DT Review
DE Alzheimer's disease; dementia; osteoarthritis; osteoporosis
ID hip fracture risk; vitamin-d; cognitive impairment; mineral density; transgenic mice; cigarette-smoking; dementia; association; metaanalysis; increases
AB Alzheimer's disease (AD), a leading cause of dementia in the elderly, is traditionally characterized by neurodegeneration driven by amyloid-beta plaques and tau tangles. However, emerging evidence reveals that AD's impact extends beyond the brain, significantly affecting skeletal health. This review integrates clinical and transgenic mouse model data to elucidate the mechanistic interplay between AD pathology and bone metabolism. AD patients exhibit increased risk for hip fractures and low bone mineral density (BMD), independent of cognitive impairment severity. We found altered calcium and alkaline phosphate levels in the blood of patients with mild cognitive impairment and AD, as assessed from the Alzheimer's Disease Neuroimaging Initiative data. Convergent risk factors-age, sex, APOE4 genotype, smoking, and vitamin D deficiency-contribute to both neurodegeneration and bone fragility. Key molecular pathways, such as Wnt/beta-catenin signaling and TREM2-mediated osteoclast regulation, underscore shared mechanisms driving disease pathology in both systems. Mouse models of AD consistently demonstrate disrupted bone remodeling, impaired osteoblast

function, and heightened osteoclast activity. Therapeutic strategies targeting overlapping pathways, including lithium, anti-FSH antibodies, and NF-kappa B inhibitors, show promise in mitigating both cognitive decline and bone loss. Collectively, these insights advocate for a more integrated view of AD that includes skeletal comorbidities, potentially guiding the development of dual-purpose interventions.

TI The research progress and potential applications of n-3 fatty acids in orthopaedics: a narrative review
SO BRITISH JOURNAL OF NUTRITION
LA English
DT Review
DE <italic>n</italic>-3 PUFA; Nutrition; Orthopaedics; Health benefits; Anti-inflammatory
ID alpha-linolenic acid; docosahexaenoic acid; omega-3 supplementation; cardiovascular-disease; eicosapentaenoic acid; rheumatoid-arthritis; omega-3-fatty-acids; management; oil; fish
AB n-3 PUFA, including ALA, EPA and DHA, are widely found in plant oils and marine organisms. These fatty acids demonstrate significant biological effects, and their adequate intake is essential for maintaining health. However, modern diets often lack sufficient n-3 PUFA, especially among populations that consume little fish or seafood, leading to a growing interest in n-3 PUFA supplementation in nutrition and health research. In recent decades, the role of n-3 PUFA in preventing and treating various diseases has gained increasing attention, particularly in cardiovascular, neurological, ophthalmic, allergic, hepatic and oncological fields. In

orthopaedics, n-3 PUFA exert beneficial effects through several mechanisms, including modulation of inflammatory responses, enhancement of cartilage repair and regulation of bone metabolism. These effects demonstrate potential for the treatment of conditions such as osteoarthritis, rheumatoid arthritis, gout, osteoporosis, fractures, sarcopenia and spinal degenerative diseases. This review summarises the clinical applications of n-3 PUFA, with a focus on their research progress in the field of orthopaedics, and explores their potential in the treatment of orthopaedic diseases.

TI 3D bioprinting bone/cartilage organoids: construction, applications, and challenges
SO JOURNAL OF ORTHOPAEDIC TRANSLATION
LA English
DT Review
DE 3D bioprinting; Bone/cartilage organoids; Regenerative medicine
ID therapeutic targets; bone; bioinks; systems; niche
AB Orthopaedic disorders, such as osteoporosis and osteoarthritis, impose

substantial suffering upon an increasing population, driving demand for accurate disease models. Bone/cartilage organoids offer a promising solution by replicating complex 3D microstructures and multi-cellular niches, overcoming limitations of 2D models and animal experiments. 3D bioprinting, an additive manufacturing technology, enables the spatially precise deposition of cells and bioactive materials, facilitating efficient construction of organoids with enhanced structural fidelity. Therefore, this review specifically focuses on bone and cartilage organoids constructed using 3D bioprinting technologies. We summarize the prevailing 3D bioprinting techniques and biomaterials employed, critically analyze the unique advantages of bioprinting for creating these organoids, explore current technical challenges, such as standardization and scalability, and discuss future research directions. By addressing current progress and key issues in bioprinting bone/cartilage organoids, this review aims to accelerate their standardization and application as powerful platforms for multiscale disease modeling, drug screening, and regenerative medicine strategies. The translational potential of this article: Bone/cartilage organoids constructed via 3D bioprinting, through precise recapitulation of bone and cartilage tissue microenvironment and physiology, enable multiscale disease modeling from localized pathologies to systemic responses, despite persisting unresolved challenges in reproducibility and stability. This review highlights their clinical translational value and elucidates the driven role of 3D bioprinting in accelerating their clinical adoption, particularly in regenerative medicine.

DT Article
DE Composite unhealthy lifestyle; Aging acceleration; Musculoskeletal disorders; Mediation
ID osteoporosis; metaanalysis; smoking; fruit; risk
AB IntroductionFew studies assessed comprehensive effects of composite unhealthy lifestyles on aging and musculoskeletal health. This study aimed to address such issues with the UK Biobank datasets.Materials and methodsAn unhealthy lifestyle score (UHLS) was constructed based on 9 lifestyle behaviors. Aging indicators were calculated from 18 clinical traits. General linear and Cox proportional hazards regression models were used to analyze associations between UHLS, aging, and musculoskeletal morbidity. Mendelian randomization (MR) analysis was performed for causal relationship exploration.ResultsAmong 396,037 participants, 54.5% and 3.3% of them were designated to the low (scored 0-2) and high UHLS (scored 6-9) groups, respectively. Increasing UHLS was associated with elevated aging acceleration (AA) based on biological age (0.343 per unit; 95% CI: 0.331, 0.355) and phenotypic age (AA_PA) (0.408 per unit; 95% CI: 0.394, 0.422), and higher morbidity of low grip strength (HR = 1.025; 95% CI: 1.001, 1.050), slow walking pace (HR = 1.134; 95% CI: 1.074, 1.198), osteoporosis (HR = 1.077; 95% CI: 1.063, 1.091), fracture (HR = 1.059; 95% CI: 1.048, 1.069) and osteoarthritis (HR = 1.036; 95% CI: 1.030, 1.042). Unhealthy lifestyles in conjunction with AA jointly increased musculoskeletal morbidity. Besides, AA mediated UHLS effects on slow walking pace, osteoporosis and fracture, with mediating proportion of 4.85%-12.79%. MR analyses revealed causal relationships between UHLS and low grip strength, osteoarthritis, and reduced femoral neck bone mineral density. In addition, AA_PA suggestively mediated the UHLS-osteoarthritis association.ConclusionsComposite unhealthy lifestyles accelerate aging and impair musculoskeletal health. Both mediating and joint effects of AA showed unhealthy lifestyle-associated musculoskeletal morbidity.

DT Review
DE Vitamin D; Bone destruction diseases; Immunoregulation
ID d deficiency; mineral density; mendelian randomization; rheumatoid-arthritis; knee osteoarthritis; 25-hydroxyvitamin d; d supplementation; polymorphisms; metaanalysis; calcium
AB Vitamin D (VD) is a pleiotropic secosteroid hormone with well-established roles in calcium homeostasis, bone metabolism, and emerging functions in immune regulation, inflammation, and chronic disease modulation. In this paper, we provide a comprehensive summary of the current research on the significance of VD for bone health, with emphasis on its mechanism of action and its clinical significance in bone health. This review starts with an overview of VD metabolism, with emphasis on the enzyme transformation of vitamin D3 (VD3) and vitamin D2 (VD2) into the active 1,25-dihydroxyvitamin D (1 alpha,25(OH)2D) and their genomic and non-genomic signaling pathways through the Vitamin D receptor (VDR). Then, we

discuss how VDR polymorphisms affect disease susceptibility and the dual role of VD in promoting innate immunity as well as inhibiting over-adaptive immunity. Our main focus is placed on VD's involvement in bone destruction diseases, including osteoarthritis (OA), osteoporosis (OP), rheumatoid arthritis (RA), and bone tuberculosis. For OA, there is conflicting evidence on whether VD supplementation reduces cartilage degradation or pain. In OP, vitamin D deficiency aggravates bone loss, but the effectiveness of supplementation is dependent on baseline and calcium supplementation. For RA, the immunomodulatory effects of VD may decrease the activity of the disease, whereas in tuberculosis, VD increases the clearance of macrophage-mediated mycobacterial clearance, although the clinical study data are still inconclusive. This review underscores VD as a critical mediator of bone-immune crosstalk while calling for rigorous translational research to clarify its therapeutic potential across diverse diseases.

TI Maternal high-fat high-sugar diet impairs bone quality and strength but not cartilage in aging mice
SO JOURNAL OF ORTHOPAEDIC RESEARCH

ID pericellular matrix; birth-weight; micromechanical property; mitochondrial dysfunction; primordial follicles; oocyte quality; obesity; mouse; mass; osteoarthritis
AB Osteoarthritis (OA) is a prevalent aging disorder of synovial joints and recent work suggests that a parental high-fat diet increases OA severity following joint injury in offspring. We hypothesized that a maternal high-fat high-sugar (HFHS) diet would promote spontaneous osteoarthritis-related cartilage and bone changes in 1-year-old offspring. Female C57BL/6 J mice were placed on either a chow control or HFHS diet for 6 weeks before mating to a chow-fed C57BL/6 J male and maintained on their assigned diets throughout pregnancy and lactation. Male and female offspring were weaned onto a chow diet, raised to 1 year of age, and evaluated for cartilage and bone changes indicative of OA. However, offspring did not show early signs of OA as measured by histological Mankin scoring, mechanical testing of the pericellular matrix, histological synovitis scoring, or subchondral bone thickening as measured by microcomputed Tomography. On the other hand, male offspring from HFHS-fed dams had reduced trabecular bone quality in the tibial metaphysis and decreased cortical thickness. Although maternal HFHS diet did not impact trabecular or cortical bone quality in tibias of female offspring, the radii of these animals had decreased cortical thickness, increased medullary area, and impaired breaking strength compared to those of control-fed dams. Finally, we evaluated bone quality and strength in male and female F2 offspring and found that the grandmaternal diet modestly impacted radial bone geometry but not strength. Together these results suggest that maternal HFHS diet impairs F1 offspring skeletal integrity in a sex and bone site-specific manner.

TI Additional cartilage treatment for small defects in chronic ankle instability shows no mid-term benefit and delays recovery: a randomized controlled trial
SO JOURNAL OF ORTHOPAEDICS AND TRAUMATOLOGY
LA English
DT Article
DE Ankle joint; Ankle injuries; Lateral ligament; Ankle; Subchondral; Osteoarthritis; Randomized controlled trial; Cartilage diseases; Arthroscopy; Joint instability
ID lateral ligament injury; quality-of-life; osteochondral lesions; arthroscopic findings; follow-up; physical-activity; repair; talus; health; reconstruction
AB Background The presence of chondral lesions in patients with chronic ankle instability is common and has been suggested as a possible cause of persistent pain in some cases, even after successful ligament reconstruction. For this reason, some authors have proposed combining ankle stabilization with cartilage microfracture; however, the results reported in literature are contradictory. Materials and methods The study was designed as a prospective randomized clinical study with two parallel arms. Patients with an anterior talofibular ligament tear causing pain and instability, associated with a Berndt-Harty stage I-IIb talar osteochondral lesion of < 150 mm2 that had not responded to conservative treatment, were blindly assigned to either isolated ligament reconstruction (REC) or reconstruction plus microfracture (REC +MIC). Evaluators were also blinded. Results A total of 71 patients were included in the study, with 36 in the REC group and 35 in the REC +MIC group. The groups were comparable in terms of anthropometry and pathology. The operating time was significantly longer in the REC +MIC group (48.0 +/- 4.5 min) compared with the REC group (24.9 +/- 3.9 min; p < 0.001). At the end of follow- up, both patient groups showed similar results on the American Orthopaedic Foot and Ankle Society (AOFAS) score (p = 0.755), Self-Reported Foot and Ankle Score (SEFAS) (p = 0.862), Karlsson score (p = 0.993), and visual analog scale (VAS) (p = 0.870). However, the time to recovery differed between the groups, with patients in the REC group recover- ing faster from before the operation (pre-op) through the third month after the operation (post-op).The difference in recovery at 3 months post-op was statistically significant on the AOFAS (p < 0.001),

SEFAS ($p < 0.001$), and Karls- son ($p < 0.001$) scores. No statistically significant difference was observed in terms of pain ($p = 0.342$).The failure rate was also comparable between the groups, with four (11.1%) reoperations in the REC group and five (14.3%) in the REC +MIC group ($p = 0.735$). Conclusions At 2 years post surgery, no differences were observed in function (according to the AOFAS, SEFAS, and Karlsson scores), pain, or complications in patients with ankle instability and associated chondral damage treated with or without microfractures. However, patients who underwent microfractures experienced a significantly slower recovery of function. Level of evidence: Level 1. Trial registration: ClinicalTrials.gov Identifier NCT06947317 (retrospectively registered). Date: 1 May 2025. (https:// clini caltrials.gov/study/NCT06947317).

TI Denosumab attenuates knee osteoarthritis progression by inhibiting synovial inflammation via the RANK/TRAF6/FSTL1 signalling
SO NATURE COMMUNICATIONS

DT Article
ID cartilage degradation; biochemical markers; bone; arthritis; cells; model; pathophysiology; histopathology; identification; risedronate
AB Synovitis has recently been shown to be a critical early stage in development of osteoarthritis (OA), and inhibiting synovitis significantly alleviates OA symptoms. Denosumab, a monoclonal antibody targeting RANKL, previously developed for osteoporosis. Here, we report the effect of denosumab on fibroblast-like synoviocytes (FLSs), attenuating synovitis and consequently OA progression. We first demonstrate that RANKL is highly expressed in the knee synovium of OA mice, as well as in patients. Next, we show that denosumab, injected systemically, accumulates in the synovium and effectively reduces synovitis through RANK/TRAF6/FSTL1 signalling in post-traumatic, inflammatory, and aged OA murine models and a beagle dog OA model, delaying OA progression. Finally, a single-arm clinical trial with primary endpoints of VAS and OKS scores, and secondary endpoints of WOMAC score and adverse events rate, shows that denosumab alleviates synovitis and pain, improving joint function in knee OA patients. These findings provide a translational basis for using denosumab to treat knee OA in the clinic.

TI Osteoarthritis risk associated with romosozumab compared with teriparatide in individuals with osteoporosis: a target trial emulation study
SO ANNALS OF THE RHEUMATIC DISEASES
LA English
DT Article
ID postmenopausal women; subchondral bone; sclerostin; cartilage; knee; hip; outcm; spine; oa
AB Objectives: To compare osteoarthritis among individuals with osteoporosis initiating romosozumab vs an active comparator. Methods: This new user comparative effectiveness study, emulating a target trial, included individuals aged >= 50 years in the administrative claims database from 2019 to 2022. Individuals who initiated romosozumab were compared with those who initiated teriparatide. The primary outcome was the incidence of osteoarthritis, while secondary outcomes included joint-specific osteoarthritis (knee, hip, and hand) at 1 year. Inverse probability of treatment weighting (IPTW) was applied to balance baseline characteristics between romosozumab and teriparatide users, and inverse probability of censoring weighting (IPCW) was employed to account for informative censoring. Absolute risk reduction (ARR) and relative risk (RR) at 1 year were estimated using a weighted Kaplan-Meier estimator. Results: A total of 22,145 individuals were included in the study (87% female; mean age, 80 years). After IPTW-IPCW adjustment, romosozumab was associated with a lower risk of osteoarthritis compared with teriparatide (ARR, 1.1% [95% CI, 0.5%-1.8%]; RR, 0.79 [0.66, 0.89]). Joint-specific analyses showed the following results: knee osteoarthritis: ARR, 0.8% (95% CI, 0.3%-1.5%), RR, 0.79 (0.66, 0.92); hip osteoarthritis: ARR, 0.2% (95% CI, 0.0%0.5%), RR, 0.68 (0.37, 1.05); and hand osteoarthritis: ARR, 0.2% (95% CI, 0.0%-0.4%), RR, 0.61 (0.35, 1.06). Conclusions: Romosozumab was associated with a lower risk of osteoarthritis than teriparatide among individuals with osteoporosis, particularly for knee osteoarthritis. Similar trends were observed for hip and hand osteoarthritis; however, the differences were not significant.

icariin
AB Epimedium brevicornu (Yin Yang Huo), a widely used traditional Chinese medicinal ingredient, has garnered significant attention for its role in treating orthopedic diseases such as osteoporosis. Our work through network pharmacology and bioinformatics analysis, we identified that out of 27 major active components in Epimedium brevicornu, 8 key components have therapeutic effects on 11 types of diseases related to orthopedic conditions. The disease-target association analysis indicated that Osteoarthritis, Osteoporosis, Muscle Spasm and Myopathy have relatively clear targets for disease treatment. The KEGG enrichment analysis results indicate that the signaling pathway of Epimedium treatment in Osteoarthritis may be closely related to the Lipid and atherosclerosis pathway, PPAR signaling pathway and Arachidonic acid metabolism. Epimedium may treat osteoporosis with Nitrogen metabolism, GABAergic synapse, and Pathways in cancer. Epimedium may affect muscle spasticity through Neuroactive ligand-receptor interaction, Serotonergic synapse and Cholinergic synapse closely related to nervous system function; Additionally, our analysis suggests that Epimedium may treat myopathy through Nitrogen metabolism and GABAergic synapse pathways. These studies have not only provided a molecular mechanism-based explanation for the pharmacological effects of Epimedium, but also laid a theoretical foundation for the development of Epimedium-based precision therapeutic regimens.

