conclusion, this review emphasizes current advancements in research and future directions in MSC-EV-based therapies for musculoskeletal disorders.

TI Sensory nerve regulation of bone homeostasis: Emerging therapeutic opportunities for bone-related diseases
SO AGEING RESEARCH REVIEWS
LA English
DT Review
DE Sensory nerves; Neuropeptides; Bone homeostasis; Bone tissue cells; Bone-related diseases; Therapeutic targets
ID gene-related peptide; substance-p; growth-factor; osteochondral junction; semaphorin 3a; calcitonin; marrow; innervation; neurons; differentiation
AB Understanding the intricate interplay between sensory nerves and bone tissue cells is of paramount significance in the field of bone biology and clinical medicine. The regulatory role of sensory nerves in bone homeostasis offers a novel perspective for the development of targeted therapeutic interventions for a spectrum of bonerelated diseases, including osteoarthritis, osteoporosis, and intervertebral disc degeneration. By elucidating the mechanisms through which sensory nerves and their neuropeptides influence the differentiation and function of bone tissue cells, this review aims to shed light on emerging therapeutic targets that harness the neuro-skeletal axis for the treatment and management of debilitating bone disorders. Moreover, a comprehensive understanding of sensory nerve -mediated bone regulation may pave the way for the development of innovative strategies to promote bone health and mitigate the burden of skeletal pathologies in clinical practice.

DT Article
DE Neuropilin; Osteoblast; Osteoclast; Osteoimmunology; Cartilage
ID mesenchymal stem-cells; growth-factor isoforms; rheumatoid-arthritis; polysialylated neuropilin-2; osteogenic differentiation; dendritic cells; semaphorin 3a; expression; bone; receptors
AB Bone remodeling is the balance between osteoblasts and osteoclasts. Bone diseases such as osteoporosis and osteoarthritis are associated with imbalanced bone remodeling. Skeletal injury leads to limited motor function and pain. Neurophilin was initially identified in axons, and its various ligands and roles in bone remodeling, angiogenesis, neuropathic pain and immune regulation were later discovered. Neurophilin promotes osteoblast mineralization and inhibits osteoclast differentiation and its function. Neuropolin-1 provides channels for immune cell chemotaxis and cytokine diffusion and leads to pain. Neuropolin-1 regulates the proportion of T helper type 17 (Th17) and regulatory T cells (Treg cells), and affects bone immunity. Vascular endothelial growth factors (VEGF) combine with neuropilin and promote angiogenesis. Class 3 semaphorins (Sema3a) compete with VEGF to bind neuropilin, which reduces angiogenesis and rejects sympathetic nerves. This review elaborates on the structure and general physiological functions of neuropilin and summarizes the role of neuropilin and its ligands in bone and cartilage diseases. Finally, treatment strategies and future research directions based on neuropilin are proposed.

AB Objective: Understanding the mechanisms of hip disease, such as osteoarthritis (OA), is crucial to advance their treatment. Such hip diseases often involve specific morphological changes. Genetic variations, called single nucleotide polymorphisms (SNPs), influence various hip morphological parameters. This study investigated the biological relevance of SNPs correlated to hip morphology in genome-wide association studies (GWAS). The SNP-associated genes were compared to genes associated with OA in other joints, aiming to see if the same genes play a role in both hip development and the risk of OA in other lower limb joints. Methodology: A systematic literature review was conducted to identify SNPs correlated with hip morphology, based on the Population, Intervention, Comparison, Outcome, and Study (PICOS) framework. Afterwards, Gene Ontology (GO) analysis was performed, using EnrichR, on the SNP-associated genes and compared with non-hip OA-associated genes, across different databases. Results: Reviewing 49 GWAS identified 436 SNPs associated with hip joint morphology, encompassing variance in bone size, structure and shape. Among the SNP-associated genes, SOX9 plays a pivotal role in size, GDF5 impacts bone structure, and BMP7 affects shape. Overall, skeletal system development, regulation of cell differentiation, and chondrocyte differentiation emerged as crucial processes influencing hip morphology. Eighteen percent of GWAS-identified genes related to hip morphology were also associated with non-hip OA. Conclusion: Our findings indicate the existence of multiple shared genetic mechanisms across hip morphology and OA, highlighting the necessity for more extensive research in this area, as in contrast to the hip, the genetic background on knee or foot morphology remains largely understudied. TI Risk and Epidemiology of Periprosthetic Knee Fractures After Primary Total Knee Arthroplasty: A Nationwide Cohort Study
SO JOURNAL OF ARTHROPLASTY
LA English
DT Article
DE periprosthetic knee fracture; epidemiology; total knee arthroplasty; risk; risk factors
AB Background: Periprosthetic knee fractures (PPKFs) following total knee arthroplasty (TKA) are uncommon, but potentially serious injuries. We analyze the risk and risk factors for a PPKF in standard primary TKA patients who have osteoarthritis and a minimally (cruciate-retaining TKAs without a femoral box cut) or posterior-stabilized TKA. In addition, we report the risk for patients who have other underlying knee disorders and/or a higher level of TKA constraint. Methods: All primary TKAs were identified from the Danish National Patient Register and the Danish Knee Arthroplasty Register using data between 1997 and 2022. Subsequent fractures were identified through the International Classification of Diseases diagnosis code, Nordic Medico-Statistical Committee procedure code, or indication for revision TKA. Results: We included 120,642 standard primary TKA patients who had 1,659 PPKFs. The cumulated proportions were 0.4% (95% confidence interval (CI) 0.3 to 0.4) at 2 years 0.8% (0.7 to 0.8) at 5 years. At 10 years, the cumulated proportion was 1.7% (1.6 to 1.8), with 1.3% in the femur, 0.2% in the patella, and 0.2% in the tibia. Significant risk factors were (hazard ratio [HR] [95% CI]); ipsilateral hip arthroplasty (2.3 [2.0 to 2.6]); women (2.1 [1.8 to 2.4]), osteoporosis (1.4 [1.2 to 1.7]); age 80+ (1.4 [1.3 to 1.6]), uncemented TKA (1.3 (1.1 to 1.5) and Charlson Comorbidity Index score 3+ (1.4 [1.1 to 1.8]). An additional 22,624 primary TKA patients who had other underlying knee disorders and/or a higher level of implant constraint were included with 633 PPKFs. The 10-year cumulated proportions were 8.3% (95% CI 6.9 to 9.8) when the underlying disorder was a previous fracture, 2.8% (2.2 to 3.5) for rheumatic disorders, and 5.2% (2.6 to 10.6) for osteonecrosis. In patients who had condylar constrained knees, it was 6.9% (5.1 to 9.4), and 12.4%

(8.0 to 16.04) for hinges. Conclusions: In standard primary TKA patients, the 10-year cumulated proportion of PPKFs was 1.7%, and ipsilateral hip arthroplasty, women, osteoporosis, advanced age, uncemented TKA and higher Charlson Comorbidity Index increased the risk. Higher risks were observed in non-osteoarthritis patients and/or patients who had a higher level of TKA constraint. (c) 2024 The Author(s). Published by Elsevier Inc. TI Multi-omics Data Integration Analysis Identified Therapeutic Targets and Potential Reuse Drugs for Osteoporosis
SO CURRENT MEDICINAL CHEMISTRY
LA English
DT Article
DE Osteoporosis; BM-MSCs; therapeutic target; drug reuse; network proximity; molecular docking
AB Aims To facilitate drug discovery and development for the treatment of osteoporosis.Background With global aging, osteoporosis has become a common problem threatening the health of the elderly. It is of important clinical value to explore new targets for drug intervention and develop promising drugs for the treatment of osteoporosis.Objective To understand the major molecules that mediate the communication between the cell populations of bone marrow-derived mesenchymal stem cells (BM-MSCs) in osteoporosis and osteoarthritis patients and identify potential reusable drugs for the treatment of osteoporosis.Methods Single-cell RNA sequencing (scRNA-seq) data of BM-MSCs in GSE147287 dataset were classified using the Seurat package. CellChat was devoted to analyzing the ligand-receptor pairs (LR pairs) contributing to the communication between BM-MSCs subsets. The LR pairs that were differentially expressed between osteoporosis samples and control samples and significantly correlated with immune score were screened in the GSE35959 dataset, and the differentially expressed gene in both GSE35959 and GSE13850 data sets were identified as targets from a single ligand or receptor. The therapeutic drugs for osteoporosis were screened by network proximity method, and the top-ranked drugs were selected for molecular docking and molecular dynamics simulation with the target targets.Results Twelve subsets of BM-MSCs were identified, of which CD45-BM-MSCS_4, CD45-BM-MSCS_5, and CD45+ BM-MSCs_5 subsets showed significantly different distributions between osteoporosis samples and osteoarthritis samples. Six LR pairs were identified in the bidirectional communication between these three BM-MSCs subsets and other BM-MSCs subsets. Among them, MIF-CD74 and ITGB2-ICAM2 were significantly correlated with the immune score. CD74 was identified as the target, and a total of 48 drugs targeting CD47 protein were identified. Among them, DB01940 had the lowest free energy binding score with CD74 protein and the binding state was very stable.Conclusion This study provided a new network-based framework for drug reuse and identified initial insights into therapeutic agents targeting CD74 in osteoporosis, which may be meaningful for promoting the development of osteoporosis treatment.

TI Patients with Hip Osteoarthritis Have a Higher Rate of Spinal Reoperation Following Lumbar Spinal Fusion
SO JOURNAL OF BONE AND JOINT SURGERY-AMERICAN VOLUME
LA English
DT Article
ID stand-alone cages; arthroplasty; dislocation; risk; instrumentation; revision
AB Background: Lumbar spinal pathology is known to affect outcomes following total hip arthroplasty (THA). However, the effect of hip osteoarthritis (OA) on outcomes following lumbar fusion has not been well studied. The purpose of this study was to determine the association between hip OA and spinal reoperation following lumbar spinal fusion. Methods: The 5% Medicare Part B claims database was queried for all patients who underwent primary elective lumbar fusion from 2005 to 2019. Patients were divided into 2 groups: those who underwent elective THA within 1 year after primary lumbar fusion, indicating that they had severe hip OA at the time of lumbar fusion, and those who underwent lumbar fusion with no

diagnosed hip OA and no THA during the study period. Exclusion criteria included THA as a result of trauma, revision THA or primary THA in the 5-year period before primary lumbar fusion, <65 years of age, and no enrollment in the database for 5 years before and 1 year after primary lumbar fusion. The primary outcome was spinal reoperation within 1, 3, and 5 years. Multivariable Cox regression was performed with age, sex, diabetes, heart disease, obesity, smoking status, osteoporosis, number of levels fused, use of posterior instrumentation, use of an interbody device, use of bone graft, and surgical approach as covariates. Results: Overall, 1,123 patients (63.4% female; 91.3% White; mean age, 76.8 +/- 4.1 years) were included in the hip OA group and 8,893 patients (56.2% female; 91.3% White; mean age, 74.8 +/- 4.9 years) were included in the control group. After multivariable analysis, patients with severe hip OA had significantly greater rates of revision surgery at 3 years (odds ratio [OR], 1.61; $p < 0.001$) and 5 years (OR, 1.87; $p < 0.001$) after the index lumbar fusion. Conclusions: Patients with severe hip OA at the time of primary lumbar fusion had a significantly increased risk of spinal reoperation at 3 and 5 years postoperatively. These data provide further evidence to support performing THA prior to lumbar fusion in the unsettled debate regarding which surgery should be prioritized for patients with simultaneous degenerative diseases of the hip and lumbar spine. Level of Evidence: Prognostic Level III. See Instructions for Authors for a complete description of levels of evidence.

TI The Advantages of Radiofrequency Echographic MultiSpectrometry in the Evaluation of Bone Mineral Density in a Population with Osteoarthritis at the Lumbar Spine
SO DIAGNOSTICS
LA English
DT Article
DE osteoarthritis; bone mineral density (BMD); dual-energy X-ray absorptiometry (DXA); radiofrequency echographic multispectrometry (REMS); osteoporosis; Kellgren/Lawrence grading score

ID osteoporosis; association; fractures; society; health; risk; tbs
AB Background: Osteoarthritis (OA) in the lumbar spine can potentially lead to an overestimation of bone mineral density (BMD), and this can be a challenge in accurately diagnosing conditions like osteoporosis, where precise measurement of BMD is crucial. Radiofrequency Echographic Multi Spectrometry (REMS) is being recognized as an innovative diagnostic tool for assessing bone status. The purpose of this study was to evaluate whether the use of REMS may enhance the identification of osteoporosis in patients with osteoarthritis. Methods: A cohort of 500 patients (mean age: 63.9 +/- 11.2 years) diagnosed with osteoarthritis and having a medical prescription for dual-energy X-ray absorptiometry (DXA) were recruited for the study. All patients underwent BMD measurements at lumbar spine and femoral sites by both DXA and REMS techniques. Results: The T-score values for BMD at the lumbar spine (BMD-LS) by DXA were significantly higher with respect to BMD-LS by REMS across all OA severity scores, and the differences were more pronounced in patients with a higher degree of OA severity ($p < 0.001$). Furthermore, the percentage of subjects classified as "osteoporotic", on the basis of BMD by REMS was markedly higher than those classified by DXA, both when considering all skeletal sites (39.4% vs. 15.1%, respectively) and the lumbar spine alone (30.5% vs. 6.0%, respectively). A similar pattern was observed when OA patients were grouped according to the Kellgren-Lawrence grading score. Conclusions: The findings from our study indicate that, in a population with varying severity levels of osteoarthritis, REMS demonstrated a higher capability to diagnose osteoporosis compared to DXA, and this could lead to earlier intervention and improved outcomes for patients with bone fragility, reducing the likelihood of fractures and associated complications.

TI Modulation of Carnitine Palmitoyl Transferase 1b Expression and Activity in

Muscle Pathophysiology in Osteoarthritis and Osteoporosis
SO BIOMOLECULES
LA English
DT Article
DE osteoporosis; osteoarthritis; muscle atrophy; energy metabolism; oxidative stress; mitochondria biogenesis; myoblast regeneration
ID oxidative stress; sarcopenia; apoptosis
AB In the pathophysiology of osteoarthritis and osteoporosis, articular cartilage and bone represent the target tissues, respectively, but muscle is also involved. Since many changes in energy metabolism occur in muscle with aging, the aim of the present work was to investigate the involvement of carnitine palmitoyl transferase 1b (Cpt1b) in the muscle pathophysiology of the two diseases. Healthy subjects (CTR, n = 5), osteoarthritic (OA, n = 10), and osteoporotic (OP, n = 10) patients were enrolled. Gene expression analysis conducted on muscle and myoblasts showed up-regulation of CPT1B in OA patients; this result was confirmed by immunohistochemical and immunofluorescence analyses and enzyme activity assay, which showed increased Cpt1b activity in OA muscle. In addition, CPT1B expression resulted down-regulated in cultured OP myoblasts. Given the potential involvement of Cpt1b in the modulation of oxidative stress, we investigated ROS levels, which were found to be lower in OA myoblasts, and gene expression of nicotinamide adenine dinucleotide phosphate hydrogen oxidase 4 (Nox4), which resulted up-regulated in OA cells. Finally, the immunofluorescence of BCL2/adenovirus E1B 19 kDa protein-interacting protein 3 (Bnip3) showed a decreased expression in OP myoblasts, with respect to CTR and OA. Contextually, through an ultrastructural analysis conducted by Transmission Electron Microscopy (TEM), the presence of aberrant mitochondria was observed in OP muscle. This study highlights the potential role of Cpt1b in the regulation of muscle homeostasis in both osteoarthritis and osteoporosis, allowing for the expansion of the current knowledge of what are the molecular biological pathways involved in the regulation of muscle physiology in both diseases.

TI Investigating and Practicing Orthopedics at the Intersection of Sex and Gender: Understanding the Physiological Basis, Pathology, and Treatment Response of Orthopedic Conditions by Adopting a Gender Lens: A Narrative Overview
SO BIOMEDICINES
LA English
DT Review
DE sex and gender; orthopedics; personalized medicine
ID degenerative lumbar scoliosis; calve-perthes disease; clinical-features; bone-formation; hip fracture; dimorphism; epidemiology; prevalence; mortality; estrogens
AB In the biomedical field, the differentiation between sex and gender is crucial for enhancing the understanding of human health and personalizing medical treatments, particularly within the domain of orthopedics. This distinction, often overlooked or misunderstood, is vital for dissecting and treating musculoskeletal conditions effectively. This review delves into the sex- and gender-specific physiology of bones, cartilage, ligaments, and tendons, highlighting how hormonal differences impact the musculoskeletal system's structure and function, and exploring the physiopathology of orthopedic conditions from an epidemiological, molecular, and clinical perspective, shedding light on the discrepancies in disease manifestation across sexes. Examples such as the higher rates of deformities (adolescent idiopathic and adult degenerative scoliosis and hallux valgus) in females and osteoporosis in postmenopausal women illustrate the critical role of sex and gender in orthopedic health. Additionally, the review addresses the morbidity-mortality paradox, where women, despite appearing less healthy on frailty indexes, show lower mortality rates, highlighting the complex interplay between biological and social determinants of health. Injuries and chronic orthopedic conditions such osteoarthritis exhibit gender- and sex-specific prevalence and progression patterns, necessitating a nuanced approach to treatment that considers these differences to optimize outcomes. Moreover, the review underscores the importance of recognizing the unique needs of sexual minority and gender-diverse individuals in orthopedic care, emphasizing the impact of gender-affirming hormone therapy on aspects like bone health and perioperative risks. To foster advancements in sex- and gender-specific orthopedics, we advocate for the strategic disaggregation of data by sex and gender and the inclusion of "Sexual Orientation and Gender Identity" (SOGI) data in research and clinical practice. Such measures can enrich clinical insights, ensure

tailored patient care, and promote inclusivity within orthopedic treatments, ultimately enhancing the precision and effectiveness of care for diverse patient populations. Integrating sex and gender considerations into orthopedic research and practice is paramount for addressing the complex and varied needs of patients. By embracing this comprehensive approach, orthopedic medicine can move towards more personalized, effective, and inclusive treatment strategies, thereby improving patient outcomes and advancing the field.

DT Review
DE regulated cell death; musculoskeletal diseases; m6A; apoptosis; autophagy-dependent cell death; ferroptosis; pyroptosis
ID messenger-rna; proliferation; osteosarcoma; promotes; mettl3; recommendations; methylation; ferroptosis; progression; apoptosis
AB Musculoskeletal diseases (MSDs), including osteoarthritis (OA), osteosarcoma (OS), multiple myeloma (MM), intervertebral disc degeneration (IDD), osteoporosis (OP), and rheumatoid arthritis (RA), present noteworthy obstacles associated with pain, disability, and impaired quality of life on a global scale. In recent years, it has become increasingly apparent that N6-methyladenosine (m6A) is a key regulator in the expression of genes in a multitude of biological processes. m6A is composed of 0.1-0.4% adenylate residues, especially at the beginning of 3 '-UTR near the translation stop codon. The m6A regulator can be classified into three types, namely the "writer", "reader", and "eraser". Studies have shown that the epigenetic modulation of m6A influences mRNA processing, nuclear export, translation, and splicing. Regulated cell death (RCD) is the autonomous and orderly death of cells under genetic control to maintain the stability of the internal environment. Moreover, distorted RCDs are widely used to influence the course of various diseases and receiving increasing attention from researchers. In the past few years, increasing evidence has indicated that m6A can regulate gene expression and thus influence different RCD processes, which has a central role in the etiology and evolution of MSDs. The RCDs currently confirmed to be associated with m6A are autophagy-dependent cell death, apoptosis, necroptosis, pyroptosis, ferroptosis, immunogenic cell death, NETotic cell death and oxeiptosis. The m6A-RCD axis can regulate the inflammatory response in chondrocytes and the invasive and migratory of MM cells to bone remodeling capacity, thereby influencing the development of MSDs. This review gives a complete overview of the regulatory functions on the m6A-RCD axis across muscle, bone, and cartilage. In addition, we also discuss recent advances in the control of RCD by m6A-targeted factors and explore the clinical application prospects of therapies targeting the m6A-RCD in MSD prevention and treatment. These may provide new ideas and directions for understanding the pathophysiological mechanism of MSDs and the clinical prevention and treatment of these diseases.

TI Family History of Arthritis, Osteoporosis, and Carpal Tunnel Syndrome and Risk

of These Conditions Among US Adults
SO ARTHRITIS CARE & RESEARCH
LA English
DT Article
ID systemic-lupus-erythematosus; rheumatoid-arthritis; united-states; diagnosed arthritis; body-mass; osteoarthritis; prevalence; population; prevention; metaanalysis
AB ObjectiveThe aim was to estimate odds ratios (ORs) of associations between family history of arthritis, osteoporosis, and carpal tunnel syndrome and prevalence in a real-world population, uncovering family histories of related conditions that may increase risk because of shared heritability, condition pathophysiology, or social/environmental factors.MethodsUsing data from 156,307 participants in the All of Us (AoU) Research Program, we examined associations between self-reported first-degree family history of five common types of arthritis (fibromyalgia, gout, osteoarthritis [OA], rheumatoid arthritis, and systemic lupus erythematosus [SLE]), osteoporosis, and carpal tunnel syndrome and prevalence. We evaluate associations across seven conditions and performed stratified analyses by race and ethnicity, sex, socioeconomic differences, body mass index, and type of affected relative.ResultsMore than 38% of AoU participants reported a family history of any arthritis, osteoporosis, or carpal tunnel syndrome. Adults with a family history of any arthritis, osteoporosis, and carpal tunnel syndrome exhibited 3.68 to 7.59 (4.90, on average) odds of having the same condition and 0.70 to 2.10 (1.24, on average) odds of having a different condition. The strongest associations observed were between family history of OA and prevalence of OA (OR 7.59; 95% confidence interval [95% CI] 7.32-7.88) and family history of SLE and prevalence of SLE (OR 6.34; 95% CI 5.17-7.74). We additionally uncover race and ethnicity and sex disparities in family history associations.ConclusionFamily history of several related conditions was associated with increased risk for arthritis, osteoporosis, and carpal tunnel syndrome, underscoring the importance of family history of related conditions for primary prevention. imageConclusionFamily history of several related conditions was associated with increased risk for arthritis, osteoporosis, and carpal tunnel syndrome, underscoring the importance of family history of related conditions for primary prevention. image

TI Opportunistic Screening of Low Bone Mineral Density From Standard X-Rays
SO JOURNAL OF THE AMERICAN COLLEGE OF RADIOLOGY
LA English
DT Article
DE Bone mineral density; machine learning; opportunistic screen; x-ray
ID osteoporosis; rationale
AB Background: Osteoporosis, characterized by loss of bone mineral density (BMD), is underscreened. Osteoporosis and low bone mass are diagnosed by a BMD T-score <= -2.5, and between -1.0 and -2.5, respectively, at the femoral neck or lumbar vertebrae (L1-4), using dual energy x-ray absorptiometry (DXA). The ability to estimate BMD at those anatomic sites from standard radiographs would enable opportunistic screening of low BMD (T-score < -1) in individuals undergoing x-ray for any clinical indication. Methods: Radiographs of the lumbar spine, thoracic spine, chest, pelvis, hand, and knee, with a paired DXA acquired within 1 year, were obtained from community imaging centers (62,023 x-ray-DXA pairs of patients). A software program called Rho was developed that uses x-ray, age, and sex as inputs, and outputs a score of 1 to 10 that corresponds with the likelihood of low BMD. The program's performance was assessed using receiver-operating characteristic analyses in three independent test sets, as follows: patients from community imaging centers (n = 3,729; 83% female); patients in the Canadian Multicentre Osteoporosis Study (n = 1,780; 71% female); and patients in the Osteoarthritis Initiative (n = 591; 50% female). Results: The areas under the receiver-operating characteristic curves were 0.89 (0.87-0.90), 0.87 (0.85-0.88), and 0.82 (0.79-0.85), respectively, and subset analyses showed similar results for each sex, body part, and race. Conclusion: Rho can opportunistically screen patients at risk of low BMD (at femoral neck or L1-4) from radiographs of the lumbar spine, thoracic spine, chest, pelvis, hand, or knee.

TI A single-centre RetrospeCtive sTudy Investigating patient-reported outcomeS of extended dressing wear time for incisional healing following orthopaedic surgery: the ARCTIS study
SO JOURNAL OF WOUND CARE
LA English
DT Article
DE incision care; PROMS; sustainability; telemedicine; undisturbed wound healing (UWH); UNSDG 12; wound care; wound dressing; wound healing
ID surgical site infection; hospital readmission; wound dehiscence; care; hip;

reasons; score
AB Objective: Orthopaedic surgery is an effective intervention for treating the symptoms of degenerative joint disease or osteoarthritis (OA). Frequent wound dressing changes, unless clinically indicated, can disrupt the healing process and increase the occurrence of incision site contamination. Protection from contamination is critical for surgical incisions and, therefore, undisturbed wound healing (UWH) in surgical wound management is vital. This article describes a retrospective study reporting the clinical performance of a self-adherent, absorbent postoperative dressing, with a focus on dressing wear time. Method: A single-centre, retrospective electronic medical record review of a convenience sample of adult patients treated with a dressing (Mepilex Border Post Op; M ölnlycke, Sweden) following elective hip or knee replacement was undertaken. Data relating to dressing wear time, rationale for dressing changes and patient-reported outcomes were extracted from a mobile health application moveUP Therapy (moveUP NV, Belgium). Health-related quality of life assessment was conducted using the EQ-5D-5L questionnaire and orthopaedic-specific quality of life (QoL) indicator tools. Results: Of the 558 records reviewed, 151 respondents (27.1%) reported outcomes relating to dressing wear time and frequency of dressing change. The average wear time of the first dressing was 13.6 days (second dressing: 5.3 days). The proportion of patients who wore the first dressing for 1-7 days, 8-13 days and for >= 14 days was 17.2%, 13.2% and 69.5%, respectively. Data from the completed questionnaires revealed improvement in QoL over time. Conclusion: The results of this study are a good indicator of the suitability of the postoperative dressing for a 14-day wear time, in line with the principles of UWH.

TI What do osteoporosis and osteoarthritis have in common? An integrated study of overlapping differentially expressed genes in bone mesenchymal stem cells of osteoporosis and osteoarthritis
SO GENE
LA English
DT Article
DE Mesenchymal stem cells; Osteoarthritis; Osteoporosis; Treatment ingredients; Bioinformatics
AB Objective: For identification of aberrantly expressed genes in mesenchymal stem cells of osteoporosis (OP) and osteoarthritis (OA), Gene Expression Omnibus

(GEO) datasets were integrated to investigate the intersection point.Methods: GSE35958 (osteoporosis) and GSE19664 (osteoarthritis) datasets were obtained from GEO database. The abnormally expressed genes were analyzed by GEO2R. Functional enrichment was explored by Metascape database and R software. The String database and Cytoscape software were used to build the protein-protein interaction network and identify hub genes. GSE35957 and GSE116925 were used as verification datasets. Single-cell analysis and pseudotime analysis were undertaken. CTDbase, Network Analyst, HPA database, HERB database and MIRW database were used to research the information, tissue and cell distribution, regulation, interaction and ingredients targeting the hub genes. Additionally, in vitro experiments such as RT-PCR, ALP staining and immunofluorescence were undertaken as verification tests.Results: Ten hub genes were identified in this study. All these genes play an important role in bone or cartilage generation. They have diagnostic values and therapeutic potential for OA and OP. Single-cell analysis visualized the cell distribution and pseudotime distribution of these genes. Some potential therapeutic ingredients of these genes were identified, such as curcumin, wogonin and glycerin. In vitro experiments, RT-PCR results showed that COL9A3 and MMP3 were downregulated and PTH1R was upregulated during osteogenic induction of BMSC. Immunohistochemical results showed the expression trend of MMP3 and COL2A1.Conclusion: Ten abnormal hub genes of osteoporosis and osteoarthritis were identified successfully by this study. They were important regulatory genes for healthy bone and cartilage. These genes could be the common con-nections between osteoporosis and osteoarthritis as well as treatment targets. Further study of the regulatory mechanism and treatment effects of these genes would be valuable. The results of this study could contribute to further research.

TI Mesenchymal stem cells and their extracellular vesicles in bone and joint diseases: targeting the NLRP3 inflammasome
SO HUMAN CELL
LA English
DT Review
DE Mesenchymal stem cells; Extracellular vesicles; NLRP3 inflammasome; Bone and joint diseases; Inflammation
ID activation; exosm; transplantation; osteoarthritis; mechanisms; receptor; repair; rats; rna
AB The nucleotide-binding oligomerization domain-like-receptor family pyrin domain-containing 3 (NLRP3) inflammasome is a cytosolic multi-subunit protein complex, and recent studies have demonstrated the vital role of the NLRP3 inflammasome in the pathological and physiological conditions, which cleaves gasdermin D to induce inflammatory cell death called pyroptosis and mediates the release of interleukin-1 beta and interleukin-18 in response to microbial infection or cellular injury. Over-activation of the NLRP3 inflammasome is associated with the pathogenesis of many disorders affecting bone and joints, including gouty arthritis, osteoarthritis, rheumatoid arthritis, osteoporosis, and periodontitis. Moreover, mesenchymal stem cells (MSCs) have been discovered to facilitate the inhibition of NLRP3 and maybe ideal for treating bone and joint diseases. In this review, we implicate the structure and activation of the NLRP3 inflammasome along with the detail on the involvement of NLRP3 inflammasome in bone and joint diseases pathology. In addition, we focused on MSCs and MSC-extracellular vesicles targeting NLRP3 inflammasomes in bone and joint diseases. Finally, the existing problems and future direction are also discussed.

TI Achyranthes bidentata Blume (Amaranthaceae): a review of its botany, traditional uses, phytochemistry, pharmacology, and toxicology
SO JOURNAL OF PHARMACY AND PHARMACOLOGY
LA English
DT Review
DE Achyranthes bidentata Blume; botany; traditional uses; phytochemistry; pharmacology
ID osteogenic differentiation; root extract; polysaccharides; saponins; osteoporosis; apoptosis; neurons; growth; cells
AB Objectives Achyranthes bidentata Blume (A. bidentata) is a plant of Amaranthaceae family, and its root is the main medicinal part, named "Huai-Niu-Xi." It is used to expel blood stasis through menstruation, tonify liver and kidney, strengthen muscles and bones, and induce diuresis. This review aimed to provide a systematic summary of botany, traditional uses, phytochemistry, pharmacology, and toxicology of A. bidentata.Methods The present review covers the literature survey. The data have been collected from various journals, books, and some of the electronic search via Internet-based information such as Web of Science, PubMed, Google Scholar, Google patents, CNKI, SpringerLink, online

electronic journals, and ScienceDirect.Key findings So far, more than 270 metabolites have been isolated from A. bidentata, including terpenoids, steroids, alkaloids, flavonoids, and so on. Among them, terpenoids and steroids are the main metabolites. The extract and metabolites exert multiple pharmacological activities such as alleviating osteoarthritis effect, antiosteoporosis activity, neuroprotective effect, antidiabetic activity-associated complications, immunoregulatory activity, and so on.Summary Some traditional uses of A. bidentata need further in-depth studies to confirm. Similarly, the separation and screening of active compounds, as well as the corresponding molecular mechanisms of action of compounds, are also needed to be studied.