TI Immunotherapies for Aging and Age-Related Diseases: Advances, Pitfalls, and Prospects
SO RESEARCH
LA English
DT Review
ID rheumatoid-arthritis; senescent cells; double-blind; t-cells; inflammation; mechanisms; antibody; protein; trial; osteoarthritis
AB Aging is characterized by a gradual decline in the functionality of all the organs and tissues, leading to various diseases. As the global population ages, the urgency to develop effective anti-aging strategies becomes increasingly critical due to the growing severity of associated health problems. Immunotherapy offers novel and promising approaches to combat aging by utilizing approaches including vaccines,

antibodies, and cytokines to target specific aging-related molecules and pathways. In this review, we summarize the recent advancements of immunotherapies to eliminate senescence cells and senescence-associated secretory phenotypes (SASPs). Next, we describe immunotherapies against age-related diseases containing neurodegenerative diseases, vascular pathologies, type 2 diabetes (T2D), arthritis, osteoporosis, chronic obstructive pulmonary disease (COPD), fibrosis, skin aging, and cancer, detailing the targets, corresponding manipulations, and clinical trials. Related problems including immunosenescence, serious adverse effects, the duality of function of senescent cells and SASPs, and inherent problems of immunotherapy are also discussed, suggesting directions for improvement. In addition to recent development and challenges in the field, we describe a blueprint of personalized aging immunotherapy by multi-omics, Big Data, artificial intelligence (AI), and nanobots in the future, aiming to inspire the development of novel strategies for healthy aging.

TI Automated Fast Prediction of Bone Mineral Density From Low-dose Computed Tomography
SO ACADEMIC RADIOLOGY
LA English
DT Article
DE Bone mineral density; Convolutional neural network; Osteoporosis
ID osteoporosis
AB Background: Low-dose chest CT (LDCT) is commonly employed for the early screening of lung cancer. However, it has rarely been utilized in the assessment of volumetric bone mineral density (vBMD) and the diagnosis of osteoporosis (OP). Purpose: This study investigated the feasibility of using deep learning to establish a system for vBMD prediction and OP classification based on LDCT scans. Methods: This study included 551 subjects who underwent both LDCT and QCT examinations. First, the U-net was developed to automatically segment lumbar vertebrae from single 2D LDCT slices near the mid-vertebral level. Then, a prediction model was proposed to estimate vBMD, which was subsequently employed for detecting OP and osteopenia (OA). Specifically, two input modalities were constructed for the prediction model. The performance metrics of the models were calculated and evaluated. Results: The segmentation model exhibited a strong correlation with manual segmentation, achieving a mean Dice similarity coefficient (DSC) of 0.974, sensitivity of 0.964, positive predictive value (PPV) of 0.985, and Hausdorff distance of 3.261 in the test set. Linear regression and Bland-Altman analysis demonstrated strong agreement between the predicted vBMD from two-channel inputs and

QCTderived vBMD, with a root mean square error of 8.958 mg/mm3 and an R2 of 0.944. The areas under the curve for detecting OP and OA were 0.800 and 0.878, respectively, with an overall accuracy of 94.2%. The average processing time for this system was 1.5 s. Conclusion: This prediction system could automatically estimate vBMD and detect OP and OA on LDCT scans, providing great potential for the osteoporosis screening.

TI Role of NEL-like molecule-1 in osteogenesis/chondrogenesis (Review)
SO INTERNATIONAL JOURNAL OF MOLECULAR MEDICINE
LA English
DT Review
DE NELL-1; bone diseases; osteogenesis; bone tissue engineering
ID perivascular stem-cells; craniosynostosis-associated gene; marrow stromal cells; spinal-fusion; bone regeneration; osteogenic differentiation; pegylated nell-1; chondrogenic differentiation; controlled-release; protein-1 nell-1
AB A dynamic balance exists between osteogenesis and osteoclastogenesis in bone tissue, which can lead to several bone diseases, such as osteoporosis, osteoarthritis, bone necrosis and bone defects, in cases of insufficient osteogenesis or excessive osteoclastogenesis. NEL-like molecule-1 (NELL-1) was first discovered in 1999 as an osteogenic factor that can prevent or treat bone diseases by increasing osteogenic levels. To date, research has identified multiple signaling pathways involved in improving osteogenic levels. Furthermore, to apply NELL-1 in clinical practice, researchers have optimized its osteogenic effect by combining it with other molecules, changing its molecular structure and performing bone tissue engineering. Currently, research on NELL-1 is gaining increasing attention. In the near future, it will definitely be applied in clinical practice to eliminate diseases. Thus, the present study provides a comprehensive review of NELL-1 in enhancing osteogenic levels from the perspectives of the molecular mechanism, interactions with other molecules/cells, molecular-level changes, applications in bone tissue engineering and its expression in tumors, providing a solid theoretical basis for its clinical application.

TI Risk factors for non-union in foot and ankle arthrodesis: a population-based case-control study using registry data
SO BMC MUSCULOSKELETAL DISORDERS
LA English
DT Article
DE Ankle arthrodesis; Foot arthrodesis; Risk factor; Nonunion
ID bone; osteoporosis
AB BackgroundNonunion is a common complication following foot and ankle arthrodesis. This study endeavoured to determine the risk factors for nonunion in foot and ankle arthrodesis.MethodsThis was a retrospective case-control study using the National Health Insurance Research Database. Patients who underwent foot and ankle arthrodesis with a minimum follow-up duration of 6 months were included. International Classification of Diseases codes were used to identify diagnoses and treatment. Patients with nonunion were matched by age and sex with patients with union at a ratio of 1:4. Logistic regression was performed to compare between patients with nonunion and controls with union to ascertain the effects of various risk factors.ResultsA total of 107 joints were identified as nonunion, and 428 age- and sex-matched controls were selected. Patients with

diabetes mellitus had a 1.710 times (95% CI = 1.060 - 2.756, p = 0.0278) higher risk of nonunion than those without. No significant differences were observed in the risk of nonunion in relation to which joint was treated; the presence of osteoarthritis, traumatic osteoarthritis, rheumatoid arthritis, osteoporosis, or open/arthroscopic arthrodesis; internal or external fixation; or the usage of a bone graft. For patients without diabetes mellitus, those who underwent arthrodesis in the tarsometatarsal joint had a 6.507 times (95% CI: 1.045 - 40.522, p = 0.0256) higher risk of nonunion compared to those who underwent arthrodesis in the ankle joint.ConclusionDiabetes mellitus increases the risk of nonunion among patients with and without diabetes mellitus. For those without diabetes mellitus, arthrodesis in the tarsometatarsal joint is associated with the highest risk of nonunion.

TI Bidirectional Regulatory Mechanisms of Disulfidptosis Govern Precision Targeting in Degenerative Bone Diseases and Osteosarcoma
SO JOURNAL OF CELLULAR PHYSIOLOGY
LA English
DT Review
DE disulfidptosis; immunometabolism; orthopedic degenerative diseases; osteosarcoma; targeted therapy
ID osteoarthritis; apoptosis; cells; microenvironment; prognosis
AB Disulfidptosis is a newly identified form of programmed cell death closely associated with cystine metabolism abnormalities and cytoskeletal damage. Orthopedic diseases, such as degenerative conditions including intervertebral disc degeneration, osteoporosis, osteoarthritis, and malignant bone tumors like osteosarcoma, all involve imbalances in the immunometabolic microenvironment. The triggering conditions for disulfidptosis, such as high expression of SLC7A11 and glucose deprivation, are highly correlated with the pathaological features of orthopedic diseases and associated immune dysregulation. However, there is currently a lack of systematic understanding regarding the regulatory networks, molecular markers, and intervention strategies of disulfidptosis in orthopedic diseases, and the specific mechanisms by which it contributes to disease onset and progression remain unclear. This review systematically summarizes the bidirectional immunometabolic regulatory molecular mechanisms, pathological associations, and potential therapeutic strategies of disulfidptosis in orthopedic degenerative diseases and bone tumors. By analyzing the immunometabolic regulatory networks of key molecules such as SLC7A11, TXNRD1, and RPN1, we propose immune-aware precision strategies combining disulfidptosis-targeted metabolic intervention with checkpoint blockade immunotherapy. This review fills the gap in the research of disulfidptosis in orthopedic diseases, providing new insights for a deeper understanding of the molecular mechanisms underlying these conditions, while establishing a theoretical framework for developing precise therapeutic strategies based on the regulation of disulfidptosis.

TI Quantitative computed tomography provides improved accuracy for diagnosis of lumbar osteoporosis in patients with facet joint osteoarthritis: a cross-sectional study
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE Bone mineral density; Dual-energy X-ray absorptiometry; Facet joint osteoarthritis; Quantitative computed tomography
ID bone-mineral density; spine; calcification; physiology; strength; men
AB This study employed both QCT and DXA to assess BMD in the same cohort and investigated the influence of FJOA on BMD measurements and the detection rates of osteoporosis. The results indicate that QCT is more accurate for assessing regional BMD in patients with FJOA.PurposeThis study aimed to compare the detection rates of lumbar osteoporosis in patients with FJOA between QCT and DXA and to analyze the impact of FJOA on regional BMD measurement using each method.MethodsThis single-center, retrospective, cross-sectional study included participants without a history of spinal instrumentation surgery, spinal fractures of > 2 levels, spinal tumors or infections, and sacralization of lumbar spine. The detection rates of lumbar osteoporosis between QCT and DXA in patients with FJOA were compared using McNemar's test. Associations between BMDs and FJOA severity were assessed using linear mixed models. Discordance in BMD classification between DXA and QCT was categorized as minor or major according to Woodson's definition.ResultsThe 219 study participants had a mean age of 65.0 +/- 10.7 years and included 155 (70.8%) women. The rate of lumbar osteoporosis identification with QCT was noticeably greater than that with DXA (58% vs 34.2%, p < 0.0001). Severe FJOA was independently associated with lower vBMD (multivariable beta = - 4.23 (95% confidence interval (CI), - 7.68 to - 0.77); p = 0.17), while both slight-to-moderate and severe FJOA were independently

associated with higher areal BMD (aBMD). With increasing FJOA severity, the aBMD measured by DXA also increased (slight-to-moderate, beta = 0.31 (95% CI, 0.16-0.46), p < 0.001; severe FJOA, beta = 1.03 (95% CI, 0.79-1.27), p < 0.001).ConclusionsMore severe FJOA was associated with higher aBMD on DXA and a lower vBMD on QCT. Additionally, the rate of lumbar osteoporosis detection was significantly higher with QCT than with DXA. These findings indicate that QCT is more accurate for assessing regional BMD in patients with FJOA, supporting the need for caution when using DXA to evaluate BMD in clinical practice.

TI Assessing the effects of immune checkpoint inhibitors on bone utilizing machine learning-assisted opportunistic quantitative computed tomography
SO JOURNAL OF BONE AND MINERAL RESEARCH
LA English
DT Article
DE immune checkpoint inhibitors; immune related adverse events; cancer; melanoma; BMD; osteoporosis; osteoarthritis; opportunistic computed tomography
ID mineral density; osteoporosis; dxa; osteoarthritis; calibration; attenuation; qct
AB Immune checkpoint inhibitors (ICIs) are widely used in cancer treatment, yet their impact on bone health remains unclear. This study aimed to perform a retrospective cohort study utilizing routine CT scans from patients with melanoma to perform opportunistic QCT analysis to investigate the effects of ICI treatment on skeletal health, including volumetric BMD (vBMD) measurements and osteoarthritis (OA) parameters. A previously established machine learning-assisted opportunistic QCT pipeline was used to estimate lumbar spine vBMD from baseline and 12-mo follow-up CT scans in patients with melanoma treated with ICI therapy and those not treated with ICI therapy. Facet joint OA, osteophyte formation, and endplate sclerosis were also graded. Independent and paired t tests were used to determine any differences in vBMD and OA parameters between ICI users and non-ICI users. Multivariable linear regression models were used to control for confounding variables. Non-ICI users had a significant decrease in vBMD of -6.96 mg/cm3 from baseline to follow-up, whereas the ICI users had no significant change. There was a significant difference in change in vBMD from baseline to follow-up between the 2 groups, with the non-ICI users experiencing a 11.22 mg/cm3 larger decrease in

vBMD. After adjusting for baseline age, sex, baseline vBMD, and change in OA parameters, this difference remained significant at -13.04 mg/cm3. Among the ICI users, those who had a decline in vBMD had a lower baseline vBMD compared with those who had increased vBMD. Neither group showed a significant change in OA parameters over the follow-up period, nor a difference in change between ICI and non-ICI users, even after adjusting for sex, age, and baseline OA parameters. While the effects of ICI treatment on vBMD may vary based on baseline bone health, ICIs do not significantly impact OA parameters in the short term. The effects of immune checkpoint inhibitors (ICIs) on BMD and degenerative spine changes are not well understood, despite the plausible relationship between ICI treatment and bone health. These findings demonstrate that depending on baseline bone health, ICI treatment may have varying effects on bone health and may even be protective against bone loss in some ICI users. ICIs appear to have no effect on osteoarthritis parameters such as osteophyte formation. This is the first study to investigate changes in bone health in humans after ICI treatment.

TI Cellular senescence in skeletal diseases: A bibliometric analysis from 2007 to 2024
SO EXPERIMENTAL GERONTOLOGY
LA English
DT Article
DE Cellular senescence; Skeletal diseases; Bibliometric; Visualized analysis
ID cells; osteoarthritis
AB Background: Cellular senescence is a state of permanent cell cycle arrest. Numerous studies have highlighted the significant role of cellular senescence in age-related skeletal diseases, including intervertebral disc degeneration (IDD), osteoporosis, and osteoarthritis (OA). This article aims to review the current research landscape and identify emerging trends. Methods: Literature concerning cellular senescence and skeletal disease was obtained from the Web of Science Core Collection database, covering publications from 2007 to 2024. The Bibliometrix R package, VOSviewer, and CiteSpace were employed to perform the bibliometric analysis. Results: A total of 2653 publications were analyzed, revealing a rapid growth trend. China emerged as the dominant contributor, with the highest publication volume (n = 1148), while the United States led in citation impact (total citations = 50,420). Key journals, such as Osteoarthritis and Cartilage and Aging Cell, served as primary platforms for high-impact studies. The most influential author was James L. Kirkland, followed by Richard F. Loeser. Keyword clustering identified cellular senescence in intervertebral disc degeneration, osteoporosis, and osteoarthritis as core research domains, while current frontiers focus on the senescence-associated secretory phenotype (SASP), mitochondrial dysfunction, extracellular vesicles, and immune infiltration. Conclusion: Research in this field has garnered substantial attention in recent years. This bibliometric analysis not only underscores the correlation between cellular senescence and skeletal diseases, but also highlights that targeting cellular senescence and the SASP may offer potential therapeutic strategies. These findings can inform future research directions and the development of targeted interventions for age-related skeletal conditions.

TI Sheep Models in Translational Surgery
SO EUROPEAN SURGICAL RESEARCH
LA English
DT Review
DE Sheep model; Surgical research; Cardiothoracic surgery; Neonatal surgery; Orthopaedic surgery; Osteoarthritis; Spinal surgery; Anaesthesia
ID animal-models; ovine model; fusion; vertebroplasty; management; stifle
AB Background: The selection of an animal model is tedious. One must consider

several factors; one of these, of utmost importance, is the translational value of the animal model. The sheep, as a translational surgical model, possesses a multiple of advantages that makes it one of the preferred models in several research domains. Summary: Sheep are the state-of-the-art test models for cardiovascular research and safety studies required for approval of cardiovascular implantable devices; the sheep's heart size, cardiac muscle, heart valves, and the mechanical, haemodynamic, and coagulation parameters are very similar to humans. Furthermore, the pregnant sheep/lamb are robust models for studying neonatal adaptation and placental physiology due to its physiological similarities with humans. Its placental structure supports efficient gas exchange, resembling human oxygen transfer mechanisms. The ovine model is mainly used in studies of adaptation at birth, foetal physiology during labour, and congenital diaphragmatic hernia. The sheep model is also used in several orthopaedic preclinical models, mainly in the study of critical bone defects, cancellous bone healing, osteomyelitis, and joint replacement surgeries. It is also a preferred model of bone healing in osteoporosis. Moreover, the sheep has gained popularity as a model of osteoarthritis (OA); it is a validated model of surgically induced OA. Several therapeutic modalities can be evaluated using validated outcome measures such as, kinetics, kinematics, imaging, repeated arthroscopic grading, synovial fluid analysis, and biomarkers. The ovine model, because of its size, is the closest to humans for the evaluation of spinal surgery techniques, devices, and spinal fusion biological enhancers/cancellous graft replacement. Finally, we will outline the different specificities of sheep analgesia and anaesthesia. Challenges encountered in ruminant anaesthesia are mainly in relation with their digestive physiology that creates a high risk of regurgitation during anaesthesia and a hindrance of diaphragm/respiratory movements due to rumen repletion and meteorism. Fasting regimen and management of recovery should encompass strategies that limit the starving sensation and allow for reduced social isolation. Clarification of the interactions between scientific objectives and anaesthesia-analgesia protocols prevents conflicts between the ethics and the purpose of the experiment while allowing for development of model-specific anaesthesia and pain management protocols. Key Messages: The sheep has become a popular model because of its size, availability, robustness, cost, and ease of handling. Furthermore, as a preclinical model, the same validated objective outcome measures used to measure success in humans can apply to sheep.