TI Adipose Mesenchymal Stem Cell-Derived Exosomes as Nanocarriers for Treating Musculoskeletal Disorders
SO INTERNATIONAL JOURNAL OF NANOMEDICINE
LA English
DT Review
DE exosomes; adipose mesenchymal stem cells; musculoskeletal disorders; regenerative medicine
ID bone-fat balance; extracellular vesicles; signaling pathways; tendon injury; cartilage; osteoporosis; biology; matrix; roles; differentiation
AB Musculoskeletal disorders are a series of diseases involving bone, muscle,

cartilage, and tendon, mainly caused by chronic strain, degenerative changes, and structural damage due to trauma. The disorders limit the function of patients due to pain and significantly reduce their quality of life. In recent years, adipose-derived mesenchymal stem cells have been extensively applied in regeneration medicine research due to their particular abilities of self-renewal, differentiation, and targeted homing and are more easily accessed compared with other sources. The paracrine effect of ADSCs plays a crucial role in intercellular communication by releasing mass mediators, including cytokines and growth factors, particularly the exosomes they secrete. Not only do these exosomes possess low immunogenicity, low toxicity, and an enhanced ability to penetrate a bio-barrier, but they also inherit their parent cells' characteristics and carry various bioactive molecules to release to targeted cells, modulating their biological process. Meanwhile, these characteristics also make exosomes a natural nanocarrier capable of targeted drug delivery to specific sites, enhancing the bioavailability of drugs within the body and achieving precision therapy with fewer toxic side effects. Furthermore, the integration of exosomes with tissue engineering and chemical modification strategies can also significantly enhance their efficacy in facilitating tissue repair. However, the current research on ADSC-Exos for improving MSDs remains at an early stage and needs further exploration. Therefore, this review summarized the ADSC-Exo as a nanodrug carrier characteristics and mechanism in the treatment of fracture, osteoporosis, osteoarthritis, intervertebral disc degeneration, and tendon injury, which push forward the research progress of ADSC-Exo therapy for MSDs.

AB Introduction: We performed consecutive checkups of the 1964 Tokyo Olympic contestants every 4 years for 50 years. This study evaluated bone mineral density (BMD) and its related factors in former Tokyo Olympic athletes. Objectives: The study population comprised 181 former Olympians (141 men and 40 women) who had undergone BMD measurement in at least one of the four checkups performed every 4 years since 2005. The mean age of the 104 subjects who participated in the last checkup in 2016 was 76.1 years for men and 74.0 years for women. Methods: Health-related information regarding medical history, regular physical activity, alcohol consumption, and smoking was obtained using questionnaires. The areal BMD of the total body was measured using dualenergy X-ray absorptiometry (DXA). The relationship between BMD and anthropometric measurements, medical history, and health behaviors was examined. Furthermore, we assessed the influence of the mode and magnitude of weight-bearing and impact loading during athletic events during their active careers on BMD. Results: The mean Z-scores of BMD of the total body, lumbar spine, pelvis, and upper and lower limbs were > 0 in both male and female subjects at each checkup. The subjects had a higher mean height and weight than the Japanese age- and sex-matched individuals. Furthermore, the subjects had higher grip strength than the age- and sex-matched individuals. BMD showed a positive correlation with body weight, lean body mass (LBM), muscle mass, and grip strength, with higher correlation coefficients found between BMD of the pelvis or lower limbs and LBM or muscle mass volume. When the association with current participation in sports activities was examined, male subjects who exercised weekly had significantly higher grip strength and greater muscle mass volume; however, no significant differences were observed among female subjects. After adjusting for age and LMB, BMD was significantly higher in both the lumbar spine and lower limbs of male subjects with relatively more impact loading in sports events during their active careers. Conclusion: The Tokyo Olympic contestants maintained a high muscle mass even at an older age, regardless of their medical history, which may be one of the reasons for their ability to maintain a high BMD.

TI Comparison of Demographic and Clinical Characteristics of Taiwan Biobank Participants with Nonparticipants
SO JOURNAL OF EPIDEMIOLOGY
LA English
DT Article
DE healthy volunteer effect; biobank; Taiwan biobank; representativeness; sociodemographic characteristics; clnical characteristics
ID population; mortality; risk
AB Background: This study investigated fundamental demographic variables within the Taiwan Biobank (TWBB) and compared them with national demographic statistics. Additionally, a matched cohort analysis compared TWBB participants with nonparticipants to uncover disparities in sociodemographic and clinical characteristics. Methods: A total of 128,663 individuals aged 30 to 70 without cancer were recruited within the TWBB, and 514,652 nonparticipants matched by age and sex were randomly selected from the National Health Insurance claims database. Sociodemographic variables, healthcare utilization metrics, underlying medical conditions, and subsequent mortality and cancer risk were analyzed. Results: TWBB participants were more likely to be female, older, married, higher educated, with higher incomes, and urban residency. Healthcare utilization metrics showed minimal differences. Pre-cohort entry, TWBB participants had a higher prevalence of certain medical conditions, such as peptic ulcer disease, osteoarthritis, osteoporosis, and uterine leiomyoma in females. During follow-up periods, elevated mortality rates were observed among TWBB participants but decreased cancer risk. Conclusion: The TWBB cohort exhibits disparities in sociodemographic and healthrelated attributes compared to the general population, comprising older, females, married, higher educated, higher income, and predominantly in urban areas. While mortality rates are slightly elevated within the TWBB cohort, cancer incidence rates are lower. Despite limitations in representativeness, the TWBB's size and exposure measures offer valuable insights into associations between exposures and health conditions.

TI Unravelling the Relacatib activity against the CTSK proteins causing pycnodysostosis: a molecular docking and dynamics approach
SO JOURNAL OF BIOMOLECULAR STRUCTURE & DYNAMICS
LA English
DT Article
DE Pycnodysostosis; CTSK protein; Relacatib; molecular docking; molecular dynamics; MMPBSA
ID cell lung-cancer; tyrosine kinases; mutant p53; expression; overexpression; therapy; complex; egfr; stem
AB Pycnodysostosis is an atypical autosomal recessive condition of Lysosomal storage disorder that originated due to the deficit of the enzyme Cathepsin K which is vital for normal osteoclast action in bone resorption. Abnormal degradation of type 1 collagen and accumulation of toxic undigested collagen fibers in lysosomes of the osteoclast cells resulting in high bone density, brittle bones, and a short stature is caused in CTSK protein-carrying individuals. The broad aim of this study is to identify the most significant variant through various computational pipelines. This study was initiated by retrieving a total number of thirty-six variants from NCBI, HGMD, and UniProt databases, and the Y283C variant was found to be more significant by various standard computational tools. A structural investigation was performed to understand and gain a better knowledge about the interaction profile for the native (1BY8) and variant (Y283C) with Relacatib (a small-molecule drug that blocks the function of Cathepsin K, an enzyme that has been linked to osteoporosis, osteoarthritis, and other bone-degrading diseases). The interaction profile was analyzed using molecular docking. Relacatib (ligand) had an average binding affinity for both native (-7.16 kcal/mol) and Y283C (-6.76 kcal/mol). Finally, Molecular dynamics simulations were done in duplicates to recognize the variant (Y283C) activity of the protein structure against Relacatib for 100 ns. This study assists in comprehending the most pathogenic amino-acid variant, the ligand interaction with the protein structure, and paves the way for understanding the steadiness of the ligand with the native and selected significant amino-acid variant.Communicated by Ramaswamy H. Sarma

TI From bone to nanoparticles: development of a novel generation of bone derived nanoparticles for image guided orthopedic regeneration
SO BIOMATERIALS SCIENCE
LA English
DT Article

ID controlled drug-release; extracellular-matrix; indocyanine green; delivery systems; aspect ratio; in-vivo; size; cell; fluorescence; medicine
AB Bone related diseases such as osteoporosis, osteoarthritis, metastatic bone cancer, osteogenesis imperfecta, and Paget's disease, are primarily treated with pharmacologic therapies that often exhibit limited efficacy and substantial side effects. Bone injuries or fractures are primarily repaired with biocompatible materials that produce mixed results in sufficiently regenerating healthy and homogenous bone tissue. Each of these bone conditions, both localized and systemic, use different strategies with the same goal of achieving a healthy and homeostatic bone environment. In this study, we developed a new type of bone-based nanoparticle (BPs) using the entire organic extracellular matrix (ECM) of decellularized porcine bone, additionally encapsulating indocyanine green dye (ICG) for an in vivo monitoring capability. Utilizing the regenerative capability of bone ECM and the functionality of nanoparticles, the ICG encapsulated BPs (ICG/BPs) have been demonstrated to be utilized as a therapeutic option for localized and systemic orthopedic conditions. Additionally, ICG enables an in situ monitoring capability in the Short-Wave Infrared (SWIR) spectrum, capturing the degradation or the biodistribution of the ICG/BPs after both local implantation and intravenous administration, respectively. The efficacy and safety of the ICG/BPs shown within this study lay the foundation for future investigations, which will delve into optimization for clinical translation. This study developed a new type of bone-based nanoparticle (BPs) directly from the entire decellularized porcine bone, additionally encapsulating indocyanine green dye (ICG) for an in vivo monitoring capability.

AB Objective: The subchondral bone is an emerging regulator of osteoarthritis (OA). However, knowledge of how specific subchondral alterations relate to cartilage degeneration remains incomplete. Method: Femoral heads were obtained from 44 patients with primary OA during total hip arthroplasty and from 30 non-OA controls during autopsy. A multiscale assessment of the central subchondral bone region comprising histomorphometry, quantitative backscattered electron imaging, nanoindentation, and osteocyte lacunocanalicular network characterization was employed. Results: In hip OA, thickening of the subchondral bone coincided with a higher number of osteoblasts (controls: 3.7 +/- 4.5 mm(-1), OA: 16.4 +/- 10.2 mm(-1), age-adjusted mean difference 10.5 mm(-1) [95% CI 4.7 to 16.4], p < 0.001) but a similar number of osteoclasts compared to controls (p = 0.150). Furthermore, higher matrix mineralization heterogeneity (CaWidth, controls: 2.8 +/- 0.2 wt%, OA: 3.1 +/- 0.3 wt%, age-adjusted mean difference 0.2 wt% [95% CI 0.1 to 0.4], p = 0.011) and lower tissue hardness (controls: 0.69 +/- 0.06 GPa, OA: 0.67 +/- 0.06 GPa, age-adjusted mean difference -0.05 GPa [95% CI -0.09 to -0.01], p = 0.032) were detected. While no evidence of altered osteocytic perilacunar/canalicular remodeling in terms of fewer osteocyte canaliculi was found in OA, specimens with advanced cartilage degeneration showed a higher number of osteocyte canaliculi and larger lacunocanalicular network area compared to those with low-grade cartilage degeneration. Multiple linear regression models indicated that several subchondral bone properties, especially osteoblast and osteocyte parameters, were closely related to cartilage degeneration (R-2 adjusted = 0.561, p < 0.001). Conclusion: Subchondral bone properties in OA are affected at the compositional, mechanical, and cellular levels. Based on their strong interaction with cartilage degeneration, targeting osteoblasts/osteocytes may be a promising therapeutic OA approach. Data and materials availability: All data are available in the main text or the supplementary materials. (c) 2024 The Author(s). TI Novel heart valve leaflet designs with stiff polymeric materials and biomimetic kinematics

SO BIO-DESIGN AND MANUFACTURING
LA English
DT Article
DE Fully polymeric heart valve; Parametric leaflet design; Finite element analysis; Leaflet kinematics; In vitro testing
ID in-vitro; hydrodynamic function; behavior
AB Despite continuous efforts to improve the robustness of cardiac valve implants, neither bioprosthetic nor mechanical valves fulfill both hemodynamic and durability requirements. This study discussed novel flexible leaflet designs, focusing on polymeric materials with proven hemocompatibility, such as polyether ether ketone, of much higher stiffness than native tissue, aiming at optimal valve implants. A biomimetic valve with a single-curvature belly-curve (B-C) was used as a reference for new design variants with a double-curvature B-C with varying radii. Soft (13.2 MPa) and stiff (2.4 GPa) leaflet materials and different thicknesses were studied using lean simulations and in vitro experiments under physiologic hemodynamic conditions. The performance was assessed using opening pressure (OP) and orifice area (OA). The latter was determined by a newly developed automatized image processing tool. Experimental trends are in agreement with simulations and demonstrated that a buckling-inspired double-curvature leaflet design significantly enhances the trileaflet valve opening behavior, which is particularly advantageous for stiffer leaflet materials. Compared to the reference, the best-performing variant showed an OP improvement of 47% and 44% based on simulations and experiments, respectively. In contrast, the achieved mean pressure differential was directly comparable to state-of-the-art bioprosthetic valves. The OA was slightly reduced for new variants but still in the satisfying range.

TI Unraveling the potential of nanozymes in the tapestry of orthopedic healing
SO MATERIALS & DESIGN
LA English
DT Article

DE Nanozymes; Bone-related Disorders; Nanoparticles; Oxidative Stress; Biomedical Applications
ID intervertebral disc degeneration; oxidative stress; cerium oxide; femoral-head; bone; angiogenesis; nanoparticles; microenvironment; osteosarcoma; osteoarthritis
AB Bone-related disorders, such as osteoporosis, osteoarthritis, and osteosarcoma, have complex origins. Genetic, environmental factors, and significantly, oxidative stress due to Reactive Oxygen Species (ROS) play pivotal roles in these disorders. With their profound implications on global health, it becomes imperative to seek innovative therapeutic solutions. Nanozymes, known for their superior stability, cost-effectiveness, and tunable properties, present themselves as a prospective answer in mitigating ROS-driven bone ailments. This review explores the diverse applications and mechanisms of nanozymes in the context of bone health. They show potential in not only counteracting ROS-induced oxidative stress but also in modulating angiogenesis and showcasing antibacterial effects. We systematically analyze the effects of nanozymes on conditions such as osteonecrosis of the femoral head, skin flap transplantation, osteomyelitis, osteoarthritis, intervertebral disc disease, osteoporosis, and osteosarcoma, highlighting their potential roles in modulating disease processes. In addition, we discuss the challenges of applying nanozymes to orthopedic diseases. It offers insights into the transformative potential of nanozymes in bone therapeutics, underscoring the need to address challenges and capitalize on opportunities for their broader application in orthopedics.

TI Icariin promotes bone marrow mesenchymal stem cells osteogenic differentiation via the mTOR/autophagy pathway to improve ketogenic diet-associated osteoporosis
SO JOURNAL OF ORTHOPAEDIC SURGERY AND RESEARCH
LA English
DT Article
DE Icariin; mTOR; Ketogenic diet; Osteoporosis; Autophagy
ID turnover markers; animal-model; autophagy; osteoarthritis; management; metabolism; mechanisms; therapy; rat
AB BackgroundIcariin, a traditional Chinese medicine, has demonstrated anti-osteoporotic properties in ovariectomized mice. However, its effectiveness in preventing bone loss induced by ketogenic diet (KD), which mimics osteoporosis in human, remains unexplored. This study aims to investigate icariin's impact on KD-induced bone loss in mice.MethodsThirty mice were divided into: sham, KD, and KD + icariin groups. Post a 12-week intervention, evaluation including bone microstructures, serum concentrations of tartrate-resistant acid phosphatase (TRAP) and bone-specific alkaline phosphatase (ALP), and femoral tissue expression levels of osteocalcin (OCN) and TRAP. The expression levels of mammalian target of rapamycin (mTOR), ALP, peroxisome proliferator-activated receptor gamma (PPAR-gamma), phosphorylated mTOR (p-mTOR), and the autophagy adaptor protein (p62) were also analyzed. Alizarin granule deposition and cellular ALP levels were measured following the induction of bone marrow mesenchymal stem cells (BMSCs) into osteogenesis.ResultsThe study found that KD significantly impaired BMSCs' osteogenic differentiation, leading to bone loss. Icariin notably increased bone mass, stimulated osteogenesis, and reduced cancellous bone loss. In the KD + icariin group, measures such as bone tissue density (TMD), bone volume fraction (BV/TV), trabecular number (Tb.N), and trabecular thickness (Tb.Th) were significantly higher than in the KD group. Additionally, bone trabecular separation (Tb.Sp) was markedly lower in the KD + icariin group. Moreover, icariin increased OCN and ALP levels while suppressing PPAR-gamma, TRAP, p62, and p-mTOR. In cellular studies, icariin encouraged osteogenic development in BMSCs under KD conditions.ConclusionsIcariin effectively counteracts bone thinning and improves bone microstructure. Its mechanism likely involves stimulating BMSCs osteogenic differentiation and inhibiting bone resorption, potentially through mTOR downregulation. These findings suggest icariin's potential as an alternative treatment for KD-induced bone loss.

TI The role of O-GlcNAcylation in bone metabolic diseases
SO FRONTIERS IN PHYSIOLOGY
LA English
DT Review
DE O-GlcNAcylation; bone; cartilage; osteoporosis; osteoarthritis; osteosarcoma
ID n-acetylglucosamine modification; glcnac transferase; osteoclast differentiation; protein modification; mineral density; in-vitro; glucosamine; expression; osteoblast; growth
AB O-GlcNAcylation, as a post-translational modification, can modulate cellular activities such as kinase activity, transcription-translation, protein degradation, and insulin signaling by affecting the function of the protein substrate, including cellular localization of proteins, protein stability, and protein/protein interactions. Accumulating evidence suggests that dysregulation of O-GlcNAcylation is associated with disease progression such as cancer, neurodegeneration, and diabetes. Recent studies suggest that O-GlcNAcylation is also involved in the regulation of osteoblast, osteoclast and chondrocyte differentiation, which is closely related to the initiation and development of bone metabolic diseases such as osteoporosis, arthritis and osteosarcoma. However, the potential mechanisms by which O-GlcNAcylation regulates bone metabolism are not fully understood. In this paper, the literature related to the regulation of bone metabolism by O-GlcNAcylation was summarized to provide new potential therapeutic strategies for the treatment of orthopedic diseases such as arthritis and osteoporosis.

TI Subchondral insufficiency fractures: overview of MRI findings from hip to ankle joint
SO ROFO-FORTSCHRITTE AUF DEM GEBIET DER RONTGENSTRAHLEN UND DER BILDGEBENDEN VERFAHREN
LA English
DT Review
DE Subchondral insufficiency fracture; Hip; Knee; ankle; Magnetic resonance imaging
ID bone-marrow edema; spontaneous osteonecrosis; transient osteoporosis; femoral-head; early-stage; knee; lesions; tear
AB Background Subchondral insufficiency fracture (SIF) represents a potentially severe condition that can advance to osteoarthritis, with collapse of the articular surface. SIF manifests as a fracture in bone weakened by non-tumorous disease, precipitated by repetitive physiological stress, without a clear history of major trauma. It is observed along the central weight-bearing region of the femoral condyle, with a higher incidence in the medial femoral condyle, but also in other large weight-bearing synovial joints, such as the femoral head, tibial plateau, or talus. Method A review of the literature from the past six years was performed by searching PubMed and ScienceDirect databases, using the keywords "subchondral insufficiency fracture" and "spontaneous osteonecrosis of the knee". The inclusion criteria were scientific papers presented in the English language that reported on the magnetic resonance imaging (MRI) aspects of SIF of the lower limb. Results and Conclusion Detecting SIF at the level of the hip, knee, and ankle may present challenges both clinically and radiologically. The MRI appearance is dominated by a bone marrow edema-like signal and subchondral bone changes that can sometimes be subtle. Subchondral abnormalities are more specific than the pattern of bone marrow edema-like signal and are best shown on T2-weighted and proton-density-weighted MR images. MRI plays an important role in accurately depicting even subtle subchondral fractures at the onset of the disease and proves valuable in follow-up, prognosis, and the differentiation of SIF from other conditions. Key Points center dot Subchondral insufficiency fractures may affect the hip, knee, and ankle. center dot Subchondral insufficiency fractures may heal spontaneously or progress to collapse. center dot MRI is important for the detection, follow-up, and prognosis of subchondral insufficiency fractures. center dot Differential diagnosis may include transient osteoporosis and osteonecrosis of systemic origin.

TI The emerging role of Piezo1 in the musculoskeletal system and disease
SO THERANOSTICS
LA English
DT Review
DE Piezo1; bone; muscle; cartilage; intervertebral disc
ID mechanosensitive ion channels; duchenne muscular-dystrophy; stem-cell; skeletal-muscle; nucleus pulposus; satellite cells; blood-pressure; tendon injury; flow; transduction
AB Piezo1, a mechanosensitive ion channel, has emerged as a key player in translating mechanical stimuli into biological signaling. Its involvement extends beyond physiological and pathological processes such as lymphatic vessel development, axon growth, vascular development, immunoregulation, and blood pressure regulation. The musculoskeletal system, responsible for structural support, movement, and homeostasis, has recently attracted attention regarding the significance of Piezo1. This review aims to provide a comprehensive summary of the current research on Piezo1 in the musculoskeletal system, highlighting its impact on bone formation, myogenesis, chondrogenesis, intervertebral disc homeostasis, tendon matrix cross -linking, and physical activity. Additionally, we explore the potential of targeting Piezo1 as a therapeutic approach for musculoskeletal disorders, including osteoporosis, muscle atrophy, intervertebral

disc degeneration, and osteoarthritis.

ID osteoporosis
AB This study aimed to evaluate the prevalence of osteopenia/osteoporosis in patients with bilateral temporomandibular joint osteoarthritis (TMJ-OA) and its correlations with clinical and radiological findings. A total of 95 patients with bilateral TMJ-OA diagnosed by CBCT were included in the study. Clinical and radiological findings and bone mineral density (BMD) scores were recorded. Descriptive statistics and the Spearman rho correlation tests were performed. Osteopenia/osteoporosis was found in 44 of 95 patients (46.32 %) (30, osteopenia; 14 osteoporosis). Osteopenia/osteoporosis is significantly associated with postmenopausal status and age over 40 years, but it is not associated with clinical and radiological findings of TMJ-OA. Patients with bilateral TMJ-OA have a high prevalence of osteopenia/osteoporosis. (c) 2024 Published by Elsevier Masson SAS.

TI Air pollution and risk of 32 health conditions: outcome-wide analyses in a population-based prospective cohort in Southwest China
SO BMC MEDICINE
LA English
DT Article
DE Air pollution; Fine particulate matter components; Prospective cohort study; Multiple exposure analysis; Outcome-wide analysis
ID fine particulate matter; chemical-composition; hospital admissions; inflammation; disease; dysfunction; exposure; aerosol; coarse
AB Background Uncertainty remains about the long-term effects of air pollutants (AP) on multiple diseases, especially subtypes of cardiovascular disease (CVD). We aimed to assess the individual and joint associations of fine particulate matter (PM2.5), along with its chemical components, nitrogen dioxide (NO2) and ozone (O-3), with risks of 32 health conditions. Methods A total of 17,566 participants in Sichuan Province, China, were included in 2018 and followed until 2022, with an average follow-up period of 4.2 years. The concentrations of AP were measured using a machine-learning approach. The Cox proportional hazards model and quantile g-computation were applied to assess the associations between AP and CVD. Results Per interquartile range (IQR) increase in PM2.5 mass, NO2, O-3, nitrate, ammonium, organic matter (OM), black carbon (BC), chloride, and sulfate were significantly associated with increased risks of various conditions, with hazard ratios (HRs) ranging from 1.06 to 2.48. Exposure to multiple air pollutants was associated with total cardiovascular disease (HR 1.75, 95% confidence intervals (CIs) 1.62-1.89), hypertensive diseases (1.49, 1.38-1.62), cardiac arrests (1.52, 1.30-1.77), arrhythmia (1.76, 1.44-2.15), cerebrovascular diseases (1.86, 1.65-2.10), stroke (1.77, 1.54-2.03), ischemic stroke (1.85, 1.61-2.12), atherosclerosis (1.77, 1.57-1.99),

diseases of veins, lymphatic vessels, and lymph nodes (1.32, 1.15-1.51), pneumonia (1.37, 1.16-1.61), inflammatory bowel diseases (1.34, 1.16-1.55), liver diseases (1.59, 1.43-1.77), type 2 diabetes (1.48, 1.26-1.73), lipoprotein metabolism disorders (2.20, 1.96-2.47), purine metabolism disorders (1.61, 1.38-1.88), anemia (1.29, 1.15-1.45), sleep disorders (1.54, 1.33-1.78), renal failure (1.44, 1.21-1.72), kidney stone (1.27, 1.13-1.43), osteoarthritis (2.18, 2.00-2.39), osteoporosis (1.36, 1.14-1.61). OM had max weights for joint effects of AP on many conditions. Conclusions Long-term exposure to increased levels of multiple air pollutants was associated with risks of multiple health conditions. OM accounted for substantial weight for these increased risks, suggesting it may play an important role in these associations.

DT Article
DE Oroxylin A; RON; Osteoclast; Breast cancer; MDA-MB-231
ID receptor tyrosine kinase; bone metastases; mechanisms; osteoporosis; pathogenesis; activation
AB Background: Malignant breast cancer cells trigger the over-activation of osteoclast precursor cells, leading to bone loss and severe pain. Targeted inhibition of osteoclast differentiation has emerged as an important strategy for treating bone syndromes induced by breast cancer. Purpose: The objective is to discover natural osteoclast inhibitor to treat osteoclastogenesis and bone destruction induced by breast cancer, and clarify the specific mechanisms. Methods: Recepteur d'origine Nantais (RON) protein was employed to search the natural osteoclast inhibitor for breast cancer-induced osteoclastogenesis by molecular docking, molecular dynamics simulation and cellular thermal shift assay (CETSA). In the in vitro experiment, breast cancer MDA-MB-231 cell-conditioned medium (MDA-MB-231 CM) was used to induce osteoclastogenesis in murine bone marrow-derived macrophages (BMMs), aiming to elucidate the effects and mechanisms of the natural osteoclast inhibitor. In the in vivo model, MDA-MB-231 cells was injected into the mouse tibia to evaluate the therapeutic effect of drug on

breast cancerinduced bone destruction. Results: We discovered a significant increase in the expression of RON during MDA-MB-231 CM-induced osteoclast differentiation in vitro. Molecular docking analysis found that oroxylin A (OA), a flavonoid derived from the Chinese medicine Scutellaria baicalensis Georgi, showed binding ability with RON, while its impact and mechanism on breast cancer-induced osteoclastogenesis and osteolysis remains unclear. Molecular dynamics simulation and CETSA further revealed that OA bound directly to the RON protein, and it also decreased RON expression in breast cancer CM-induced osteoclastogenesis. Correspondingly, OA suppressed the MDA-MB-231 CM-induced osteoclastogenesis and bone resorption in vitro. The downstream signals of RON including Src and NFATc1, as well as the osteoclast-specific genes, were downregulated by OA. Of interesting, the suppressive effect of OA on osteoclastogenesis induced by MDA-MB-231 CM was abolished after RON was knocked down by the specific RON-siRNA, this further confirmed that OA showed inhibitory effects on osteoclasts through targeting RON. In addition, we found that OA attenuated MDA-MB-231 cell-induced osteolysis and reduced the number of osteoclasts in vivo. Conclusion: Our results indicate that OA acts as a natural RON inhibitor to suppress breast cancer-induced osteoclastogenesis and osteolysis. This provides new strategy for treating breast cancer-induced bone destruction and related syndromes.

TI Prevalence of Common Metabolic Bone Diseases Diagnosed by Dual-Energy

X-Ray Absorptiometry Scanning and Blood Test in Outpatients With Osteoarthritis the Knee
SO GERIATRIC ORTHOPAEDIC SURGERY & REHABILITATION
LA English
DT Article
DE metabolic bone diseases; vitamin D; osteoarthritis of the knee
ID mineral density; kidney-disease; osteoporosis; hip; population; fractures; femur; women
AB Introduction: Osteoarthritis of the knee (OA knee) is a common geriatric disease that require total knee arthroplasty. Periprosthetic fracture is one of the common complications, which is strongly related to metabolic bone disease. Materials and methods: We conducted a prospective study on 291 outpatients with OA knee between November 2020 and April 2021. Baseline characteristics, dual-energy X-ray absorptiometry and blood test results were analysed using logistic regression analysis and expressed as odds ratio, 95% confidence intervals and P-values. Results: Overall metabolic bone diseases were found in 82.91% of patients. Vitamin D insufficiency (53.38%) was the most prevalent, followed by osteopenia (44.38%), impaired renal function (26.69%), and osteoporosis (17.45%). Risk factors of vitamin D insufficiency are age >= 71 years (OR 0.33, P = 0.003) and bilateral affected side (OR 1.99, P = 0.007). For osteopenia and osteoporosis, risk factors were age, body mass index, affected side, and chronic kidney disease (P < 0.05). Discussion: In the aspect of Vit D insufficiency, age>70 and bilateral OA knee were significantly related in many ways, such as reduction in cutaneous synthesis and daily exposure to sunlight and various diseases, including CKD and GI malabsorption. The risk factors of osteopenia and osteoporosis can be explained throughout several mechanisms. For instance, abnormality in hormone and cytokines metabolism will lead to the increase in adipocyte differentiation and fat accumulation. And that situation may lead to the decrease in osteoblast differentiation and increased osteoclast activity which could lead to negative impact on bone strength. Conclusions: Metabolic bone diseases were common in most patients with OA knee, and the insufficiency in amount of vitamin D(serum 25-hydroxyvitamin D), osteoporosis, and osteopenia conditions were mainly identified. These preventable conditions have risk factors that are mostly correctable These preventable conditions have risk factors that are mostly correctable, for example gain more outdoor activities, consume vitamin D supplement or start osteoporosis treatment program. Further analysis is necessary to establish solid evidence in the comparison of risk factors between the OA and non-OA groups.

TI In Vitro and In Vivo Bone-Forming Effect of a Low-Molecular-Weight Collagen Peptide
SO JOURNAL OF MICROBIOLOGY AND BIOTECHNOLOGY

LA English
DT Article
DE collagen hydrolysate; Gly-Pro-Hyp; bone remodeling; Sprague-Dawley rats
ID pro-hyp; differentiation; tripeptide; microarchitecture; osteoarthritis; mineralization; proliferation; hydrolysate; metabolism; blood
AB This study reveals that low -molecular -weight collagen peptide (LMWCP) can stimulate the differentiation and the mineralization of MC3T3-E1 cells in vitro and attenuate the bone remodeling process in ovariectomized (OVX) Sprague-Dawley rats in vivo. Moreover, the assessed LMWCP increased the activity of alkaline phosphatase (ALP), synthesis of collagen, and mineralization in MC3T3-E1 cells. Additionally, mRNA levels of bone metabolism -related factors such as the collagen type I alpha 1 chain, osteocalcin (OCN), osterix, bone sialoprotein, and the Runt family -associated transcription factor 2 were increased in cells treated with 1,000 mu g/ml of LMWCP. Furthermore, we demonstrated that critical bone morphometric parameters exhibited significant differences between the LMWCP (400 mg/kg)-receiving and vehicle -treated rat groups. Moreover, the expression of type I collagen and the activity of ALP were found to be higher in both the femur and lumbar vertebrae of OVX rats treated with LMWCP. Finally, the administration of LMWCP managed to alleviate osteogenic parameters such as the ALP activity and the levels of the bone alkaline phosphatase, the OCN, and the procollagen type 1 N -terminal propeptide in OVX rats. Thus, our findings suggest that LMWCP is a promising candidate for the development of food -based prevention strategies against osteoporosis.