TI Mechanical complications and revision following total joint arthroplasty in acromegalic patients: A nationwide US-based study
SO BONE
LA English
DT Article
DE Total joint arthroplasty; Revision; Mechanical complication; Acromegaly; Outcome
ID osteoarthritis; arthropathy; outcm; burden
AB Background: Acromegaly is associated with significant osteoarthritis (OA) and increased risk of vertebral and hip fractures. There is limited data on total joint arthroplasty (TJA) outcomes in patients with acromegaly. Methods: In this retrospective study, we identified patients with acromegaly who underwent total hip arthroplasty (THA), total knee arthroplasty (TKA), and total shoulder arthroplasty (TSA) between 2010 and 2022 using the PearlDiver national database. Patients with a prior history of osteoporosis and follow-up duration of less than one year were excluded. Non-acromegalic control groups were selected through matching based on confounding factors. We compared all-cause revision and implant-related complications between the groups using R software integrated with the PearlDiver database. Results: We identified 1440 patients with acromegaly: 665 underwent THA, 618 underwent TKA, and 157 underwent TSA. Compared to the control group (2634 THA, 2445 TKA, and 600 TSA), there was no significant association with post-op revision following THA (OR(1-year) = 0.76[0.42-1.28], OR(5-year) = 0.68 [0.42-1.06]), TKA (OR(1-year) = 0.89[0.48-1.55], OR(5-year) = 0.78[0.49-1.17]), and TSA (OR(1-year) = 0.19 [0.02-1.40], OR(5-year) = 0.32[0.10-1.07]). Additionally, the risk of mechanical complications did not significantly increase in patients with acromegaly, either one year or five years post-operation. Conclusion: The study showed no significant increase in risk of revisions or mechanical complications in patients with acromegaly compared to controls. These findings bridge an important gap in the understanding of postarthroplasty complications in patients with acromegaly and offer valuable insights into surgical expectations.

TI Pharmacological landscape of linarin: From benchside mechanisms to potential bedside applications
SO FITOTERAPIA
LA English
DT Review
DE Linarin; Flavonoids; Medicinal plants; Anti-inflammatory; Antioxidant
ID in-vitro; inhibitory-activity; flavonoids; apoptosis; acacetin; injury; glioma; cells
AB Linarin, a glycosylated flavonoid derived from medicinal plants such as Buddleja and Chrysanthemum species, has emerged as a bioactive compound with significant pharmacological potential. This review provides a comprehensive overview of linarin's chemical structure, extraction methods, pharmacokinetics, and therapeutic applications. Linarin exhibits diverse biological activities, including anti-inflammatory, antioxidant, neuroprotective, and anticancer effects, making it a promising candidate for drug development. The flavonoid demonstrates protective effects against hyperuricemia, acute kidney injury, spinal cord injury, ischemic stroke, diabetes, osteoporosis, and inflammatory bowel disease, primarily through modulation of signaling pathways such as Nrf2/Keap1, NF-kappa B, and MAPK. Additionally, linarin has shown potential in managing neurodegenerative disorders, including Alzheimer's disease, through its acetylcholinesterase inhibitory activity. Its anti-cancer effects have been linked to the inhibition of proliferation, apoptosis induction, and suppression of metastasisrelated pathways in lung, prostate, and brain cancers. Moreover, recent studies highlight its potential for ameliorating osteoarthritis, liver injury, and infectious diseases. The mechanisms underlying linarin's therapeutic effects involve its ability to modulate oxidative stress, inflammation, apoptosis, and metabolic pathways. Given its low toxicity, bioavailability, and structural versatility, linarin represents a compelling natural compound for future pharmaceutical applications. However, further preclinical and clinical investigations are warranted to fully elucidate its pharmacokinetics, optimize its bioavailability, and establish its clinical efficacy. This review advances a systems-level perspective that unifies linarin's pleiotropic mechanisms across several diseases. By linking structure-activity relationships with translational bottlenecks such as poor bioavailability and limited clinical validation, we outline a forward-looking roadmap for its development as a multi-target therapeutic scaffold.

TI Application of artificial intelligence-assisted Traditional Chinese medicine formula granules in bone and joint degenerative diseases in the field of holistic health
SO FRONTIERS IN MEDICINE
LA English
DT Review
DE artificial intelligence; AI assisted; TCM formula granules; plant-based natural products; bone and joint degenerative diseases; bone aging and osteoporosis
AB As global aging intensifies, the incidence of degenerative bone and joint diseases such as osteoarthritis bone aging and osteoporosis continues to rise. Traditional treatment methods face bottlenecks in long-term management, including drug side effects and low patient compliance. Traditional Chinese medicine (TCM) formula granules, which utilize plant-based natural products, show excellent clinical efficacy in managing these conditions. With the development of technology, artificial intelligence (AI) technology has enhanced the clinical efficacy of TCM formula granules through multiple approaches such as intelligent syndrome differentiation and formula optimization, drug efficacy prediction and mechanism analysis, as well as patient management and therapeutic effect monitoring, providing a new approach for the prevention and treatment of complex degenerative diseases. This paper systematically reviews the core advantages of TCM formula granules and their suitability for orthopedic diseases such as bone aging and osteoporosis. It analyzes the application models of AI technology in optimizing TCM formula granules, predicting drug efficacy, and personalized treatment. The main research results show that the artificial intelligence-driven TCM formula granule system is beneficial for promoting the full-cycle integration of "prevention - treatment - rehabilitation" in the chronic disease management of bone and joint degenerative diseases. However, challenges persist in clinical evidence standardization, algorithm interpretability, and ethical frameworks. Future directions require interdisciplinary technological innovation, policy-industrial synergy, and global collaboration to advance intelligent TCM transformation for degenerative disease management.

TI Multi-omics joint analysis reveals the mechanism underlying Chinese herbal Yougui Pill in the treatment of knee osteoarthritis
SO JOURNAL OF ETHNOPHARMACOLOGY
LA English
DT Article
DE Knee osteoarthritis; Yougui pill; Metabolomics; Transcriptomics
ID osteoporosis; chondrocytes; model
AB Ethnopharmacological relevance: Yougui Pill (YGP), originating from Jingyue Quanshu, comprises 10 traditional Chinese medicines (TCMs). This classic prescription is renowned for its ability to tonify the kidney, warm the kidney, promote yang, warm the interior, and dispel cold. YGP has proven effective in treating degenerative knee arthritis, osteoporosis, delayed fracture healing, and other orthopedic conditions, making it a widely used clinical prescription for knee osteoarthritis (KOA). Aim of the study: Although YGP is commonly used in clinical practice, its pharmacodynamic material basis and anti-arthritis mechanisms remain unclear. This study aims to comprehensively analyze the chemical constituents of YGP and elucidate its anti-arthritis mechanisms. Materials and methods: Ultra-high performance liquid chromatography coupled with electrospray ionizationtriple quadrupole-linear ion trap mass spectrometry(ESI-Q TRAP-MS/MS) was used to identify the chemical constituents of YGP. The Hulth method was utilized to establish KOA rat model, and pathological examinations were performed to assess

the anti-arthritis effects of YGP. Integrated metabolomics and transcriptomics analyses were conducted to explore the anti-arthritis mechanisms of YGP. Key targets were confirmed via immunohistochemistry. Results: A total of 1981 chemical components were identified in YGP, predominantly phenolic acids and flavonoids. Compared with the model group, 422 differentially expressed metabolites and 214 differentially expressed genes were identified, primarily involving the MAPK signaling pathway, FoxO signaling pathway, and PI3K-Akt pathway. YGP exerted an anti-osteoarthritis effect by inhibiting the excessive activation of the EGFR/ERT/FOS signaling pathway. Conclusions: TCM offers significant advantages in the treatment of KOA, addressing the shortcomings of current clinical medications. YGP displayed exceptional pharmacodynamic effects. This study elucidated its pharmacodynamic material basis and anti-osteoarthritis mechanisms, providing substantial support for its clinical application and the development of related drugs.

TI WALANT Proximal Row Carpectomy Under Field Sterility: A Case Report and Description of Technique
SO PLASTIC SURGERY
LA English
DT Article
DE WALANT; field sterility; proximal row carpectomy; champ st & eacute;rile; carpectomie proximale
ID osteoarthritis; population
AB Field sterility and Wide Awake Local Anesthesia No Tourniquet (WALANT) technique is a commonly used operative technique for many hand and wrist pathologies. We present a case of a successful proximal row carpectomy using WALANT and field sterility in a minor surgery operating theatre setting. These techniques can be applied in appropriate patients to reduce the overall cost of surgery, anesthetic complications, and prolonged hospital stay. Le champ st & eacute;rile et l'anesth & eacute;sie locale sans garrot (WALANT, d'apr & egrave;s l'acronyme anglais) sont une technique op & eacute;ratoire courante pour de

nombreuses pathologies de la main et du poignet. Les chercheurs pr ésentent le cas d'une carpectomie proximale r éussie à l'aide de la technique de WALANT et du champ st érile dans un bloc op ératoire pour chirurgie mineure. Ces techniques peuvent être utilis ées aupr ès de patients bien choisis pour r éduire le co ût global de l'op ération et le risque de complications anesth ésiques et pour éviter un s éjour hospitalier prolong é.

TI The function of GPCRs in different bone cells
SO INTERNATIONAL JOURNAL OF BIOLOGICAL SCIENCES
LA English
DT Review
DE GPCR; MSC; osteoblast; osteoclast; chondrocyte
ID calcium-sensing receptor; prostaglandin ep2 receptor; protein-coupled receptors; mesenchymal stem-cells; beta-arrestin; osteoblast differentiation; osteoclast differentiation; osteogenic differentiation; chondrocyte hypertrophy; allosteric modulators
AB G protein-coupled receptors (GPCRs) are recognized as critical therapeutic targets in bone disorders, owing to their multifaceted regulatory roles across diverse bone cell lineages. This review systematically catalogs GPCR expression and functional heterogeneity in key bone cells: 12 GPCRs in mesenchymal stem cells (MSCs) orchestrate lineage specification; 21 GPCRs in osteoblasts/osteocytes mediate matrix mineralization and mechanotransduction; 23 GPCRs in macrophages/osteoclasts regulate inflammatory bone resorption; 31 GPCRs in chondrocytes govern endochondral ossification and osteoarthritis pathogenesis; and 8 GPCRs in other cell types modulate bone-related physiological processes. By integrating canonical signaling axes-cAMP/PKA-dependent transcriptional networks, PLC-beta/IP3-driven calcium signaling, and NF-kappa B-modulated immuno-skeletal interactions-we elucidate how GPCRs dynamically coordinate cellular plasticity to maintain skeletal homeostasis. This work establishes a multidimensional research framework integrating historical context, molecular mechanisms, and cutting-edge methodologies to advance GPCR-targeted therapies for bone-related diseases. Moreover, this review provides insights for clinical translation, including biased agonism and allosteric modulation precision strategies to restore skeletal equilibrium in osteoporosis, arthritis, and regenerative medicine.

TI Role of Body Fat and Metabolic Rate in Site-Specific Fracture Risk: A 20-Year Taiwanese Cohort Study
SO MEDICAL SCIENCE MONITOR
LA English
DT Article
DE Body Mass Index; Bone Density; Fractures, Bone; Osteoarthritis; Retrospective Studies
ID bone-mineral density; physical-activity; mass index; lean mass; strength
AB Background: Osteoporotic fractures are a significant public health problem, yet traditional risk assessment methods have limitations. This retrospective study used the integrated Healthcare information (iHi) Data Platform of China Medical University Hospital (CMUH) (2000-2020) to evaluate associations between body mass index (BMI), bone mineral density (BMD), body fat percentage (BFP), basal metabolic rate (BMR), and site-specific fracture risk in 9583 Taiwanese individuals. Material/Methods: We extracted DXA-measured BMD, BMI, BFP, and BMR data from CMUH's iHi Platform. Fracture events were identified using ICD-9/10 codes and verified through radiology reports. Cox proportional hazards regression models estimated fracture risk, adjusting for demographic and clinical factors. Mediation analysis quantified the contributions of BFP and BMR to the BMI-fracture relationship. Results: During median follow-up of 8.7 years, 1672 fractures (17.4%) occurred. Individuals with normal BMD showed an 82% lower fracture risk compared to those with osteoporosis (adjusted hazard ratio [aHR]=0.18, 95% CI: 0.15-0.22, p<0.001). Normal BFP significantly reduced fracture risk by 77% versus low BFP (aHR=0.23, 95% CI: 0.07-0.72, p=0.012). Higher BMR was consistently protective, with aHR=0.54 (95% CI: 0.36-0.82, p=0.004) for BMR >= 1500 versus BMR <1000. While underweight increased fracture risk (aHR=1.75, 95% CI: 1.29-2.36, p<0.001), obesity conferred no significant protection (aHR=1.04, 95% CI: 0.89-1.21, p=0.58). Conclusions: This study demonstrates that fracture risk assessment should incorporate BFP and BMR alongside BMD and BMI. The "BMI paradox" was explained through mediation analysis, revealing BFP and BMR as critical intermediaries accounting for 50% and 32% of the BMI-fracture relationship, respectively. These findings support stratification.

TI Dysregulation of miR-106a-5p/PTEN axis associated with progression and diagnostic of postmenopausal osteoporosis
SO JOURNAL OF ORTHOPAEDIC SURGERY AND RESEARCH
LA English
DT Article
DE miR-106a-5p; PTEN; Postmenopausal osteoporosis; Iron accumulation
ID iron-metabolism; serum ferritin; differentiation; osteoarthritis; microrna; health; stores; women
AB ObjectivePostmenopausal osteoporosis (PMOP) is a bone disorder in postmenopausal women and a significant risk factor for fragility fractures. This study aims to explore the role of miR-106a-5p in the pathogenesis of PMOP and its potential as a diagnostic biomarker.Methods220 postmenopausal women were recruited. The levels of miR-106a-5p, PTEN, and osteogenic-related genes were quantified using qRT-PCR. The relative protein of PTEN was detected using Western blotting. ROC curve and Pearson correlation were employed to evaluate the diagnostic value and relationships between variables. To model iron accumulation, hFOB1.19 osteoblasts were treated with ferric ammonium citrate (FAC). Cell proliferation and apoptosis were assessed using the CCK-8 and flow cytometry. The target relationship was verified using dual-luciferase assays.ResultsmiR-106a-5p levels were reduced, while PTEN levels were increased in PMOP. miR-106a-5p was positively correlated with bone mineral density and negatively correlated with ferritin. In the FAC-treated cells, miR-106a-5p decreased, and PTEN increased. Dual-luciferase assays confirmed that miR-106a-5p targets PTEN. Successful transfection was confirmed by observing the corresponding changes in miR-106a-5p and PTEN expression. Up-regulated miR-106a-5p increased the PTEN protein level, mRNA expression of RUNX2, OPN, and OCN, promoted cell proliferation, and decreased cell apoptosis under iron accumulation conditions. These effects were reversed by the upregulation of PTEN.ConclusionmiR-106a-5p has the potential to diagnose osteoporosis in postmenopausal women and is linked to ferritin levels. miR-106a-5p plays a protective role in PMOP by regulating PTEN under conditions of iron accumulation, suggesting its potential as a promising biomarker for PMOP.

TI Phytochemicals in Bone Therapy: Exploring Natural Alternatives for Bone Health
SO INTERNATIONAL JOURNAL OF NANOMEDICINE
LA English
DT Review
DE phyto-nanomedicine; phytochemicals; bone; natural compounds; plant-based nanoparticles
ID osteoblast differentiation; in-vitro; phenolic-compounds; basic science; scaffolds; quercetin; nanoparticles; osteogenesis; berberine; repair
AB Bone diseases such as osteoporosis and osteoarthritis are increasingly prevalent, particularly in aging populations. While conventional treatments, including synthetic drugs and mineral supplements, are effective yet often associated with side effects and long-term economic burdens. Active compounds derived from nature, "Phytochemicals" have garnered attention due to their potential to provide safer and more sustainable alternative therapeutic options. However, due to their complex structure and poor pharmacokinetics, their clinical applications are limited. Nano-drug delivery systems address these limitations by developing phytochemicalbased nanocarriers, which enable targeted delivery,

protect active compounds, and enhance both pharmacokinetics and pharmacodynamics. Given the limitations of synthetic treatments, there is growing interest in exploring phytochemicals and plants and herbal extracts to support bone health. This review focuses on nano-phytochemical approaches for bone therapy, outlining key phytochemicals, their natural sources, nanoformulations, and mechanisms of action. It also evaluates current commercial supplements and highlights the challenges and future directions for clinical translation of nano-phytomedicine in bone health management.