TI The biomedical applications of nanozymes in orthopaedics based on regulating reactive oxygen species
SO JOURNAL OF NANOBIOTECHNOLOGY
LA English
DT Review
DE Bone tissue engineering; Biomedical applications; Nanozymes; Orthopaedics; Reactive oxygen species
ID glutathione-peroxidase; nanoparticles; inflammation; mechanism; horizons; catalase; stress; enzyme; ros
AB Nanozymes, a category of nanomaterials with enzyme-like activity, have

garnered growing interest in various biomedical contexts. Notably, nanozymes that are capable of regulating reactive oxygen species levels by emulating antioxidant or prooxidant enzymes within cells hold significant therapeutic potential for a range of disorders. Herein, we overview the catalytic mechanisms of four exemplary nanozymes within the orthopedic domain. Subsequently, we emphasize recent groundbreaking advancements in nanozyme applications in orthopaedics, encompassing osteoarthritis, osteoporosis, intervertebral disc degeneration, bone defects, spinal cord injury, gout, rheumatoid arthritis, osteosarcoma and bone infection. Furthermore, we discuss the emerging area's future prospects and several noteworthy challenges in biomedical application. This review not only fosters the ongoing development of nanozyme research but also fosters the emergence of more potent nanozymes for the treatment of orthopaedical diseases in the future.

TI Oleanolic acid exerts bone anabolic effects via activation of osteoblastic 25-hydroxyvitamin D 1-alpha hydroxylase
SO BIOMEDICINE & PHARMACOTHERAPY
LA English
DT Article
DE 25-Hydroxyvitamin D 3 1-alpha-hydroxylase; Vitamin D; Osteoporosis; Oleanolic acid; Aging
ID vitamin-d-receptor; messenger-rna expression; parathyroid-hormone; gene-expression; cells; cyp27b1; differentiation; osteoporosis; d-3
AB Oleanolic acid (OA) is previously shown to exert bone protective effects in aged animals. However, its role in regulating osteoblastic vitamin D bioactivation, which is one of major causes of age-related bone loss, remains unclear. Our results revealed that treatment of OA significantly increased skeletal CYP27B1 expression and circulating 1,25(OH)(2)D-3 in ovariectomized mice ($p < 0.01$). Moreover, OA upregulated CYP27B1 protein expression and activity, as well as the vitamin D-responsive bone markers alkaline phosphatase (ALP) activity and osteopontin (OPN) protein expression, in human osteoblast-like MG-63 cells ($p<0.05$). CYP27B1 expression increased along with the osteoblastic differentiation of human bone marrow derived mesenchymal stem cells (hMSCs). CYP27B1 expression and cellular 1,25(OH)(2)D-3 production were further potentiated by OA in cells at mature osteogenic stages. Notably, our study suggested that the osteogenic actions of OA were CYP27B1 dependent. In summary, the bone protective effects of OA were associated with the induction of CYP27B1 activity and expression in bone tissues and osteoblastic lineages. Hence, OA might be a potential approach for management of age-related bone loss.

DT Review
DE bone targeting; receptor mediation; glycobiology; bone and cartilage development
ID enzyme replacement therapy; mesenchymal stem-cells; osteogenic differentiation; delivery-system; receptor; matrix; osteopontin; expression; binding; channels
AB Bone development is characterized by complex regulation mechanisms, including signal transduction and transcription factor-related pathways, glycobiological processes, cellular interactions, transportation mechanisms, and,

importantly, chemical formation resulting from hydroxyapatite. Any abnormal regulation in the bone development processes causes skeletal system-related problems. To some extent, the avascularity of cartilage and bone makes drug delivery more challenging than that of soft tissues. Recent studies have implemented many novel bone-targeting approaches to overcome drawbacks. However, none of these strategies fully corrects skeletal dysfunction, particularly in growth plate-related ones. Although direct recombinant enzymes (e.g., Vimizim for Morquio, Cerezyme for Gaucher, Elaprase for Hunter, Mepsevii for Sly diseases) or hormone infusions (estrogen for osteoporosis and osteoarthritis), traditional gene delivery (e.g., direct infusion of viral or non-viral vectors with no modifications on capsid, envelope, or nanoparticles), and cell therapy strategies (healthy bone marrow or hematopoietic stem cell transplantation) partially improve bone lesions, novel delivery methods must be addressed regarding target specificity, less immunogenicity, and duration in circulation. In addition to improvements in bone delivery, potential regulation of bone development mechanisms involving receptor-regulated pathways has also been utilized. Targeted drug delivery using organic and inorganic compounds is a promising approach in mostly preclinical settings and future clinical translation. This review comprehensively summarizes the current bone-targeting strategies based on bone structure and remodeling concepts while emphasizing potential approaches for future bone-targeting systems.

TI Effect of Osteoporosis Treatments on Osteoarthritis Progression in Postmenopausal Women: A Review of the Literature
SO CURRENT RHEUMATOLOGY REPORTS
LA English
DT Review
DE Osteoporosis; Osteoarthritis (OA); Bisphosphonate; Selective estrogen receptor modulators (SERMs); Parathyroid hormone (PTH); Denosumab
ID parathyroid-hormone 1-34; knee osteoarthritis; bisphosphonate use; rat model; denosumab; estrogen; bone; cartilage; metaanalysis; association
AB Purpose of ReviewThe purpose of this literature review was to determine if medications used to treat osteoporosis are also effective for treating osteoarthritis (OA).Recent FindingsA total of 40 relevant articles were identified. Studies were categorized into those (1) discussing estrogen and selective estrogen receptor modulators (SERMs), (2) bisphosphonates, (3) parathyroid hormone (PTH) analogs, and (4) denosumab, and (5) prior review articles. A large amount of evidence suggests that estrogen and SERMs are effective at reducing OA symptoms and disease progression. Evidence suggests that bisphosphonates, the most common medications used to treat osteoporosis, can reduce OA symptoms and disease progression. In vivo studies suggest that PTH analogs may improve the cartilage destruction associated with OA; however, few human trials have examined its use for OA. Denosumab is approved to treat osteoporosis, bone metastases, and certain types of breast cancer, but little study has been done with respect to its effect on OA.SummaryThe current evidence indicates that medications used to treat osteoporosis are also effective for treating OA. Estrogen, SERMs, and bisphosphonates have the most potential as OA therapies. Less is known regarding the effectiveness of PTH analogs and denosumab in OA, and more research is needed.

TI Influence of Sex and Gender on Musculoskeletal Conditions and How They Are Reported
SO JOURNAL OF BONE AND JOINT SURGERY-AMERICAN VOLUME
LA English
DT Review
ID 17-beta-estradiol; risk; testosterone; chondrocytes; responses; severity; exhibit
AB There is increasing evidence that musculoskeletal tissues are differentially regulated by sex hormones in males and females. The influence of sex hormones, in addition to other sex-based differences such as in anatomical alignment and immune-system function, impact the prevalence and severity of disease as well as the types of injuries that affect the musculoskeletal system and the outcomes of prevention measures and treatment. Literature specifically addressing sex differences related to the musculoskeletal system is limited, underscoring the imperative for both basic and clinical research on this topic. This review highlights areas of research that have implications for bone and cartilage health, including growth and development, sports injuries, osteoarthritis, osteoporosis, and bone frailty. It is clear that important aspects of the musculoskeletal system have been understudied. Consideration of how sex hormone therapy will affect musculoskeletal tissues in prepuberty, during puberty, and in adults is vital, yet little is known. The purpose of this article is to foster awareness and interest in advancing our understanding of how sex differences influence orthopaedic practice.

TI Development and validation of a three-dimensional nomogram prediction model for knee osteoarthritis in middle-aged population
SO JOURNAL OF ORTHOPAEDIC SURGERY AND RESEARCH
LA English
DT Article
DE Knee osteoarthritis; Middle-aged; Risk factor; Uncomfortable symptom; Nomogram
ID risk-factors; prevalence; management
AB ObjectivesThis study aims to identify predictors of knee osteoarthritis (KOA) risk in middle-aged population, construct and validate a nomogram for KOA in this demographic.MethodsFrom June to December 2020, we conducted a cross-sectional survey on 5,527 middle-aged individuals from Changsha and Zhangjiajie cities in Hunan Province, selected using a stratified multi-stage random sampling method. Data collection involved a structured questionnaire

encompassing general demographic, physical condition, and lifestyle behaviors dimensions. The dataset was randomly split into a training set (n = 3868) and a validation set (n = 1659) at a 7:3 ratio via computerized randomization. We analyzed the prevalence of self-reported KOA and identified its influencing factors using logistic regression. A nomogram was constructed based on these "three-dimensional" factors. Subsequent validation was conducted, and the nomogram's performance was further evaluated through ROC curves, C-index, Hosmer-Lemeshow test, and calibration curves.ResultsThe self-reported prevalence of KOA in the middle-aged population was 11.4% (632/5527). The risk factor with the greatest impact is: diagnosed with osteoporosis(95% CI 2.269-3.568, OR = 2.845), followed by age between 51 to 60 years (95% CI 2.176-3.151, OR = 2.619), diagnosed with hypertension(95% CI 1.633-2.499, OR = 2.02), diagnosed with diabetes (OR = 1.689), ethnic Han Chinese (OR = 1.673), exercise according to physical condition (OR = 1.643), pay attention to keeping the knee joint warm (OR = 1.535), eating habits are mainly light vegetables (OR = 1.374), male gender (OR = 1.343), drink occasionally in small amounts (OR = 1.286); a higher level of education (OR = 0.477) and frequently or always apply an external or plaster to relieve symptoms after knee discomfort (OR = 0.377; OR = 0.385) are protective factors.The C-index of the training set model was 0.8107 (95% CI: 0.8102-0.8111), with a statistically significant area under the ROC curve (AUC = 0.818), and the calibration curve showed a good fit. The C-index for the validation set was 0.8124 (95% CI: 0.8109-0.8140), with an AUC of 0.812. The Hosmer-Lemeshow test resulted in a P-value of 0.46 (P >= 0.05)indicating good calibration of the model.ResultsThe self-reported prevalence of KOA in the middle-aged population was 11.4% (632/5527). The risk factor with the greatest impact is: diagnosed with osteoporosis(95% CI 2.269-3.568, OR = 2.845), followed by age between 51 to 60 years (95% CI 2.176-3.151, OR = 2.619), diagnosed with hypertension(95% CI 1.633-2.499, OR = 2.02), diagnosed with diabetes (OR = 1.689), ethnic Han Chinese (OR = 1.673), exercise according to physical condition (OR = 1.643), pay attention to keeping the knee joint warm (OR = 1.535), eating habits are mainly light vegetables (OR = 1.374), male gender (OR = 1.343), drink occasionally in small amounts (OR = 1.286); a higher level of education (OR = 0.477) and frequently or always apply an external or plaster to relieve symptoms after knee discomfort (OR = 0.377; OR = 0.385) are protective factors.The C-index of the training set model was 0.8107 (95% CI: 0.8102-0.8111), with a statistically significant area under the ROC curve (AUC = 0.818), and the calibration curve showed a good fit. The C-index for the validation set was 0.8124 (95% CI: 0.8109-0.8140), with an AUC of 0.812. The Hosmer-Lemeshow test resulted in a P-value of 0.46 (P >= 0.05)indicating good calibration of the model. ConclusionThe three dimensions nomogram generated in this study was a valid and easy-to-use tool for assessing the risk of KOA in middle-aged population, and helped healthcare professionals to screen the high-risk population.

TI Lumbar Osteoarthritis in Patients with Osteoporosis Evaluated with the Lane and Wilke Scale and its Effect on Dexa Scores
SO JOURNAL OF CLINICAL DENSITOMETRY
LA English
DT Article
DE Dexa; Lane and Wilke Scale; Lumbar osteoarthritis; Osteoporosis
ID bone-mineral density; radiographic osteoarthritis; hand osteoarthritis; association; knee; hip; population; turnover; fracture; women
AB Objective: This study aimed to compare bone mineral density (BMD) values in patients with lumbar osteoarthritis (OA) with and without osteoporosis (OP). This study evaluated the effect of lumbar osteoarthritis in patients with osteoporosis on Dexa scores using the Lane and Wilke scale. Methods: A total of 51 individuals with OA, 20 with OP, and 31 without OP were included in the study. Lumbar osteoarthritis was assessed and recorded using the Lane and Wilke scale. BMD was measured by dual-energy X-ray absorptiometry (DEXA) at the waist and hip (femoral neck, lumbar vertebrae). Frax assessed the risk of osteoporosis and fracture risk. Results: The mean age of patients with OP was 68.1 +/- 8.2 years, and the mean age of patients without OP was 68.6 +/- 9.4 years. There was a significant decrease between the lumbar vertebrae and femoral neck BMD values of the two groups in favor of the osteoporosis group. The t-scores of the OP group were significantly lower ($p = 0.045$). All variables showed a statistically significant difference between the group with OP and those without OP ($p<0.05$). The median values of L1-L2, L2-L3, L3-L4, and total L1-L4 were higher in absolute value in the group with OP. In frax hip and frax primary osteoporosis, the median values were higher in the group with OP than in the group without OP ($p = 0.023/p = 0.020$). All L1-L2, L2-L3, and L3-L4 dexa parameters with and without OP were not significantly different between the groups according to the Lane and Wilke classification ($p> 0.05$). Conclusion: There was no statistically significant difference between DEXA parameters in osteoporosis and non-osteoporosis patients with low back osteoarthritis (according to the Lane and Wilke classification).

TI Regional disparities, age-related changes and sex-related differences in knee osteoarthritis
SO BMC MUSCULOSKELETAL DISORDERS
LA English
DT Article
DE Knee osteoarthritis; Age-standardized rates; Incidence; Sex-Related Differences; Risk factors
ID body-mass index; risk; hip; osteoporosis; association; prevention; injury; obesity; level; women
AB BackgroundThe objective of the study is to analyse the regions, age and sex differences in the incidence of knee osteoarthritis (KOA).MethodsData were extracted from the global burden of diseases (GBD) 2019 study, including incidence, years lived with disability (YLD), disability-adjusted life-years (DALYs) and risk factors. Estimated annual percentage changes (EAPCs) were calculated to quantify the temporal trends in age standardized rate (ASR) of KOA. Paired t-test, paired Wilcoxon signed-rank test and spearman correlation were performed to analyze the association of sex disparity in KOA and socio-demographic index (SDI).ResultsThere were significant regional differences in the incidence of knee osteoarthritis. In 2019, South Korea had the highest incidence of knee osteoarthritis (474.85,95%UI:413.34-539.64) and Thailand had the highest increase in incidence of knee osteoarthritis (EAPC = 0.56, 95%CI = 0.54-0.58). Notably, higher incidence, YLD and DALYs of knee osteoarthritis were associated with areas with a high socio-demographic index ($r = 0.336$, $p < 0.001$; $r = 0.324$, $p < 0.001$; $r = 0.324$, $p < 0.001$). In terms of age differences, the greatest increase in the incidence of knee osteoarthritis was between the 35-39 and 40-44 age groups. (EAPC = 0.52, 95%CI = 0.40-0.63; 0.47, 95%CI = 0.36-0.58). In addition, there were significant sex differences in the disease burden of knee osteoarthritis ($P < 0.001$).ConclusionsThe incidence of knee osteoarthritis is significantly different with regions, age and sex.

DT Article
DE Aged; Comorbidity; Chronic disease; Network analysis
ID urinary-incontinence; peptic-ulcer; otitis-media; depression; association; regulator; women
AB The detailed comorbidity patterns of community-dwelling older adults have not yet been explored. This study employed a network-based approach to investigate the comorbidity patterns of community-dwelling older adults living alone. The sample comprised a cross-sectional cohort of adults 65 or older living alone in a Korean city (n = 1041; mean age = 77.7 years, 77.6% women). A comorbidity network analysis that estimates networks aggregated from measures of significant co-occurrence between pairs of diseases was employed to investigate comorbid associations between 31 chronic conditions. A cluster detection algorithm was employed to identify specific clusters of comorbidities. The association strength was expressed as the observed-to-expected ratio (OER). As a result, fifteen diseases were interconnected within the network (OER > 1, p-value < .05). While hypertension had a high prevalence, osteoporosis was the most central disease, co-occurring with numerous other diseases. The strongest associations among comorbidities were found between thyroid disease and urinary incontinence, chronic otitis media and osteoporosis, gastric duodenal ulcer/gastritis and anemia, and depression and gastric duodenal ulcer/gastritis (OER > 1.85). Three distinct clusters were identified as follows: (a) cataracts, osteoporosis, chronic otitis media, osteoarthritis/rheumatism, low back pain/sciatica, urinary incontinence, post-accident sequelae, and thyroid diseases; (b) hyperlipidemia, diabetes mellitus, and hypertension; and (c) depression, skin disease, gastric duodenal ulcer/gastritis, and anemia. The results may prove valuable in guiding the early diagnosis, management, and treatment of comorbidities in older adults living alone.

TI Vitamin K2 in Health and Disease: A Clinical Perspective
SO FOODS
LA English
DT Review
DE vitamin K2; VK2; menaquinone; health; therapeutic potential
ID matrix gla protein; hepatocellular-carcinoma; k intake; gamma-carboxylation; growth-inhibition; kappa-b; monocytic differentiation; dietary phylloquinone; insulin-resistance; metabolic syndrome
AB Vitamins are essential organic compounds that vary widely in chemical structure

and are vital in small quantities for numerous biochemical and biological functions. They are critical for metabolism, growth, development and maintaining overall health. Vitamins are categorised into two groups: hydrophilic and lipophilic. Vitamin K (VK), a lipophilic vitamin, occurs naturally in two primary forms: phylloquinone (VK1), found in green leafy vegetables and algae, and Menaquinones (VK2), present in certain fermented and animal foods and widely formulated in VK supplements. This review explores the possible factors contributing to VK deficiency, including dietary influences, and discusses the pharmacological and therapeutic potential of supplementary VK2, examining recent global clinical studies on its role in treating diseases such as osteoporosis, osteoarthritis, rheumatoid arthritis, cardiovascular disease, chronic kidney disease, diabetes, neurodegenerative disorders and cancers. The analysis includes a review of published articles from multiple databases, including Scopus, PubMed, Google Scholar, ISI Web of Science and CNKI, focusing on human studies. The findings indicate that VK2 is a versatile vitamin essential for human health and that a broadly positive correlation exists between VK2 supplementation and improved health outcomes. However, clinical data are somewhat inconsistent, highlighting the need for further detailed research into VK2 ' s metabolic processes, biomarker validation, dose-response relationships, bioavailability and safety. Establishing a Recommended Daily Intake for VK2 could significantly enhance global health.

TI Current knowledge of bone-derived factor osteocalcin: its role in the management and treatment of diabetes mellitus, osteoporosis, osteopetrosis and inflammatory joint diseases
SO JOURNAL OF MOLECULAR MEDICINE-JMM
LA English
DT Review
DE Osteocalcin; Preclinical and clinical studies; Diabetes mellitus; Osteoporosis; Osteopetrosis; Inflammatory joint diseases
ID serum undercarboxylated osteocalcin; glucocorticoid-induced osteoporosis; endoplasmic-reticulum stress; diet-induced obesity; mineral density; turnover markers; postmenopausal women; glucose-metabolism; alkaline-phosphatase; biochemical markers
AB Osteocalcin (OC) is the most abundant non-collagenous and osteoblast-secreted protein in bone. It consists of two forms such as carboxylated OC (cOC) and undercarboxylated OC (ucOC). While cOC promotes bone mineralization and increases bone strength, ucOC is regarded an endocrinologically active form that may have several functions in multiple end organs and tissues. Total OC (tOC) includes both of these forms (cOC and ucOC) and is considered a marker of bone turnover in clinical settings. Most of the data on OC is limited to

preclinical studies and therefore may not accurately reflect the situation in clinical conditions. For the stated reason, the aim of this review was not only to summarize current knowledge of all forms of OC and characterize its role in diabetes mellitus, osteoporosis, osteopetrosis, inflammatory joint diseases, but also to provide new interpretations of its involvement in the management and treatment of aforementioned diseases. In this context, special emphasis was placed on available clinical trials. Significantly lower levels of tOC and ucOC could be associated with the risk of type 2 diabetes mellitus. On the contrary, tOC level does not seem to be a good indicator of high bone turnover status in postmenopausal osteoporosis, osteoarthritis and rheumatoid arthritis. The associations between several pharmacological drugs used to treat all disorders mentioned above and OC levels have also been provided. From this perspective, OC may serve as a medium through which certain medications can influence glucose metabolism, body weight, adiponectin secretion, and synovial inflammation.

TI Resolving Organic Aerosol Components Contributing to the Oxidative Potential of PM2.5 in the North China Plain
SO JOURNAL OF GEOPHYSICAL RESEARCH-ATMOSPHERES
LA English
DT Article
ID ambient particulate matter; mass spectrometers ams; air-pollution; severe haze; humic-like; oxygen; dithiothreitol; particles; dtt; generation
AB The oxidative potential (OP) of ambient particulate matter (PM) is a common metric for estimating PM toxicity and linking PM exposure to adverse health effects. Organic aerosol (OA), a dominant fraction of ambient PM worldwide, may significantly contribute to PM toxicity. Here, we investigated the source-based OA components contributing to the OP of PM in the urban (Beijing, summer and winter) and rural (Gucheng, winter) environments of the North China Plain (NCP). Various OA components as identified by the aerosol mass spectrometer/aerosol chemical speciation monitor (AMS/ACSM), transition metals, and black carbon were compared with the OP of PM measured by dithiothreitol assays. The results consistently demonstrate the importance of OA as a contributor to PM's OP in both urban and rural NCP environments. Higher intrinsic OP was observed in winter Beijing than in summer, possibly due to OA being predominantly from anthropogenic sources in winter. Furthermore, different OA components were

found to drive the response of OP in the two environments. More-oxidized oxygenated OA (MO-OOA), cooking OA, and oxidized primary OA (during winter) are the OA contributors to OP in the urban environment, with a dominant contribution from MO-OOA. In contrast, biomass burning OA (BBOA) and OOA play a major role in the OP in the rural environment, with BBOA making the largest contribution. Overall, this work highlights the significance of OA in determining PM's OP and calls for more work to reveal the sources and characteristics of OA components contributing to OP across different regions.

TI Prevalence of comorbidities and cardiovascular risk factor management in hand osteoarthritis: a cross-sectional study
SO RHEUMATOLOGY INTERNATIONAL
LA English
DT Article
DE Hand osteoarthritis; Cardiovascular risk profile; Comorbidities
ID population; disease; events
AB ObjectivesTo assess the prevalence of comorbidities and management of cardiovascular risk factors according to established guidelines for patients with hand osteoarthritis.MethodsA cross-sectional study was conducted that included 110 hand osteoarthritis patients. The clinical parameters (pain, function, grip strength, quality of life, sarcopenia, and comorbidities) were assessed along with cardiovascular (CV) risk factors (blood pressure, body mass index, and dyslipidaemia). CV risk was assessed using SCORE2 or SCORE2-OP algorithms. Comparisons of patient characteristics were performed using Student's or chi-squared tests.ResultsTwenty-eight patients were identified with comorbidities, and they tended to be older, male, and with a lower quality of life. The median SCORE2 was 5.1%. SCORE2 was negatively associated with grip strength (r=-0.27, p = 0.02). There was no difference in SCORE2 between hand osteoarthritis patients with (n = 60) and without (n = 50) neuropathic-like pain (5.6 +/- 3.7 versus 6.2 +/- 3.3%; p = 0.38). Among the 40 patients with an intermediate or high CV risk, 33 (82.5%) were off target for low-density lipoproteins (LDL) level with no lipid-lowering treatment (n = 29) or an insufficient statin treatment (n = 4). Obesity

was observed in 24 patients (21.8%) and 30 (27.3%) were overweight. Forty-two patients (41.2%) had blood hypertension (41 systolic and one diastolic patient) despite treatment for 9 patients.ConclusionsWe found an increased CV risk in hand osteoarthritis patients who had an insufficient LDL cholesterol target achievement. Hand osteoarthritis patients appear to have a pro-atherogenic profile. These results suggest that CV risk factors should be assessed in patients with hand osteoarthritis and managed according to recommended guidelines.

TI The interplay between osteoarthritis and osteoporosis: Mechanisms, implications, and treatment considerations - A narrative review
SO EXPERIMENTAL GERONTOLOGY
LA English
DT Review
DE Osteoarthritis; Osteoporosis; Pathophysiological mechanisms
ID foxo transcription factors; bone-mineral density; articular-cartilage; osteopontin; association; pathogenesis; polymorphism; progression; severity; mediator
AB This comprehensive review examines the relationship between osteoarthritis (OA) and osteoporosis (OP), two common disorders in the elderly. OA involves joint cartilage degeneration and pain, while OP leads to fractures due to reduced bone mass. Despite different pathologies, both conditions share risk factors such as age and genetics. Studies reveal mixed results: some show higher bone mineral density (BMD) in OA patients, suggesting an inverse relationship, while others find no significant link. Proposed mechanisms include mechanical loading, bone remodeling, and inflammation. Clinical strategies focus on maintaining bone health in OA and monitoring joint health in OP, with treatments like bisphosphonates and exercise. Understanding these interactions is crucial for developing integrated treatments to improve patient outcomes and quality of life. Further research is needed to clarify these complex mechanisms.

TI Evidence-Based Guideline for the management of osteoporosis in men
SO NATURE REVIEWS RHEUMATOLOGY
LA English
DT Article
ID trabecular bone score; fracture risk reduction; cost-utility analysis; hip fracture; older men; postmenopausal women; parathyroid-hormone; zoledronic acid; mineral density; european-society
AB Historically, osteoporosis has been viewed as a disease of women, with research, trials of interventions and guidelines predominantly focused as such. It is apparent, however, that this condition causes a substantial health burden in men also, and that its assessment and management must ultimately be addressed across both sexes. In this article, an international multidisciplinary working group of the European Society for Clinical and Economic Aspects of Osteoporosis, Osteoarthritis and Musculoskeletal Diseases presents GRADE-assessed recommendations for the diagnosis, monitoring and treatment of osteoporosis in men. The recommendations are based on a comprehensive review of the latest research related to diagnostic and screening approaches for osteoporosis and its associated high fracture risk in men, covering disease burden, appropriate interpretation of bone densitometry (including the use of a female reference database for densitometric diagnosis in men) and absolute fracture risk, thresholds for treatment, and interventions that can be used therapeutically and their health economic evaluation. Future work should specifically address the efficacy of anti-osteoporosis medications, including denosumab and bone-forming therapies.

In this Evidence-Based Guideline article, an international multidisciplinary working group of the European Society for Clinical and Economic Aspects of Osteoporosis, Osteoarthritis and Musculoskeletal Diseases presents recommendations for the diagnosis, monitoring and treatment of osteoporosis in men.

TI Prediction of prognosis in supramalleolar osteotomy with or without additional fibula osteotomy by approaching a biomechanical study: a finite element analysis
SO BIOMEDICAL ENGINEERING LETTERS
LA English
DT Review
DE Supramalleolar osteotomy; Fibular osteotomy; Osteoarthritis; Finite element analysis; Ankle joint
ID low tibial osteotomy; ankle osteoarthritis; wedge osteotomy; varus deformity; opening wedge; arthritis; joint; foot
AB Supramalleolar osteotomy (SMO) is a representative procedure to restore a malalignment in the varus ankle deformity by shifting the concentrated pressure on the medial ankle joint to the lateral area. Additionally, fibula osteotomy (FO) is selectively selected and performed according to the surgeon's preference. However, it is controversial whether FO is effective in shifting the abnormal

pressure from the medial to the lateral area on the ankle joint. Some cadaveric studies have been performed to prove this. However, it is difficult to consistently reconstruct amount of the varus ankle deformities angle in cadavers and to guarantee reliable contact pressure between the ankle joint. Thus, the aim of this study was predicted and quantitatively compared a peak pressure between single SMO and SMO with FO procedure by using a finite element analysis as a powerful biomechanical tool to those limitations of cadaveric study. This study reconstructed total 4 3D foot and ankle models including a normal and pre-op model and 2 post-op models. The pre-op model was modified by assigning 10 degrees varus tilting corresponding to stage 3b in the classification of varus ankle osteoarthritis based on the validated normal model. Also, the post-op models were reconstructed by applying single SMO and SMO with FO, respectively. All of the models were assumed as one-leg standing position and to mimic smooth ankle joint motion. Peak contact pressure change was predicted at the medial ankle joint by using computational simulation. As a result, 2 post-op models showed a remarkably peak pressure reduction by up to 5.5 times on the medial tibiotalar joint. However, a comparison between single SMO and SMO with FO model showed no appreciable differences. In conclusion, this study predicted that single SMO may be as effective as SMO with FO in reducing peak contact pressure on the medial tibiotalar joint in varus ankle osteoarthritis.

TI Euthanasia and Physician-Assisted Suicide in People With an Accumulation of Health Problems Related to Old Age: A Cross-Sectional Questionnaire Study Among Physicians in the Netherlands
SO INTERNATIONAL JOURNAL OF PUBLIC HEALTH
LA English
DT Article
DE accumulation of health problems related to old age; euthanasia; physician-assisted suicide; end-of-life care; medical decision-making
ID requests
AB Objectives: We explored characteristics of people with an accumulation of health problems related to old age requesting euthanasia or physician-assisted suicide (EAS) and identified characteristics associated with granting EAS requests.

Methods: We conducted a cross-sectional questionnaire study among Dutch physicians on characteristics of these people requesting EAS (n = 123). Associations between characteristics and granting a request were assessed using logistic regression analyses. Results: People requesting EAS were predominantly >80 years old (82.4%), female (70.0%), widow/widower (71.7%), (partially) care-dependent (76.7%), and had a life expectancy >12 months (68.6%). The most prevalent health problems were osteoarthritis (70.4%) and impaired vision and hearing (53.0% and 40.9%). The most cited reasons to request EAS were physical deterioration (68.6%) and dependence (61.2%). 44.7% of requests were granted. Granting a request was positively associated with care dependence, disability/immobility, impaired vision, osteoporosis, loss of control, suffering without prospect of improvement and a treatment relationship with the physician >12 months. Conclusion: Enhanced understanding of people with an accumulation of health problems related to old age requesting EAS can contribute to the ongoing debate on the permissibility of EAS in people without life-threatening conditions.