TI Prediction of Fractures After Open Wedge High Tibial Osteotomy Based on the Distance From the Tibial Osteotomy Point to the Medial Edge of the Tibia
SO JOURNAL OF ARTHROPLASTY
LA English
DT Article
DE high tibial osteotomy; lateral hinge fracture; preventive strategy; osteoarthritis; osteotomy position

ID lateral hinge fracture; unicompartmental knee arthroplasty; computed-tomography; safe zone; risk; osteoarthritis
AB Background: To investigate the relationship between the distance from the medial tibial osteotomy point to the medial tibial edge and the development of lateral tibial hinge fracture (type II) and intra-articular tibial plateau fracture (type III) in patients who have degenerative disease undergoing open wedge high tibial osteotomy (OWHTO). This information will aid surgeons in avoiding the occurrence of fractures. Methods: This retrospective study analyzed 304 patients who underwent OWHTO from January 2018 to January 2024 in the Affiliated Hospital of Qingdao University. The distance from the tibial osteotomy point to the medial tibial edge on imaging was analyzed to determine its association with fracture. A oneway analysis of variance was used to compare the differences in height, weight, body mass index, the distance from the medial tibial osteotomy point to the medial tibial edge, sex, left and right sides of the knee, and osteoporosis in the occurrence of types II and III fractures. Receiver operating characteristic curves were used to identify the critical distances associated with type II and type III fractures. Logistic regression analyses were used to obtain the OR of the critical distance adjusted for age, sex, left and right sides, body mass index, and T value. Results: There were 40 fractures (13.3%) in 304 patients after OWHTO, comprising 21 type II fractures (7.0%) and 19 type III fractures (6.3%). A single-factor variance analysis showed that the tibial bone cutting distance to the medial tibial edge (P = 0.02) and osteoporosis (P = 0.01) were significantly different from the fracture. Receiver operating characteristic curves showed that the critical distances for types II and III fractures were 40.5 and 47.1 mm, respectively. Logistic regression analysis showed that the ORs [odds ratios] of types II and III fractures were 1.061 (95% CI [confidence interval] = 1.010 to 1.115) and 1.064 (95% CI = 1.011 to 1.119), respectively. Conclusions: In patients undergoing OWHTO, the risk factors for type II and III fractures are osteoporosis and the distance from the tibial bone cutting point to the medial tibial edge. This distance should be minimized during OWHTO to avoid type II and III fractures. (c) 2024 Published by Elsevier Inc.

TI The effect of medical comorbidity on HOOS/KOOS/FAOS: a national register-based cohort study of 7850 representative citizens
SO CLINICAL RHEUMATOLOGY
LA English
DT Article
DE Comorbidity; HOOS/KOOS/FAOS; Outcome; PROM
ID osteoarthritis outcome score; knee injury; health; koos
AB ObjectivesDespite extensive validation, the impact of medical comorbidities on the outcomes of the Hip Disability and Osteoarthritis Outcome Score (HOOS), Knee Injury Osteoarthritis Outcome Score (KOOS), and Foot and Ankle Outcome Score (FAOS) remains underexplored. This study aimed to evaluate the effect of medical comorbidities on HOOS, KOOS, and FAOS subscales using a large, nationally representative sample.MethodsThis national register-based cohort study invited 26,877 participants to complete HOOS, KOOS, or FAOS questionnaires. Medical comorbidities-including diabetes, chronic obstructive pulmonary disease/asthma, rheumatological diseases, osteoporosis, stroke, obesity, and heart disease-were identified through the Danish National Patient Register.ResultsA total of 7850 participants (29%) responded, with 1863 (24%) having medical comorbidities. HOOS/KOOS/FAOS subscale scores were significantly worse in patients with comorbidities, particularly in the Sport/Rec, ADL, and QOL subscales. Mean score differences between participants with and without comorbidities were pain (- 5.7, 95% CI - 6.6 to - 4.7), symptoms (- 4.6, 95% CI - 5.5 to - 3.6), ADL (- 7.1, 95% CI -

8.0 to - 6.1), Sport/Rec (- 10.4, 95% CI - 11.9 to - 8.9), and QOL (- 6.9, 95% CI - 8.2 to - 5.7). Diabetes, rheumatological diseases, and obesity were associated with the greatest complaints.ConclusionPatients with medical comorbidity reported significantly lower HOOS/KOOS/FAOS subscale scores compared to participants without medical comorbidity. Diabetes, chronic rheumatological diseases, and adiposities were observed with the most complaints.Key Points center dot Medical comorbidity predicts considerably lower HOOS/KOOS/FAOS subscale scores.center dot Diabetes, rheumatological diseases, and obesity exerted the most pronounced negative effects on the HOOS/KOOS/FAOS.center dot Findings underscore the importance of considering comorbidities when interpreting HOOS/KOOS/FOAS subscale scores.ConclusionPatients with medical comorbidity reported significantly lower HOOS/KOOS/FAOS subscale scores compared to participants without medical comorbidity. Diabetes, chronic rheumatological diseases, and adiposities were observed with the most complaints.Key Points center dot Medical comorbidity predicts considerably lower HOOS/KOOS/FAOS subscale scores.center dot Diabetes, rheumatological diseases, and obesity exerted the most pronounced negative effects on the HOOS/KOOS/FAOS.center dot Findings underscore the importance of considering comorbidities when interpreting HOOS/KOOS/FOAS subscale scores.

AB Purpose of ReviewOsteoporosis and musculoskeletal diseases, including osteoarthritis and sarcopenia, contribute substantially to global morbidity and healthcare costs. This review explores how proteogenomics integrates genomic and proteomic data to refine disease classification, identify causal pathways, and accelerate biomarker and drug target discovery.Recent FindingsLarge-scale proteomic studies, including UK Biobank-based research, have identified circulating proteins associated with musculoskeletal disease risk and progression. Proteomic risk models outperform conventional clinical metrics in predicting outcomes. Genomics, proteomics, and proteogenomics have facilitated the identification of causal markers through methods such as genome-wide association studies, effector gene mapping, and proteome-wide Mendelian randomization. Pathways implicated in disease mechanisms include extracellular matrix remodeling (e.g., COL6A3, COL9A1), metabolic regulation (e.g., IGFBP2, GDF15), inflammatory processes (e.g., TNF family ligands, CXCL17), and sex-hormone-related signaling (e.g., FSHB, SHBG). While these biological processes contribute across osteoporosis, osteoarthritis, and sarcopenia, distinct proteins have also been linked to disease-specific pathophysiology, offering potential therapeutic targets.SummaryGenomics, proteomics, and proteogenomics refine our understanding of musculoskeletal conditions and hold strong potential for improving early diagnosis, enhancing risk stratification, and advancing precision treatments.

TI Prevalence, clinical characteristics, and biological markers of postmenopausal osteoporosis and knee osteoarthritis in Beijing: study protocol for a cross-sectional and prospective study
SO FRONTIERS IN MEDICINE
LA English
DT Article
DE postmenopausal osteoporosis; knee osteoarthritis; cross-sectional study; prospective; follow-up; risk factors
ID epidemiology
AB Background Postmenopausal osteoporosis (PMOP) and knee osteoarthritis (KOA) are common musculoskeletal disorders that share risk factors such as aging, hormonal changes, and inflammation. PMOP often remains asymptomatic until fractures occur, while KOA leads to pain and disability. Their comorbidity remains underexplored, particularly in community settings. This study aims to investigate the prevalence, risk factors, and clinical features of PMOP-KOA comorbidity among Beijing residents aged 45-80 years, providing evidence-based recommendations for early identification, prevention, and management. Methods Over 2 years, this study will conduct a PMOP-KOA screening and prospective follow-up in the Beijing community to investigate the incidence, risk factors, and clinical characteristics of PMOP-KOA. This study will undertake bone mineral density detection, collect biological samples, and record information via questionnaires. Discussion The study

aims to investigate the incidence, risk factors, and clinical characteristics of PMOP-KOA comorbidity and explore related traditional Chinese medicine syndromes based on large community-based samples in Beijing. Data on PMOP-KOA occurrence and associated risk factors over the 2 years follow-up will be available on the Chinese Clinical Trial Registry (ChiCTR2300073575).

TI Trolox, r-irisin and resveratrol cocktail to counteract osteoblast metabolism alterations in osteoarthritis and osteoporosis
SO JOURNAL OF BONE AND MINERAL METABOLISM
LA English
DT Article
DE Osteoporosis; Osteoarthritis; Bone metabolism; Musculoskeletal aging; Physiology
ID oxidative stress; prevents; sirt1
AB IntroductionOsteoarthritis and osteoporosis are age-related musculoskeletal disorders characterized by increased oxidative stress and cellular senescence, which contribute to altered metabolism and disease progression. Although research in this field is constantly evolving, the discovery of new molecular targets and drug combinations to counteract musculoskeletal disorders remains a goal of great interest. This study aimed to evaluate the efficacy of a cocktail of trolox, recombinant irisin (r-irisin) and resveratrol in modulation of osteoblastic metabolism by investigating the expression of NADPH oxidase 4 (NOX4), sirtuin 1 (SIRT1) and pentraxin 3 (PTX3).Materials and methods20 male patients undergoing hip arthroplasty were enrolled, including ten patients with coxarthrosis and ten patients with osteoporosis. Femoral head biopsies were taken from each patient to isolate primary osteoblast cultures, which were treated with the cocktail for 6 days.ResultsThe cocktail of trolox, r-irisin and resveratrol increased cell viability, and

reduced ROS and senescence beta-galactosidase activity (SA-beta-Gal) levels. In addition, western blotting analysis showed reduced expression of NOX4 and increased expression of SIRT1 and PTX3 in both experimental groups, although with more pronounced effects in osteoarthritic patients, highlighting lower treatment efficacy in the presence of osteoporosis.ConclusionsThe improvement in cell viability and reduction in oxidative stress and cellular senescence observed through treatment-induced modulation of the NOX4-SIRT1 axis and PTX3 suggests a protective role for these biomarkers in bone metabolism. These findings could offer new perspectives in counteracting the effects of aging on the skeletal system by improving bone health and mitigating metabolic alterations.

TI Senescence of bone marrow mesenchymal stromal cells: a narrative review of mechanisms, functional consequences, and rejuvenation strategies for age-related disorders
SO STEM CELL RESEARCH & THERAPY
LA English
DT Review

DE Bone marrow mesenchymal stromal cells; Cellular senescence; Telomere shortening; Oxidative stress; Senescence-associated secretory phenotype; Anti-Aging therapeutics
ID stem-cells; in-vitro; oxidative stress; telomerase; autophagy; survival; inhibit
AB With the intensification of global population aging, research on aging-related diseases has become increasingly critical. Bone marrow mesenchymal stromal cells (BMSCs), residing in bone marrow microvironment, serve as precursors for osteoblasts and adipocytes while playing unique roles in regulating hematopoietic and immune systems. However, BMSCs undergo progressive senescence during aging, characterized by diminished proliferative capacity, skewed differentiation potential, compromised immunomodulatory functions, and the development of a senescence-associated secretory phenotype (SASP). These age-related alterations exacerbate inflammatory responses within the bone marrow microenvironment, contributing to the pathogenesis of degenerative diseases such as osteoporosis and osteoarthritis, while potentially inducing hematopoietic dysfunction and oncogenic transformation. Notably, senescent BMSCs secrete pro-inflammatory cytokines that establish a chronic inflammatory milieu, which not only impairs hematopoietic stem cells (HSCs) functionality but also promotes bone marrow adipogenesis. Despite these insights, the intricate interplay between BMSC senescence and microenvironmental alterations remains incompletely understood. This narrative review Comprehensively synthesizes current knowledge on the molecular mechanisms underlying BMSCs senescence, with particular emphasis on telomere attrition, DNA damage accumulation, oxidative stress, epigenetic dysregulation, and bidirectional microenvironmental crosstalk. Furthermore, we critically evaluate emerging therapeutic strategies aimed at mitigating BMSCs senescence and optimizing their clinical applications in age-related disorders.

TI Advances in 3D-Printed Drug Delivery and Screening Platforms for Bone Disease Therapy
SO PHARMACEUTICS
LA English
DT Review
DE 3D printing; drug delivery; drug screening; bone diseases; patient-specific; orthopedics; physiopathology
ID gaucher-disease; in-vitro; mechanical-property; composite scaffolds; regeneration; vancomycin; release; nanoparticles; ciprofloxacin; antibiotics
AB Bone diseases such as osteomyelitis, osteosarcoma, and osteoarthritis, as well as conditions caused by metabolic imbalances, including osteoporosis, require more efficient and optimized therapies. Systemic drug administration entails major disadvantages like cytotoxicity and adverse reactions, which can lead to serious complications or death. Therefore, local drug administration alternatives are currently under investigation for different pharmacological therapies. New vectors were created to improve control over administration, and 3D-printed and patient-specific drug delivery systems have been tested, revealing great potential. Moreover, 3D-printed platforms that mimic human tissues for drug testing are innovative solutions emerging for the pharmaceutical industry. Situated between in vitro and in vivo testing on human patients, they offer the advantage of reproducing functional architecture, providing results that are closer to those encountered in clinical trials performed on patients. In our article, we present the two categories of 3D systems, from the perspective of main drug groups (antibiotics, anticancer, and anti-inflammatory) as well as other categories, alongside their advantages, limitations, and their adaptations to 3D printing technologies. This article also highlights the technological drawbacks encountered in both delivery and screening systems, as well as the printing methods and materials used, including their physical and biological properties.

TI Hip fractures and type 2 diabetes in the elderly: Risk factors analysis of the Nedices cohort

SO DIABETES & METABOLISM
LA English
DT Article
DE Elderly; Hip fracture; Risk factors; Type 2 diabetes
ID bone turnover; population; mellitus; women; health; metaanalysis; density
AB Aim:- To analyze the association between type 2 diabetes (T2D) and the incidence of hip fractures in the elderly, while also considering the influence of socioeconomic status (SES), and other risk factors (RFs). Methods:- Data were collected from 5278 participants aged >= 65 years. The study included a baseline and a follow-up survey 3 years later. Participants completed a questionnaire, anthropometric measurements, blood tests, and physical and cognitive tools. The research was conducted in three Spanish communities with different socioeconomic backgrounds. Results:- At baseline, there were 874 T2D and 4494 controls. Body mass index (BMI) was slightly higher in individuals with hip fractures. Significant differences were observed in BMI, education level, physical activity, osteoporosis, cataracts, and osteoarthritis. In the follow-up survey, 96 newly, 615 previously T2D, and 2985 controls were compared. Those with hip fractures were associated with lower educational attainment, sedentary life, and higher diagnoses of osteoporosis, cataracts, and osteoarthritis. Charlson index was higher in individuals with hip fractures. A higher proportion of fractures occurred in urban areas. The rate of incidence of T2D between individuals with and without fractures was not different. Conclusion:- RFs for hip fractures in T2D are similar to those in the general population. Osteoporosis, being female, and advancing age were independent RFs for hip fractures. There was an inverse association between educational level, community allocation, and physical activity which may further contribute to hip fracture risk. These highlights the need for research to better understand the role of T2D and these RFs in hip fracture incidence.

DE Rheumatoid arthritis; Elderly-onset rheumatoid arthritis; Serum 14-3-3 eta
ID health-assessment questionnaire; population-based cohort; clinical-practice; indian version; joint damage; young-onset; disease; prevalence; validation; antibody
AB Background: Rheumatoid Arthritis (RA) in older adults is a chronic inflammatory condition causing severe disability and impacting patients' physical, psychological, and social health. It lowers productivity in society and puts pressure on healthcare systems. This study aims to explore the different aspects of RA and investigate the diagnostic potential of serum marker 14-3-3 eta. Method: This Cross-sectional study recruited 205 arthritis patients (63 RA and 142 OA) over sixty years old. The participants underwent a thorough clinical evaluation according to the established design. Anti-CCP and serum 14-3-3 eta levels were measured. Simple logistic regression was performed to identify significant predictors of RA. ROC curve determined optimal cut-off value for 14-3-3 eta. Results: This study reported an average age of 63.67 years with a high female-to-male ratio of 4:1 in the RA cohort, while in the OA cohort, the mean age was 65.5 years with a low female-to-male ratio of 2:1 overall. Symptomatically, RA patients exhibited earlier onset, pronounced early morning stiffness, fever, weight loss, myalgia, and fatigue, all with highly significant p-values (< 0.001). Comorbidities showed higher incidences of anemia, ILD, and osteoporosis in RA patients. Impaired ADL and IADL were noted in 17.5% and 73.2%, respectively. Impaired HMSE and GDS were found in 36.5% and 74.6%, respectively. Logistic regression analysis identified key predictors distinguishing RA from OA, including EMS (OR: 1.09, $p < 0.001$), fever (OR: 6.68, $p < 0.001$), weight loss (OR: 6.35, $p < 0.001$), myalgia (OR: 5.07, $p < 0.001$), osteoporosis (OR: 2.21, $p = 0.013$), ACCP levels (OR: 1.28, $p < 0.001$), and the novel marker 14-3-3 eta (OR: 2.87, $p = 0.047$). Using both ACCP and14-3-3 eta markers, 88.88% of RA patients were positive for at least one marker, enhancing its diagnostic coverage. Elderly onset RA (EORA) patients had a significantly higher age and shorter disease duration compared to those with young onset RA (YORA). The

female-to-male ratio in the YORA and EORA group were 6.97:1 and 1.66:1 respectively. PMR-like symptoms were more prevalent in the EORA group (31.25% vs.14.9%). Hypothyroidism was more frequent in the EORA group (31% vs. 17%). Sulfasalazine was more commonly prescribed in both EORA (100%) and YORA (89%) groups. Conclusion: This study contributes to a better understanding of distinguishing RA from OA. It also highlights the differences between young and elderly onset RA, and supports the diagnostic potential of the serum marker 14-3-3 eta.

DT Review
DE stem cells; extracellular vesicle; mesenchymal stem cells; regenerative medicine
ID mesenchymal stem-cells; intervertebral disc degeneration; extracellular vesicles; femoral-head; osteonecrosis
AB Nano-sized extracellular vesicles enclosed by a lipid bilayer and secreted by various cell types including mesenchymal stem cells, exosomes act as natural transporters, carrying bioactive molecules such as proteins, lipids, and nucleic acids that mediate intercellular communication. Exosomes influence a range of cellular processes, including immune modulation, tissue repair, and disease progression. Compared to whole-cell therapies, exosomes provide anti-inflammatory, immunosuppressive, and regenerative effects with reduced risks linked to cellular components, such as infusion toxicity, immunogenicity, and tumorigenic phenomena. This article reviews isolation, modification, characterization, and storage techniques, challenges in clinical translation, and innovative engineering strategies to enhance targeting and efficacy. It also examines preliminary evidence suggesting that exosomes may have potential in managing degenerative disorders such as osteoarthritis, intervertebral disc degeneration, osteoporosis, osteonecrosis, and tendinopathy, as well as non-degenerative disorders such as sciatic nerve injury, fractures, and soft tissue trauma.

TI Causality between coffee intake and bone health: A Mendelian randomization study

SO MEDICINE
LA English
DT Article
DE coffee intake; Mendelian randomization; osteoarthritis; osteoporosis; rheumatoid arthritis
ID rheumatoid-arthritis; mineral density; caffeic acid; risk; consumption; cells; differentiation
AB Observational studies have reported associations between coffee intake and osteoarthritis (OA), rheumatoid arthritis (RA), and osteoporosis (OP). However, it remains unknown whether these relationships are causal. In this study, we applied a 2-sample bidirectional Mendelian randomization (MR) analysis to comprehensively evaluate the causal association between coffee intake and OA, RA, and OP. Genetic data for OA (40,425 controls and 10,083 cases), RA (22,350 controls and 74,823 cases), OP (476,847 controls and 7751 cases), and coffee intake (263,464 Europeans) were obtained from the UK Biobank. The causal relationship between coffee intake and OA-, RA-, and OP-related traits was investigated using 2-sample MR analysis with a pooled dataset from genome-wide association studies. Inverse variance weighting (IVW) was used as the main outcome, whereas MR-Egger and weighted median were used to supplement the IVW estimates. Heterogeneity was assessed using Cochran Q statistic. Confounding-related single-nucleotide polymorphisms and single-nucleotide polymorphisms with P < .05 in MR-PRESSO analysis were excluded. There was no evidence of a causal relationship between coffee intake and the risk of RA (odds ratio [OR]: 0.84; 95% confidence interval [CI]: 0.24-2.93) using the IVW with random effect. Genetic predisposition to coffee intake was not associated with OA (OR: 1.21; 95% CI: 1.01-1.45) and OP (OR: 1; 95% CI: 0.99-1.0) using the main IVW method. Reverse MR analysis did not reveal evidence of a significant causal effect of OA, RA, and OP on coffee intake. Our findings do not support a causal relationship between coffee intake and the risk of OA, RA, and OP.

TI Network Toxicology and Molecular Docking Reveal the Toxicological Mechanisms of DEHP in Bone Diseases
SO INTERNATIONAL JOURNAL OF MOLECULAR SCIENCES

LA English
DT Article
DE Di(2-ethylhexyl) phthalate (DEHP); network toxicology; molecular docking; osteoporosis; osteoarthritis; osteonecrosis of the femoral head
ID osteogenic differentiation
AB Di(2-ethylhexyl) phthalate (DEHP), a widely employed exogenous plasticizer, has become pervasive in the environment and living organisms due to its extensive use in food packaging, medical devices, and daily consumer products, and is established as a typical endocrine-disrupting chemical. Growing evidence indicates a strong association between DEHP exposure and the incidence of chronic bone disorders, including osteoporosis (OP), osteoarthritis (OA), and osteonecrosis of the femoral head (ONFH). However, the molecular mechanisms underlying its pathogenic effects across these diseases remain poorly defined. In this study, we applied an environmental network toxicology approach to integrate predicted protein targets of DEHP with known disease-associated targets of the three bone disorders using multiple databases. Through Venn analysis, protein-protein interaction (PPI) network construction, and Gene Ontology (GO) and Kyoto Encyclopedia of Genes and Genomes (KEGG) enrichment analyses, we identified core targets and key signaling pathways. Molecular docking and molecular dynamics (MD) simulations were further employed to validate the binding modes and stability between DEHP and the core targets, thereby elucidating common and distinct mechanisms of DEHP across these bone diseases. A total of 109 overlapping targets of DEHP and the three bone diseases were identified, among which 7 core targets-AKT1, SRC, ESR1, CASP3, MMP9, BCL2, and BCL2L1-were common to all three disorders. These are implicated in critical biological processes such as apoptosis regulation, inflammation, extracellular matrix degradation, and estrogen signaling. KEGG enrichment analysis revealed significant involvement of the PI3K-Akt, MAPK, Ras, TNF, and estrogen signaling pathways across all three diseases. Molecular docking and MD simulations confirmed stable binding of DEHP to key targets including AKT1, ESR1, and MMP9, supporting its potential to disrupt bone metabolic homeostasis via multi-target and multi-pathway mechanisms. Further analysis indicated that DEHP exerts both shared and disease-specific effects: it disrupts osteoblast/osteoclast balance in OP, amplifies inflammatory responses and matrix degradation in OA, and contributes to impaired angiogenesis and osteocyte necrosis in ONFH. This study systematically reveals how DEHP disrupts bone homeostasis through a multi-target and multi-pathway network, constructing a cross-disease osteotoxicity framework. It is the first to delineate the common and distinct molecular mechanisms of DEHP in OP, OA, and ONFH. Although these insights are derived from computational models and require further experimental validation, they provide a novel theoretical basis for combined intervention strategies targeting multiple bone diseases and for environmental health risk assessment.

AB Objective: The purpose of this study was to examine methods of pharmacologic and nonpharmacological pain management for people with bone-related diseases. Methods: Bone-related disease incidence, treatment, and pain management strategies were assessed using an anonymous online survey in 2021. The survey included questions about demographics, disease characteristics, and pain coping. One-sample x2 goodness of fit tests, 2-way Pearson x2 tests of independence, and probability values were used for data analysis. Results: Respondents were primarily postmenopausal females, aged 55-60 years old, with moderate disease activity, with osteoporosis most commonly reported. Responses suggest medical professionals' advice for pain management included multiple medications, especially analgesics. Dietary interventions also played an important role with vitamin D and calcium supplementation regularly being reported. Patients seek to use alternative methods of pain relief and disease management, with many respondents reporting nonpharmacological pain relief treatments playing a significant role in coping with their bone disease. Although respondents aged 46 to 50 opted against nonpharmacological relief, those aged 56 to 60 years reported they were willing to try nonpharmacological interventions that reduced pain, with the choice of treatment based on "how it made me feel." Conclusion: A substantial number of respondents believed that more research is required into pain relief for bone-related diseases, with those affected by these conditions seeking a more acute and analgesic approach to managing pain. Most respondents answered "yes" when asked if nonpharmacological pain relief treatments play a sufficient role in

coping with their bone-related pain. (J Manipulative Physiol Ther 2025;48;365-372)

TI NLRP3 Inflammasome-Mediated Pyroptosis in Osteoporosis: Osteoimmune Mechanisms and Therapeutic Targeting
SO JOURNAL OF CELLULAR AND MOLECULAR MEDICINE
LA English
DT Review
DE action mechanism; cell pyroptosis; intervention measures; NLRP3 inflammasome; osteoimmunology; osteoporosis
ID oxidative stress; in-vitro; activation; macrophages; inhibition; cells; osteoarthritis; progression; osteoblast; exosm
AB Osteoporosis (OP) is a chronic, age-related skeletal disorder characterised by progressive bone loss and microstructural deterioration, which increases bone fragility and fracture risk. The NOD-like receptor family pyrin domain-containing 3 (NLRP3) inflammasome, a multi-subunit protein complex involved in bone homeostasis, mediates inflammatory cascades in response to external stimuli and pathological conditions. This process triggers pyroptosis in various bone-related cells, disrupting bone repair and remodelling. Oestrogen deficiency and aging lead to the overactivation of the NLRP3 inflammasome, stimulate bone immunity, metabolism and other abnormalities and disrupt angiogenesis-osteogenesis coupling. These factors contribute significantly to the pathological progression of OP. However, the precise mechanisms remain poorly understood and are lacking clinical validation. Therefore, this review summarises the mechanisms of NLRP3 inflammasome in response to bone immune signals, external stress and intercellular communication, as well as its role in metabolic regulation, including reprogramming and post-translational modification, thereby influencing pyroptosis in macrophages, endothelial cells, mesenchymal stem cells and osteoblasts. It explores potential therapeutic strategies that target NLRP3 activation, including exosome (Exos)-based interventions and traditional Chinese medicine components, which may modulate its differential expression and affect angiogenesis-osteogenesis differentiation. These approaches offer promising avenues for the prevention and treatment of OP.

DT Review
ID human articular-cartilage; muscle satellite cells; single-cell; proteomic analysis; stem-cells; transcriptome analysis; intervertebral discs; human osteoarthritis; dna methylation; gene-expression
AB Musculoskeletal disorders, including osteoarthritis, rheumatoid arthritis, osteoporosis, bone fracture, intervertebral disc degeneration, tendinopathy, and myopathy, are prevalent conditions that profoundly impact quality of life and place substantial economic burdens on healthcare systems. Traditional bulk transcriptomics, genomics, proteomics, and metabolomics have played a pivotal role in uncovering disease-associated alterations at the population level. However, these approaches are inherently limited in their ability to resolve cellular heterogeneity or to capture the spatial organization of cells within tissues, thus hindering a comprehensive understanding of the complex cellular and molecular mechanisms underlying these diseases. To address these limitations, advanced single-cell and spatial omics techniques have emerged in recent years, offering unparalleled resolution for investigating cellular diversity, tissue microenvironments, and biomolecular interactions within musculoskeletal tissues. These cutting-edge techniques enable the detailed mapping of the molecular landscapes in diseased tissues, providing transformative insights into pathophysiological processes at both the single-cell and spatial levels. This review presents a comprehensive overview of the latest omics technologies as applied to musculoskeletal research, with a particular focus on their potential to revolutionize our understanding of disease mechanisms. Additionally, we explore the power of multi-omics integration in identifying novel therapeutic targets and highlight key challenges that must be overcome to successfully translate these advancements into clinical applications.

TI Prevalence, comorbidities, and disease-related complications of rheumatoid

arthritis in Colombia: a national cross-sectional study based on administrative claims data
SO ADVANCES IN RHEUMATOLOGY
LA English
DT Article
DE Latin America; Comorbidity; Complications; Prevalence; Rheumatoid arthritis
ID population; care
AB BackgroundTo date, there has been limited exploration, particularly on a national scale, of the prevalence patterns of comorbidities and complications associated with rheumatoid arthritis (RA) in Colombia. We aimed to analyze the prevalence patterns of comorbidities and disease-related complications of RA patients enrolled in Colombia's contributory healthcare regime.MethodsWe performed a nationwide observational descriptive cross-sectional study using administrative claims data. We used a set of sensitive and specific electronic algorithms (i.e., a set of rules) applied to linked data based on ICD-10 codes and unique medication use codes. We compared all those algorithms with several sources, including governmental agencies and scientific literature, to identify all the known adults treated for RA.ResultsA total of 123,080 RA cases for 2018 were identified, corresponding to a point prevalence of 0.86 (95% CI 0.86-0.87) per 100. Compared to a non-RA reference population, hypertension (68.2 vs. 20.0%), osteoarthritis (43.6 vs. 6.1%), and osteoporosis (18.6 vs. 1.1%) provided larger standardized mean differences. Lupus (30.04; 95%CI 29.3-30.8), multiple sclerosis (7.18; 95%CI 6.6-7.8), and osteoporosis (5.57; 95%CI 5.5-5.6) provided higher age- and sex-adjusted prevalence ratios. Disease-related complications were found in 62.2% of cases.ConclusionsWe describe the first comprehensive assessment of the prevalence patterns of disease-related complications and comorbidities that define the RA burden of disease within a multimorbidity profile. Also, our study provides a narrower and more reliable point prevalence estimate for RA in Colombia.

TI Research advances in the study of traditional Chinese medicine formula granules on signaling pathway-mediated disease mechanisms
SO FRONTIERS IN PHARMACOLOGY
LA English
DT Review
DE traditional Chinese medicine formula granules; signaling pathways; mechanisms of disease; secondary metabolites; orthopedic diseases; plant-based natural products
ID tgf-beta; decoction; injury
AB As a modern dosage form of traditional Chinese medicine, Traditional Chinese Medicine Formula Granules (TCMFG) maximally retains active metabolites through standardized production processes, including dynamic countercurrent extraction and low-temperature concentration. This serves as a critical material basis for elucidating its multi-target regulatory mechanisms. Recent studies have highlighted the significant potential of TCMFG in treating complex diseases, such as inflammation, tumors, metabolic disorders, fibrosis, and orthopedic conditions like osteoarthritis and osteoporosis, by modulating signaling pathways such as TLR4/NF-kappa B, MAPK, NLRP3 inflammasome, PI3K/Akt/mTOR, Wnt/beta-catenin, and TGF-beta/Smads. For example, berberine alleviates acute lung injury by inhibiting the TLR4/NF-kappa B pathway, while tetramethylpyrazine derived from Ligusticum chuanxiong Hort granules mitigate joint destruction in rheumatoid arthritis by suppressing MAPK signaling. Curcumin analogs inhibit tumor metabolic reprogramming via the PI3K/Akt pathway. Despite these advances, current research encounters challenges, such as single-component analysis, unclear synergistic mechanisms of compound mixtures, and insufficient clinical evidence for translational applications. In the future, integrating multi-omics technologies (e.g., metabolomics, spatial transcriptomics) will be crucial for exploring supramolecular synergistic effects of compound mixtures. Furthermore, large-scale clinical trials are necessary to validate its potential in precision medicine. This article systematically reviews the progress of TCMFG research in signaling pathway-mediated disease mechanisms and outlines future directions to enhance its application in modern precision medicine.

TI Unraveling the role of FGF7 in osteoarthritis and osteoporosis: Therapeutic implications and challenges
SO FASEB JOURNAL
LA English
DT Review
DE FGF7; osteoarthritis; osteoporosis
AB Fibroblast growth factors (FGF) are involved in the regulation of cellular and physiological processes. Recent findings indicate that FGF7 shields osteoblasts from oxidative stress, diminishes apoptosis, and maintains osteogenic differentiation, thereby offering protection against osteoporosis. In contrast, within the context of osteoarthritis (OA), FGF7 intensifies disease progression through the upregulation of matrix-degrading enzymes, erosion of articular cartilage, and remodeling of subchondral bone. This review underscores the necessity for further investigation into the mechanisms driving FGF7's dual roles and its potential as a therapeutic target. Future research should focus on validating FGF7-targeted therapies in clinical trials and assessing the effects of FGF7 modulators on skeletal health across various orthopedic conditions, including osteoporosis and OA. These efforts are crucial for unraveling the multifaceted nature of FGF7 in bone metabolism and advancing precision medicine approaches for skeletal disorders.

TI Perspectives of exosomal ncRNAs in the treatment of bone metabolic diseases: Focusing on osteoporosis, osteoarthritis, and rheumatoid arthritis
SO EXPERIMENTAL CELL RESEARCH
LA English
DT Review
DE Exosome; ncRNA; Bone metabolism; Osteoporosis; Osteoarthritis; Rheumatoid arthritis
ID nf-kappa-b; pi3k/akt/mtor signaling pathway; osteoblast differentiation; chondrocyte proliferation; articular chondrocytes; down-regulation; cells; osteoclastogenesis; biogenesis; microrna
AB Bone metabolic disorders, constituting a group of prevalent and grave conditions, currently have a scarcity of therapeutic alternatives. Over the recent past, exosomes have been at the forefront of research interest, owing to their nanoparticulate nature and potential for therapeutic intervention. ncRNAs are a class of heterogeneous transcripts that they lack protein-encoding capacity, yet they can modulate the expression of other genes through multiple mechanisms. Mounting evidence underscores the intricate role of exosomes as ncRNAs couriers implicated in the pathogenesis of bone metabolic disorders. In this review, we endeavor to elucidate recent insights into the roles of three ncRNAs - miRNAs, lncRNAs, and circRNAs - in bone metabolic ailments such as osteoporosis, osteoarthritis, and rheumatoid arthritis. Additionally, we examine the viability of exosomal ncRNAs as innovative, cell-free modalities in the diagnosis and therapeutic management of bone metabolic disorders. We aim to uncover the critical function of exosomal ncRNAs within the context of bone metabolic diseases.