TI Why Pharmacovigilance of Non-steroidal Anti-inflammatory Drugs is Important in India?
SO ENDOCRINE METABOLIC & IMMUNE DISORDERS-DRUG TARGETS
LA English
DT Review
DE Adverse drug reaction; drug safety design; NSAIDS; patient safety; pharmacovigilance; regulatory affairs
ID cancer pain management; low-dose aspirin; adverse-reactions; rheumatoid-arthritis; gastrointestinal toxicity; current perspectives; cardiovascular risk; human pharmacology; nsaids; barriers
AB Background Non-steroidal Anti-Inflammatory Drugs (NSAIDs) are among the drugs that are most regularly administered to manage inflammation and pain. Over-the-Counter (OTC) NSAIDs are widely accessible, particularly in developing countries like India. This casual approach to using NSAIDs may operate as a magnet for NSAID-related adverse drug reactions (ADRs) among

patients.Objectives As patients in India are less informed about the appropriate use of NSAIDs and consumption patttern, adverse drug reactions, and the importance of reporting ADRs, the current study's objective is to promote patient safety by using pharmacovigilance as a tool to educate patients.Methods A targeted literature methodology was utilized to gather the data pertaining to NSAIDs, their ADRs and their pharmacovigilance. Different scientific databases, such as Science Direct, PubMed, Wiley Online Library, Springer, and Google Scholar, along with authentic textbooks, were explored as reference literature.Results In general, NSAIDs consumption pattern depends upon the different age groups. Around 1.6 billion tablets of NSAIDs are consumed in India for ailments, such as headaches, arthritis, menstrual cramps, osteoarthritis, back pain, rheumatoid arthritis, gout, osteoporosis, tendinitis, cancer pain and chronic pain. Common ADRs of NSAIDs include nausea, vomiting, headache, gastritis, abdominal pain, and diarrhoea. Also, they can cause renal damage and cardiovascular problems if not consumed in a dose-dependent manner. However, Diclofenac and Ibuprofen have both been linked to depression and dementia. There have been reports of aplastic anaemia, agranulocytosis linked to phenylbutazone, Stevens-Johnson, and Lyell's syndrome linked to isoxicam and piroxicam, as well as the vulnerability of new-borns to Reye's syndrome after aspirin use. Lack of awareness, time constraints and unpredictability, poor training in ADRs identification, etc., are some of the reasons for the under-reporting of ADR of NSAIDs in India.Conclusion In order to rationally prescribe NSAIDs, it is essential to be aware of probable ADR's and establish prescription guidelines. Prescribers' behaviour can be changed toward excellent prescribing practices by conducting routine prescription assessments dealing with NSAIDs and providing feedback. In the near future, it will be critical to strengthen ADR data management and expand the reach of pharmacovigilance programs, ADR monitoring centers, and healthcare professionals' especially pharmacists' training in rural locations.

TI Parathyroid hormone (1-34) retards the lumbar facet joint degeneration and activates Wnt/β-catenin signaling pathway in ovariectomized rats
SO JOURNAL OF ORTHOPAEDIC SURGERY AND RESEARCH
LA English
DT Article
DE Joint degeneration; Lumbar facet joint; Parathyroid hormone; Wnt/beta-catenin signaling; Cartilage; Subchondral bone; Ovariectomized rat model
ID subchondral bone; differentiated osteoblasts; terminal differentiation; articular chondrocytes; disc degeneration; back-pain; osteoarthritis; cartilage; estrogen; model
AB Purpose Facet joint degeneration (FJD) is a major cause of low back pain. Parathyroid hormone (PTH) (1-34) is commonly used to treat osteoporosis. However, little is known about its effects on FJD induced by estrogen deficiency.

This study aims to investigate the effects of PTH (1-34) on FJD induced by estrogen deficiency and the underlying pathogenesis of the disease.Methods Forty 3-month-old female Sprague-Dawley rats were randomly divided into four groups: 30 received bilateral ovariectomy (OVX) followed by 12 weeks of treatment with normal saline, PTH (1-34) or 17 beta-estradiol (E2), and 10 received sham surgery followed by administration of normal saline. Status and Wnt/beta-catenin signaling activity in the cartilage and subchondral bone of the L4-L5 FJs and serum biomarkers were analyzed.Results Administration of PTH (1-34) and E2 ameliorated cartilage lesions, and significantly decreased MMP-13 and caspase-3 levels and chondrocyte apoptosis. PTH (1-34) but not E2 significantly increased cartilage thickness, number of chondrocytes, and the expression of aggrecan. PTH (1-34) significantly improved microarchitecture parameters of subchondral bone, increased the expression of collagen I and osteocalcin, and decreased RANKL/OPG ratio. E2 treatment significantly increased the OPG level and decreased the RANKL/OPG ratio in the subchondral bone of ovariectomized rats, but it did not significantly improve the microarchitecture parameters of subchondral bone. Wnt3a and beta-catenin expression was significantly reduced in the articular cartilage and subchondral bone in OVX rats, but PTH (1-34) could increase the expression of these proteins. E2 significantly increased the activity of Wnt/beta-catenin pathway only in cartilage, but not in subchondral bone. The restoration of Wnt/beta-catenin signaling had an obvious correlation with the improvement of some parameters associated with the FJs status.Conclusion Wnt/beta-catenin signaling may be a potential therapeutic target for FJD induced by estrogen deficiency. PTH (1-34) is effective in treating this disease with better efficacy than 17 beta-estradiol, and the efficacy may be attributed to its restoration of Wnt/beta-catenin signaling.

TI Well-known polypeptides of deer antler velvet with key actives: modern pharmacological advances
SO NAUNYN-SCHMIEDEBERGS ARCHIVES OF PHARMACOLOGY
LA English
DT Review
DE Deer antler polypeptides; System-related diseases; Pharmacology; Review
ID negative breast-cancer; neural stem-cells; pilose-antler; osteoblast differentiation; oxidative stress; gut microbiota; peptide; proliferation; injury; prevents
AB Deer antler velvet, with kidney tonifying, promoting the production of essence and blood, strengthening tendons and bones, not only has a thousand-year medicinal history but also its modern pharmacology mainly focuses on its active polypeptides on motor, nerve, and immune systems. The purpose of this report is to fill the gap in the comprehensive, systematic, and detailed review of polypeptides during the recent 30 years (1992-2023). The research method was to review 53 pharmacological articles from the Public Medicine, Web of science, ACS, and Science Direct database sources by searching the keywords " pilose antler," "deer velvet," "Pilose Antler Peptide (PAP) and Velvet Antler Polypeptide (VAP)." The results showed that deer antler polypeptides (DAPs), by regulating EGF, EGFR, MAPK, P38, ERK, NF-.B, Wnt, PI3K, Akt, MMP, AMPK, Stir1, NLRP3, HO-1, Nrf, Rho, TLR, TGF-beta, Smad, Ang II, etc., revealed their effects on seven system-related diseases and their mechanisms, including osteoarthritis, intervertebral disc degeneration, osteoporosis, Alzheimer's, Parkinson's, triplenegative breast cancer, liver injury, liver fibrosis, cardiovascular disease, acute lung injury, and late-onset hypogonadism. In conclusion, DAPs have good effects on motor and other system-related diseases, but the secondary and tertiary structures of DAPs (0.5-1800 KDa) need to be further elucidated, and the structure-activity relationship study is still unavailable and needs to be covered. It is expected that this review may provide

the necessary literature support for further research.

AB Chronic pancreatitis (CP), a progressive inflammatory disease, poses diagnostic challenges due to its initially asymptomatic nature. While CP's impact on exocrine and endocrine functions is well-recognized, its potential influence on other body systems, particularly in young individuals, remains underexplored. This study investigates the hypothesis that CP in growing pigs leads to alterations in articular cartilage and subchondral bone, potentially contributing to osteoarthritis (OA) development. Utilizing a pig model of cerulein-induced CP, we examined the structural and compositional changes in subchondral bone, articular cartilage, and synovial fluid. Histological analyses, including Picrosirius Red and Safranin-O staining, were employed alongside immuno-histochemistry and Western blotting techniques. Our findings reveal significant changes in the subchondral bone, including reduced bone volume and alterations in collagen fiber composition. Articular cartilage in CP pigs exhibited decreased proteoglycan content and alterations in key proteins such as MMP-13 and TGF-beta 1, indicative of early cartilage degradation. These changes suggest a link between CP and musculoskeletal alterations, underscoring the need for further research into CP's systemic effects. Our study provides foundational insights into the relationship

between CP and skeletal health, potentially guiding future pediatric healthcare strategies for early CP diagnosis and management.

TI Work intensity and fat mass percentage are associated with asymptomatic morphometric vertebral fractures in knee osteoarthritis patients: A cross-sectional study
SO PLOS ONE
LA English
DT Article
ID risk; osteoporosis; prevalence; men; index; women; pain
AB Knee osteoarthritis (OA) is a common condition with a prevalence of 365 million individuals globally, and it is an independent risk factor for falls and fractures, notably asymptomatic morphometric vertebral fractures (AMVF). The high prevalence of knee OA, the severity of AMVF, and their combined impacts on quality of life underscore the need for early detection, appropriate treatment and management. To address this, our cross-sectional study aims to identify potential predictive factors associated with AMVF in knee OA patients. Our cohort consisted of 76 patients diagnosed with knee OA, predominantly female (84.2%), of Malay ethnicity (84.2%), and obese (55.3%). In univariable analysis, significant association was found between occupation (moderate or heavy work) and AMVF ($p<0.001$). Diabetes mellitus comorbidity ($p = 0.016$) and fat mass percentage ($p = 0.027$) also demonstrated a significant association with AMVF in knee OA patients. Multivariable logistic regression analysis revealed that an increase in fat mass percentage resulted in decreased AMVF incidence (HR: 0.83, 95% CI: 0.70-0.97; $p = 0.018$), while occupation (moderate or heavy work) remained a highly significant predictor (HR: 57.76, 95% CI: 4.23-788.57; $p = 0.002$). These findings support the potential importance of considering occupational activities and body fat composition in managing AMVF among knee OA patients, but further research is required to establish causal relationships.

TI Diagnostic Reliability of Plain Radiography in Osteonecrosis of the Femoral Head: General Radiological Features Revised
SO CURRENT MEDICAL IMAGING
LA English
DT Article
DE Osteonecrosis of the femoral head; Avascular necrosis of the hip; Radiological diagnosis; Radiograph; Reliability; Ficat and Arlet classification
ID total hip-arthroplasty; avascular necrosis; interobserver; reproducibility; classification; ficat; ct
AB Background and Objectives: Osteonecrosis of the femoral head (ONFH) is an incapacitating disease that frequently results in the collapse of the femoral head and secondary osteoarthritis. The diagnosis and staging of this pathology, which usually rely on imaging studies, are challenging. Currently, conventional radiography is the basis of the initial diagnostic assessment. In recent decades, however, radiographs have been considered insensitive to early changes in ONFH and thus, a suboptimal diagnostic tool. Paradoxically, the imaging features of radiographs are often profuse, substantial, and characteristic. This study aimed to elucidate the real limitations of this radiologic tool by assessing the diagnostic reliability of the key radiologic features and staging.Methods: This was a retrospective study in which radiographs from 28 idiopathic ONFH confirmed cases who underwent hip arthroplasty were analyzed by eight observers who were asked to identify the presence or absence of ONFH universally reported imaging features in AP hip radiographs.Results: Concordance analysis revealed a poor agreement between observers for most of the assessed imaging features. Only the identification of femoral head flattening and osteoarthritis signs exhibited moderate agreement with statistical significance. In contrast, the detection of radiological osteoporosis and the loss of trabeculation showed the lowest reliability, with negative kappa coefficients.Conclusion: There is a lack of agreement between qualified observers, even for the identification of the most characteristic ONFH radiographic features. The reliability of plain radiography for the detection

of basic radiological elements is even weaker in the early stages of the disease.

TI Length-Weight Relationship, Condition Factor and Otolith Shape Indices of Four Creek-Associated Fish of the Northeastern Arabian Sea
SO ACTA ZOOLOGICA BULGARICA
LA English
DT Article
DE Otolith; condition factor; mean area; marine fish
ID size; river; morphology; basin; history; growth; north; bay
AB This study aimed to estimate the relationship between fish size and otolith size of four creek-associated fishes (Anodontostoma chacunda, Epinephelus diacanthus, Johnius glaucus and Mugil cephalus) collected from the north-eastern Arabian Sea from November 2021 to November 2022. The numerical relations were established using regression between fish size (Total length-TL and Body weight-BW) and otolith dimensions (Length-OL, Weight-Owt, Area-OA, Width-OW and Perimeter-OP). All regressions between the fish size and otolith morphometric measurements were highly correlated (R-2 > 0.8), which indicates the robustness of the model. Taxonomists can use findings from this study for species confirmation and reconstruction of past species assemblages. These findings might provide insight into predicting the prey size in food and feeding studies to explore the food web dynamics.

TI Sex differences of NF-KB-targeted therapy for mitigating osteoporosis associated with chronic inflammation of bone
SO BONE & JOINT RESEARCH
LA English
DT Article
ID kappa-b kinase; rheumatoid-arthritis; resorption; female; osteoarthritis; osteonecrosis; prevention; inhibitor; particles; mediator
AB Aims Transcription factor nuclear factor kappa B (NF -KB) plays a major role in the pathogenesis of chronic inflammatory diseases in all organ systems. Despite its importance, NF -KB targeted drug therapy to mitigate chronic inflammation has had limited success in preclinical studies. We hypothesized that sex differences affect the response to NF -KB treatment during chronic inflammation in bone. This study investigated the therapeutic effects of NF -KB decoy oligodeoxynucleotides (ODN) during chronic inflammation in male and female mice. Methods We used a murine model of chronic inflammation induced by continuous intramedullary delivery of lipopolysaccharide-contaminated polyethylene particles (cPE) using an osmotic pump. Specimens were evaluated using micro-CT and histomorphometric analyses. Sex-specific osteogenic and osteoclastic differentiation potentials were also investigated in vitro, including alkaline phosphatase, Alizarin Red, tartrate-resistant acid phosphatase staining, and gene expression using reverse transcription polymerase chain reaction (RT-PCR). Results Local delivery of NF -KB decoy ODN in vivo increased osteogenesis in males, but not females, in the presence of chronic inflammation induced by cPE. Bone resorption activity was decreased in both sexes. In vitro osteogenic and osteoclastic differentiation assays during inflammatory conditions did not reveal differences among the groups. Receptor activator of nuclear factor kappa B ligand (Rankl) gene expression by osteoblasts was significantly decreased only in males when treated with ODN. Conclusion We demonstrated that NF -KB decoy ODN increased osteogenesis in male mice and decreased bone resorption activity in both sexes in preclinical models of chronic inflammation. NF -KB signalling could be a therapeutic target for chronic inflammatory diseases involving bone, especially in males.

TI Contribution of macrophage polarization in bone metabolism: A literature review
SO CYTOKINE
LA English
DT Article
DE Macrophages polarization; Rheumatoid arthritis; Osteoarthritis; Osteoporosis; Bone metabolism
ID cell; nanoparticles

AB Macrophage polarization divides macrophages into two main cell subpopulations, classically and alternatively activated macrophages (M1 and M2, respectively). M1 polarization promotes osteoclastogenesis, while M2 polarization promotes osteogenesis. The physiological homeostasis of bone metabolism involves a high dynamic balance between osteoclastic-mediated bone resorption and formation. Reportedly, M1/M2 imbalance causes the onset and persistence of inflammation-related bone diseases. Therefore, understanding the research advances in functions and roles of macrophages in such diseases will provide substantial guidance for improved treatment of bone diseases. In this review, we underscore and summarize the research advances in macrophage polarization, and bone-related diseases, such as rheumatoid arthritis, osteoarthritis, and osteoporosis, over the last 5 years. Our findings showed that targeting macrophages and balancing macrophage polarization can effectively reduce inflammation and decrease bone destruction while promoting bone formation and vascular repair. These results indicate that regulating macrophage and macrophage polarization to restore homeostasis is a prospective approach for curing bone-related diseases.

TI Role of signaling pathways in age-related orthopedic diseases: focus on the fibroblast growth factor family
SO MILITARY MEDICAL RESEARCH
LA English
DT Review
DE Fibroblast growth factor (FGF); Fibroblast growth factor receptor (FGFR); Osteoarthritis (OA); Intervertebral disc degeneration (IVDD); Orthopedic degeneration; Osteoporosis (OP); Sarcopenia
ID factor receptor 1; skeletal-muscle mass; protein-kinase-c; articular-cartilage; knee osteoarthritis; intraarticular sprifermin; chondrocyte proliferation; heparan-sulfate; fgf receptor-3; high-affinity
AB Fibroblast growth factor (FGF) signaling encompasses a multitude of functions, including regulation of cell proliferation, differentiation, morphogenesis, and patterning. FGFs and their receptors (FGFR) are crucial for adult tissue repair processes. Aberrant FGF signal transduction is associated with various pathological conditions such as cartilage damage, bone loss, muscle reduction, and other core pathological changes observed in orthopedic degenerative diseases like osteoarthritis (OA), intervertebral disc degeneration (IVDD), osteoporosis (OP), and sarcopenia. In OA and IVDD pathologies specifically, FGF1, FGF2, FGF8, FGF9, FGF18, FGF21, and FGF23 regulate the synthesis, catabolism, and ossification of cartilage tissue. Additionally, the dysregulation of FGFR expression (FGFR1 and FGFR3) promotes the pathological process of cartilage degradation. In OP and sarcopenia, endocrine-derived FGFs (FGF19, FGF21, and FGF23) modulate bone mineral synthesis and decomposition as well as muscle tissues. FGF2 and other FGFs also exert regulatory roles. A growing body of research has focused on understanding the implications of FGF signaling in orthopedic degeneration.

Moreover, an increasing number of potential targets within the FGF signaling have been identified, such as FGF9, FGF18, and FGF23. However, it should be noted that most of these discoveries are still in the experimental stage, and further studies are needed before clinical application can be considered. Presently, this review aims to document the association between the FGF signaling pathway and the development and progression of orthopedic diseases. Besides, current therapeutic strategies targeting the FGF signaling pathway to prevent and treat orthopedic degeneration will be evaluated.

TI Denosumab ameliorates osteoarthritis by protecting cartilage against degradation and modulating subchondral bone remodeling
SO REGENERATIVE THERAPY
LA English
DT Article
DE Osteoarthritis; Denosumab; Osteoclast; Chondrocyte
ID chondrocyte apoptosis; differentiation; osteoporosis; pathogenesis; teriparatide; mice
AB Osteoarthritis (OA) is the most prevalent degenerative joint disease worldwide. Effective management for early-stage OA is crucial. Denosumab (DS) has been widely used to treat osteoporosis (OP) and rheumatoid arthritis, but its potential for managing OA remains clear. We assessed the effects of DS on osteoclast activity and chondrocyte apoptosis using tartrate-resistant acid phosphatase (TRAP) assay, quantitative real-time polymerase chain reaction (qRT-PCR), flow cytometry, and TUNEL staining. To assess the impact of DS on the NF-kB pathway, we performed Western blot and immunofluorescence staining. Additionally, we used an OA model to explore the influence of DS on subchondral bone remodeling and cartilage degeneration in vivo. We found that DS hindered receptor activator of nuclear factor kappa B ligand (RANKL)-induced osteoclastogenesis by inhibiting the activity of the NF-kB pathway. Besides, DS alleviated reactive oxygen species (ROS)-induced apoptosis in chondrocytes by regulating the expression of genes related to apoptosis. Moreover, we observed an attenuation of OArelated subchondral bone remodeling and cartilage degeneration in vivo. Our findings indicate that DS could effectively suppress osteoclast activity and chondrocyte apoptosis, thereby mitigating OA-related subchondral bone remodeling and cartilage degeneration. These results provide a mechanistic basis for using DS to treat OA. (c) 2024, The Japanese Society for Regenerative Medicine. Production and hosting by Elsevier B.V. TI The difference in bone mineral density between femur and tibia is related to tibia deformation in endstage knee osteoarthritis
SO KNEE
LA English
DT Article
DE Osteoporosis; Knee osteoarthritis; Varus alignment
ID varus osteoarthritis; proximal tibia; alignment; osteoporosis; progression; women; risk
AB Background: This study investigated bone mineral density (BMD) around the knee joint to clarify the mechanism by which tibia deformation exceeds that of the femur in patients with end-stage knee osteoarthritis (KOA). Methods: We retrospectively analyzed 193 patients who underwent total knee arthroplasty for end-stage KOA with varus alignment. Preoperative T-score of the femur neck and femur total using dual-energy X-ray absorptiometry (DXA) and hounsfield units (HU) of the distal femur and proximal tibia using computed tomography (CT) were measured to asess the BMD. HU was measured by dividing the femur and tibia into medial, lateral, and total parts, respectively. Patients with medial proximal tibial angle (MPTA) < 85 degrees were considered 'group 1 , and MPTA < 85 degrees were 'group 2 . The HU between femur and tibia were compared in group 1. T-score, HU, and HU difference between group 1 and group 2 were compared. Results: The HU of the proximal tibia was lower than that of the distal femur (femur lateral > femur medial > tibia medial > tibia lateral). T-score (femur neck, femur total) and HU (femur lateral, femur total, tibia lateral) were lower in group 2 than in group 1. There was no difference in femur-tibia HU difference between groups. Conclusion: The medial tibia collapse more than the medial femur in varus endstage KOA was associated with the lower BMD of the proximal tibia than that of the distal femur, and the MPTA collapse was affected by the absolute value of BMD rather than by the femur-tibia BMD difference. TI Vitamin K2 ameliorates osteoarthritis by suppressing ferroptosis and extracellular matrix degradation through activation GPX4's dual functions
SO BIOMEDICINE & PHARMACOTHERAPY
LA English
DT Article
DE Vitamin K2; GPX4's dual functions; Knee osteoarthritis; Ferroptosis; Extracellular matrix degradation; MAPK/NF kappa B pathway
ID articular-cartilage; inactivation; regulator
AB Vitamin K2 (VK2) is an effective compound for anti-ferroptosis and anti-osteoporosis, and Semen sojae praeparatum (Dandouchi in Chinese) is the

main source of VK2. Chondrocyte ferroptosis and extracellular matrix (ECM) degradation playing a role in the pathogenesis of osteoarthritis (OA). Glutathione peroxidase 4 (GPX4) is the intersection of two mechanisms in regulating OA progression. But no studies have elucidated the therapeutic effects and mechanisms of VK2 on OA. This study utilized an in vivo rat OA model created via anterior cruciate ligament transection (ACLT) and an in vitro chondrocyte oxidative damage model induced by TBHP to investigate the protective effects and mechanisms of action of VK2 in OA. Knee joint pain in mice was evaluated using the Von Frey test. Micro-CT and Safranin O-Fast Green staining were employed to observe the extent of damage to the tibial cartilage and subchondral bone, while immunohistochemistry and PCR were used to examine GPX4 levels in joint cartilage. The effects of VK2 on rat chondrocyte viability were assessed using CCK-8 and flow cytometry assays, and chondrocyte morphology was observed with toluidine blue and alcian blue staining. The impact of VK2 on intracellular ferroptosis-related markers was observed using fluorescent staining and flow cytometry. Protein expression changes were detected by immunofluorescence and Western blot analysis. Furthermore, specific protein inhibitors were applied to confirm the dual-regulatory effects of VK2 on GPX4. VK2 can increase bone mass and cartilage thickness in the subchondral bone of the tibia, and reduce pain and the OARSI score induced by OA. Immunohistochemistry results indicate that VK2 exerts its anti-OA effects by regulating GPX4 to delay ECM degradation. VK2 can inhibit the activation of the MAPK/NF kappa B signaling pathway caused by reduced expression of intracellular GPX4, thereby decreasing ECM degradation. Additionally, VK2 can reverse the inhibitory effect of RSL3 on GPX4, increase intracellular GSH content and the GSH/GSSG ratio, reduce MDA content, and rescue chondrocyte ferroptosis. The protective mechanism of VK2 may involve its dualtarget regulation of GPX4, reducing chondrocyte ferroptosis and inhibiting the MAPK/NF kappa B signaling pathway to decelerate the degradation of the chondrocyte extracellular matrix.

TI Pulsed Electromagnetic Field Stimulation in Bone Healing and Joint Preservation: A Narrative Review of the Literature
SO APPLIED SCIENCES-BASEL
LA English
DT Review
DE pulsed electromagnetic fields; PEMFs; capacitively coupled electric fields; CCEFs; bone healing; joint preservation; traumatology; sport medicine; hip and knee replacement; reverse shoulder arthroplasty
ID double-blind; biophysical stimulation; knee osteoarthritis; electrical-stimulation; adenosine receptors; therapy; cells; pain; osteonecrosis; osteoporosis
AB Background: Biophysical stimulation therapy, Pulsed Electromagnetic Fields (PEMFs) and Capacitively Coupled Electric Fields (CCEFs) have significantly increased in the last twenty years. Due to this, it is necessary to have clear information regarding their efficacy, therapeutic indications and expected objectives. Application fields: There is a unanimous opinion regarding the usefulness of applying biophysical therapy on the bone compartment both in

terms of the tissue-healing process and the symptoms associated with this situation. Differently, but no less important, positive results were observed in the joint compartment, especially with regard to the inhibition of the inflammatory process. Good results for chondroprotection were obtained in vitro and after a surgical procedure. New studies have shown the effectiveness also in cases of osteoporosis. Conclusions: The effectiveness of PEMFs and CCEFs on the bone-healing process and on joint preservation in the orthopedic and traumatology fields has consolidated evidence in the literature. We have also found positive results for symptoms and patient compliance with rehabilitation therapies. Therefore, their notable applications can be envisaged in the fields of prosthetic surgery and sports medicine.

TI The Role of Extracellular Vesicles in Bone Regeneration and Associated Bone Diseases
SO CURRENT ISSUES IN MOLECULAR BIOLOGY
LA English
DT Review
DE EVs; bone regeneration; mechanisms; diagnosis; treatment
ID mesenchymal stem-cells; promote angiogenesis; exosm; osteoarthritis; delivery; differentiation; microvesicles; osteoporosis; diagnosis; membrane
AB Extracellular vesicles (EVs) are nanoscale particles with a lipid bilayer membrane structure secreted by various cell types. Nearly all human cells secrete EVs, primarily mediating intercellular communication. In recent years, scientists have discovered that EVs can carry multiple biological cargos, such as DNA, non-coding RNAs (ncRNAs), proteins, cytokines, and lipids, and mediate intercellular signal transduction. Bone is a connective tissue with a nerve supply and high vascularization. The repair process after injury is highly complex, involving interactions among multiple cell types and biological signaling pathways. Bone regeneration consists of a series of coordinated osteoconductive and osteoinductive biological processes. As mediators of intercellular communication, EVs can promote bone regeneration by regulating osteoblast-mediated bone formation, osteoclast-mediated bone resorption, and other pathways. This review summarizes the biogenesis of EVs and the mechanisms by which EV-mediated intercellular communication promotes bone regeneration. Additionally, we focus on the research progress of EVs in various diseases related to bone regeneration. Finally, based on the above research, we explore the clinical applications of engineered EVs in the diagnosis and treatment of bone regeneration-related diseases.

TI Should trochanteric fractures in elderly patients be treated by arthroplasty or internal fixation?
SO ORTHOPAEDICS & TRAUMATOLOGY-SURGERY & RESEARCH
LA English
DT Review
DE Trochanteric fractures; Arthroplasty; Internal fixation; Extramedullary fixation; Intramedullary fixation
ID unstable intertrochanteric fractures; cementless bipolar hemiarthroplasty; total hip-arthroplasty; proximal femoral nail; intramedullary fixation; femur fractures; replacement; complications; mortality; failure
AB Most trochanteric fractures are treated by fixation, most often intramedullary. Nevertheless, the desire to have patients walk as soon as possible and the fear of fixation failure has driven some surgeons to carry out an arthroplasty instead,

especially for unstable fractures and/or in patients with severe osteoporosis, in order to avoid the difficult conversion to arthroplasty later on if the fixation fails. The aim of this review was to specify the role, technique and results of performing arthroplasty in this context. In which fractures? Unstable fractures (A2.2, A2.3 and A3), especially in osteoporotic bone, which are the most difficult to reduce and fix, and in cases with associated osteoarthritis. For which patients? Arthroplasty should not be done in patients who have ASA = 3 due to greater blood loss and longer operative time. Since the postoperative Parker score often drops, arthroplasty should not be done in patients having a Parker score < 6. What are the technical problems? Arthroplasty must be done by an experienced surgeon because of the lack of anatomical landmarks, although fracture fixation has its own demands (satisfactory reduction, appropriate length and position of cervicocephalic screw). What are the results and complications? Despite several comparative studies (randomized trials, meta-analysis and prospective studies), it is difficult to draw any conclusions. These studies show worse performance of dynamic hip screws relative to intramedullary nails. The complication and revision rates were higher for nails than arthroplasty, but not in every study, while the functional outcomes with nails (with or without immediate weightbearing) were better than those of arthroplasty beyond 6 months. What is the mortality rate? It was lower after nailing in a few studies but was mainly determined by the patient's comorbidities and preoperative Parker score. The best indication for arthroplasty may be self-sufficient patients over 70 years of age who have an unstable fracture with severe osteoporosis. Nevertheless, new studies should be done to compare arthroplasty to nailing with immediate return to weightbearing in patients having the same type of fracture, defined using 3D CT scan. TI IVD fibrosis and disc collapse comprehensively aggravate vertebral body disuse osteoporosis and zygapophyseal joint osteoarthritis by posteriorly shifting the load transmission pattern
SO COMPUTERS IN BIOLOGY AND MEDICINE
LA English
DT Article
DE Intervertebral disc fibrosis; Disuse osteoporosis; Disc collapse; Load transmission pattern; Numerical models
ID finite-element-analysis; end-plate; clinical-applications; calibration method; hounsfield units; lumbar spine; degeneration; model; epidemiology; accuracy
AB Background: Disuse is a typical phenotype of osteoporosis, but the underlying mechanism has yet to be identified in elderly patients. Disc collapse and intervertebral disc (IVD) fibrosis are two main pathological changes in IVD degeneration (IDD) progression, given that these changes affect load transmission patterns, which may lead to disuse osteoporosis of vertebral bodies and zygapophyseal joint (ZJ) osteoarthritis (ZJOA) biomechanically. Methods: Clinical data from 59 patients were collected retrospectively. Patient vertebral bony density, ZJOA grade, and disc collapse status were judged via CT. The IVD fibrosis grade was determined based on the FA measurements. Regression analyses identified

potential independent risk factors for osteoporosis and ZJOA. L4L5 numerical models with and without disc collapse and IVD fibrosis were constructed; stress distributions on the bony endplate (BEP) and zygapophyseal joint (ZJ) cartilages were computed in models with and without disc collapse and IVD fibrosis. Results: A significantly lower disc height ratio and significantly greater FA were recorded in patients with ZJOA. A significant correlation was observed between lower HU values and two parameters related to IDD progression. These factors were also proven to be independent risk factors for both osteoporosis and ZJOA. Correspondingly, compared to the intact model without IDD. Lower stress on vertebral bodies and greater stress on ZJOA can be simultaneously recorded in models of disc collapse and IVD fibrosis. Conclusions: IVD fibrosis and disc collapse simultaneously aggravate vertebral body disuse osteoporosis and ZJOA by posteriorly shifting the load transmission pattern.

TI The Value of Computer Vision in Identifying the Bone of Dialysis Patients
SO CURRENT MEDICAL IMAGING
LA English
DT Article
DE Dialysis; Osteoporosis; Computer vision; Convolution neural networks; ResNet; Kidney disease
ID osteoporosis; management
AB Background: In the end stage of kidney disease, abnormal levels of blood calcium, phosphorus, and parathyroid hormone lead to bone metabolism disorders, manifesting as osteoporosis or fibrocystic osteoarthritis. X-ray, CT, and MR are useful for detecting bone lesions in dialysis patients, but currently, computer vision has not yet been used for this purpose. Methods: ResNet is a powerful deep CNN model, which has not yet been used to distinguish between the bones of dialysis patients and healthy people. Therefore, this study aimed to

investigate the ability of the Resnet50 model to identify the bone of dialysis patients from normal bone. Results: CT images of 200 cases (100 dialysis patients and 100 healthy people aged 31-72 years with male:female ratio of 51:49) were randomly divided into the training and testing groups at the ratio of 8:2. The module of 'torch' was used to train the model of Resnet50 for the current task of image classification. In the test cohort, the accuracy, sensitivity, and specificity with hyper-parameter=0 were 60%, 65%, and 55%, respectively. When the hyper-parameter was 0.6 or 0.7 versus 0, the accuracy was significantly higher ($P<0.05$). When the hyper-parameter was another number, the accuracy was not significantly different from that with no hyper-parameter ($P>0.05$). Conclusion: This study has indicated computer vision to be suitable for identifying bone changes caused by dialysis; a hyper-parameter has been found necessary for improving model accuracy. The ResNet50 model with hyper-parameter = 0.7 has exhibited 90% sensitivity in identifying the bone of dialysis patients.