DT Review
ID bioelectrical-impedance analysis; hydroxy-beta-methylbutyrate; lumbar multifidus muscle; cross-sectional area; bone-mineral density; human growth-hormone; asian working group; fat-free mass; skeletal-muscle; body-composition
AB Sarcopenia, a progressive and systemic skeletal muscle disorder marked by the accelerated deterioration of both muscle function and mass, is highly prevalent among the elderly population, significantly contributing to an elevated risk of adverse outcomes, including falls, fractures, and muscle weakness. Clinical investigations have identified a strong correlation between sarcopenia and several prevalent degenerative skeletal muscle disorders. This correlation is attributed to imbalances in joint mechanics resulting from localized muscle atrophy and the influence of musculoskeletal secretory factors. In this review, we discuss the broader implications of sarcopenia and critically evaluate the currently established assessment methods. Furthermore, the clinical significance of prevalent musculoskeletal disorders (including osteoporosis, osteoarthritis, and spinal pathologies) in relation to sarcopenia, alongside the underlying mechanisms influencing this relationship, is summarized. Additionally, the effects of sarcopenia on the therapeutic efficacy of medications and surgical interventions for musculoskeletal conditions are reviewed. Sarcopenia is intricately linked to the onset, progression, and prognosis of musculoskeletal disorders. Future research should prioritize elucidating the potential mechanisms that connect muscle loss with skeletal muscle diseases, and investigating whether mitigating sarcopenia symptoms could decelerate the progression of these disorders, thereby paving new pathways for therapeutic interventions.

TI High Prevalence of Symptomatic Knee Osteoarthritis Among Patients Who Have Fragility Hip Fractures
SO JOURNAL OF ARTHROPLASTY
LA English
DT Article
DE fall; fragility hip fracture; knee; osteoarthritis; osteoporosis; subsequent fracture
ID osteoporotic fractures; risk-factors; elderly-men; fall risk; women; pain; epidemiology; questionnaire; instability; mortality
AB Background: Knee osteoarthritis (OA) is a common degenerative musculoskeletal condition that impairs mobility and balance, increasing fall risk. When combined with osteoporosis, it further increases the risk of fragility fractures. Despite its prevalence, the frequency of knee OA in patients who have fragility hip fractures (FHFs) is not well established. This study aimed to determine the prevalence of knee OA among FHF patients. Methods: We conducted a cross-sectional analysis of patients who underwent surgical treatment for FHF. The knee OA diagnoses followed the American College of Rheumatology criteria, and severity was assessed via the Kellgren-Lawrence classification system. Bone mineral density (BMD) was evaluated at the lumbar spine and contralateral hip, and fall risk was assessed using a self-report questionnaire. Results: Among the 162 patients

who had FHF (mean age 79 +/- 8.1 years; 80.2% women), 66% had symptomatic knee osteoarthritis (SKOA). Of these, 21.0% were classified as end-stage knee osteoarthritis. Notably, 47.1% of these end-stage knee osteoarthritides were recommended for knee OA surgery before their hip fracture. The presence of SKOA was significantly associated with a history of multiple falls (P = 0.013) and a high fall risk (P = 0.020). Among the 120 patients who had BMD data, 68% had low BMD (T-score <-2.5) at the contralateral hip or lumbar spine. Almost half (45%) of the FHF patients had concurrent SKOA and low BMD, whereas approximately 20% had SKOA, low BMD, and a high fall risk. Conclusions: There is a high prevalence of SKOA among FHF patients. Comprehensive evaluation and management of knee OA and osteoporosis are essential to reduce the risk of subsequent fractures in this vulnerable population.

TI Osteoporosis should be evaluated by bone mineral density at the combination of the lumbar spine and ipsilateral femoral neck in female patients with knee osteoarthritis scheduled for knee arthroplasty: A retrospective observational study
SO JOURNAL OF ORTHOPAEDIC SCIENCE
LA English
DT Article
DE Knee arthroplasty; Osteoporosis; Dual-energy X-ray absorptiometry; Bone mineral density; Lumbar spine; Ipsilateral femoral neck
ID prevalence; hip
AB Background: Knee arthroplasty is a well-established surgery with good clinical outcomes. However, periprosthetic fractures and aseptic loosening negatively impact clinical outcomes, and osteoporosis is one of the causes of such complication. Osteoporosis is usually evaluated by bone mineral density of the lumbar spine and hip using dual-energy X-ray absorptiometry (DXA). However, the prevalence of this disease in patients with knee osteoarthritis scheduled for knee arthroplasty may be underestimated due to differences in the measurement sites. This study aimed to determine the appropriate measurement site for DXA that would not miss osteoporosis in female patients with knee osteoarthritis undergoing knee arthroplasty. Methods: We measured bone mineral density preoperatively in the consecutive 50 female patients with knee osteoarthritis scheduled for knee arthroplasty by dual-energy X-ray absorptiometry at five sites: the lumbar spine, bilateral-total hip, and femoral neck. We then compared the prevalence of osteoporosis among the four combinations of the lumbar spine and single hip site (ipsilateral or contralateral total hip or femoral neck). Results: Osteoporosis prevalence in the combination of the lumbar spine and ipsilateral or contralateral total hip was 32%, and that in the combination of the lumbar spine and contralateral femoral neck was 44%. Notably, the disease's prevalence in the combination of the lumbar spine and ipsilateral femoral neck was 50%, which was significantly higher than that in the other combinations. Conclusion: Osteoporosis should be evaluated by bone mineral density in the combination of the lumbar spine and ipsilateral femoral neck in female patients with knee osteoarthritis scheduled for knee arthroplasty. TI Osteonecrosis: A disabling disease not to be ignored in asthma and atopic conditions
SO ANNALS OF ALLERGY ASTHMA & IMMUNOLOGY
LA English
DT Review
ID femoral-head; avascular necrosis; nontraumatic osteonecrosis; idiopathic osteonecrosis; aseptic necrosis; atraumatic osteonecrosis; natural-history; bone; risk; pathophysiology
AB Osteonecrosis, also referred to as avascular necrosis, is a disease characterized by necrosis or death of a bone secondary to impairment in blood supply. The condition affects the epiphyseal ends of the bones such as the femur and the humerus, but it can also involve the metacarpal and metatarsal bones, the patella, the knee, the vertebrae, and the jaw. A plethora of inflammatory, autoimmune, hematological, thrombotic, and vascular diseases can lead to osteonecrosis. Corticosteroids are intimately linked to the development of osteonecrosis. The frequent use of systemic corticosteroids in patients with asthma, eczema, nasal polyposis, sinusitis, urticaria and angioedema, or anaphylaxis makes this disease of great relevance to the practicing allergist and pulmonologist. Untreated, bone

necrosis leads to frustrated bone remodeling and angiogenesis, leading to subchondral fractures and collapse of the articular heads of the bones, and culminating in debilitating osteoarthritis, often requiring arthroplasty. Recent studies have shed light on the molecular mechanisms underlying osteonecrosis and on the role of glucocorticoids. The gold standard test in patients suspected of having the disease is magnetic resonance imaging scanning, with plain radiographs having a lower sensitivity and specificity. Early diagnosis and intervention are essential. The allergist should avoid the frequent use of glucocorticoids and consider early introduction of steroid-sparing alternatives for asthma or sinusitis. Smoking and alcohol ingestion need to be addressed, and the management of glucocorticoid-induced osteoporosis may be helpful. It is essential for allergists to familiarize themselves with the disease and its diagnosis and to consider early referral to an orthopedic surgeon for surgical intervention. TI Further Evidence That Chondrocalcinosis 1 (CCAL1) is a Confirmed Mendelian Phenotype With a Known Molecular Basis
SO AMERICAN JOURNAL OF MEDICAL GENETICS PART A
LA English
DT Article
DE c.1205A>T; calcium pyrophosphate dehydrate deposition disease; CCAL1; chondrocalcinosis 1; CPPDD; osteoarthritis; osteoprotegerin; TNFRSF11B
ID deposition disease; osteoarthritis; mutation
AB Chondrocalcinosis (CCAL), also known as calcium pyrophosphate dihydrate deposition disease (CPPDD), is a frequent multifactorial condition in the elderly, but there are two rare autosomal dominant Mendelian forms, CCAL1 (OMIM %600668) and CCAL2. Only three families with molecularly proven CCAL1 have been reported. Here, we describe an additional family from Germany (12 individuals, nine living) with CPPDD manifesting in the third decade of life, presenting with severe spinal problems and variable levels of disability, only two of them with hip problems. The mildly impaired growth in this family (median height at age 20: 10th percentile) may represent an as yet undescribed sign of CCAL1, or alternatively familial short stature. In all documented families and in this family, the disorder resulted from the recurrent heterozygous stop-loss variant NM_002546.4:c.1205A>T; p.(Ter402Leuext*19) in TNFRSB11B on chromosome 8q24, which predicts an extended osteoprotegerin protein with 19 additional amino acid residues. The pathomechanism of CCAL1 is not known. Biallelic TNFRSF11B loss-of-function variants cause autosomal recessive juvenile Paget's disease of bone (PDB5); shared features between CCAL1 and PDB5 include demineralization, osteoporosis, increased fractures, and a progressive height loss with age, but PDB5 and CCAL1 have very different phenotypes and heterozygous carriers of PDB5-associated variants are asymptomatic. Summing up, NM_002546.4:c.1205A>T represents a rare type of stop-lost variant, likely a gain-of-function variant, and to date no other variant is known to cause CCAL1. Our findings expand the phenotypic spectrum of CCAL1 and underscore that CCAL1 is a distinct rare Mendelian disorder for which the underlying molecular basis is now known.

TI Lipid-Driven Immunometabolism in Mesenchymal Stromal Cells: A New Axis for Musculoskeletal Regeneration
SO INTERNATIONAL JOURNAL OF MOLECULAR SCIENCES
LA English
DT Review
DE lipids; immunometabolism; mesenchymal stromal cells; tissue regeneration; post-traumatic osteoarthritis; osteoporosis; inflammation
ID energy-metabolism; stem-cells; bioactive lipids; bone-resorption; inflammation; resolution; cartilage; gpr120; mechanisms; mediators
AB The immunosuppressive and anti-inflammatory potential of mesenchymal stromal cells (MSCs) underpins their therapeutic value in musculoskeletal disorders. However, the underlying mechanisms remain ill-defined. Traditionally associated with immune cells, immunometabolism (the cellular metabolism-immune system interplay) is now recognized as central in a broader range of processes, including tissue homeostasis, repair, and chronic inflammation. Depending on the context and cell type, distinct metabolic pathways (e.g., fatty acid oxidation, lipid mediator biosynthesis) can drive pro-inflammatory/pro-resolving immune phenotypes. This dynamic is salient in musculoskeletal tissues: macrophage polarization, T-cell activation, and MSC immunomodulation are governed by metabolic cues. Emerging evidence highlights lipid-driven immunometabolism as a key player in MSC function, particularly in post-traumatic osteoarthritis (PTOA) and osteoporosis (OP). Unlike immune cells, MSCs rely on distinct metabolic programs (e.g., lipid sensing, uptake, and signaling) to exert context-dependent immunoregulation. In PTOA, persistent inflammation triggers lipid-centric metabolic pathways, enhancing MSC-driven immunomodulation and therapeutic outcomes. In OP, low-grade inflammation and altered lipid metabolism impair bone regeneration, modulating lipid-driven routes that can restore MSC osteogenic function and influence osteoclast precursors. This review explores how lipid-derived mediators and signaling contribute to MSCs' immunosuppressive capacity, positioning lipid

immunometabolism as a novel axis for rebalancing the inflamed joint microenvironment and encouraging musculoskeletal regeneration.

TI Targeting p38 MAPK: A potential bridge between ER stress and age-related bone loss
SO CELLULAR SIGNALLING
LA English
DT Article
DE Endoplasmic reticulum stress; p38 MAPK; Age-related bone loss; Therapeutic strategies
ID endoplasmic-reticulum stress; activated protein-kinase; osteoblast differentiation; regulates osteoclast; pathway; osteoarthritis; apoptosis; mechanisms; decreases; inhibitor
AB The endoplasmic reticulum (ER) is crucial in the development of numerous age-related bone disorders. Notably, ER stress can precipitate bone loss by orchestrating inflammatory responses, apoptosis, and autophagy through the activation of the p38 MAPK pathway. Age-related bone loss diseases pose a significant burden on society and healthcare as the global population ages. This review provides a comprehensive analysis of recent research advancements, delving into the critical role of ER stress-activated p38 MAPK in inflammation, apoptosis, and autophagy, as well as its impact on bone formation and bone resorption. This review elucidates the molecular mechanisms underlying the involvement of ER stress-activated p38 MAPK in osteoporosis, rheumatoid arthritis, periodontitis, and osteoarthritis and discusses the therapeutic potential of targeting p38 MAPK. Furthermore, this review provides a scientific foundation for new therapeutic strategies by highlighting prospective research directions.

TI Extracellular vesicles from adipose-derived stem cells in bone regeneration: Mechanisms and therapeutic advances
SO WORLD JOURNAL OF STEM CELLS
LA English
DT Review
DE Adipose-derived stem cell; Extracellular vesicle; Bone regeneration; Fracture healing; Osteoarthritis; Osteoporosis; Therapeutic mechanism

ID exosm; osteoarthritis; osteoporosis; alleviate; diagnosis
AB Extracellular vesicles (EVs) secreted by adipose-derived stem cells (ADSCs) have emerged as a promising cell-free therapeutic tool for bone regeneration. These EVs deliver a diverse array of bioactive molecules, including proteins, lipids, and nucleic acids, thereby modulating the bone microenvironment, activating key signaling pathways, and promoting bone regeneration. Innovative strategies involving preconditioning, genetic modification, and biomaterial-assisted delivery have been explored, with preclinical studies demonstrating synergistic effects that enhance targeting specificity and therapeutic efficacy. Functionally, EVs derived from ADSCs promote osteogenesis by enhancing osteoblast and mesenchymal stem cell activity, support angiogenesis through vascular endothelial growth factor signaling, and modulate inflammation by shifting macrophages from pro-inflammatory to anti-inflammatory phenotypes. In disease-specific contexts, they reduce cartilage degradation and support subchondral bone restoration in osteoarthritis, while in osteoporosis, they help restore the balance between bone formation and resorption and mitigate bone loss. Despite these promising developments, challenges remain in standardizing production protocols, optimizing delivery systems, and confirming long-term safety and efficacy in clinical settings. This review summarizes current insights into the mechanisms of EVs derived from ADSCs in bone-related diseases and highlights recent innovations and future directions that may accelerate their clinical application as a regenerative therapy.

TI Multivariate analysis of Raman spectra for discriminating human collagens: In vitro identification of extracellular matrix collagens produced by an osteosarcoma cell line
SO SPECTROCHIMICA ACTA PART A-MOLECULAR AND BIOMOLECULAR SPECTROSCOPY
LA English
DT Article
DE Collagen; Raman spectroscopy; Multivariate analysis; Extracellular matrix; Bone; Connective tissues
ID morphometric-analysis; bone; spectroscopy; biomarkers; mechanism
AB Background: The NHS spends 4.3 pound billion annually to address musculoskeletal conditions, encompassing age- related bone disorders like osteoarthritis and osteoporosis. Traditional X-ray diagnostic methods are commonly employed for bone disorder diagnosis, primarily assessing gross anatomical bone structure changes. However, these methods are unable to identify subtle biochemical alterations within the bone. More detailed information, particularly about protein changes, may lead to enhanced diagnostics and treatment. Raman spectroscopy is a non-invasive, laser-based technique capable of detecting changes in the collagen component of bone. Despite its long-standing application in discerning mineral and protein changes within bone, there is limited

evidence on Raman spectral signatures of purified human collagens and their differentiation. This study aimed to test the hypothesis that Raman spectroscopy could detect different types of collagen in the human body. Results: A Raman microspectrometer with a 785 nm laser was used to measure unmineralized human collagens types I - VI and collagenous extracellular matrix (ECM) secreted by MG63 osteoblast-like cells. The results demonstrated the efficacy of Raman spectroscopy and subsequent multivariate analysis in distinguishing human collagen types I - VI. This implies that Raman spectroscopy, coupled with multivariate analysis, can identify pure human collagens and offers reference spectra similar to natural human collagen in the bone extracellular matrix. Significance: This study establishes Raman spectroscopy as a tool for identifying and characterizing human collagens, aiding in the diagnosis of connective tissue disorders. The creation of a spectral reference library for pure human collagen types I - VI holds potential for medical diagnostics, analytical chemistry, and materials science applications.

function; mammalian dna; dnmt3a; methylation; expression; deletion; gene
AB DNA methylation, catalyzed by DNA methyltransferases (DNMT), plays pivotal role in regulating embryonic development, gene expression, adaption to environmental stress, and maintaining genome integrity. DNMT family consists of DNMT1, DNMT3A, DNMT3B, and the enzymatically inactive DNMT3L. DNMT3A and DNMT3B establish novel methylation patterns maintained by DNMT1 during replication. Genetic variants of DNMT3A and DNMT3B cause rare diseases such as Tatton-Brown-Rahman and ICF syndromes. Additionally, somatic mutations cause common conditions such as osteoarthritis, osteoporosis, clonal hematopoiesis of indeterminate potential (CHIP), hematologic malignancies, and cancer. While DNMTs have been extensively studied in vitro, in early development and in disease, their detailed physiologic roles remain less understood as in vivo investigations are hindered by the embryonic or perinatal lethality of the knockout mice. To circumvent this problem, tissue-specific Dnmt3a and Dnmt3b knockouts were engineered. This review explores their diverse molecular roles across various organs and cell types and characterizes the phenotype of the knockout mice. We provide a comprehensive collection of over forty tissue-specific knockout models generated by cre recombinase. We highlight the distinct functions of DNMT3A and DNMT3B in germ cells, early development, uterus, hematopoietic differentiation, musculoskeletal development, visceral organs, and nervous system. Our findings indicate that DNMT3A primarily regulates hematopoietic differentiation, while DNMT3B is crucial for cartilage homeostasis and ossification. We emphasize the context-dependent roles of DNMT3A and DNMT3B and demonstrate that they also complement DNMT1 maintenance methyltransferase activity. Overall, the expression patterns of DNMTs across tissues provide insights into potential therapeutic applications for treating neurologic diseases, cancer, and osteoporosis.

ID bd odon device(tm); fetal head; birth; lacerations; protection; risk
AB Objectives: The aim of this study was to analyse influence of the fetal head position and the type of instrument used (forceps, vacuum, OdonAssist (TM)) on perineal deformation, during simulated vaginal deliveries monitored by stereophotogrammetry. Methods: An exploratory study was conducted using mannequins simulating vaginal births. Fifty simulated deliveries were performed with different fetal head positions and instruments: Pajot's forceps, Kiwi-vacuum, and OdonAssist (TM). Stereophotogrammetry measured perineal deformations called equivalent strains E-eq. Results: E-eq during spontaneous deliveries were minimal, average, and maximal at 0.8 %, 5.8 %, and 11.6 %, respectively. Assisted vaginal births (AVB) showed slightly higher strains compared to spontaneous deliveries. In the occipito-posterior position (OP), strains were significantly higher ($p < 0.05$). Equivalent strain Eeq trend towards higher mean (6.7 f 0.6 %) and maximum (12.3 f 0.8 %) with forceps compared to other methods in the occiput anterior position (OA), especially against spontaneous (mean: 5.3 f 0.5 % and max: 9.9 f 0.6; $p = 0.06$), vacuum AVB (mean: 4.6 f 1.0 % and max: 9.4 f 0.1 %, $p = 0.06$) and OdonAssistTM AVB (mean: 3.8 f 0.9 % and max: 8.8 f 1.0 %, $p = 0.06$). Forceps induced greater strains compared to vacuum and OdonAssits (TM). In OP position, OdonAssistTM tend to lower mean equivalent strain Eeq compared to spontaneous vaginal deliveries (4.9 f 0.6 % vs 6.4 f 0.5 %, $p = 0.06$). Conclusion: Results confirmed increased mechanical perineal stress for OP fetal position and for forceps assisted deliveries compared to others devices. The OdonAssistTM may offer a less invasive alternative, reducing perineal strains. Stereophotogrammetry provides valuable data on the mechanical effects of childbirth.

TI The role of TRIM proteins in chronic inflammation-associated musculoskeletal diseases
SO AGEING RESEARCH REVIEWS
LA English
DT Review
DE TRIM proteins; Chronic inflammation; Musculoskeletal disorders
ID nf-kappa-b; drug-delivery systems; innate immune; artificial-intelligence; tnf-alpha; ubiquitin; degradation; osteoarthritis; cells; activation
AB Musculoskeletal disorders (MSDs), including osteoarthritis (OA), rheumatoid arthritis (RA), osteoporosis (OP), and intervertebral disc degenerative disease (IVDD), are among the most common and serious health problems worldwide. However, despite extensive research, drug therapy for these diseases remains a major challenge. This is likely due to a poor understanding of the underlying mechanisms. Recent evidence suggests that the development of these MSDs is associated with protein dysregulation and ongoing chronic inflammation. Protein turnover is controlled by the ubiquitin-proteasome system (UPS), in which E3 ubiquitin ligases, including tripartite motif proteins (TRIMs), are responsible for substrate specificity. Since multiple TRIMs are involved in the development of MSDs, their targeting may be used to correct impaired protein turnover. The recent development of targeted protein degradation technologies has revolutionized drug discovery by selectively degrading specific proteins using the UPS. It is hypothesized that failure to resolve chronic inflammation plays a critical role in the development of MSDs, suggesting that its successful resolution will result in the alleviation of MSD-related symptoms. The process of inflammation resolution is enabled by specialized pro-resolving mediators (SPMs), which are enzymatically generated from dietary essential polyunsaturated fatty acids. Supplementation with SPMs or their stable, small-molecule receptor mimetics and agonists has shown beneficial effects in MSD animal models. In this review, we substantiate the idea that the combined use of TRIM-targeting drugs and inflammation-resolving compounds represents a promising new therapeutic approach to mitigate OA, RA, OP, and IVDD manifestations and improve patient outcomes. Methods: Aligning with the primary objectives of this review, we used a narrative-style review design to explore and critically analyze the potential links between TRIMs, chronic inflammation, and musculoskeletal disorders. Articles included in this review were identified through literature searches using PubMed (English-language original and review articles published until May 2025). The following search terms were used considering all possible combinations: "TRIM proteins", "ubiquitin proteasome system", "ubiquitin ligases", "targeted protein degradation", "proteolytic targeting chimeras", "molecular glues", "musculoskeletal disorders", "osteoarthritis", "rheumatoid arthritis", "osteoporosis", "intervertebral disc degenerative disease", "chronic inflammation", "inflammation resolution", "specialized pro-resolving mediators". Search results were supplemented by reviewing reference citations from the articles identified in the initial searches and drawing on the authors' familiarity with the published literature.

TI Porous PLGA microspheres loaded with PTH1-34 peptide for long-term treatment of OA
SO JOURNAL OF ORTHOPAEDIC TRANSLATION
LA English
DT Article
DE Osteoarthritis; PTH1-34; Porous PLGA microspheres; Sustained release; Cartilage repair
ID osteoarthritis; teriparatide; diagnosis; osteoporosis; degradation; women
AB Background: Osteoarthritis (OA) is a chronic disease characterized by degeneration of articular cartilage, affecting over 530 million patients worldwide. Current oral medications such as non-steroidal anti-inflammatory drugs (NSAIDs) can only alleviate symptoms and are associated with numerous adverse effects. Although teriparatide (PTH1-34) exhibits dual functions of chondroprotection and osteogenic effects, its clinical application is significantly limited by its short biological half-life (30-60 min) and accelerated degradation within the inflammatory microenvironment of joint cavities. Methods: Porous sustained-release microspheres (M@PTH1-34) were fabricated using FDA-approved poly (lactic-co-glycolic acid) (PLGA) as the matrix, encapsulating PTH1-34 within their multi-channel porous structure. Uniform microsphere preparation and high-efficiency drug loading were achieved through membrane emulsification and temperature-controlled embedding techniques. To systematically evaluate the sustained-release profile and therapeutic outcomes, both in vitro and in vivo OA models were established, enabling comprehensive analysis of cartilage repair efficacy, anti-inflammatory regulation, and immunomodulatory effects. Results: PTH1-34 could be efficiently loaded into microspheres after self-healing and achieve consistent release over 30 days with biological activity being maintained. In OA model rats, M@PTH1-34 significantly improved behavioral and radiological outcomes, increased cartilage smoothness and thickness, and increased the expression of chondrogenic markers. Additionally, in vitro and in vivo safety tests revealed no significant safety issues. These findings indicate that M@PTH1-34 holds promise as a long-lasting, cost-effective, and safe therapeutic approach for OA. Conclusion: This study successfully developed a uniform-sized PLGA-based sustained-release microsphere system (M@PTH1-34) that enables continuous drug release for over 30 days following single intra-articular administration. M@PTH1-34

exerts its therapeutic effects on osteoarthritis through the following two ways: (1) Promoting cartilage repair by enhancing the chondrogenic differentiation ability of bone marrow mesenchymal stem cells (BMSCs); (2) Improve the inflammatory microenvironment of joints by inhibiting the expression of inflammatory factors (such as IL-1 beta) and regulating the polarization state of M1/M2 macrophages. The translation potential of this article: The system demonstrates prominent clinical translation advantages: (1) Innovative utilization of FDA-approved PLGA carrier combined with membrane emulsification technique ensures precise size control and standardized production; (2) Localized delivery strategy achieves targeted retention within articular cavity, validated by animal studies showing no systemic exposure risks; (3) Standardized preparation process demonstrates the feasibility of industrial-scale production.

TI Botany, traditional uses, phytochemistry, pharmacology, processing, and applications of Cibotium barometz (L.) J. Sm.: A review
SO FITOTERAPIA
LA English
DT Review
DE Traditional uses; Phytochemistry; Pharmacology; Processing; Applications; Cibotium barometz (L.) J. Sm
ID osteoporosis; polysaccharides; proliferation; glioblastoma; metabolism; extracts; rhizome; cells
AB Cibotium barometz (L.) J. Sm. (C. barometz), an ancient fern has a long history as a natural medicine in China, India, Vietnam, and other countries. In the traditional medical system, it is often used to treat bone pain, urinary system diseases, reproductive disorders, and so on. This paper aims to provide a comprehensive overview of current research on botany, traditional uses, phytochemistry, pharmacology, processing, and applications of C. barometz. In addition, resource conservation, quality control, and perspectives for future research on C. barometz are also discussed. Recent phytochemical studies of C. barometz have shown that over 100 compounds have been isolated from the plant, including phenylpropanoids, polyphenols, flavonoids, terpenoids, steroids, polysaccharides, and other compounds. Modern pharmacological studies have also confirmed that C. barometz has anti-osteoporosis activity, anti-microorganism activity, anti-osteoarthritis activity, anti-cancer activity, hepatoprotective activity, protective activity on muscle, alleviating Alzheimer's disease, and so on. As an important means of preclinical application, the type and content of the components contained in C. barometz changed significantly before and after processing, and the strength of its pharmacological activity also changed. Furthermore, it has many applications in the fields of compound preparations and biomedicine, which have great development potential. Nevertheless, there are also some research gaps in C. barometz. This review appeals for more studies on C. barometz to better understand its pharmacological mechanism and active substance basis. Besides, more research on resource conservation and quality control is also necessary to ensure its sustainable use and development.

DT Review
DE Epigenetics; Histone modifications; Degenerative skeletal diseases; Small molecule inhibitors; Epigenetic therapy
ID intervertebral disc degeneration; inhibitor vorinostat saha; deacetylase inhibitor; gene-expression; bone-marrow; lysine 2-hydroxyisobutyrylation; osteogenic differentiation; clinical pharmacokinetics; metabolic-regulation; chromatin-structure
AB Degenerative skeletal diseases, including osteoporosis, osteoarthritis, and intervertebral disc degeneration, are prevalent age-related conditions characterized by progressive tissue degeneration and functional decline. Histone modifications are covalent modifications of histone residues, catalyzed by specific enzymes, that modulate chromatin architecture and transcriptional activity. Accumulating evidence highlights the critical involvement of histone modifications in orchestrating disease-associated transcriptional programs. In osteoporosis, histone modifications regulate osteoblast and osteoclast differentiation, thereby disrupting bone homeostasis. In osteoarthritis, they drive the expression of matrix-degrading enzymes in chondrocytes, contributing to cartilage degradation. In intervertebral disc degeneration, they are implicated in nucleus pulposus cell senescence, apoptosis, and extracellular matrix degradation. This review summarizes the distinct mechanistic roles of histone modifications across these conditions and explores the therapeutic potential of targeting histone-modifying enzymes, underscoring epigenetic regulation as a promising strategy for precision intervention in degenerative skeletal diseases. The translational potential of this article: This review comprehensively explores the role of histone modifications in degenerative skeletal diseases and evaluates the potential of histone-modifying enzyme inhibitors as therapeutic targets. These insights provide new strategies and directions for the treatment of degenerative skeletal diseases.

DT Review
DE Bone remodelling; Bone resorption; Bone formation; Histone demethylases; Osteoporosis; Osteoarthritis; Osteosarcoma
ID mesenchymal stem-cells; osteogenic differentiation; domain; osteosarcoma; hypertrophy; adipocyte; therapy; protein; target; growth
AB Histone lysine demethylases (KDMs), as important epigenetic regulators, are involved in various biological processes such as energy metabolism, apoptosis, and autophagy. Recent research shows that KDMs activate or silence downstream target genes by removing lysine residues from histone tails, and participate in the regulation of bone marrow mesenchymal stem cells (BM-MSCs), osteoblasts (OB), osteoclasts (OC), chondrocytes and other skeletal cell development, differentiation and formation. Moreover, several members of the KDM family affect the occurrence and development of bone diseases such as osteoporosis (OP), osteoarthritis (OA), osteosarcoma (OS), by regulating target genes. Specific regulation mechanisms of KDMs suggest new strategies for bone disease treatment and prevention. Despite the unique function and importance of KDMs in the skeletal system, previous studies have never systematically summarized their specific role, molecular mechanism, and clinical treatment in bone physiology and

pathology. Therefore, this review summarises the expression pattern, intracellular signal transduction, and mechanism of action of the KDM family in several bone physiological and pathological conditions, aiming to highlight the important role of KDMs in bone diseases and provide a reference for the future treatment of bone diseases.

TI The role of LGR4 in bone metabolism and tumor bone metastasis
SO FRONTIERS IN ENDOCRINOLOGY
LA English
DT Review
DE LGR4; bone metabolism; bone metastasis; osteoclasts; osteoblasts
ID molecular-mechanisms; multiple-myeloma; cancer; differentiation; expression; receptor; cells; disease; gpr48; gene
AB The Leucine-rich repeat-containing G protein-coupled receptor 4 (LGR4) is a member of the G protein-coupled receptor family and plays an important role in bone metabolism and tumor bone metastasis. LGR4 affects bone metabolism by regulating the differentiation and activity of osteoblasts and osteoclasts, and is involved in the balance between bone resorption and bone formation. Deficiency of LGR4 leads to osteoporosis, whereas the up-regulation of LGR4 may help to alleviate the development of traumatic osteoarthritis. Furthermore, in breast cancer and multiple myeloma, LGR4 promotes tumor cell metastasis to bone tissue by activating related signaling pathways. Therefore, LGR4 may be a potential target for the treatment of bone metabolic diseases and tumor bone metastasis.

TI Cumulative Burden of Digital Health Technologies for Patients With Multimorbidity: A Systematic Review
SO JAMA NETWORK OPEN
LA English
DT Article
ID care
AB Importance: Digital health technologies (DHTs) aiming to monitor, treat, and manage diseases can be prescribed for patients with multimorbidity; yet most DHTs are designed for individual conditions or problems, while approximately half of patients with chronic conditions have multiple chronic conditions. Objectives: To identify DHTs approved by the US Food and Drug Administration (FDA) or listed in the Organisation for the Review of Care and Health Apps (ORCHA) library and prescribable for a hypothetical patient with 5 conditions and to model the number of DHTs this patient should be prescribed to receive benefits health professionals considered important. Evidence review: The FDA databases (Premarket Notification 510(k), Premarket Approval, and De Novo) and the ORCHA App Library from National Health Service Somerset were systematically searched for DHTs registered or updated between January 1, 2019, and December 31, 2022, that could be prescribed to a hypothetical woman with 5 chronic conditions (type 2 diabetes, hypertension, chronic obstructive pulmonary disease, osteoporosis, and osteoarthritis). After abstracting each DHT's elementary functions (ie, simple and delineated features to monitor, treat, and/or manage conditions), an assessment was undertaken to determine the fewest DHTs this hypothetical patient should be prescribed to receive benefit from digital functions health professionals considered important. Findings: A total of 148 DHTs were identified (68 [46%] from FDA databases), of which 96 (65%) involved devices and 52 (35%) were standalone health apps. Only 5 DHTs (3.4%) were intended for 2 or more conditions. DHTs offered 140 elementary functions, ranging from recording, tracking, or visualizing health parameters to providing information to digital therapeutics with just-in-time interventions. The hypothetical patient would need to be prescribed up to 13 apps and 7 devices (a blood pressure monitor, a smartwatch, a pulse oximeter, a connected weight scale, a sensor-attached inhaler to monitor adherence, a lung function monitor, and a blood glucose sensor) to receive benefits from 28 functions at least 3 of 5 health professionals considered important. Conclusions and relevance: This systematic review found that almost all prescribable DHTs were developed for a single condition or problem. Thus, patients with multiple chronic conditions would have to routinize many DHTs concurrently in daily life to benefit from digital functions health professionals considered important.