TI Similarities and differences between European guidelines for the management of postmenopausal osteoporosis
SO ARCHIVES OF OSTEOPOROSIS
LA English
DT Article
DE European guidelines; Postmenopausal osteoporosis; Fracture risk
ID risk; denosumab; fracture
AB We conducted a review of 10 national guidelines from five EU countries to identify similarities or differences in recommendations for the management of patients with osteoporosis. We found general alignment of key recommendations; however, there are notable differences, largely attributed to country-specific approaches to risk assessment and reimbursement conditions. Introduction The classification of fracture risk is critical for informing treatment decisions for post-menopausal osteoporosis. The aim of this review was to summarise 10 national guidelines from five European countries, with a focus on identifying similarities or differences in recommendations for the management of patients with osteoporosis. Methods We summarised the European Society for Clinical and Economic Aspects of Osteoporosis, Osteoarthritis and Musculoskeletal Disease-International Osteoporosis Foundation guidelines and reviewed guidelines from France, Germany, Italy, Spain and the UK. Results The approach to risk assessment differed across the guidelines. In France, and Spain, risk assessment was based on DXA scans and presence of prior fractures, whereas UK, German and Italian guidelines recommended use of a validated risk tool. These differences led to distinct definitions of very high and high-risk patients. Guidelines aligned in recommending antiresorptive and anabolic agents as pharmacologic options for the management of osteoporosis, with sequential treatment recommended. There was agreement that patients at high or very high risk of fracture or with severe osteoporosis should receive anabolic agents first, followed by antiresorptive drugs. Variations were identified in recommendations for follow up of patients on anti-osteoporosis therapies. Reimbursement conditions in each country were a key difference identified. Conclusions Criteria for risk assessment of fractures differ across European guidelines which may impact treatment and access to anabolic agents. Harmonisation across EU guidelines may help identify patients eligible for treatment and impact treatment uptake. However, country-specific reimbursement and prescribing processes may present a challenge to achieving a consistent approach across Europe.

TI Controlled mechanical loading affects the osteocyte transcriptome in porcine trabecular bone in situ

ID endothelial growth-factor; nf-kappa-b; differential gene; fluid-flow; rna; expression; strength; tnf; osteoblasts; adaptation
AB Introduction: Osteocytes modulate bone adaptation in response to mechanical stimuli imparted by the deforming bone tissue in which they are encased by communicating with osteoclasts and osteoblasts as well as other osteocytes in the lacuna-canalicular network through secreted cytokines and chemokines. Understanding the transcriptional response of osteocytes to mechanical stimulation in situ could identify new targets to inhibit bone loss or enhance bone formation in the presence of diseases like osteoporosis or metastatic cancer. We compared the mechanically regulated transcriptional response of osteocytes in trabecular bone following one or three days of controlled mechanical loading. Methods: Porcine trabecular bone explants were cultured in a bioreactor for 48 h and subsequently loaded twice a day for one day or 3 days. RNA was isolated and sequenced, and the Tuxedo suite was used to identify differentially expressed genes and pathway analysis was conducted using Ingenuity Pathway Analysis (IPA). Results: There were about 4000 differentially expressed genes following in situ culture relative to fresh bone. One hundred six genes were differentially expressed between the loaded and non-loaded groups following one day of loading compared to 913 genes after 3 d of loading. Only 45 of these were coincident between the two time points, indicating an evolving transcriptome. Clustering and principal component analysis indicated differences between the loaded and non-loaded groups after 3 d of loading. Discussion: With sustained loading, there was a nine-fold increase in the number of differentially expressed genes, suggesting that osteocytes respond to loading through sequential activation of downstream genes in the same pathways. The differentially expressed genes were related to osteoarthritis, osteocyte, and chondrocyte signaling pathways. We noted that NFkB and TNF signaling are affected by early loading and this may drive downstream effects on the mechanobiological response. Moreover, these genes may regulate catabolic effects of mechanical disuse through their actions on pre-osteoclasts in the bone marrow niche.

TI Investigating mechanical and inflammatory pathological mechanisms in osteoarthritis using MSC-derived osteocyte-like cells in 3D
SO FRONTIERS IN ENDOCRINOLOGY

LA English
DT Article
DE osteocyte; mechanical load; osteoarthritis; inflammation; 3D model; RNAseq analysis
ID excitatory amino-acids; bone-marrow lesions; glutamate receptors; synovial-fluids; tnf-alpha; knee pain; expression; interleukin-6; differentiation; association
AB Introduction Changes to bone physiology play a central role in the development of osteoarthritis with the mechanosensing osteocyte releasing factors that drive disease progression. This study developed a humanised in vitro model to detect osteocyte responses to either interleukin-6, a driver of degeneration and bone remodelling in animal and human joint injury, or mechanical loading, to mimic osteoarthritis stimuli in joints. Methods Human MSC cells (Y201) were differentiated in 3-dimensional type I collagen gels in osteogenic media and osteocyte phenotype assessed by RTqPCR and immunostaining. Gels were subjected to a single pathophysiological load or stimulated with interleukin-6 with unloaded or unstimulated cells as controls. RNA was extracted 1-hour post-load and assessed by RNAseq. Markers of pain, bone remodelling, and inflammation were quantified by RT-qPCR and ELISA. Results Y201 cells embedded within 3D collagen gels assumed dendritic morphology and expressed mature osteocytes markers. Mechanical loading of the osteocyte model regulated 7564 genes (Padj $p<0.05$, 3026 down, 4538 up). 93% of the osteocyte transcriptome signature was expressed in the model with 38% of these genes mechanically regulated. Mechanically loaded osteocytes regulated 26% of gene ontology pathways linked to OA pain, 40% reflecting bone remodelling and 27% representing inflammation. Load regulated genes associated with osteopetrosis, osteoporosis and osteoarthritis. 42% of effector genes in a genome-wide association study meta-analysis were mechanically regulated by osteocytes with 10 genes representing potential druggable targets. Interleukin-6 stimulation of osteocytes at concentrations reported in human synovial fluids from patients with OA or following knee injury, regulated similar readouts to mechanical loading including markers of pain, bone remodelling, and inflammation. Discussion We have developed a reproducible model of human osteocyte like cells that express >90% of the genes in the osteocyte transcriptome signature. Mechanical loading and inflammatory stimulation regulated genes and proteins implicated in osteoarthritis symptoms of pain as well as inflammation and degeneration underlying disease progression. Nearly half of the genes classified as 'effectors' in GWAS were mechanically regulated in this model. This model will be useful in identifying new mechanisms underlying bone and joint pathologies and testing drugs targeting those mechanisms.

DT Review
DE WWP1; WWP2; Bone; Cartilage
ID regulates craniofacial development; c2 domain; bone; protein; expression; cancer; ubiquitination; proliferation; mir-140; pten
AB Bone and cartilage diseases are often associated with trauma and senescence, manifested as pain and limited mobility. The repair of bone and cartilage lesion by mesenchymal stem cells is regulated by various transcription factors. WW domain-containing protein 1 (WWP1) and WW domain-containing protein 2 (WWP2) are named for WW domain which recognizes PPXY (phono Ser Pro and Pro Arg) motifs of substrate. WWP1and WWP2 are prominent components of the homologous to the E6-AP carboxyl terminus (HECT) subfamily, a group of the ubiquitin ligase. Recently, some studies have found that WWP1 and WWP2 play an important role in the pathogenesis of bone and cartilage diseases and regulate the level and the transactivation of various transcription factors through ubiquitination. Therefore, this review summarizes the distribution and effects of WWP1 and WWP2 in the development of bone and cartilage, discusses the potential mechanism and therapeutic drugs in bone and cartilage diseases such as osteoarthritis, fracture, and osteoporosis.

TI Pyroptosis in Skeleton Diseases: A Potential Therapeutic Target Based on

Inflammatory Cell Death
SO INTERNATIONAL JOURNAL OF MOLECULAR SCIENCES
LA English
DT Review
DE pyroptosis; inflammation; skeleton diseases; treatment; cell death
ID intervertebral disc degeneration; spinal-cord-injury; nlrp3 inflammasome; gasdermin-d; rheumatoid-arthritis; propionibacterium-acnes; metformin protects; caspase activation; aim2 inflammasome; pore formation
AB Skeletal disorders, including fractures, osteoporosis, osteoarthritis, rheumatoid arthritis, and spinal degenerative conditions, along with associated spinal cord injuries, significantly impair daily life and impose a substantial burden. Many of these conditions are notably linked to inflammation, with some classified as inflammatory diseases. Pyroptosis, a newly recognized form of inflammatory cell death, is primarily triggered by inflammasomes and executed by caspases, leading to inflammation and cell death through gasdermin proteins. Emerging research underscores the pivotal role of pyroptosis in skeletal disorders. This review explores the pyroptosis signaling pathways and their involvement in skeletal diseases, the modulation of pyroptosis by other signals in these conditions, and the current evidence supporting the therapeutic potential of targeting pyroptosis in treating skeletal disorders, aiming to offer novel insights for their management.

TI Advancements in deep learning-based image screening for orthopedic conditions: Emphasis on osteoporosis, osteoarthritis, and bone tumors
SO AGEING RESEARCH REVIEWS
LA English
DT Review
DE Deep learning; Osteoporosis; Osteoarthritis; Bone tumor; Imaging screening
ID artificial-intelligence; spinal metastases; mineral density; prediction; classification; sacroiliitis; diagnosis; model
AB Artificial intelligence (AI) has garnered increasing attention in the medical field. As the core technology of AI, deep learning (DL) has been extensively applied to the imaging-based screening of orthopedic diseases, primarily including image classification, segmentation, and risk prediction. This review systematically summarizes recent research advances, methodologies, and clinical applications of AI-assisted diagnostic technologies in orthopedic imaging, highlighting the practical value and development trends of DL in this field. By retrieving literature published over the past five years in PubMed and the Web of Science Core Collection, this study emphasizes the application of DL-based techniques in the screening of orthopedic conditions, such as osteoarthritis (OA), osteoporosis (OP), and bone tumors. The results demonstrate that DL-based methods exhibit excellent diagnostic performance and considerable clinical potential. However, despite the rapid increase in research output, there are still several challenges in this field, including the lack of high-quality datasets, the limited cross-institutional generalizability of models, the absence of standardized quality control protocols, and the urgent demand for multicenter clinical validation. Overall, DL holds great promise for enhancing diagnostic accuracy and improving patient outcomes in

orthopedic imaging.

TI Proximal tibial stress fracture in patients with advanced knee osteoarthritis: a narrative review
SO EFORT OPEN REVIEWS
LA English
DT Review
DE knee; osteoarthritis; stress fracture; total knee arthroplasty
ID arthritic knees; arthroplasty; management
AB In patients with knee osteoarthritis, tibial stress fractures are mostly associated with osteoporosis and lower limb malalignment. Nonoperative management may lead to knee stiffness (due to prolonged immobilization), persistence of pain (due to the underlying knee osteoarthritis), and fracture nonunion. Acute unstable tibial

stress fractures can be managed with long-stem total knee arthroplasty. Exposing the fracture site should be avoided as much as possible because it may be associated with skin necrosis and delayed union. In irreducible cases or fractures with persistent gaps, fibular osteotomy, by increasing the mobility and compression across the fracture site, may help with fracture reduction and decrease the rate of nonunion.

TI Preoperative Osteoporosis Is Associated With Increased Health Care Utilization and Compromised Pain and Function Improvement After Primary Total Hip Arthroplasty: A Prospective Cohort Analysis
SO JOURNAL OF ARTHROPLASTY
LA English
DT Article
DE THA; osteoporosis; imaging; patient oriented outcomes; total hip arthroplasty
ID patient-reported outcm; acceptable symptom state; osteoarthritis; diagnosis; tha; responsiveness; replacement; management; fractures; index
AB Background: Osteoporosis (OP) has been linked to complications after total hip arthroplasty (THA), but its impact on health care utilization and patient-reported outcomes remains unclear. This study aimed to evaluate the association between: 1) pre-THA OP and health care utilization as well as patient-reported pain and function outcome measures; and 2) dual energy X-ray absorptiometry (DEXA) scan-based Tscores and the aforementioned outcomes. Methods: A retrospective analysis of prospectively collected data of primary THA (2015 to 2018) was performed (n 1/4 5,321) from a validated academic institutional database of a large North American tertiary health care system; of which 4,074 (76.6%) completed 1-year follow-up. Outcomes included prolonged length of stay [LOS] > three days, discharge disposition, 90-day readmission, and 1-year reoperation, as well as Hip Disability and Osteoarthritis Outcome Score (HOOS]) Pain, HOOS-function (PS), and minimal clinically important difference thresholds (MCID), and satisfaction. Results: The prevalence of OP pre-THA was 56.9%, of which 39.8% were not prescribed OP medications and 15.3% had a DEXA scan. Compared to those who did not have OP, those who had OP were independently associated with higher odds of prolonged LOS, nonhome discharge, 90-day readmission, and 1-year reoperation ($P < 0.005$). Furthermore, they had significantly higher odds of failing to achieve MCID (odds ratio: 1.41 (95% confidence interval: 1.06 to 1.89)) for HOOS-PS and satisfaction (odds ratio: 1.5 (95% confidence interval: 1.16 to 1.93)) at one year. Higher T-scores were associated with lower odds of prolonged LOS, nonhome discharge, failure to achieve MCID in HOOS-Pain, and HOOS-PS. Conclusions: Over half of patients had OP; however, only 15.3% of patients had a DEXA scan before THA. Patients who had OP were at higher risk of prolonged LOS, nonhome discharge, 90-day readmission, and 1-year reoperation in addition to poor pain/function improvement and dissatisfaction one year after THA. ID induced apoptosis; osteonecrosis; inflammation; osteoarthritis; inhibition; activation; cells
AB Reactive oxygen species (ROS) are molecules that are generated primarily during energy production in cells. ROS are involved in critical biological functions such as signal transduction; when the production of ROS is imbalanced, excessive ROS causes oxidative stress, and subsequent cellular damage. Oxidative stress is linked to numerous pathological disorders in major organs including the skeletal system. In an aging society, understanding the role of ROS in skeletal health is critical to developing preventative and therapeutic interventions. Oxidative stress causes defects in cellular differentiation, apoptosis, mitochondrial dysfunction, and inflammation. The effects of oxidative stress on the skeletal system have been implicated in the development of osteoporosis, knee osteoarthritis, and osteonecrosis by inhibiting bone remodeling, increasing osteoclast activity, and decreasing osteoblast function. ROS are also involved in many signaling pathways that regulate immune defense, cell proliferation, and inflammation. This underscores the importance of maintaining a balance between ROS and antioxidants to prevent oxidative stress and related diseases. Targeting ROS and oxidative stress mechanisms may offer new treatments for diseases affecting the skeletal system and other organs, potentially improving health outcomes, and extending healthy lifespans. This review highlights the significant impact of oxidative stress on skeletal health and explores potential preventative and therapeutic strategies to mitigate the adverse effects of ROS.

DT Article
DE Statin; Osteoporosis; Osteoarthritis; Mendelian randomization; Causality
ID mendelian randomization; mechanisms; instruments; population; expression; diagnosis; bias
AB BackgroundObservational studies suggest that statins may be protective against osteoporosis and osteoarthritis. However, the association between statins and the risk of osteoporosis and osteoarthritis has not been fully clarified.ObjectiveThe association between statins and the risk of osteoporosis and osteoarthritis was explored by Mendelian randomization analyses using pooled data from a large population-based genome-wide association study (GWAS).MethodsData on statin-associated single-nucleotide polymorphisms were obtained from version 10 of the FinnGen database, while information regarding osteoporosis and osteoarthritis was sourced from IEU Open GWAS and UK Biobank, database. The primary analytical method employed was inverse variance weighting to assess causal effects. Additional methods including weighted median, simple median, weighted mode, and MR-Egger regression were utilized for further clarification. Odds ratios along with 95% confidence intervals were calculated to evaluate the causal relationship between statins and the risks associated with osteoarthritis and osteoporosis. Subsequently, sensitivity analyses were conducted to verify result reliability by employing Cochran's Q test for heterogeneity assessment, MR-Egger intercept for detecting horizontal pleiotropy presence, as well as leave-one-out analysis to identify potentially influential single nucleotide polymorphisms.Results(1) The results of the inverse variance weighting method showed a negative causal relationship between genetically predicted statins and osteoporosis (OR = 0.998, 95% CI 0.996-0.999, P = 0.01) risk; and a negative causal relationship between statins and osteoarthritis (OR = 0.974, 95% CI 0.951-0.998, P = 0.037) risk; (2) MR-Egger-intercept analysis did not detect potential horizontal

pleiotropy (osteoporosis: P = 0.848; osteoarthritis: P = 0.483); and (3) the findings provide favorable evidence that statins reduce the risk of osteoporosis and osteoarthritis as described in the observational study, but further research is needed on the specific mechanisms of statins for osteoporosis and osteoarthritis.ConclusionStatins reduce the risk of osteoporosis and osteoarthritis, which is consistent with the results of observational studies. Further studies are essential to validate these results and explore the underlying mechanisms in detail.

TI Mechanical robust, pH responsive hemicellulose-based PVA film with barrier performance for fruit preservation and monitoring
SO FOOD CHEMISTRY
LA English
DT Article
DE Barrier film; PVA; Fruit preservation; Hemicellulose; Blueberry anthocyanins
ID antibacterial activity; anthocyanins; cellulose; nmr
AB Barrier films are essential for food packaging, but conventional solutions hinder the circular economy. This study introduces hemicellulose-based antioxidant crosslinked composite films as a sustainable alternative. We develop pH-responsive films (K-B/PVA/OA) using polyvinyl alcohol (PVA), silanized hemicellulose (KHC), blueberry anthocyanin (BA) as a pH indicator, and oxalic acid (OA) as a crosslinker. The films exhibit excellent oxygen and water vapor barrier properties and can be easily fabricated via solution casting with food-safe dispersions. The oxygen permeability (OP) decreases from 13.22 f 0.65 x 10-14 to 3.24 f 0.98 x 10- 14 cm3 center dot mu m/(m2 center dot d center dot Pa), and the water vapor permeability coefficient (Pv) drops from 15.43 f 0.85 x 10-13 to 7.27 f 0.46 x 10-13 g center dot cm/ (cm2 center dot s center dot Pa). Tensile strength and modulus increase from 32.63 MPa and 765.80 MPa to 41.24 MPa and 1281.39 MPa. Esterification between PVA and hemicellulose raises surface energy, increasing the contact angle from 39.4 degrees to 78.34 degrees. Strawberries packaged in these films maintain their structure and exhibit a visible color change after 7 days, offering sustainable, real-time monitoring packaging.

TI Personalized Design of 3D-Printed Osteochondral Scaffold for Osteoarthritis Patients with Different Bone Conditions and Mechanical Evaluation
SO BIOENGINEERING-BASEL
LA English
DT Article
DE scaffold structure; 3D printing; knee joint bioreactor; mechanical simulation; osteoarthritis
AB As osteoarthritis is a common disease in elderly people and large cartilage defects can only be treated by joint replacement surgery, a scaffold is seen as a potential treatment that could help patients to delay or avoid surgery. An ideal scaffold should have similar properties to the surrounding tissues. Thus, for different levels of OA, patients with different bone properties should use different scaffold structures with different mechanical or biological properties. In this paper five structures (A-E) are designed for young OA patients or patients with good bone mechanical properties, middle-age OA patients with weak bone mechanical properties or patients with little osteoporosis, and elderly OA patients who have severer OA and osteoporosis who are not able to perform normal activities. And these five scaffold structures are 3D-printed by an EOS machine with Ti6Al4V powder and evaluated by experiments based on a biomechanical bioreactor simulating the human knee joint and simulation through ANSYS. Structure D with a solid thick beam in the middle has the highest loading force, which is 3707.835 N, and structure E, composed of the polyhedron with the highest specific surface area, has the lowest loading force, which is 1837.402 N. Structures A, B, and C are intended for young OA patients or patients with good bone mechanical properties. Structures D and E are designed for patients who need to avoid or delay joint replacement surgery.

TI The Hippo pathway in bone and cartilage: implications for development and disease
SO PEERJ
LA English
DT Article
DE Hippo; Bone; RANKL; Yes; TAZ
ID signaling pathway; cell-proliferation; regulating osteoclast; rheumatoid-arthritis; global burden; osteosarcoma; yap/taz; yap1; osteoarthritis; osteoporosis
AB Bone is the main structure of the human body; it mainly plays a supporting role and participates in metabolic processes. The Hippo signaling pathway is composed of a series of protein kinases, including the mammalian STE20-like kinase MST1/2 and the large tumor suppressor LATS1/2, which are widely involved in pathophysiological processes, including cell proliferation, differentiation, apoptosis and death, especially those related to biomechanical transduction in vivo. However, the role of it in regulating skeletal system development and the evolution of bone-related diseases remains poorly understood. The pathway can intervene in and regulate the physiological activities of bone-related cells such as osteoclasts and chondrocytes through its own or other bone-related signaling pathways, such as the Wnt pathway, the Notch pathway, and receptor activator of nuclear factor-kappa B ligand (RANKL), thereby affecting the occurrence and development of bone diseases. This article discusses the role of the Hippo signaling pathway in bone development and disease to provide new insights into the treatment of bone-related diseases by targeting the Hippo signaling pathway.

DT Article
DE Bone microenvironment; Osteoimmunology; Acid-base balance; Bone homeostasis; Immune cells; Therapeutic strategies
ID v-h+-atpase; in-vitro; slc4a2-mediated cl-/hco3; selective inhibitor; acid; nanoparticles; exchange; cells; differentiation; methotrexate
AB The bone microenvironment represents a highly sophisticated ecosystem comprising diverse cellular components-including osteoblasts, osteoclasts, immune cells, endothelial cells, and mesenchymal stem cells-that interact dynamically to maintain skeletal homeostasis and facilitate repair. Emerging insights from osteoimmunology have revealed that acid-base balance serves as a central regulatory node in bone remodeling, working synergistically with other physiological signals to fine-tune osteoclast/osteoblast activity through intricate molecular crosstalk. Notably, even subtle pH fluctuations within this microenvironment can exert profound effects on both bone and immune cell function. This review provides a comprehensive examination of: (1) the physiological principles governing acid-base balance in bone, (2) the pathological consequences of its dysregulation on bone remodeling via osteoimmune networks, and (3) the therapeutic promise of pH-modulating strategies for bone disorders such as osteoporosis and osteoarthritis. Our synthesis positions bone as a precision

acid-base regulatory organ while establishing a mechanistic framework for developing targeted therapies that restore pH equilibrium in skeletal tissues.

AB AimThis study aims to investigate the impact of aging on brain volume among community residents in Japan, focusing on trends over time and specific brain structures.MethodsWe analyzed data from the fourth survey (2015-2016) of the Research on Osteoarthritis/Osteoporosis Against Disability project, encompassing 2146 community residents from Japan's mountainous and coastal regions. A total of 1755 participants (81.8% of the baseline population) underwent extensive data collection including lifestyle and health questionnaires, anthropometric measurements and brain magnetic resonance imaging. The imaging data were

processed to examine correlations between total brain volume, gray matter volume (GMV), white matter volume (WMV), cerebrospinal fluid volume and participant age.ResultsAnalysis showed significant sex differences in total brain volume, with GMV demonstrating a strong negative correlation with age - more pronounced than the moderate negative correlation seen in WMV. Cerebrospinal fluid volume exhibited a strong positive correlation with age. Notably, specific brain regions such as the bilateral amygdala, hippocampus, thalamus and primary motor cortex showed significant age-related volume reductions.ConclusionThis study confirms that GMV and WMV are smaller in older individuals in the Japanese population, with more pronounced differences in GMV. The amygdala, hippocampus, thalamus and primary motor cortex were particularly affected. Geriatr Gerontol Int 2025; center dot center dot: center dot center dot-center dot center dot.

TI Liver injury severity determines skeletal deterioration: a shared pathophysiological axis between MASLD and osteoarthritis
SO GEROSCIENCE

DT Article
DE MASH; Fibrosis; Osteoarthritis; Osteoporosis
ID articular chondrocytes; synovial inflammation; gene-regulation; diet; fructose; resistin; disease; nash
AB Nonalcoholic fatty liver disease (NAFLD) and metabolic syndrome (MetS) have been linked to osteoporosis and osteoarthritis (OA), where the prevalence of all increase with age. Many individuals with NAFLD also exhibit MetS, a condition that is now termed metabolic dysfunction-associated steatotic liver disease (MASLD). MASLD spans from simple hepatic steatosis to hepatocyte ballooning and inflammation, termed metabolic dysfunction-associated steatohepatitis (MASH), which may occur with or without fibrosis. To delineate the contribution of liver injury to skeletal deterioration within the context of metabolic syndrome (MetS), we fed male mice a high-fat, cholesterol, and fructose (HFCF) diet that induces metabolic syndrome-associated steatohepatitis (MASH) and liver fibrosis, associated with moderate obesity but without profound insulin resistance. A nutrient-matched diet with high carbohydrates but low in fat, cholesterol, and fructose (LFCF), which induced steatosis in adult mice, served as the control. Micro-CT analysis of the femur of HFCF-fed mice that developed MASH with fibrosis revealed significant cortical thinning (reduced bone area and thickness),

decreased trabecular thickness, and lower bone mineral density compared to LFCF-fed mice, with no liver fibrosis. In the knee joint, MASH with fibrosis was associated with subchondral bone loss, medial cartilage erosion, and elevated chondrocyte expression of iNOS, NLRP3, and beta-galactosidase. Bulk RNA-seq of knee tissue identified 152 differentially expressed genes: interferon-related (Oas3, Nlrc5, Zbp1) and stress-response (Slc6a4, Alox12, Cirbp, Trpc6, Tap1, Ubash3, Nrg1) pathways were upregulated, while extracellular matrix organization pathways were downregulated. Our findings reveal a mechanistic connection between the degree of liver injury and deterioration of bone and joint integrity, pointing to a shared pathophysiological axis in MASLD and OA. Clinically, this raises the prospect that a single therapeutic, designed to modulate inflammation, or hepatic lipid metabolism, could be repurposed or developed to concurrently treat both steatohepatitis and osteoarthritic degeneration.

TI Genetic causality between insomnia and specific orthopedic conditions: Insights from a two-sample Mendelian randomization study
SO EXPERIMENTAL GERONTOLOGY
LA English
DT Article
DE Insomnia; rheumatoid arthritis; Ankylosing spondylitis; Osteoporosis; Gout; Genetic

ID necrosis-factor-alpha; ankylosing-spondylitis; risk-factors; sleep; osteoporosis; prevalence; gout; osteoarthritis; frailty; epidemiology
AB Objective: To investigate the genetic causality for the insomnia and common orthopedic diseases, such as rheumatoid arthritis (RA), ankylosing spondylitis (AS), osteoporosis (OP), and gout (GT). Methods: The genome-wide association study (GWAS) summary data on insomnia were obtained from a published study, while the GWAS summary data on RA, AS, OP, and GT were sourced from the FinnGen consortium. We utilized the TwoSampleMR package of the R software (version 4.1.2) to conduct a two-sample Mendelian randomization (MR) analysis. Our primary method of analysis was the random-effects inverse variance weighted (IVW) approach. Subsequently, we conducted a series of sensitivity analyses for the MR analysis. Results: The MR analysis revealed a positive genetic causal relationship between insomnia and RA (P = 0.016, odds ratio [OR] 95 % confidence interval [CI] = 1.112 [1.020-1.212]). However, no significant genetic causal relationship was observed between insomnia and AS (P = 0.194, OR 95 % CI = 1.121 [0.944-1.331]), OP (P = 0.788, OR 95 % CI = 1.016 [0.904-1.142]), and GT (P = 0.757, OR 95 % CI = 1.018 [0.912-1.136]). The MR analysis did not exhibit heterogeneity, horizontal pleiotropy, outlier effects, or dependence on a single SNP, and demonstrated normal distribution, which guaranteed the robustness of the results. Conclusion: The results of this study suggest that insomnia may be a significant risk factor for RA, and controlling insomnia may represent a promising strategy for preventing RA. While insomnia was not observed to be associated with AS, OP, and GT at the genetic level, other levels of association cannot be excluded.

TI Assessing causality between mitochondrial-associated proteins with musculoskeletal diseases: A Mendelian randomization study
SO MEDICINE
LA English
DT Article
DE ankylosing spondylitis; Mendelian randomization; mitochondria; musculoskeletal disease; osteoarthritis; osteoporosis; rheumatoid arthritis
ID variance weighted estimator; transporter family slc25; identification; dysfunction; robust; genes
AB Musculoskeletal diseases are the leading cause of disability-adjusted life years. Mitochondria, often referred to as the "powerhouses" of cells, are believed to play a role in regulating cellular metabolism and differentiation, potentially influencing the occurrence and progression of musculoskeletal diseases. However, the exact causal relationships remain to be defined. This study aimed to investigate the causal relationships between mitochondrial biological functions and musculoskeletal diseases (including osteoarthritis (OA), osteoporosis, rheumatoid arthritis (RA), and ankylosing spondylitis through Mendelian randomization (MR) analysis). We systematically summarized data related to mitochondrial functional proteins and musculoskeletal diseases from the IEU OpenGWAS and UK Biobank databases. We used single nucleotide polymorphisms significantly associated with musculoskeletal diseases as instrumental variables. The inverse variance weighting method performed the main MR analysis. We used Mendelian randomized residual sum of pleiotropy and outliers, MR-Egger regression, Cochran Q statistic, Rucker Q statistic, Radial-MR, weighted median, simple mode, weighted mode, and leave-one-out analysis methods as supplementary analyses. First, 14 positive mitochondrial functional proteins were screened out. After Bonferroni correction, COA3 and COX4I2 were found to be causally related to OA and act as protective factors. We identified a causal relationship between SLC25A18 and RA as a risk factor. This study provides genetic support and offers new evidence regarding the roles of COA3, COX4I2, and SLC25A18 in the pathophysiology of OA and RA. This study paves the way for a deeper understanding of the pathological mechanisms of musculoskeletal diseases and provides information for their prevention strategies and treatments.

TI Mesenchymal Stem Cell-Derived Extracellular Vesicles: Seeking into Cell-Free Therapies for Bone-Affected Lysosomal Storage Disorders
SO INTERNATIONAL JOURNAL OF MOLECULAR SCIENCES
LA English
DT Review
DE extracellular vesicles; lysosomal storage disorders; mesenchymal stem cells; microenvironment
ID mucopolysaccharidosis type-i; enzyme replacement therapy; gene-therapy; ex-vivo; exosm; mouse; promote; growth; transplantation; osteogenesis
AB Lysosomal storage disorders (LSDs) constitute a group of monogenic systemic diseases resulting from deficiencies in specific lysosomal enzymes that cause the intralysosomal accumulation of non- or partially degraded substrates, leading to lysosomal dysfunction. In some cases of LSDs, the bone is more severely affected, thus producing skeletal manifestations in patients. Current therapies, such as enzyme replacement therapy (ERT) and gene therapy (GT), show limited efficacy in correcting skeletal abnormalities. Increasing evidence suggests that microenvironmental disturbances also contribute significantly to disease pathogenesis. Therefore, therapeutic strategies targeting lysosomal dysfunction and microenvironmental dysregulation are needed. Mesenchymal stem-cell-derived extracellular vesicles (MSC-EVs) are emerging as promising candidates in regenerative medicine due to their immunomodulatory, pro-regenerative, and paracrine properties. MSC-EVs have shown potential to

modulate the microenvironment and favor tissue repair in bone-related disorders such as osteoarthritis and osteoporosis. Interestingly, MSC-EVs can be engineered to reach the bone and carry therapeutics, including ERT- and GT-related molecules, enabling targeted delivery to hard-to-reach bone regions. This review describes the main features of MSC-EVs and discusses the therapeutic potential of MSC-EVs as a potential cell-free strategy for bone-affected LSDs.

TI High Prevalence of Osteopenia and Osteoporosis in Total Hip and Total Knee Arthroplasty Patients and Effects of Anti-Resorptive Agents on Bone Health Optimization: A Systematic Review and Meta-Analysis

SO JOURNAL OF CLINICAL MEDICINE
LA English
DT Review
DE arthroplasty; bone health optimization; osteoporosis; periprosthetic fracture; revision surgery
ID prior fragility fractures; mineral density loss; periprosthetic fractures; bisphosphonate use; risk; replacement; alendronate; revision; association; therapy
AB Background: Osteoarthritis is a leading cause of chronic pain and long-term disability in adults, which commonly affects the hip and knee joints. Joint arthroplasties are one of the management strategies for end-stage osteoarthritis. Periprosthetic fractures after hip or knee arthroplasties have mortality rates comparable to hip fractures. Recent studies assessed bone health optimization and the use of anti-osteoporotic agents in elective hip and knee arthroplasty surgeries. This systematic review and meta-analysis aimed to determine the prevalence of osteoporosis before surgery and the effect of bone health optimization on periprosthetic fractures and revisions. Methods: A systematic search was carried out on three databases, including PubMed, Embase, and Web of Science. The keywords used were (Revision or Periprosthetic fracture) AND (osteop*) and (Total Knee* or Total Hip*). Studies that included subjects aged >50 years with investigated outcomes were included in the review. The quality of selected randomized controlled trials was assessed using the Cochrane Collaboration tool, and non-randomized studies were assessed using the Newcastle-Ottawa Scale. The review was not registered with the International Prospective Register of Systematic Reviews (PROSPERO). Results: A total of 2482 records were identified. Twenty-three studies were included, and eighteen were used for quantitative analysis. Pooled overall prevalence of osteopenia in patients undergoing total knee arthroplasty (TKA)/total hip arthroplasty (THA) surgery was 42.87% (95% confidence interval (CI) 32.65 to 53.09). Pooled overall prevalence of osteoporosis in patients undergoing TKA/THA surgery was 23.99% (95% CI 15.72 to 32.26). The overall mean difference was in favor of anti-resorptive treatment on periprosthetic BMD of the medial calcar region (Gruen zone 7) after THA (12.16% (95% CI 8.78 to 15.53, $p < 0.00001$). Pooled odds ratio of periprosthetic fracture was 1.27 (95% CI 1.08 to 1.48, $p = 0.003$) in favor of the control group compared to bisphosphonate treatment. The pooled hazard ratio for all-cause revisions after TKA/THA for both osteopenia and osteoporotic patients was 0.26 (95% CI 0.13 to 0.51, $p = 0.0001$, I-2 76%), signifying an improvement with bisphosphonates. Limitations of this study include the heterogeneity and retrospective nature of the included studies, with the average level of evidence subject to bias. Conclusions: There was a high prevalence of osteopenia/osteoporosis amongst patients undergoing total knee and total hip arthroplasty at 66.86%. Whilst bone health optimization with bisphosphonates may decrease the risk of revisions, the risk of periprosthetic fracture appeared to increase. Further research will be required to evaluate the effects of bone health optimization on the risk of periprosthetic fracture and revisions, and the effects of anabolic agents on periprosthetic fractures.

AB Our understanding of the different developmental origins of osteoclast progenitors and their respective roles during homeostatic bone remodeling at different skeletal sites as well as their roles within bone regeneration and degenerative conditions is evolving. In this narrative review article, we summarize what is known about the developmental origins, anatomical sources, and markers of osteoclast progenitors. We touch on how osteoclast progenitors vary during different disease contexts, including periodontitis, rheumatoid arthritis, and osteoarthritis. In addition, we also characterize osteoclast progenitors that contribute to bone healing and define changes observed with advancing age. In this regard, we offer a critical review of gaps within our understanding and opportunities for future development within the field. Because of their diverse nature under different contexts, identifying and characterizing osteoclast progenitors may help to advance condition-specific therapies.

TI Rheumatoid arthritis and subsequent fracture risk: an individual person meta-analysis to update FRAX
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE Epidemiology; Fracture risk; FRAX; Glucocorticoids; Hip fracture; Major osteoporotic fracture; Meta-analysis; Osteoporosis; Rheumatoid arthritis; Risk factors
ID modifying antirheumatic drugs; bone-mineral density; osteoporosis; prediction; women; score
AB The relationship between rheumatoid arthritis (RA) and fracture risk was estimated in an international meta-analysis of individual-level data from 29 prospective cohorts. RA was associated with an increased fracture risk in men and women, and these data will be used to update FRAX (R). Introduction RA is a well-documented risk factor for subsequent fracture that is incorporated into the FRAX algorithm. The aim of this study was to evaluate, in an international meta-analysis, the association between rheumatoid arthritis and subsequent fracture risk and its relation to sex, age, duration of follow-up, and bone mineral density (BMD) with a view to updating FRAX. Methods The resource comprised 1,909,896 men and women, aged 20-116 years, from 29 prospective cohorts in which the prevalence of RA was 3% or less (primary analysis) and an additional 17 cohorts with a prevalence greater than 3% (supplementary analysis). The association between RA and fracture risk (any clinical fracture, osteoporotic fracture, major osteoporotic fracture (MOF), and hip fracture) was examined using an extension of the Poisson regression model in each cohort and each sex, followed by random-effects meta-analyses of the weighted beta coefficients. Results In the primary analysis, RA was reported in 1.3% of individuals. During 15,683,133 person-years of follow-up, 139,002 fractures occurred, of which 27,518 were hip fractures. RA was associated with an increased risk of any clinical fracture (hazard ratio [HR] 1.49, 95% confidence interval [CI] 1.35-1.65). The HRs were of similar magnitude for osteoporotic fracture and MOF but higher for hip fracture

(HR=2.23; 95% CI 1.85-2.69). For hip fracture, there was a significant interaction with age with higher HRs at younger ages. HRs did not differ between men and women and were independent of exposure to glucocorticoids and femoral neck BMD. Lower HRs were observed in the supplementary analysis cohorts, particularly in those with a high apparent prevalence of RA, possibly from conflation of RA with osteoarthritis. Conclusions A diagnosis of RA confers an increased risk of fracture that is largely independent of BMD, sex, and corticosteroids. RA should be retained as a risk factor in future iterations of FRAX with updated risk functions to improve fracture risk prediction.

TI More severe microdamage and micromechanical alterations: altered subchondral bone remodeling in varus knee osteoarthritis with osteoporosis
SO OSTEOPOROSIS INTERNATIONAL

AB Previous studies show osteoporosis causes tibial varus in knee osteoarthritis patients. Our analysis of tibial plateau specimens from osteoarthritic patients reveals that osteoporosis accelerates the deterioration of the subchondral microstructure of the tibial plateau, exacerbating tibial varus. Introduction The relationship between osteoporosis (OP) and knee osteoarthritis (OA) has garnered

significant clinical interest, particularly regarding the prevelence of tibial varus in patients suffering from both conditions. This study aimed to elucidate the association between OP and knee OA by examining bone remodeling and microstructural parameters of cartilage and subchondral bone. Methods We analyzed tibial plateau specimens from 50 patients, with 25 in the OA group and 25 in the OP-OA group. These specimens were further categorized into four subgroups: OA medial plateau, OA lateral plateau, OP-OA medial plateau, and OP-OA lateral plateau. Comprehensive analyses, including cartilage histology, micro-CT, immunohistochemical techniques, basic fuchsin histological analysis, and micro-finite elements, revealed significant microstructural differences and aberrant bone remodeling processes between the groups. Results The OARSI cartilage score of the medial tibial plateau was 13.71% higher in the OP-OA group compared to the OA group ($P < 0.05$), indicating more severe cartilage degeneration. Micro-CT analysis revealed a lower BV/TV in the subchondral bone of the medial tibial plateau in the OP-OA group (0.58 +/- 0.02) compared to the OA group (0.68 +/- 0.02) ($P < 0.05$). Additionally, significant decreases were observed in Tb.N and Tb.Th, while Tb.Sp and SMI increased. The number of osteoblasts in the subchondral bone of the medial tibial plateau was lower in the OP-OA group than in the OA group, while the number of osteoclasts was 55.90% higher ($P < 0.05$). Result of basic fuchsin staining showed that the CrDn in the subchondral bone of the medial tibial plateau was 69.01% higher in the OP-OA group ($P < 0.05$), with greater microdamage severity. Micro-finite element analysis showed that subchondral bone stresses in the OP-OA group were higher and more localized to the medial side compared to the OA group. Conclusions Our findings indicate that osteoporosis significantly intensifies cartilage degeneration in the medial tibial plateau of patients with knee osteoarthritis. It aggravates aberrant subchondral bone remodeling, increases microdamage, impairs mechanical structure, and accelerates tibial varus.

TI Influence of Comorbidities on Health-Related Quality of Life in Alcohol-Related Liver Disease: A Population-Based Survey
SO CLINICAL GASTROENTEROLOGY AND HEPATOLOGY
LA English
DT Article
DE Health-Related Quality Of Life; Alcohol-Related Liver Disease; Cirrhosis; Comorbidities; Patient-Reported Outcomes
AB BACKGROUND AND AIMS: Extrahepatic comorbidities are common in alcohol-related liver disease (ALD). We examined associations between burden of comorbidities, alcohol, and smoking with low health-related quality of life (HRQoL) among patients with ALD. METHODS: Patients with ALD and matched comparators were identified among respondents of the Danish National Health Survey waves in 2010-2017. Survey data included generic measures of physical and mental HRQoL (12-Item Short Form Health Survey), comorbidities, alcohol and smoking. Low HRQoL in ALD was defined as >= 1.5 SD worse than the average HRQoL in the comparators. Odds ratios (ORs) of low HRQoL were estimated with multivariable logistic regression, adjusting for potential confounders. RESULTS: We included 772 ALD patients, 53% of whom had cirrhosis; 37% had low physical HRQoL and 22% had low mental HRQoL. Disc herniation (found in 21%), osteoarthritis (36%), chronic obstructive pulmonary disease (11%), cancer (6%), stroke (1%), and psychiatric disease (9%) were associated with low physical and/or mental HRQoL, whereas alcohol use disorder (24%), diabetes (19%), acute myocardial infarction (1%), hypertension (34%), and osteoporosis (12%) were not. For example, osteoarthritis was associated with low physical (OR, 2.17; 95% confidence interval, 1.54-3.05) and low mental (OR, 1.91; 95% confidence interval, 1.27-2.88) HRQoL. For lifestyle factors, drinking >= 20 units/week was associated with low physical and smoking >= 20 cigarettes/day with low mental HRQoL when compared with abstainers and nonsmokers, respectively. CONCLUSIONS: Common comorbidities including chronic obstructive pulmonary disease, musculoskeletal disease, and psychiatric disease are associated with low HRQoL in ALD, independent of liver

disease severity, and so are alcohol consumption and smoking. These findings highlight the importance of multidisciplinary management of patients with ALD.

TI Treatment with a superoxide dismutase mimetic for joint preservation during 35 and 75 days in orbit aboard the international space station, and after 120 days recovery on Earth
SO LIFE SCIENCES IN SPACE RESEARCH
LA English
DT Article
DE International space station; Rodent spaceflight; Osteoarthritis; Osteoporosis; Antioxidant; Countermeasure
ID cartilage atrophy; down-regulation; osteoarthritis; progression; stress; antioxidants; knees
AB Reduced weight-bearing during spaceflight has been associated with musculoskeletal degradation that risks astronaut health and performance in transit and upon reaching deep space destinations. Previous rodent experiments aboard the international space station (ISS) have identified that the spaceflight-induced

molecular arthritic phenotype was characterized with an increase in oxidative stress. This study evaluated if treatment with a superoxide dismutase (SOD) mimetic on orbit could prevent spaceflight-induced damage to the knee and hip articular cartilage, and the menisci in rodents. Cartilage and meniscal degradation in mice were measured via microCT, histology, and transcriptomics after: (1) similar to 35 days on the ISS, (2) similar to 35 days on the ISS followed by 120 days weight-bearing readaptation on Earth or (3) similar to 75 days on the ISS. The study had a limited sample size, so both significant effects and generalized patterns are reported. After 35 days aboard the ISS, cartilage volume at the tibial-femoral cartilage-cartilage contact point decreased, meniscal volume decreased concurrent with an increase in pro-osteoarthritic signaling in the joint soft tissue. Similarly, a decrease in cortical and trabecular bone volume of the tibia was observed. Treatment with the SOD mimetic preserved the trabecular bone, articular cartilage and the menisci after 35 days aboard the ISS, but had limited efficacy retaining that recovery after 120 days of weight bearing, and after 75 days on orbit. Antioxidants including BuOE may serve as a potential countermeasure option to protect musculoskeletal health during spaceflight missions, and continued use may be necessary upon reaching a destination.

DT Review
DE Mitochondria; mitochondrial physiological function; osteocyte; bone disease
ID steroid-induced osteonecrosis; endothelial progenitor cells; mesenchymal stem-cells; oxidative stress; energy-metabolism; activation; antioxidants; dysfunction; receptors; mitophagy
AB Mitochondrial health is maintained in a steady state through mitochondrial dynamics and autophagy processes. Recent studies have identified healthy mitochondria as crucial regulators of cellular function and survival. This process involves adenosine triphosphate (ATP) synthesis by mitochondrial oxidative phosphorylation (OXPHOS), regulation of calcium metabolism and inflammatory responses, and intracellular oxidative stress management. In the skeletal system, they participate in the regulation of cellular behaviors and the responses of osteoblasts, osteoclasts, chondrocytes, and osteocytes to external stimuli. Indeed, mitochondrial damage or dysfunction occurs in the development of a few bone diseases. For example, mitochondrial damage may lead to an imbalance in osteoblasts and osteoclasts, resulting in osteoporosis, osteomalacia, or poor bone production, and chondrocyte death and inflammatory infiltration in osteoarthritis are the main causes of cartilage degeneration due to mitochondrial damage.

However, the opposite exists for osteosarcoma, where overactive mitochondrial metabolism is able to accelerate the proliferation and migration of osteosarcoma cells, which is a major disease feature. Bone is a dynamic organ and osteocytes play a fundamental role in all regions of bone tissue and are involved in regulating bone integrity. This review examines the impact of mitochondrial physiological function on osteocyte health and summarizes the microscopic molecular mechanisms underlying its effects. It highlights that targeted therapies focusing on osteocyte mitochondria may be beneficial for osteocyte survival, providing a new insight for the diagnosis, prevention, and treatment of diseases associated with osteocyte death.

AB Objective Skeletal aging, a core determinant of systemic aging, poses a global public health challenge due to its association with chronic diseases and functional decline. This study aimed to decode the genetic architecture of skeletal aging by identifying novel loci and multi-system crosstalk using genomic structural equation modeling (Genomic SEM). Methods We integrated genome-wide association study (GWAS) data from five musculoskeletal-related traits (osteoporosis [OP], osteoarthritis [OA], lumbar spinal stenosis [LSS], telomere length [TL], and low back pain [LBP]) across 462,933 to 472,174 European individuals. Genomic SEM, FUMA, FUSION, and fine-mapping tools (SuSIE/FINEMAP) were applied to model latent skeletal aging ("mvSAge") and identify causal variants, enriched pathways, and tissue-specific gene expression. Results The latent factor model (CFI = 0.993, SRMR = 0.065) revealed shared genetic architecture among OP, OA, LSS, TL, and LBP. We identified 514 lead SNPs (P < 5 x 10(-)(12)), including 136 novel loci enriched in

regulatory regions (e.g., brain putamen, frontal cortex). Fine-mapping prioritized causal variants (posterior probability > 0.95) near MTPAP, GRAMD4, and DPP8, implicating mitochondrial function and immune regulation. Transcriptome-wide analyses highlighted PPP6R3 (bone mineral density) and SLC33A1 (anticancer target) as key genes. Enrichment analyses linked mvSAge to Wnt signaling, ER stress, and Mendelian disorders (e.g., ALS). Chromosomes 1, 2, and 4 showed elevated heritability contributions, driven by conserved regulatory elements (RUNX2, SP7) and chromatin accessibility hotspots. Conclusion This study establishes mvSAge as a genetically cohesive construct and uncovers novel loci, pathways, and multi-system interactions underlying skeletal aging. These findings advance precision medicine strategies for aging-related musculoskeletal disorders.

TI Femoral neck shape and trabecular bone microarchitecture association with hip osteoarthritis - Results from the QUALYOR study
SO JOINT BONE SPINE
LA English
DT Article
DE Hip osteoarthritis; Subchondral bone; Microarchitecture; QCT

ID subchondral bone; osteoporosis; fracture; geometry; density
AB Objectives: Hip osteoarthritis (OA) is a major public health concern. The determinants of hip OA, however, are not as well understood as those of other OA sites, such as the knee. In recent years, the role of subchondral bone in the pathogenesis of OA has been emphasized but data are lacking for hip OA. Therefore, we aimed to determine which bone characteristics were associated to hip OA. Methods: We made a cross-sectional analysis of 1537 postmenopausal women included in the QUALYOR prospective cohort. At baseline, we measured areal BMD by DXA at the lumbar spine and the hip, volumetric BMD and geometry by hip quantitative computerized tomography (QCT) using the Bone Investigational Toolkit (BIT) software, as well as microarchitecture at the distal radius and tibia by high-resolution peripheral quantitative tomography (HR-pQCT). We built a hip OA score (CT OA score) with images from the hip QCT, based on the depiction of the four major signs of osteoarthritis: subchondral bone sclerosis, joint space narrowing, osteophytes and subchondral cysts. The severity of each of these four signs was graded as absent, mild, moderate or severe (semi-quantitative score ranging from 0 to 3 for each sign). The absence of hip OA was defined as CT score equal to 0, mild hip OA as CT score between 1 and 4 and moderate to severe hip OA as CT score>4. Women with and without hip OA were compared using t tests and multivariable modeling. Results: The mean age was 65.9 (+/- 6.7) years and the mean body mass index was 24.6 (+/- 3.6) kg/m(2). Among these 1537 women, 601 had an OA score of 0, 756 between 1 and 4 (mild OA) and 180 greater than 4 (severe OA). Women with hip osteoarthritis had lower trabecular total hip vBMD (125 vs. 129mg/cm(3), P<0.01). Cortical hip vBMD did not differ between women with and without hip OA (966.5 vs. 963.5mg/cm(3), P n.s). Patients with hip OA also had larger femoral neck volume (11.55 vs. 11.27mm(3), P<0.001). The BIT analysis showed greater bone resistance to bending (cross-sectional moment of inertia [CSMI] min with 6.03 vs. 5.6cm(4) and section modulus [Z] polar with 7.98 vs. 7.59cm(3), P<0.05) at the femoral neck in patients with mild hip OA and even greater in women with severe hip OA. Patients with hip OA had significantly higher trabecular area measured at the radius by HR-pQCT (205.11 vs. 192.61mm(2), between group difference 12.50 95% CI [8.15-16.86] P<0.01), lower trabecular number at the tibia (1.57/mu m vs. 1.63/mu m, between group difference -0.06 95% CI [-0.09 to -0.03] P<0.001) and higher trabecular spacing at the tibia (0.58 vs. 0.56 mu m, between group difference 0.02 95% CI [0.011-0.038] P<0.005). Cortical parameters were not different in patients with hip OA compared to controls. Conclusion: Women with hip OA have larger femoral neck and lower trabecular bone parameters, suggesting a sizeable role of hip bone geometry and remodeling in the pathophysiology of hip OA. TI Role of YAP/TAZ in bone diseases: A transductor from mechanics to biology
SO JOURNAL OF ORTHOPAEDIC TRANSLATION
LA English
DT Review
DE Bone diseases; Mechanoresponse; Mechanosensing; Mechanotransduction; TAZ; YAP
ID yes-associated protein; hippo signaling pathway; mesenchymal stem-cells; smooth muscle actin; organ size control; osteogenic differentiation; regulating osteoclast; yap pathway; growth; taz
AB Wolff's Law and the Mechanostat Theory elucidate how bone tissues detect and convert mechanical stimuli into biological signals, crucial for maintaining bone equilibrium. Abnormal mechanics can lead to diseases such as osteoporosis, osteoarthritis, and nonunion fractures. However, the detailed molecular mechanisms by which mechanical cues are transformed into biological responses in

bone remain underexplored. Yes-associated protein (YAP) and transcriptional coactivator with PDZ-binding motif (TAZ), key regulators of bone homeostasis, are instrumental in this process. Emerging research highlights bone cells' ability to sense various mechanical stimuli and relay these signals intracellularly. YAP/TAZ are central in receiving these mechanical cues and converting them into signals that influence bone cell behavior. Abnormal YAP/TAZ activity is linked to several bone pathologies, positioning these proteins as promising targets for new treatments. Thus, this review aims to provide an in-depth examination of YAP/TAZ's critical role in the interpretation of mechanical stimuli to biological signals, with a special emphasis on their involvement in bone cell mechanosensing, mechanotransduction, and mechanoresponse. The translational potential of this article: Clinically, appropriate stress stimulation promotes fracture healing, while bed rest can lead to disuse osteoporosis and excessive stress can cause osteoarthritis or bone spurs. Recent advancements in the understanding of YAP/TAZ-mediated mechanobiological signal transduction in bone diseases have been significant, yet many aspects remain unknown. This systematic review summarizes current research progress, identifies unaddressed areas, and highlights potential future research directions. Advancements in this field facilitate a deeper understanding of the molecular mechanisms underlying bone mechanics regulation and underscore the potential of YAP/TAZ as therapeutic targets for bone diseases such as fractures, osteoporosis, and osteoarthritis.

TI Direct lateral vs. posterior-lateral approach in robotic-assisted total hip arthroplasty: clinical and radiographic comparison
SO ARCHIVES OF ORTHOPAEDIC AND TRAUMA SURGERY
LA English
DT Article
DE Lateral approach; Posterior approach; Robotic THA; Mako; WOMAC; HHS
ID surgical approach; anteversion; quality; offset
AB IntroductionThe main goal of this study was to compare patient outcomes following robotic-arm assisted THA (RTHA) using the direct lateral approach (DLA) and the posterior-lateral approach (PLA) by analysing the clinical and radiographical data.Materials and Methods203 consecutive patients diagnosed with end stage hip osteoarthritis underwent RTHA at the same orthopaedic centre between 2015 and 2019. Patients were divided in two groups based on the surgical approach where 95 patients received PLA and 108 received DLA. All patients were assessed pre-operatively and at minimum 3-year follow-up using Harris Hip Score (HHS) and Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC). A radiographic evaluation was performed for every patient to assess the incidence of heterotopic ossification (HO).ResultsPatients in the PLA cohort had higher scores in the post-operative WOMAC when compared to the DLA group (PLA: 96.2 +/- 8.2 vs. DLA: 93.6 +/- 10.3, p = 0.05). There was no statistical difference in the post-op HHS (PLA 86.3 +/- 7 vs. DLA: 86.3 +/- 9.5, p = 0.97).

Accurate component positioning was achieved according to the pre-operative planning in both groups. There were no cases of dislocation. We found a significantly higher incidence of HO in the DLA group (59.3%) compared to the PLA group (12.6%). However, this difference was not associated with a poorer clinical outcome.ConclusionsCurrent controversy still persists regarding the surgical approach without clear evidence about which one is more appropriate. Nowadays, it seems that surgeons' skill and experience to perform an approach are still more relevant than the choice of the approach. Both PLA and DLA represent valid surgical options for performing RTHA, yielding excellent clinical outcomes without clear evidence of superiority of one approach over the other.

TI Alternative Splicing: A Critical Regulator in Human Bone Biology and Tumor Progression
SO RESEARCH
LA English
DT Review
ID prostate-cancer cells; mechano-growth-factor; messenger-rna; differential expression; dna-damage; sr proteins; recessive osteopetrosis; transcriptional control; isoform expression; variant expression
AB Alternative splicing (AS) is the central mechanism of transcriptional regulation and generates diverse splice variants that influence protein structure, function, and intracellular activity. AS plays critical roles in tissue differentiation, organ development, and disease progression. This review focuses on the pivotal roles of AS in bone biology, highlighting its regulatory effects on osteoblasts, osteoclasts, chondrocytes, bone matrix remodeling, and bone remodeling, as well as the involvement of AS-related RNA-binding proteins in these processes. We also emphasize bone-specific AS events and their physiological importance in skeletal development and maintenance. Furthermore, the pathological role of AS is emphasized in bone-related tumors such as osteosarcoma, Ewing sarcoma, and

chondrosarcoma. This review also explores aberrant AS mechanisms in bone metastatic cancers, including prostate, bladder, and breast cancers, with an in-depth analysis of their roles in tumor progression and alterations in the bone microenvironment. This review provides a comprehensive perspective on how AS factors, signaling pathways, and mechanical stimulation collaboratively regulate bone cells under both physiological and pathological conditions, paving the way for identifying potential intervention strategies. The mechanisms of AS in other pathological bone conditions, such as osteoporosis, osteoarthritis, and hereditary bone disorders, are also summarized. The potential applications of targeting AS in the diagnosis and treatment of bone diseases are discussed, offering insights into the underlying mechanisms and clinical translational potential.

TI The Role of Adipokines in Spinal Disease: A Narrative Review
SO JOR SPINE
LA English
DT Review
DE adipokines; degeneration; intervertebral disc; leptin; spinal pathology
ID posterior longitudinal ligament; adipose-tissue; oxidative stress; messenger-rna; skeletal-muscle; gene-expression; cord-injury; tnf-alpha; leptin; resistin
AB BackgroundAdipokines are bioactive molecules secreted by adipose tissue that influence both local and systemic physiological processes. Although adipokine dysregulation has been widely implicated in the pathogenesis of cardiovascular, gastrointestinal, nervous, immune, and musculoskeletal disorders- especially osteoarthritis, rheumatoid arthritis, and osteoporosis- their involvement in spinal pathology remains comparatively underinvestigated. Recent evidence indicates that

certain adipokines may influence spinal disease progression by affecting bone, intervertebral discs, musculature, and neural structures.MethodsA comprehensive literature review was conducted to evaluate preclinical and clinical studies investigating the role of adipokines in spinal pathology. PubMed and related databases were searched for studies reporting associations between adipokine expression and structural or functional changes in spinal tissues, including vertebral bone, intervertebral discs, paraspinal muscles, spinal ligaments, and the spinal cord. Particular attention was given to mechanistic insights and translational relevance.ResultsThe review identified emerging evidence implicating several adipokines, including leptin, adiponectin, resistin, and visfatin, in degenerative and inflammatory changes across various spinal structures. Adipokines were found to influence matrix degradation, bone turnover, muscle atrophy, and neural inflammation through cytokine signaling, oxidative stress, and metabolic dysregulation. However, findings are often heterogeneous and context-dependent, with limited longitudinal or interventional data.ConclusionsAdipokines represent a promising yet underexplored avenue in spinal disease research. Their diverse functions in both structural and metabolic regulation highlight their potential as both biomarkers and therapeutic targets. Further mechanistic and clinical studies are needed to elucidate causal relationships and therapeutic efficacy, particularly in degenerative spine disorders.

TI Uncemented reverse total shoulder arthroplasty: is it a safe option for elderly patients with proximal humerus fractures?
SO INTERNATIONAL ORTHOPAEDICS
LA English
DT Article
DE Reverse shoulder arthroplasty; Proximal humerus fracture; Osteoporosis; Uncemented stem; Stem loosening; Tuberosity healing
ID 4-part fractures; fixation; hemiarthroplasty; osteoarthritis; outcm; quality; stem
AB PurposeReverse shoulder arthroplasty (RSA) is a common surgical procedure for elderly patients with proximal humerus fractures. Cement fixation of the humeral stem is considered the gold standard for this procedure. Due to the high prevalence of osteoporosis in this patient population, the risk of intraoperative fractures is increased when uncemented stems are used. Stem loosening is another concern of uncemented stems. However, the use of cement is associated with the risk of cement embolisation, impairment of tuberosity healing, and technical difficulties for later revisions. This study aimed (i) to evaluate the clinical and

radiological outcomes of patients treated with uncemented RSA for proximal humerus fractures at two years postoperatively, and (ii) to compare these outcomes between patients with and without decreased low bone quality as measured by the deltoid tuberosity index.MethodsThe single-centre prospective study included 54 shoulders (52 patients) with a proximal humerus fracture between 2019 and 2022. Enrolled were patients aged 65 and older with acute or secondary displaced three- or four-part fractures or head-split fractures treated with RSA using the same uncemented system and tubercula refixation. At 24 months post-surgery, clinical evaluations included range of motion (ROM), Constant-Murley Score (CS), Subjective Shoulder Value (SSV), and American Shoulder and Elbow Surgeons (ASES) Score. Radiological assessments evaluated scapular notching, radiolucent lines, and greater tuberosity healing.ResultsThe mean age was 79 years (+/- 8), 87% were female, and 69% had osteoporotic fractures. At the two-year follow-up, the median SSV was 90% (IQR 80-95), the median CS Score was 76.5 (IQR 72-81), and the median ASES Score was 89.9 (IQR 82-93). The ROM measurements were: median active forward flexion 140 degrees (IQR 120-160), median external rotation 30 degrees (IQR 20-40), and median active internal rotation 6 (IQR 4-8). The greater tuberosity healing rate was 94.5%. Although osteoporotic fractures occurred more often in older patients (mean 81 vs. 72 years, respectively), no other significant differences were detected between the groups. One case of aseptic stem loosening occurred in the non-osteoporotic group.ConclusionEven in osteoporotic proximal humerus fractures, cementless stems combined with tubercula refixation resulted in favourable outcomes and were not associated with increased complications.

TI Osteosarcopenia, osteoarthritis and frailty: a two-sample Mendelian

randomization study
SO AGING CLINICAL AND EXPERIMENTAL RESEARCH
LA English
DT Article
DE Osteosarcopenia; Osteoarthritis; Frailty; Mendelian randomization
ID c-reactive protein; older-adults; association; risk; bone; knee; interleukin-6; metaanalysis; population; prevalence
AB Background Musculoskeletal disease, which has a complicated relationship with frailty, is a common clinical problem among elderly individuals. AimsThis study evaluated the potential causal relationships between osteosarcopenia, osteoarthritis and frailty by Mendelian Randomization (MR) analysis. Methods This study employed a two-sample MR approach to investigate the causal relationships among osteosarcopenia, osteoarthritis and frailty. Published summary statistics were used to obtain instrumental variables at the genome-wide significance level. Results Among the age groups with osteoporosis, high total bone mineral density (TBMD) (45-60, OR = 0.966, 95% CI 0.940-0.993, P = 0.013) and TBMD (over 60, OR = 0.974, 95% CI 0.954-0.994, P = 0.011) reduced the risk of frailty. Similarly, high forearm BMD (FA-BMD), high ultradistal forearm BMD (UFA-BMD), and high Heel-BMD at different sites also reduced the risk of frailty (OR = 0.966, 95% CI 0.936-0.996, P = 0.028; OR = 0.975, 95% CI 0.953-0.997, P = 0.029; OR = 0.981, 95% CI 0.967-0.995, P = 0.008). Among the characteristics related to sarcopenia, grip strength in the left hand, grip strength in the right hand, appendicular lean mass, and walking pace were all protective factors for frailty (OR = 0.788, 95% CI 0.721-0.862, P < 0.001; OR = 0.800, 95% CI 0.737-0.869, P < 0.001; OR = 0.955, 95% CI 0.937-0.974, P = 0.000; OR = 0.480, 95% CI 0.388-0.593, P < 0.001), with low grip strength in those over 60 years of age significantly positively correlated with frailty (OR = 1.168, 95% CI 1.059-1.289, P = 0.002). The MR results of osteoarthritis and frailty revealed a causal relationship between specific joint sites and frailty, including KOA (OR = 1.086, 95% CI 1.017-1.160, P = 0.014), HOA (OR = 1.028, 95% CI 1.007-1.049, P = 0.009), and KOA/HOA (OR = 1.082, 95% CI 1.053-1.113, P = 0.000), increasing the risk of frailty. Conclusion Osteosarcopenia, osteoarthritis and frailty exhibit significant causal effects, rendering them risk factors for frailty. Therefore, in clinical practice, patients with osteosarcopenia and osteoarthritis should be required to undergo relevant interventions to reduce the risk of frailty.

AB Nanozymes, an emerging class of nanomaterials, demonstrate enzyme-like activities and have significantly broadened the enzyme mimicry field by extending it from organic to inorganic materials. Their affordability, multifunctionality, and enhanced stability under harsh conditions position them as potential replacements for natural enzymes in various applications. Nanozymes have demonstrated tremendous application potential in orthopedic diseases including osteoarthritis, osteoporosis, bone regeneration, bacteria-related infections, rheumatoid arthritis, and osteosarcoma. The regenerative repair of bone defects is a critical research direction in modern medicine, where bone remodeling and regeneration are essential for maintaining skeletal integrity and mineral homeostasis. Nanozymes play a significant role in bone regeneration and repair by regulating the balance between osteoblasts and osteoclasts, promoting vascular and neural regeneration, controlling infections, and modulating cellular immune functions. This article discusses the latest advancements in applying nanozymes in bone tissue regenerative medicine. It reviews the mechanisms through which nanozymes facilitate osteogenesis and enhance bone regeneration. Additionally, this review examines the current uses of various nanozymes in bone regeneration and explores

both the prospects and the challenges of nanozymes in clinical therapies.

TI Nutrition supplementation combined with exercise versus exercise alone in treating knee osteoarthritis: a double-blinded, randomised, placebo-controlled trial
SO AGE AND AGEING
LA English
DT Article
DE knee osteoarthritis; nutrition supplementation; exercise; older people
ID glucosamine sulfate; chondroitin sulfate; obese adults; therapy; pain; osteoporosis; combination; outcm; womac; hip

AB Objective: To investigate the effectiveness of formula nutrition supplementation (mainly containing glucosamine sulphate, chondroitin sulphate and rhizoma drynariae) plus supervised exercise versus exercise alone for the treatment of knee osteoarthritis (OA). Methods: This was a double-blinded, single-centre, randomised, placebo-controlled trial. The study recruited 65 participants (40-75 years) with knee OA. Participants were randomly allocated to nutrition supplementation plus exercise (N + E) group or placebo plus exercise (P + E) group. The intervention lasted for 6 months. The primary outcome was the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) score. Secondary outcomes included physical function and performance scores, lower extremity strength and serum biomarkers. Results: Among the 65 randomised patients, 56 (86%) completed the trial. At 3 months, more participants in the N + E group than in the P + E group achieved minimum clinically important difference (MCID) in WOMAC total score (19/30 [63.3%] vs 8/26 [30.8%]; P < .01). At 6 months, more participants in the N + E group than in the P + E group achieved MCID in WOMAC stiffness score (19/30 [63.3%] vs 10/26 [38.5%]; P < .05). Meanwhile, at 6 months the decreased percentages of WOMAC stiffness score in the N + E group was greater than in the P + E group (P < .05). The flexor peak torque at 120 degrees/s and 180 degrees/s in the N + E group were significantly higher than those in the P + E group at 3 months (P < .05). Moreover, compared with baseline, improvements in the WOMAC overall and pain score, visual analogue scale pain and 30-second chair stand test were observed in both groups at 6 months. However, these indicators in the N + E group were improved as early as 3 months (P < .05). Conclusions: The improvement effects of nutrition supplementation plus exercise were superior to those of exercise alone, and the improvement occurred earlier. Nutrition supplementation plus exercise would be a more efficient strategy for knee OA.

TI Locomotive syndrome and increased musculoskeletal disorder incidence in older adults: a prospective study
SO JOURNAL OF BONE AND MINERAL METABOLISM
LA English
DT Article
DE Locomotion Disorders; Musculoskeletal Diseases; Incidence; Prospective Studies; Geriatric Assessment
ID quality-of-life; knee osteoarthritis; risk; pain; epidemiology; prevalence; disability; decrease; diseases; people
AB Introduction With the population aging, musculoskeletal disorders increasingly impair older adults' quality of life and escalating healthcare costs, necessitating effective prevention strategies. Locomotive syndrome (LS), characterized by mobility decline due to musculoskeletal dysfunction, is closely linked to these disorders. However, its role in predicting future musculoskeletal conditions remains unclear. This study examined the association between LS and the incidence of newly diagnosed musculoskeletal disorders. Material and Methods This prospective study included 367 community-dwelling adults aged >= 40 years who were independent in daily activities. LS was assessed using the five-question Geriatric Locomotive Function Scale (GLFS-5). The primary outcome was the incidence of musculoskeletal disorders, including osteoarthritis, lumbar spinal stenosis, and osteoporosis. Cox proportional hazards regression analyzed associations between LS and future diagnoses, while receiver operating characteristic (ROC) analysis determined the GLFS-5 cutoff score for risk prediction. Results At baseline, 19.1% of participants had LS. Over four years, musculoskeletal disorders occurred more frequently in participants with LS than in those without (22.2 vs. 8.8 per 100 person-years, $p < 0.001$). After adjusting for covariates, LS remained a significant risk factor (hazard ratio 1.98, 95% confidence interval 1.16-3.36, $p = 0.011$). ROC analysis identified a GLFS-5 cutoff score of 2 (sensitivity: 62.0%, specificity: 62.0%). Conclusions LS nearly doubled the risk of musculoskeletal disorders, with a GLFS-5 score >= 2 serving as an early risk indicator. Proactive screening and targeted interventions may mitigate this risk in aging populations.

TI Statins and long-term risk of revision surgery after total hip arthroplasty in osteoarthritis: a multi-source data linkage study
SO FRONTIERS IN PHARMACOLOGY
LA English
DT Article
DE osteoarthritis; statins; orthopedic surgery; total hip arthroplasty; prosthesis outcomes
ID knee arthroplasty; simvastatin; gender; differentiation; osteoporosis; disease
AB Background Statins, widely used lipid lowering drugs, have been associated with pleiotropic beneficial effects. Notably, studies conducted in vitro and in vivo suggest a link between statins and bone metabolism. Observational data in humans also hint at a decreased fracture rate among statin users. Revision of total hip arthroplasty (THA) is a serious and costly medical event. Whether statins might influence THA failure is not clear. Aim of the current study is to assess how the preoperative use of statins may influence the risk of THA revision in patients with hip osteoarthritis (OA). Methods We performed a retrospective analysis of patients

who underwent THA for OA in the Italian RIPO registry of Emilia-Romagna. Electronic health records were scrutinized to gather information regarding comorbidities and statin prescriptions. We employed propensity score (PS) matching to pair 1:1 statin users (SU) with statin non-users (SNU), considering factors such as age, sex, and the duration of follow-up. Survival of THA was compared between the two groups; secondary analyses were performed to ascertain the role of mortality, sex, indication for statin treatment, and statin potency or lipophilicity. Results 10,927 patients were classified as SU and PS-matched with SNU. SU showed a reduced risk of THA revision over a 15-year period (adjHR 0.76, 95% CI: 0.67-0.88; p < 0.001). Notably, this observation remained consistent regardless of the indication for statin therapy or the specific characteristics of the statin medications prescribed, and it was more pronounced among male patients (adjHR 0.64, 95% CI: 0.52-0.80, p < 0.001). Conclusion Our findings suggest that statin treatment is associated with a decreased risk of long-term THA revision in patients with OA, irrespective of the original indication for statin therapy.

TI Salidroside ameliorates lipopolysaccharide-induced ferroptosis in chondrocytes via regulation of the sirt1/foxo1 axis
SO MOLECULAR MEDICINE REPORTS
LA English
DT Article
DE salidroside; osteoarthritis; sirt1/foxo1 signaling; ferroptosis
ID osteoarthritis; osteoporosis; cartilage; cancer
AB Salidroside (SAL) is a bioactive constituent extracted from Rhodiola rosea plant and exerts antioxidant and anti-inflammatory properties. However, understanding of SAL for the treatment of arthritis is limited. The aim of the present study was to investigate whether SAL treats lipopolysaccharide (LPS)-induced chondrocyte injury by modulating the sirt1 silent information regulator 1)/FoxO1 (forkhead transcription factors O1) signaling pathway. Network pharmacology was used to screen the potential pathway of SAL for the treatment of osteoarthritis via the ferroptosis pathway. Subsequently, a chondrocyte inflammation model was established in vitro using LPS and SAL was used as a drug treatment. Effects of SAL treatment of chondrocytes was evaluated by western blot analysis, fluorescence, cell viability and oxidative assay. Analysis revealed that SAL significantly attenuated

LPS-induced apoptosis and accumulation of oxides in chondrocytes, thereby protecting the integrity of cartilage extracellular matrix. In addition, SAL promoted the activation of the sirt1/foxo1 signaling cascade, which alleviated LPS-induced ferroptosis in chondrocytes. The present study demonstrated that SAL attenuated LPS-induced chondrocyte ferroptosis by regulating the sirt1/foxo1 pathway. This may provide a potential therapeutic avenue for cartilage damage in osteoarthritis.

TI Oral microbiome, periodontal disease and systemic bone-related diseases in the era of homeostatic medicine
SO JOURNAL OF ADVANCED RESEARCH
LA English
DT Article
DE Oral microbiome; Homeostatic medicine; Dysbiosis; Periodontal disease; Bone-related diseases; Targeted therapies
ID tumor-necrosis-factor; porphyromonas-gingivalis; rheumatoid-arthritis; osteoclast differentiation; gut microbiota; synovial-fluid; bacterial-dna; factor-alpha; stem-cells; lipopolysaccharide
AB Background: Homeostasis is a state of self-regulation and dynamic equilibrium, maintaining the good physiological functions of each system in living organisms. In the oral cavity, the interaction between the host and the oral microbiome forms oral microbial homeostasis. Physiological bone remodeling and renewal can occur under the maintenance of oral microbial homeostasis. The imbalance of bone homeostasis is a key mechanism leading to the occurrence of systemic bone-related diseases. Considering the importance of oral microbial homeostasis in the maintenance of bone homeostasis, it still lacks a complete understanding of the relationship between oral microbiome, periodontal disease and systemic bone-related diseases. Aim of review: This review focuses on the homeostatic changes, pathogenic routes and potential mechanisms in the oral microbiome in periodontal disease and systemic bone-related diseases such as rheumatoid arthritis, osteoarthritis, osteoporosis and osteomyelitis. Additionally, this review discusses oral microbiome-based diagnostic approaches and explores probiotics, mesenchymal stem cells, and oral microbiome transplantation as promising treatment strategies. Key scientific concepts of review: This review highlights the association between oral microbial homeostasis imbalance and systemic bone-related diseases, and highlights the possibility of remodeling oral microbial homeostasis for the prevention and treatment of systemic bone-related diseases.

TI A development of machine learning models to preoperatively predict insufficient clinical improvement after total knee arthroplasty
SO JOURNAL OF ORTHOPAEDIC SURGERY AND RESEARCH
LA English
DT Article
DE Total knee arthroplasty; Insufficient clinical improvement prediction; WOMAC; Minimal clinically important difference; Machine learning

ID reported outcome measures; patient satisfaction; risk-factor; total hip; pain; quality; comorbidity; replacement; algorithms; health
AB BackgroundIdentifying patients unlikely to achieve meaningful improvement following total knee arthroplasty (TKA) supports more effective shared decision-making (SDM). This study aimed to develop and validate machine learning (ML) models that preoperatively predict insufficient clinical improvement one year after TKA using Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) subscales and total scores, and to assess the important predictive variables.MethodsA retrospective analysis was performed on consecutive primary TKA patients from 2004 to 2022 at a single tertiary hospital was conducted. Insufficient clinical improvement was defined as not achieving the minimal clinically important difference (MCID) for each WOMAC subscale and total. Candidate preoperative variables included demographics, comorbidities, knee range of motion, radiologic variables, and WOMAC scores. A variety of ML models were evaluated using performance metrics for calibration and discrimination, as well as decision curve analysis and Shapley additive explanations.ResultsAmong the 3,810 TKAs included, the ExtraTrees model performed best for WOMAC pain, stiffness, function, and total scores, achieving AUCs of 0.92, 0.90, 0.87, and 0.89; recall rates of 0.79, 0.86, 0.70, and 0.83; and Brier scores of 0.09, 0.10, 0.11, and 0.06, respectively, along with demonstrating good calibration curves and net clinical benefit. Shapley additive explanations identified better preoperative WOMAC scores, osteoporosis, diabetes mellitus, older age, malignancy, and coronary artery disease as important predictors of insufficient clinical improvement.ConclusionsThe ML models demonstrated good performance in preoperatively predicting insufficient clinical improvement at 1 year after TKA based on WOMAC. These models have the potential to enhance SDM and perioperative patient management by preoperatively identifying approximately 70% to over 80% of patients likely to experience insufficient clinical improvement, with a specificity of about 80%, and by providing explanations regarding associated factors.

TI Shockwave-driven activation of endoplasmic reticulum stress in osteoblasts to enhance bone formation under osteoporotic conditions
SO REGENERATIVE BIOMATERIALS

LA English
DT Article
DE extracorporeal shockwave; osteoporosis; endoplasmic reticulum stress; cellular senescence; osteogenesis
ID er stress; therapy; waves; nanoparticles; apoptosis; autophagy; fracture
AB Extracorporeal shockwave (ESW) therapy is a noninvasive physical intervention widely applied in orthopedics for the treatment of musculoskeletal disorders such as plantar fasciitis, osteoarthritis, delayed fracture healing and tendinopathies. In recent years, accumulating evidence has suggested that ESW may also have beneficial effects on bone regeneration and local bone mineral density, particularly under osteoporotic conditions. However, the precise biological mechanisms underlying these effects remain incompletely elucidated. In this study, we systematically investigated the effects of different radial extracorporeal shockwave (r-ESW) intensities on osteoblasts derived from osteoporotic bone (OPOB), with a specific focus on osteogenic activity and the involvement of endoplasmic reticulum (ER) stress. Our in vitro results demonstrated that moderate-intensity r-ESW (3 bar) significantly enhanced osteoblast proliferation, upregulated the expression of osteogenic markers including Runx2, Col I, OPN and OCN and promoted matrix mineralization. Mechanistically, this was accompanied by mild ER stress and activation of the PERK-eIF2 alpha-ATF4 signaling pathway, which contributed to improved osteogenic differentiation and alleviated cellular senescence. In contrast, high-intensity stimulation (5 bar) induced excessive ER stress, calcium overload and subsequent apoptosis and necrosis, ultimately impairing osteogenesis. Furthermore, in an ovariectomy (OVX)-induced osteoporotic rat model, 3 bar r-ESW treatment effectively increased bone mass, stimulated new bone formation and decreased osteoclast activity and senescence-associated markers in vivo. These findings collectively highlight the potential of moderate-intensity r-ESW as a promising nonpharmacological strategy for osteoporosis management, providing novel insights into the modulation of ER stress as a therapeutic target in OPOB remodeling.

TI Evaluation of Vitamin E in Trauma and Orthopaedics: A Narrative Synthesis
SO INDIAN JOURNAL OF ORTHOPAEDICS
LA English
DT Review
DE Vitamin E; Antioxidant; Anti-inflammatory; Oxidative stress; Arthroplasty; Orthopaedic surgery; Osteoporosis
ID cross-linked polyethylene; total hip-arthroplasty; e supplementation; alpha-tocopherol; spinal-cord; bone mass; cells; wear; differentiation; tocotrienols
AB BackgroundThere is an emerging role for vitamin E in orthopaedics due to its antioxidant, immunomodulation and anti-inflammatory effects. The current review aims to comprehensively evaluate evidence regarding the use, benefits, pitfalls and future implications of vitamin E in diverse subspecialties of orthopaedics.Materials and MethodologyA comprehensive search of literature was performed on 5 databases on January 5, 2025. The manuscripts, which pertain to examining the role of vitamin E in orthopaedics, were considered. Among them, opinions, editorials, letters, case reports and non-English manuscripts were excluded.Results19 manuscripts were selected for our review. Vitamin E is utilised in diverse forms in orthopaedic patients: administered systemically, intraarticularly or locally. Systemically-administered vitamin E can mitigate osteoarthritis progression through strengthening of adjoining musculature, gene regulation, protection of subchondral vasculature, and anti-inflammatory properties. Vitamin E incorporation has been demonstrated to improve the wear characteristics of highly crosslinked polyethylene and metal alloys in arthroplasty through its antioxidant and osteointegrative abilities. Antioxidant vitamin E has been shown to mitigate postoperative arthrofibrosis and septic loosening. Vitamin E can positively

influence late callus formation during secondary fracture healing. Through its effects on osteoblastic cells, proinflammatory cytokines, growth factors, antioxidant mechanism, hormones and micro-RNA, systemic vitamin E administration can meliorate osteoporosis and mitigate fractures.ConclusionThere is emerging evidence regarding the roles of vitamin E in diverse orthopaedic conditions like osteoarthritis, osteoporosis, fracture healing, osteomyelitis and arthroplasty. These actions are attributed to its antioxidant, anti-inflammatory, and immunomodulatory functions. Large-scale trials are needed to ascertain its safety and future prospects.

TI Role of leptin as a factor regulating bone metabolism
SO MEDYCYNA WETERYNARYJNA-VETERINARY MEDICINE-SCIENCE AND PRACTICE
LA English
DT Review
DE adipokines; leptin; bone; health; animals
ID mineral density; growth-hormone; mass; physiology; serotonin; cells; body; deficiency; expression; endocrine
AB Discovered in 1994, leptin is one of the most important anorexigenic factors in the body. This hormone is synthesized and released mainly by white adipose tissue, but could also be released by other tissues. Its main function is suppressing the feeling of hunger by interacting with LEPRs receptors located in the hypothalamus, which makes it one of the main factors regulating the food intake. Appetite regulation is not the only function of leptin in the organism. By interacting with LEPRs, it can also influence the metabolism of various body tissues and organs, such as gonads, immune system cells, bone marrow, and bones. A very important aspect of leptin activity, though seldom discussed in the literature, is its impact on bone tissue metabolism. Leptin can affect bone cells through two different pathways: a peripheral one and a central one. The peripheral pathway involves a direct interaction of leptin with LEPRs located on the surface of bone cell. The central pathway, on the other hand, involves the interaction of leptin with structures of the central nervous system, which regulates the secretion of many hormones, such as serotonin, growth hormone, and thyroid hormones, directly affecting the metabolic activity of bone cells. Determining the overall effect of leptin on bone metabolism is not an easy task. This is due to significant differences in the way individual leptin activity pathways may affect bone metabolism. Indirect pathways stimulate bone tissue in bone anabolic or bone katabolic processes, leading to an increase or a decrease in bone mass, depending on the hormone

through which bone metabolism is regulated. However, most of the literature data suggest that the leptin regulation of bone turnover is determined mainly by the direct pathway, and the overall effect of its activity is an increase in bone tissue mechanical parameters. Nevertheless, a complete understanding of these mechanisms requires further research. It is worth mentioning that this hormone is also involved in the development of several disorders of the skeletal system, such as osteoarthritis, osteoporosis, and rheumatoid arthritis, but the exact impact of leptin on the course of these diseases is still not fully understood.

ID senescence; sarcopenia; interleukin-1-beta
AB Background/Objectives: Cellular aging represents a crucial element in the progression of musculoskeletal diseases, contributing to muscle atrophy, functional decline, and alterations in bone turnover, which promote fragility fractures. However, knowledge about expression patterns of factors potentially involved in aging and senescence at the tissue level remains limited. Our pilot study aimed to characterize the expression profile of cell cycle regulators, factors released by aged cells, and sirtuin 1 (SIRT1) in the muscle tissue of 26 elderly patients undergoing hip arthroplasty, including 13 with low-energy fracture and 13 with osteoarthritis (OA). Methods: The mRNA expression levels of cyclin-dependent kinase inhibitor 1A (CDKN1A), cyclin-dependent kinase inhibitor 1B (CDKN1B), cyclin-dependent kinase inhibitor 2A (CDKN2A), p53, tumor necrosis factor alpha (TNF-alpha), interleukin-1 beta (IL-1 beta), interleukin-6 (IL-6), interleukin-15 (IL-15), chemokine (C-C motif) ligand 2 (CCL2), chemokine (C-C motif) ligand 3 (CCL3), growth differentiation factor 15 (GDF15), and SIRT1 were evaluated in muscle tissue by qRT-PCR. In addition, immunohistochemistry and Western blotting analysis were conducted to measure the protein levels of SIRT1. Results: A marked muscle atrophy was observed in fractured patients compared to the OA group, in association with an up-regulation of cell cycle regulators and factors released by the aged cells. The expression of matrix metallopeptidase 3 (MMP3), plasminogen

activator inhibitor 1 (PAI-1), and fas cell surface death receptor (FAS) was also investigated, although no significant differences were observed between the two experimental groups. Notably, SIRT1 expression was significantly higher in OA patients, confirming its role in maintaining muscle health during aging. Conclusions: Further studies will be needed to clarify the role of SIRT1 in the senescence characteristic of age-related musculoskeletal disorders, counteracting the muscle atrophy that predisposes to fragility fractures.

ID pre-messenger-rnas; osteogenic differentiation; regulates adipogenesis; comprehensive analysis; intervertebral disc; gene-expression; fat mass; methyltransferase; promotes; progression
AB Elucidating the molecular mechanisms underlying orthopedic diseases is crucial for guiding therapeutic strategies and developing innovative interventions. N6-methyladenosine (m(6)A)-an epitranscriptomic modification-has emerged as a key regulator of cellular fate and tissue homeostasis. Specifically, m(6)A plays a pivotal role in several RNA biological processes such as precursor RNA splicing, 3'-end processing, nuclear export, translation, and stability. Recent advancements indicate that m(6)A methylation regulates stem cell proliferation and osteogenic differentiation by modulating various signaling pathways. Extensive research has shown that abnormalities in m(6)A methylation contribute significantly to the onset and progression of various orthopedic diseases such as osteoporosis (OP), osteoarthritis (OA), rheumatoid arthritis (RA), and bone tumors. This review aims to

summarize the key proteases involved in m(6)A methylation and their functions. The detailed mechanisms by which m(6)A methylation regulates osteogenic differentiation of bone marrow mesenchymal stem cells (BMSCs) through direct and indirect ways are also discussed, with a focus on specific molecular pathways. Finally, this review analyzes the roles and mechanisms of m(6)A modification in the development and progression of multiple orthopedic diseases, offering a comprehensive understanding of the pathophysiology of these conditions and proposing new directions and molecular targets for innovative treatment strategies.

TI A comprehensive review of Drynariae rhizoma: botany, traditional applications, and active flavonoid components
SO JOURNAL OF PHARMACY AND PHARMACOLOGY
LA English
DT Review
DE Drynariae rhizoma; traditional applications; flavonoid components; extraction methods; analytical characterization; biological activities; quality control
ID osteoprotective fraction; flavan-3-ols; fortunei; expression; naringin
AB Objectives Drynaria fortunei, a species within the Drynaria genus, is a widely distributed medicinal plant with abundant resources. Its rhizome, Drynariae rhizoma, has been extensively utilized in traditional Chinese medicine for its therapeutic efficacy in promoting wound healing, alleviating pain, tonifying the kidneys, and strengthening bones. With a well-documented historical presence in classical texts, Drynariae rhizoma has played a significant role in traditional medical systems across various cultures. Recent phytochemical investigations have identified a diverse array of compounds in Drynariae rhizoma, including flavonoids, phenolic acids, lignans, steroids, and glycosides. Among these, flavonoids represent the principal active constituents, attracting considerable research attention due to their extensive pharmacological activities. This review systematically integrates and critically analyzes the recent research progress in this field,providing a comprehensive overview of the current research landscape,with the aim of identifying promising future directions for Drynariae rhizome.Methods This review leveraged a wide range of online databases, including SciFinder, PubMed, SpringerLink, Baidu Scholar, Google Scholar, ScienceDirect, American Chemical Society (ACS) Publications, Web of Science, and China National Knowledge Infrastructure (CNKI), to collect relevant literature. Comprehensive searches were

conducted using keywords such as "Drynariae Rhizoma", "flavonoids", "extraction", "chemical constituents", "analytical characterization". To ensure the scientific accuracy of this study, the botanical name of the plant was meticulously cross-verified using authoritative platforms such as "World Flora Online" and "The Plant List."Key findings This article provides a comprehensive overview of the botany (including characteristics, distribution, and origin) and traditional applications (such as its historical evolution, botanical sources, and multi-ethnic as well as cross-national therapeutic practices) of Drynariae rhizoma. Additionally, it highlights the latest research advancements on its flavonoid compounds, encompassing extraction methods (e.g. solvent extraction, ultrasound-assisted extraction, and microwave-assisted extraction), analytical characterization (e.g. ultraviolet spectroscopy, high-performance liquid chromatography, and nuclear magnetic resonance), chemical constituents (with 60 flavonoid compounds identified to date), biological activities (e.g. anti-osteoporosis, anti-osteoarthritis, renal protection, dental health promotion, neuroprotection, lipid-lowering, and immunomodulation), and clinical applications. Furthermore, the review discusses current quality control strategies, highlighting the impact of geographical origin and processing methods on flavonoid content. Further in-depth studies are essential to comprehensively explore these areas, paving the way for enhanced understanding and application of Drynariae rhizoma in both traditional and modern medicines.Conclusions A comprehensive analysis of existing literature reveals that the flavonoid constituents of Drynariae rhizoma exhibit remarkable therapeutic potential owing to their structural diversity and extensive pharmacological properties. Nevertheless, current understanding of its pharmacodynamic material basis and quality control parameters remains inadequate, highlighting the urgent need for more rigorous investigations to facilitate its broader applications in both traditional and contemporary medical practices. This review is anticipated to provide a rigorous scientific basis for subsequent investigations and clinical translation of therapies based on Drynariae rhizoma.

ID polyunsaturated fatty-acids; pro-resolving mediators; gmp-amp synthase; factor-kappa-b; dna-damage; myocardial-infarction; estrogen deficiency; knee osteoarthritis; metabolic diseases; senescent cells
AB Musculoskeletal disorders (MSDs) comprise diverse conditions affecting bones, joints, and muscles, leading to pain and loss of function, and are one of the most prevalent and major global health concerns. One of the hallmarks of MSDs is DNA damage. Once accumulated in the cytoplasm, the damaged DNA is sensed by the cyclic GMP-AMP synthase (cGAS)/stimulator of interferon genes (STING) pathway, which triggers the induction of type I interferons and inflammatory cytokines. Thus, this pathway connects the musculoskeletal and immune systems. Inhibitors of cGAS or STING have shown promising therapeutic effects in the pre-clinical models of several MSDs. Systemic, chronic, low-grade inflammation (SCLGI) underlies the development and maintenance of many MSDs. Failure to resolve SCLGI has been hypothesized to play a critical role in the development of chronic diseases, suggesting that the successful resolution of SCLGI will result in the alleviation of their related symptomatology. The process of inflammation resolution is feasible by specialized pro-resolving mediators (SPMs), which are enzymatically generated from dietary essential polyunsaturated fatty acids (PUFAs). The supplementation of SPMs or their stable, small-molecule mimetics and receptor agonists has revealed beneficial effects in inflammation-related animal models, including arthropathies, osteoporosis, and muscle dystrophy, suggesting a translational potential in MSDs. In this review, we substantiate the hypothesis that the use of cGAS-STING signaling pathway inhibitors together with SCLG-resolving compounds may serve as a promising new therapeutic approach for MSDs.

TI Beyond Bone Remodeling: Denosumab's Multisystemic Benefits in Musculoskeletal Health, Metabolism, and Age-Related Diseases-A Narrative Review
SO BIOMEDICINES
LA English
DT Review
DE osteoporosis; sarcopenia; osteosarcopenia denosumab; RANKL inhibitor; RANK/RANKL/OPG pathway (RRO pathway)

ID smooth-muscle-cells; postmenopausal women; vertebral fractures; insulin-resistance; receptor activator; osteoporosis; osteoprotegerin; management; beta
AB Background: Denosumab, a receptor activator of nuclear factor kappa-Beta ligand (RANKL) inhibitor, demonstrates therapeutic effects beyond traditional osteoporosis management through the RANK/RANKL/osteoprotegerin pathway. Methods: This narrative review analyzed 37 studies (2018-2024) examining denosumab's broader physiological effects and clinical applications. Results: Long-term safety data spanning 10 years showed sustained fracture prevention efficacy with a favorable benefit/risk profile. Compared to bisphosphonates, denosumab demonstrated superior outcomes in bone mineral density improvement and fracture risk reduction, particularly in elderly and frail populations. It enhanced muscular function by improving appendicular lean mass and grip strength while reducing fall risk. The drug showed potential cardiovascular benefits through its effects on cardiac and smooth muscle function. Notably, denosumab use was associated with reduced Type II diabetes mellitus risk through improved glucose metabolism. Additionally, it demonstrated promise in osteoarthritis treatment by suppressing osteoclast activity and chondrocyte apoptosis. While there are multisystem benefits, vigilance is required regarding adverse events, including hypocalcemia, infection risk, cutaneous reactions, and osteonecrosis of the jaw. Conclusions: Denosumab exhibits potential benefits in bone and systemic metabolism. Further research is needed to fully understand its therapeutic potential beyond osteoporosis and optimize clinical applications across different populations.

AB With the advancement of global population aging, the incidence of skeletal diseases (e.g. osteoporosis, fractures, and osteoarthritis) in clinical diagnosis increases and poses a serious threat to human health. Skeletal diseases usually occur as a result of disturbed cellular metabolism in a specific period or environment. The bone microenvironment, as an important physiological environment of bone tissue, consists of various cell types, and cell-cell interactions play a decisive role in the biological behavior and metabolic regulation of bone cells. Disorders of the bone microenvironment can exacerbate bone diseases. Conventional therapeutic for skeletal diseases often suffer from poor efficacy, low targeting, and side effects. Therefore, a new therapeutic strategy should be developed urgently to improve the existing deficiencies. With the continuous advancement of nanomedicine, the application of nanomaterials provides new research perspectives and application value for the treatment of skeletal diseases. With their unique physicochemical properties, nanomaterials can directly or indirectly mediate the bone microenvironment to regulate the bone metabolic process through self-regulation, drug carriers, and in vivo scaffolds. All the above strategies are extensively explored in this study. In this paper, we systematically summarize the nanomaterials currently used in the clinical treatment of bone diseases and discuss the application strategies of nanomaterials to regulate the bone microenvironment and thus bone metabolism. Moreover, we evaluated the challenges faced by nanomaterials in the clinical treatment of bone diseases. We aim to provide basic theories and new perspectives for the design and development of novel nanomaterials for improved clinical applications.

TI Subchondral insufficiency fractures of the medial tibial condyle are associated with medial meniscus extrusion: A retrospective observational study
SO JOURNAL OF ORTHOPAEDIC SCIENCE
LA English
DT Article
DE Medial tibial condyle; Subchondral insufficiency fracture; Medial meniscus extrusion; Lower extremity alignment
ID spontaneous osteonecrosis; knee; tear; osteoarthritis; subluxation; mri
AB Background: To the best of our knowledge, no prior studies have identified any risk factors for subchondral insufficiency fractures of the medial tibial condyle. This study aimed to explain relationships between subchondral insufficiency fractures of the medial tibial condyle and the meniscus status, lower extremity alignment, or osteoporosis. Methods: This retrospective study included 325 consecutive patients whose chief complaint is knee joint pain and who had visited one institution between April 2016 and March 2021, of which 70 patients (8 men and 62 women) who had suspected subchondral insufficiency fractures of the medial tibial condyle had undergone magnetic resonance imaging and radiographic examination. These patients were divided into two groups based on the results of their magnetic resonance imaging: the insufficiency fracture group included 46 patients who had subchondral insufficiency fractures of the medial tibial condyle and the nonfracture group included 24 patients without fractures. The meniscus injury and medial meniscus extrusion (MME) were evaluated by using magnetic resonance imaging. The Kellgren-Lawrence grade, the femorotibial angle, and the percent mechanical axis (%MA) were evaluated with the use of knee radiographs. T-scores were also measured by using dual-energy X-ray absorptiometry with a bone densitometer. Results: MME were significantly larger and the %MA was significantly smaller in the insufficiency fracture group than that in the nonfracture group. The prevalence of medial meniscus injuries and pathological MME were higher in the insufficiency fracture group than those in the nonfracture group. The prevalence of varus knee and osteoporosis did not vary remarkably different between the two groups. Conclusion: The patients who had insufficiency fractures of the medial tibial condyle tended to have medial meniscus extrusion. (c) 2024 The Authors. TI Salvage tibiotarsal arthrodesis with circular external fixator for end-stage posttraumatic ankle arthritis, infection, and bone loss
SO INJURY-INTERNATIONAL JOURNAL OF THE CARE OF THE INJURED
LA English
DT Article
DE Ankle arthrodesis; Ankle fusion; Ilizarov external fixator; Tibiotalar arthrodesis; Tibiocalcaneal arthrodesis
ID gait analysis; arthroplasty; metaanalysis; foot
AB Background: Chronic posttraumatic sequelae, such as chronic ankle joint

infection with loss of the articular cartilage, significant ankle deformities with advanced osteoarthritis, or significant bone loss of the distal tibia or talus, cause chronic ankle pain and functional impairment. Arthrodesis is usually required to relieve pain and improve function. These disabling conditions cannot be treated with ordinary arthrodesis methods, particularly if they are associated with severe osteoporosis and/or poor soft-tissue coverage. The present study aimed to report the outcomes and complications of ankle arthrodesis with circular external fixators in patients with end-stage, posttraumatic ankle arthritis, infection, and/or bone loss. Methods: Patients treated with tibiotalar and tibiocalcaneal fusion for posttraumatic sequelae using the circular external fixator between January 2001 and January 2022 were retrospectively reviewed. The outcomes were evaluated using the Catagni tibiotarsal fusion score, and the complications were recorded. Results: The study included 81 consecutive patients; 58 were males, and 23 were females. The mean age of the patients was 41.52 years (range, 18-75). Successful arthrodesis was obtained in 73 patients (90.1 %). Twenty-four patients (29.6 %) developed complications. Most complications were minor except for unacceptable deformity in four patients, refracture of the arthrodesis site in one patient, and failure of arthrodesis in seven patients. At the final evaluation, the mean Catagni Score was 85.4 (range, 52-96). Fifty-eight patients achieved excellent results, 13 patients achieved good results, two patients achieved fair results, and eight patients achieved poor results. Higher Catagni scores were associated with patients without pre-operative infection, with union, without unplanned additional surgical procedures, without complications, and with better final results (all $p < 0.001$). In the multivariate regression analyses, we observed that the Catagni score tends to decrease as patient age increases ($p = 0.010$). Catagni scores of the anterior arthrodesis position were higher than the cases of the sinus tarsi position ($p < 0.001$). Conclusion: Tibiotarsal arthrodesis with the circular external fixator can effectively treat complex ankle joint problems resulting from severe injuries. The Catagni score is a simple and reliable evaluation score after tibiotarsal arthrodesis surgeries.

TI Tree shrew as a new animal model for musculoskeletal disorders and aging
SO BONE RESEARCH
LA English
DT Article
ID intervertebral disc degeneration; articular-cartilage; mouse models; osteoarthritis; age; depression
AB Intervertebral disc degeneration (IDD), osteoarthritis (OA), and osteoporosis (OP) are common musculoskeletal disorders (MSDs) with similar age-related risk factors, representing the leading causes of disability. However, successful therapeutic development and translation have been hampered by the lack of clinically-relevant animal models. In this study, we investigated the potential suitability of the tree shrew, a small mammal with a close genetic relationship to primates, as a new animal model for MSDs. Age-related spontaneous IDD in parallel with a gradual disappearance of notochordal cells were commonly observed in tree shrews upon skeletal maturity with no sex differences, while age-related osteoporotic changes including bone loss in the metaphyses were primarily presented in aged females, similar to observations in humans. Moreover, in the osteochondral defect model, tree shrew cartilage exhibited behavior similar to that of humans, characterized by a more restricted self-healing capacity compared to the rapid spontaneous healing of joint surfaces observed in rats. The

induced OA model in tree shrews was highly efficient and reproducible, characterized by gradual deterioration of articular cartilage, recapitulating the human OA phenotype to some degree. Surgery-induced IDD models were successfully established in tree shrews, in which the lumbar spine instability model developed slow progressive disc degeneration with more similarity to the clinical state, whereas the needle puncture model led to the rapid development of IDD with more severe symptoms. Taken together, our findings pave the way for the development of the tree shrew as a new animal model for the study of MSDs and aging.

TI A randomized controlled trial comparing romosozumab and denosumab in elderly women with primary osteoporosis and knee osteoarthritis
SO SCIENTIFIC REPORTS
LA English
DT Article
DE Denosumab; Knee osteoarthritis; Osteophyte; Osteoporosis; Romosozumab
ID postmenopausal women; prevention; fractures; alendronate; risk
AB We compared the efficacy of romosozumab and denosumab in elderly women with primary osteoporosis and knee osteoarthritis in a randomized controlled trial. A total of 112 participants aged 75-90 years were randomized equally into the romosozumab and denosumab groups. Among these, 49 and 52 participants, respectively, who received their initial dose were included in the analysis. The primary outcome was change in lumbar spine (LS)-bone mineral density (BMD) at 12 months in the romosozumab group versus the denosumab group. Secondary outcomes were changes in knee osteophyte development, patient-reported outcomes (PROs), and the incidence of serious adverse events. Mean age of participants was 80.9 years. There was no difference in baseline LS-BMD between the two groups, with a T-score of -2.6. The mean percentage change in LS-BMD at 12 months was significantly higher in the romosozumab group (13.7%) than in the denosumab group (8.5%; p = 0.0035). No significant differences were observed in knee osteophyte development and PROs between the two groups. Serious adverse events included a case of mitral regurgitation in the romosozumab group. These findings emphasize the need for refined treatment strategies in high-risk populations, highlighting romosozumab's benefits and the need to monitor cardiovascular risks.

TI Peptide-Oligonucleotide Nanohybrids Designed for Precise Gene Therapy of Rheumatoid Arthritis
SO ADVANCED MATERIALS
LA English
DT Article

DE bioorthogonal click reaction; cell-penetrating peptide; gene therapy; oligonucleotide; rheumatoid arthritis
ID cathepsin-k activity; delivery; osteoarthritis; mechanisms; defense
AB Rheumatoid arthritis (RA) is a chronic autoimmune disease characterized by excessive inflammation, pathological bone resorption, and systemic osteoporosis. It lacks effective treatment due to the complex pathogenesis. Gene therapy, especially targeted oligonucleotide (ON) delivery therapy, offers a new prospect for the precise treatment of RA. Nevertheless, the clinical application of ON delivery therapy still faces various challenges such as the rapid enzymolysis by RNAse, the lack of tissue targeting ability, difficulty in cell membrane penetration, and the incapability of endolysosomal escape. To address these issues, a novel kind of engineered peptide and oligonucleotide (PON) nanohybrids are designed and fabricated, which provide various advantages including good biosafety, inflammatory region-targeted delivery, cell membrane penetration, reactive oxygen species (ROS) scavenging, and endolysosomal escape. The PON nanohybrids produce promising effects in suppressing inflammatory responses and osteoclastogenesis of macrophages via multiple signaling pathways. In vivo administration of PON nanohybrids not only ameliorates local joint bone destruction and systemic osteoporosis in the pathological state, but also demonstrates good prophylactic effects against the rapid progression of RA disease. In conclusion, the study presents a promising strategy for precise RA treatment and broadens the biomedical applications of gene therapy based on delivery system.

TI FOXC1 and FOXC2 in Osteogenesis: Emerging roles and therapeutic potential in bone regeneration and remodeling
SO EXPERIMENTAL CELL RESEARCH
LA English
DT Review
DE FOXC1; FOXC2; Bone fracture; Osteoporosis; Osteoarthritis
ID mesenchymal stem-cells; hematopoietic stem; osteoblast differentiation; transcription factors; stromal cells; up-regulation; expression; growth; gene; naringin
AB Bone is a remarkable dynamic tissue, continually undergoing intricate processes of development, repair, and lifelong remodeling, all vital for maintaining skeletal integrity, facilitating injury recovery, and preserving overall health. Mesenchymal stem cells (MSCs) are central to these processes, characterized by their self-renewal capacity, multipotent differentiation (including osteoblasts), and crucial roles in secreting growth factors and remodeling the extracellular matrix. The highly conserved transcription factors FOXC1 and FOXC2 are crucial for correct skeletal development, profoundly influencing both intramembranous and endochondral ossification. Beyond these established developmental functions, recent evidence illuminates their critical emerging roles in actively regulating MSC osteogenic commitment and promoting osteoblastic differentiation, particularly in early cellular stages. FOXC1, for instance, orchestrates the expression of key osteogenic and chondrogenic transcription factors such as SOX9 (vital for endochondral ossification) and MSX2 (paramount in intramembranous bone formation). FOXC2, in turn, significantly contributes to osteoblast maturation through robust activation of the WNT/beta-catenin signaling pathway. Furthermore, compelling experimental studies now directly implicate FOXC1 and FOXC2 in adult bone repair, the

maintenance of bone mineral density (BMD), and the modulation of joint health. This bridges their developmental significance to substantial therapeutic potential in adult skeletal pathologies. This review comprehensively synthesizes current understanding of the developmental and emerging adult roles of FOXC1 and FOXC2 in bone biology, with a focused exploration of their underlying molecular and cellular mechanisms in osteogenesis. We also critically discuss their promising therapeutic potential in prevalent skeletal conditions such as fractures, osteoporosis, and osteoarthritis, illustrating how insights from embryonic bone formation can directly inform novel strategies for enhancing adult bone regeneration and remodeling.

TI Skeletal progenitor LRP1 deficiency causes severe and persistent skeletal defects with Wnt pathway dysregulation

AB Low-density lipoprotein receptor-related protein 1 (LRP1) is a multifunctional endocytic receptor whose dysfunction is linked to developmental dysplasia of the hip, osteoporosis and osteoarthritis. Our work addresses the critical question of how these skeletal pathologies emerge. Here, we show the abundant expression of LRP1 in skeletal progenitor cells at mouse embryonic stage E10.5 and onwards, especially in the perichondrium, the stem cell layer surrounding developing limbs essential for bone formation. Lrp1 deficiency in these stem cells causes joint fusion,

malformation of cartilage/bone template and markedly delayed or lack of primary ossification. These abnormalities, which resemble phenotypes associated with Wnt signalling pathways, result in severe and persistent skeletal defects including a severe deficit in hip joint and patella, and markedly deformed and low-density long bones leading to dwarfism and impaired mobility. Mechanistically, we show that LRP1 regulates core non-canonical Wnt/planar cell polarity (PCP) components that may explain the malformation of long bones. LRP1 directly binds to Wnt5a, facilitates its cell-association and endocytic degradation and recycling. In the developing limbs, LRP1 partially colocalises with Wnt5a and its deficiency alters abundance and distribution of Wnt5a and Vangl2. Finally, using Xenopus as a model system, we show the regulatory role for LRP1 in Wnt/PCP signalling. We propose that in skeletal progenitors, LRP1 plays a critical role in formation and maturity of multiple bones and joints by regulating Wnt signalling, providing novel insights into the fundamental processes of morphogenesis and the emergence of skeletal pathologies.

TI Metabolic, skeletal, and cartilage effects of a high-fat diet and the therapeutic impact of MGL3196 are age- and sex-dependent in mice
SO BONE
LA English
DT Article
DE Type 2 diabetes; Osteoarthritis; Osteoporosis; Cortical bone; Aging; High fat diet
ID articular-cartilage; adipose-tissue; bone-marrow; obesity; fracture; mouse; osteoporosis; androgens; estrogen; mgl-3196
AB Aged individuals with type 2 diabetes (T2D) may suffer from complications of common comorbid conditions like osteoporosis or osteoarthritis. MGL3196 (MGL) is a therapeutic thyroid hormone receptor beta (TR beta) agonist that has been shown to rescue non-alcoholic steatohepatitis by enhancing lipid metabolism. In a previous study, we demonstrated that MGL treatment protected against high-fat diet (HFD)-induced adiposity but increased HFDinduced trabecular bone loss in male mice. In this study, we explored the impact of MGL treatment on adiposity, bone, and cartilage in aged-21-month-old C57BL/6J mice after a 12-week HFD regimen. Our results show that MGL reduced body weight as well as adverse effects caused by HFD adiposity, in male mice only. Aged HFD-fed male mice experienced cortical bone loss, in contrast to the trabecular bone loss observed in adult male mice. Notably, MGL treatment further exacerbated the cortical bone loss. Mechanical testing of tibias from aged male mice by 3-point bending revealed a reduced maximum load and tibia stiffness with HFD and MGL treatment. Transcriptome analyses for cortical bone formation regulators unveiled a decreased expression of Wnt16 and increased expression of the Wnt inhibitor, Sost, in the bones of HFD-fed male mice. Additionally, measurements of articular cartilage indicated that MGL treatment reduced articular cartilage degradation in both sexes, which was attributed to aging and a HFD. Our findings suggest tailored therapies are necessary to address the adverse effects of a HFD on fat, bone, and cartilage metabolism, specifically considering factors such as age and sex.

TI Effect of Ag Nanoparticles Containing Ocimum basilicum Leaf Extract on Complete Freund Adjuvant-Induced Arthritis and Methyl Prednisolone Sodium Succinate-Induced Osteoporosis in Rats
SO APPLIED ORGANOMETALLIC CHEMISTRY
LA English
DT Article
DE Ag nanoparticles; anti-arthritis; anti-osteoporosis; <fixed-case><italic>Ocimum

basilicum</italic></fixed-case>; therapeutic supplements
ID medicinal-plants
AB In the current research, we developed and formulated an innovative therapeutic agent utilizing silver nanoparticles infused with the Ocimum basilicum leaves, aimed at addressing arthritis and osteoporosis. The AgNPs characterization was conducted using techniques such as field emission-scanning electron microscopy (FE-SEM), X-ray diffraction (XRD), ultraviolet-visible spectroscopy (UV-Vis), and transmission electron microscopy (TEM). The distinct peak observed at 448 nm in the UV-Vis spectrum indicated the successful formation of silver nanoparticles. Furthermore, the TEM and FE-SEM images revealed that these NPs were predominantly spherical (10-50 nm). The potential for anti-osteoarthritic activity was assessed in vitro through protein denaturation methods involving egg albumin and bovine serum albumin, as well as membrane stabilization techniques, utilizing several concentrations (1-1000 mu g/mL). In vivo evaluations were conducted using formaldehyde, CFA, and turpentine oil models at several doses. Additionally, the in vitro antioxidant capacity was evaluated through a reducing power assay. The findings demonstrated concentration-dependent inhibition of albumin denaturation, along with significant stabilization of RBC membranes, with optimal results achieved at 1000 mu g/mL. Similarly, the nanoparticles demonstrated the anti-osteoarthritic effect with the highest activity noted at 1 mg/kg. The CFA model findings indicated a more pronounced protective efficacy against osteoarthritic lesions and changes in body weight. Furthermore, silver NPs reduced significantly rheumatoid parameters levels, ameliorated the altered hematological factors, and positively influenced both histopathological and radiographic alterations. Additionally, silver nanoparticles showed strong antioxidant qualities. In Wistar rats, osteoporosis was induced by the combination of MPSC (10 mg/kg, subcutaneously, three times a week for 4 weeks) and silver nanoparticles (5 mu g/kg/day, oral, for 30 days). This treatment led to an elevation in serum levels of markers associated with bone mineral content, while simultaneously causing a reduction in both urinary and serum levels of bone resorption markers indicative. An increase in the tibia and femur strength was reported, especially at 5 mu g/kg of silver NPs. The mechanisms by which silver nanoparticles may counteract glucocorticoid-induced osteoporosis likely include calcium homeostasis regulation, collagen synthesis, and free radicals neutralization. Collectively, these findings endorse the conventional application of silver nanoparticles as effective agents against osteoarthritis and osteoporosis in humans.

TI Metabolites mediate the effects of healthy lifestyles on the risks of common age-related diseases
SO FRONTIERS IN ENDOCRINOLOGY
LA English
DT Article
DE healthy lifestyle; metabolites; age-related disease; diabetes; chronic diseases
ID cardiovascular-disease; diet quality; inflammation; insights; albumin; burden; score
AB Background Limited research is available on the associations between healthy lifestyles and age-related diseases, particularly those involving multiple diseases and their underlying mechanisms. We aimed to determine whether healthy lifestyles are associated with a lower likelihood of age-related diseases, and whether metabolites mediate these associations.Methods The UK Biobank data cohort was used in this study. Five lifestyle factors (diet, physical activity, sedentary behavior, sleep duration, and alcohol consumption) were combined to determine that composite lifestyle scores. Lifestyle-related metabolic signatures were analyzed using Cox proportional hazards models. We then conducted sequential analyses combining Cox regression, linear regression, extreme gradient boosting (XGBoost), and Shapley additive explanation (SHAP) values to identify metabolites associated with age-related diseases and healthy lifestyle scores. Mediation analysis was performed to investigate the potential mediating effects of the identified metabolites on age-related diseases.Results Healthy lifestyle scores contributed the most to prevention of chronic obstructive pulmonary disease (COPD) (hazard ratio [HR] [95% confidence interval (CI): 0.72 (0.71, 0.74)], followed by emphysema [HR

(95% CI): 0.75 (0.71, 0.78)]. Furthermore, intermediate or healthy lifestyles significantly decreased the age-related risk of stroke, chronic liver disease, chronic kidney disease (CKD), osteoporosis, osteoarthritis, and hypertension. Age-related diseases were associated with the top 10 metabolites, and these associations were individually or jointly mediated. For example, glycoprotein acetylation contributed 14.43% to the overall association between healthy lifestyle scores and inflammatory bowel disease (IBD), whereas low-density lipoprotein (LDL) cholesterol level attenuated this association by 2.92%, the fatty acid content based on the degree of unsaturation showed a 21.64% contribution to the association between the healthy lifestyle score and type 2 diabetes, whereas cholesterol esters in large high-density lipoproteins (HDLs) accounted for 4.57%. Sensitivity analyses verified the robustness and validity of these findings.Conclusions These findings provide a deeper understanding of the intricate relationships among lifestyle and metabolites and the development of age-related diseases.

TI Association between sleep duration, sleep apnea risk, and osteoporosis in older adults: a cross-sectional study in elder care institutions in Taiwan
SO BMC GERIATRICS
LA English
DT Article
DE Sleep duration; Sleep apnea; Osteoporosis; Older adults; Heart rate variability
ID heart-rate-variability; population; health; impact; women; bone
AB Background This study investigated the relationship between sleep disturbance, obstructive sleep apnea (OSA), and osteoporosis in older adults. Methods This cross-sectional study involved 326 older adults (mean age: 83.46 years) in elder care institutions in Taiwan. The presence of osteoporosis was assessed using dual-energy X-ray absorptiometry, while sleep quality and OSA risk were evaluated using the Pittsburgh Sleep Quality Index and STOP-Bang questionnaire, respectively. Heart rate variability (HRV) was measured to assess autonomic function. Logistic regression models, adjusted for age, body mass index (BMI), and comorbidities, were used to examine the associations among sleep duration, OSA risk, and osteoporosis. Results Osteoporosis was more prevalent in females and those with lower BMI and neck circumference, and less common in individuals with knee osteoarthritis. Intermediate-to-high OSA risk was associated with the male sex, higher BMI, higher neck circumference, and cardiovascular comorbidities. Short sleep duration (< 4 h) was initially correlated with a higher osteoporosis risk, but this association disappeared after adjusting for covariates. However, after adjusting for covariates, intermediate-to-high OSA risk was significantly associated with osteoporosis. HRV showed no significant difference in assessing osteoporosis or OSA risk in this study. Conclusion Short sleep duration (< 4 h) and intermediate-to-high OSA risk were associated with a higher prevalence of

osteoporosis among older adult participants, compared to those with 6-7 h of sleep or low OSA risk. Further research is required to explore the relationship between sleep and osteoporosis in older adults.

TI Role and mechanism of Integrin α5β1 in bone formation and disease
SO FRONTIERS IN CELL AND DEVELOPMENTAL BIOLOGY
LA English
DT Review
DE integrin alpha 5 beta 1; bone formation; osteoporosis; osteoarthritis; bone metastasis
ID peptide atn-161 ac-phscn-nh2; mesenchymal stromal cells; skeletal development; stem-cells; cancer; adhesion; metastasis; expression; cartilage; binding
AB Integrin alpha 5 beta 1 is a key signaling protein between cells and the extracellular matrix. It plays crucial roles in biological processes such as cell adhesion, migration, and differentiation. Recent studies have shown that integrin alpha 5 beta 1 is significantly involved in bone formation and related diseases. Integrin alpha 5 beta 1 participates in the differentiation of mesenchymal stem cells into osteoblasts. It interacts with the CCN family and the bone morphogenetic protein pathway to upregulate the expression of osteogenic markers, promoting the formation of mineralization nodules. Additionally, it can mediate mechanical force stimulation to upregulate osteogenic gene expression and promote bone formation. In diseases such as osteoporosis, osteoarthritis, and bone metastasis, integrin alpha 5 beta 1 mediates abnormal cell-matrix adhesion and migration, promoting pathological bone resorption and inhibiting bone formation, thereby exacerbating bone loss. Therefore, integrin alpha 5 beta 1 may be a potential therapeutic target for these bone diseases. Elucidating its mechanism of action will

help understand the homeostatic regulation of bone metabolism and provide ideas for the development of novel therapeutic strategies for skeletal diseases.

TI Lactylation Dynamics and Its Regulatory Roles in Orthopedic Pathologies: A Research Update
SO JOURNAL OF PROTEOME RESEARCH
LA English
DT Review
DE lactylation; intervertebral disc degeneration; osteoporosis; osteoarthritis; spinal cord injury
ID activation; lactate; promotes; differentiation; osteoblast; cells; rat
AB Post-translational modifications (PTMs) dynamically regulate cellular processes by modifying protein function. Among these, lactylation, a modification derived from lactate, functions through direct or indirect modification of histones or

nonhistone proteins. While glycosylation and phosphorylation have established roles in bone metabolism and joint disorders, the biological significance of lactylation in musculoskeletal diseases remains underexplored. This study synthesizes current evidence investigating lactylation in four major orthopedic diseases: intervertebral disc degeneration (IVDD), osteoporosis (OP), osteoarthritis (OA), and spinal cord injury (SCI). The evidence indicates that lactylation modulates disease progression through dual mechanisms: coordinating cellular metabolism with extracellular matrix remodeling in IVDD and OA and regulating neuroimmune responses during SCI recovery. Notably, lactylation's regulatory patterns differ from classical PTMs by serving as a molecular bridge linking metabolic reprogramming to pathological tissue remodeling. This contrasts with phosphorylation, which primarily dominates signal transduction pathways. These insights reposition lactate from a metabolic byproduct to a disease-modifying signaling molecule, suggesting lactylation could inform therapeutic strategies for inflammatory, degenerative, and regenerative musculoskeletal disorders.

TI Ophiopogonin D Attenuates Mitochondrial Dysfunction in Chondrocytes via Nrf2

Signaling to Ameliorate Osteoarthritis
SO JOURNAL OF HARD TISSUE BIOLOGY
LA English
DT Article
DE Ophiopogonin D; Osteoarthritis; Chondrocytes; Mitochondrial dysfunction; Nrf2 signaling
AB Osteoarthritis (OA) is a progressive joint disorder characterized by cartilage degradation, inflammation, and chondrocyte dysfunction, with mitochondrial dysfunction and oxidative stress being central to its pathogenesis. The Nrf2 pathway is vital for maintaining redox homeostasis and mitochondrial integrity. This study investigated the protective effects of Ophiopogonin D (OP-D), a natural saponin compound, on IL-1(3-induced chondrocyte injury in vitro. Using C28/I2 cells, we demonstrated that OP-D restored cell viability and reduced the secretion of proinflammatory cytokines following IL-1(3 exposure. OP-D also alleviated mitochondrial dysfunction by decreasing mitochondrial ROS production and preserving mitochondrial membrane potential. Furthermore, OP-D mitigated extracellular matrix degradation. Mechanistically, OP-D activated the Keap1/Nrf2 pathway. These findings suggest that OP-D exerts chondroprotective effects by improving mitochondrial function and maintaining ECM integrity via Nrf2 pathway activation, highlighting its therapeutic potential for the treatment of osteoarthritis.

TI Correlation between paraspinal muscle fat infiltration and thoracic vertebral degeneration based on phantom-less QCT: a novel insight into thoracic vertebral degeneration
SO EUROPEAN SPINE JOURNAL
LA English
DT Article
DE Fat infiltration; Bone mineral density; Phantom-less quantitative computed tomography; Thoracic vertebral degeneration; Paraspinal muscles
ID lumbar; tomography; herniations; pain
AB Purpose This study aimed to elucidate the correlation between the degree of fat infiltration (FI) in thoracic paraspinal muscles and thoracic vertebral degeneration (TVD). Methods This cross-sectional study comprised 474 patients who underwent standard thoracic computed tomography (CT) scans. The FI was quantified as the percentage of adipose tissues within the cross-sectional area of thoracic paraspinal muscles. Thoracic vertebra was assessed in terms of osteoporosis, ossification of the anterior longitudinal ligament (OALL), ossification of the posterior longitudinal ligament (OPLL), intervertebral disc calcification, intervertebral disc cavity, and facet joint osteoarthritis (FJO). Logistic regression, linear regression, subgroup, and receiver operating characteristic (ROC) analyses were assessed to evaluate the association between FI and TVD. Results Multivariate logistic regression revealed that more severe FI was closely associated with more serious osteoporosis ($P < 0.001$). Furthermore, after adjusting for only age, higher FI was significantly associated with nastier FJO ($P < 0.05$). In male patients, severe FI was greatly associated with worse osteoporosis ($P < 0.05$). In female patients, severe FI maintained close correlations with more severe osteoporosis and FJO ($P < 0.05$). Furthermore, in patients aged < 60 or >= 60 years, higher FI had a strong correlation with more severe osteoporosis ($P < 0.001$). In patients aged < 60 years, higher FI was associated with worse intervertebral disc calcification, OALL, and FJO ($P < 0.05$). Meanwhile, in patients aged >= 60 years, increased FI was only associated with severe OPLL ($P < 0.05$). Multivariate linear regression showed that FI negatively correlated with bone mineral density in the general population and different sex and age groups ($P < 0.001$). ROC analysis indicated that FI could predict the occurrence of TVD ($P < 0.05$). Conclusion Higher FI is associated with more severe TVD. Studies on TVD are currently limited; therefore, this study enriches the related research on TVD, and our findings would facilitate the early prediction and diagnosis of TVD in clinical practice. Furthermore, our findings indicate that thoracic spine pain (TSP) caused by TVD can be prevented, potentially improving the prognosis of patients with TSP.

ID intervertebral disc degeneration; nucleus pulposus cells; nlrp3 inflammasome activation; mesenchymal stem-cells; tumor-necrosis-factor; nerve growth-factor; interleukin-1 receptor antagonist; stimulates osteoclast formation; vertebral end-plates; kappa-b pathway
AB Background: As people age, degenerative bone and joint diseases (DBJDs) become more prevalent. When middle-aged and elderly people are diagnosed with one or more disorders such as osteoporosis (OP), osteoarthritis (OA), and intervertebral disc degeneration (IVDD), it often signals the onset of prolonged pain and reduced functionality. Chronic inflammation has been identified as the underlying cause of various degenerative diseases, including DBJDs. Recently, excessive activation of pyroptosis, a form of programed cell death (PCD) mediated by inflammasomes, has emerged as a primary driver of harmful chronic inflammation. Consequently, pyroptosis has become a potential target for preventing and treating DBJDs. Aim of Review: This review explored the physiological and pathological roles of the pyroptosis pathway in bone and joint development and its relation to DBJDs. Meanwhile, it elaborated the molecular mechanisms of pyroptosis within individual cell types in the bone marrow and joints, as well as the interplay among different cell types in the context of DBJDs. Furthermore, this review presented the latest compelling evidence supporting the idea of regulating the pyroptosis pathway for DBJDs treatment, and discussed the potential, limitations, and challenges of various therapeutic strategies involving pyroptosis regulation. Key Scientific Concepts of Review: In summary, an interesting identity for the unregulated pyroptosis path-way in the context of DBJDs was proposed in this review, which was undertaken as a spoiler of peaceful coexistence between cells in a degenerative environment. Over the extended course of DBJDs, pyroptosis pathway perpetuated its activity through crosstalk among pyroptosis cascades in different cell types, thus exacerbating the inflammatory environment throughout the entire bone marrow and joint degeneration environment. Correspondingly, pyroptosis regulation therapy emerged as a promising option for clinical treatment of DBJDs. (c) 2024 The Authors.