TI Antioxidative fullerol prevents bone loss due to its anti-osteoclastogenic and pro-osteogenic activities
SO NANOMEDICINE-NANOTECHNOLOGY BIOLOGY AND MEDICINE
LA English
DT Article
DE Fullerene derivative; Signal pathways; Osteoclast formation; Osteogenesis; Osteoporosis
ID oxidative stress; redox regulation; differentiation; osteoporosis; osteoarthritis; adipogenesis; activation; mechanisms; cells; foxo1
AB Purpose: Previous studies have demonstrated a role for oxidative stress in promoting osteoclastogenesis and bone loss. This study aimed to assess the ability of fullerol, a powerful nano-antioxidant, to prevent bone loss and promote osteogenesis, and additionally provide novel insight into mechanisms of action. Methods: Osteoclastogenesis assays were conducted in murine progenitor cells stimulated with receptor activator of nuclear factor kappa-B ligand (RANKL), with and without fullerol. The cells were stained to detect the presence of osteoclastic markers and RT-PCR was used to measure the expression of osteoclastic genes. To assess osteogenesis, stem cells were incubated in osteogenic medium with or without fullerol, as well as with an inhibitor of p38-MAPK, then stained to determine mineralization. RT-PCR was used to measure osteoblastic gene expression. In the animal model, rabbits were injected with methylprednisolone with or without fullerol, or a control. Animals were later euthanized and spine fragments underwent imaging assessment. Results: Fullerol prevented formation of osteoclasts in RAW264.7 cells exposed to RANKL as well as the expression of osteoclastic genes TRAP, CATK, and MMP9. D1 cells exposed to fullerol displayed an increase in extracellular matrix mineralization and expression of osteoblastic genes. However, when fullerol was added in the presence of a p38-MAPK inhibitor, its effects on mineralization were attenuated. In a rabbit model of steroid-induced osteoporosis, simultaneous injection of fullerol reduced vertebral bone loss, decreased trabecular separation, and increased trabecular number. Conclusion: Fullerol shows early potential for use in osteoporosis therapy, due to its ability to inhibit osteoclast formation and stimulate osteogenesis.

TI Advances in 3D bioprinting to enhance translational applications in bone tissue engineering and regenerative medicine
SO HISTOLOGY AND HISTOPATHOLOGY
LA English
DT Review
DE 3D bioprinting; Bioink; TERM; Bone; Biomaterials; Hydrogel
ID cell; limitations; challenges; cellulose; glycol)
AB . Bone defects are due to trauma, infections, tumors, or aging, including bone fractures, bone metastases, osteoporosis, or osteoarthritis. The global burden of these demands research into innovative strategies that overcome the limitations of conventional autografts. In this sense, the development of threedimensional (3D) bioprinting has emerged as a promising approach in the field of tissue engineering and regenerative medicine (TERM) for the on-demand generation and transplantation of tissues and organs, including bone. It combines biological materials and living cells, which are precisely positioned layer by layer. Despite obtaining some promising results, 3D bioprinting of bone tissue still faces several challenges, such as generating an effective vascular network to increase tissue viability. In this review, we aim to collect the main knowledge on methods and techniques of 3D bioprinting. Then, we will review the main biomaterials, their composition, and the rationale for their application in 3D bioprinting for the TERM of bone.

TI The Outcome of Post-Surgical Hip Prosthesis Rehabilitation: Results from a Monocentric Cohort Study

DE outcome; orthopedic rehabilitation; hip prothesis; post-surgical
ID total joint arthroplasty; total knee arthroplasty; body-mass-index; quality-of-life; screening tools; united-states; risk-factors; obesity; replacement; osteoarthritis
AB Background: With the increase in life expectancy, more patients are undergoing total hip arthroplasty, primarily due to the rising incidence of osteoarthritis. The outcomes of rehabilitation following these surgical interventions are influenced by various factors. This study aims to explore the impact of age, gender, and body mass index (BMI) on pain and functional and rehabilitative outcomes after surgical hip prosthesis rehabilitation. Methods: We enrolled all patients admitted to a private clinic from January 2021 to December 2023 for rehabilitation after unilateral hip arthroplasty. For each patient, we collected data of Barthel Index, Tinetti Scale, Numeric Rating Scale (NRS), and range of motion (ROM) at the beginning and end of the hospitalization. We assessed whether the evaluated outcomes differed based on gender, age, and BMI using the Mann-Whitney and Kruskal-Wallis tests. Results: A total of 2.167 patients were studied (56% female and 36.5% over 75 years old). Male patients, adults (18-64 years), and those with a BMI < 30 showed higher values of Barthel Index, Tinetti Scale, and ROM at both admission and discharge ($p < 0.05$), along with significantly lower NRS scores. Each subgroup based on age, gender, and BMI showed an improvement in NRS (difference between admission and discharge) of at least 40%, it was about 50% for men and adults. The improvement in ROM (difference between admission and discharge) was more than 10% in both active and passive flexion, around 20% for passive abduction, and 50% for active abduction, with no significant differences based on age, gender, or BMI. Conclusions: Despite the absence of specific contraindications for arthroplasty procedures, a high BMI, age over 75 years, and female gender are associated with slightly worse functional and rehabilitation outcomes compared to other patients undergoing the same procedures. A preoperative screening for the evaluation of osteopenia, osteoporosis, and BMI could be a valuable tool for studying and improving outcomes in these patients.

DT Article
DE Osteoporotic Osteoarthritis; Jiawei Yanghe Decoction; Mesenchymal stem cell; Bone formation; Cell migration
ID subchondral bone; articular-cartilage; degeneration; inhibition; increases; migration; severity; model; axis
AB Background: Osteoporotic osteoarthritis (OPOA), a distinct subtype of osteoarthritis (OA), has imposed a significant health and economic burden

worldwide. However, mechanistic studies and therapeutic strategies for this disease remain in the exploratory stage. Purpose: This study aimed to investigate the specific molecular mechanisms by which osteoporosis (OP) exacerbates OA progression through accelerated subchondral bone (SB) sclerosis and the potential of Jiawei Yanghe Decoction (JWYHD) in treating OPOA. Methods: Key genes in the progression of OPOA were investigated through human clinical sample studies, GEO database analysis, and RNA-seq. The OPOA mouse model was established by a combination of OVX and DMM, with JWYHD administered at different concentrations. In vivo, the pathological status of OPOA and the therapeutic effects of JWYHD were evaluated using behavioral tests, micro-CT, and histopathological examinations. In vitro, the osteogenic differentiation and migration capabilities of mesenchymal stem cells (MSC) were assessed by WB, qRT-PCR, Transwell assays, wound healing assays, and IF co-staining. Results: ITGB6/TGF-(3 plays a vital role in the pathogenesis of OPOA. A novel concept, the 'Diaphysis-Epiphysis paradox', is hereby proposed, providing a new theoretical framework for research into the pathomechanisms of OPOA from the perspective of abnormal bone mass distribution. By protecting cartilage, regulating the balance of bone mass, and modulating the migration of MSC, JWYHD improves cartilage degeneration and bone mass distribution abnormalities caused by OPOA in an all-around manner. Conclusion: Abnormal migration and osteogenic differentiation disorders of MSC accelerate OPOA progression. JWYHD achieved bidirectional regulation of OPOA through ITGB6/TGF-(3/(3-catenin and CXCL12/CXCR4 multiple signaling pathways.

TI Immunometabolic regulation of disulfidptosis in orthopedic diseases: mechanistic heterogeneity and therapeutic targets
SO FRONTIERS IN IMMUNOLOGY
LA English
DT Review
DE disulfidptosis; bone diseases; oxidative stress; immunometabolism; targeted therapy
ID osteoarthritis; apoptosis
AB Disulfidptosis is a novel form of programmed cell death triggered by cystine metabolic disorders and disulfide stress, initially studied primarily in the context of tumors. In recent years, its role in the occurrence and development of orthopedic diseases has gained increasing attention. This review systematically explores the dual regulatory mechanisms of disulfidptosis in degenerative orthopedic diseases, such as intervertebral disc degeneration, osteoporosis, and osteoarthritis, as well as in malignant bone tumors like osteosarcoma, along with their immunometabolic basis. The research findings indicate that in degenerative lesions, microenvironmental stresses such as ischemia and hypoxia exacerbate tissue degeneration by promoting abnormal accumulation of disulfide bonds and damaging the cytoskeleton. In osteosarcoma, tumor-associated oxidative stress can induce metabolism-dependent cell death, providing new opportunities for targeted therapy. The article further summarizes key signaling pathways and molecular

regulatory networks, discussing the potential value of targeted intervention strategies in slowing disease progression and achieving precision treatment.

TI Proximal Tibia Fractures in Osteoporosis
SO INDIAN JOURNAL OF ORTHOPAEDICS
LA English
DT Review
DE Osteoporosis; Proximal tibia; ORIF; Osteoarthritis; Elderly
ID total knee arthroplasty; plateau fractures; internal-fixation; condylar fractures; surgical-treatment; trabecular bone; risk-factors; infection; microstructure; complications

AB BackgroundTibial plateau fractures are frequently observed in elderly patients, often resulting from low-energy trauma. The treatment of tibial plateau fractures in this population is further complicated by factors such as osteoporosis, osteoarthritis, and other medical comorbidities.ObjectiveThis article provides a comprehensive review of the different treatment strategies for proximal tibial fractures in the elderly. A variety of internal and external fixation techniques, medical management as well as acute arthroplasty, are discussed as potential approaches for achieving optimal reconstruction and functional recovery.What is already knownExisting literature emphasizes that osteoporotic bones, characterized by reduced bone density and compromised structural integrity, pose significant challenges to fracture fixation. These factors often diminish the efficacy of fixation devices in proximal tibial fractures, leading to an increased likelihood of fixation failure.Gap in literatureWhile the high failure rates associated with osteoporotic bone fixation are wellrecognized, there is a notable lack of comprehensive studies that integrate biomechanical, biological, and technological advancements to improve fixation outcomes, in proximal tibial fractures. This article aims to address this gap by reviewing current diagnostic approaches and exploring innovative strategies involving advanced materials and regenerative technologies designed to enhance fixation success.ConclusionThe management of proximal tibial fractures in the elderly requires a nuanced approach that integrates surgical intervention with medical management. A tailored treatment plan, based on specific fracture characteristics and overall health, is critical to optimizing postoperative functional outcomes. This article emphasizes the importance of a comprehensive, individualized treatment strategy to improve recovery and quality of life for elderly patients suffering from tibial plateau fractures.

TI 3D-printed β-TCP/curcumin scaffolds as a local drug delivery system for bone tissue regeneration
SO BIOMEDICAL MATERIALS
LA English
DT Article
DE scaffolds; <italic>beta</italic>-tricalcium phosphate; curcumin; 3D printing; tissue engineering
ID in-vitro; curcumin; microstructure; complexes; silicate; release
AB The growing clinical need for filling defects and bone voids has led to the development of scaffolds that stimulate bone regeneration and serve as temporary models for vascularised bone growth. Additionally, these scaffolds can function as drug delivery systems to reduce inflammatory processes associated with diseases such as osteoarthritis, rheumatoid arthritis, osteoporosis, and bone cancer. Among the materials used to manufacture scaffolds, beta-tricalcium phosphate (beta-TCP, Ca3(PO4)2) stands out due to its excellent biocompatibility and chemical composition, closely resembling minerals from bone tissue. When combined with curcumin, calcium phosphate scaffolds offer a promising platform for drug delivery, as their tailored porous structure can provide controlled release. Curcumin enhances anti-inflammatory and antioxidant properties, thereby promoting tissue

regeneration. In this study, beta-TCP powders loaded with 5 and 10 mg ml-1 of curcumin (designated as beta-TCP/Curc 5 and beta-TCP/Curc 10) were successfully obtained via freeze-drying and characterised using x-ray diffraction and Fourier-transform infrared spectroscopy to assess their crystallinity and chemical composition. The beta-TCP/Curc powders were evaluated for their ability to load and release curcumin. Subsequently, beta-TCP and beta-TCP/Curc 5 scaffolds were prepared using 3D printing. The beta-TCP/Curc 5 scaffolds were assessed for curcumin release, cytotoxicity profile, and antimicrobial activity. The beta-TCP/Curc 5 powders exhibited significantly higher curcumin adsorption and good release capacity, whereas the beta-TCP/Curc 10 powders displayed reduced curcumin loading and limited release efficiency. The combination of beta-TCP/Curc 5 with sodium alginate produced a suitable paste for 3D printing scaffold fabrication, and the beta-TCP/Curc 5 scaffolds demonstrated high similarity to the computational model. Importantly, the beta-TCP scaffolds did not exhibit cytotoxicity in the MC3T3-E1 cell line, and after curcumin loading, there was no increase in cellular cytotoxicity observed. In fact, an increase in cell viability was noted compared to the control after three days of indirect assays, suggesting that this combination may be beneficial for promoting cell growth. However, the scaffolds did not show any antibacterial effects against S. aureus and E. coli under the tested conditions. This study demonstrates that adequate curcumin loading in 3D-printed beta-TCP scaffolds can facilitate curcumin release at the bone healing site, potentially influencing the cellular processes involved in bone regeneration and remodelling.

TI Musculoskeletal disease in acromegaly-a population-based registry study
SO EUROPEAN JOURNAL OF ENDOCRINOLOGY
LA English

DT Article
DE acromegaly; musculoskeletal disease; osteoarthritis; osteoporosis; joint replacement surgery
ID quality-of-life; vertebral fractures; arthropathy; progression; prevalence; patient
AB Objective Acromegaly is associated with multiple musculoskeletal complications that affect the quality of life and work ability. We aimed to examine the risk of osteoarthritis, musculoskeletal surgery (including joint replacement), osteoporosis, fractures, and analgesic consumption in Danish acromegaly patients.Design National, registry-based cohort study.Methods All validated incidents and prevalent cases of acromegaly in the period 1977-2021 (n = 844) were included and matched 1:100 with healthy controls. Outcomes were identified using diagnosis, surgical procedure, and medication codes and analyzed using Cox regression and Kaplan-Meier plots.Results Patients were at significantly increased risk of osteoarthritis of the shoulder [hazard ratio (HR): 5.25 (3.05; 9.06)], hip [HR: 3.15 (2.57; 3.87)], and knee [HR: 2.25 (1.85; 2.72)], and medically treated osteoporosis [HR: 2.13 (1.64; 2.78)] even before acromegaly diagnosis. The risk of joint replacement surgery of the shoulder [HR: 4.60 (2.57; 8.25)], hip [HR: 3.32 (2.67; 4.12)], and knee [HR: 2.52 (1.89; 3.36)] was increased in acromegaly patients, as was the risk of being prescribed weak analgesics [HR: 1.22 (1.04; 1.44)] or opioids [HR: 1.58 (1.38; 1.82)]. Surgical complications [HR: 2.19 (1.59; 3.03)] and repeat hip surgery [HR: 3.64 (2.09; 6.34)] also exhibited increased risk in patients.Conclusion In acromegaly, severe osteoarthritis involving multiple joints develops even before acromegaly diagnosis and continues to progress over time after acromegaly treatment. Furthermore, acromegaly imposes an increased risk of medically treated osteoporosis, musculoskeletal surgery-particularly joint replacement surgery-, surgical complications, and the necessity of analgesic medication. Our findings warrant further research into the management of musculoskeletal disease in acromegaly.

TI Diameter Control and Optical Properties of CsPbBr3 Nanowires Based on the Oleylamine-Octylamine System
SO JOURNAL OF PHYSICAL CHEMISTRY C
LA English
DT Article
ID halide; size; shape
AB Metal halide perovskites (MHPs) have emerged as prominent materials in optoelectronics due to their exceptional photoelectric conversion efficiency and tunable band structures. Traditional perovskite nanocrystal synthesis systems often employ oleic acid (OA) to accelerate the crystallization kinetics, which inadvertently hinders nanowire growth and morphology control. In this study, we adopted a dual-ligand system using oleylamine (OAm) and octylamine (OctAm) without preadding OA. By postinjecting a cesium oleate solution, we achieved precise control over Pb2+ ion release, enabling the controllable synthesis of cesium lead halide (CsPbBr3) nanowires (NWs) across 100-160 degrees C. This strategy yielded micrometer-scale NWs with tunable diameters (8.3-12.6 nm) and lengths reaching the microscale. Temperature-dependent optical studies revealed that elevated synthesis temperatures weakened quantum confinement effects, leading to systematic red-shifts in ultraviolet-visible (UV-vis) absorption (505-507 nm) and photoluminescence (PL) emission (516-518 nm) peaks. Concurrently, time-resolved PL measurements revealed a significant enhancement in carrier lifetime (24.72-91.99 ns), reflecting reduced nonradiative recombination pathways. Variable-temperature PL spectroscopy (80-300 K) demonstrates that CsPbBr3 NWs synthesized at 140 degrees C exhibit higher exciton binding energy (E b = 44.7 meV) and enhanced exciton-phonon coupling strength (Gamma OP = 46.48 meV) compared to samples prepared at 120 degrees C. These findings demonstrate that

high-temperature synthesis confers superior thermal stability on CsPbBr3 NWs. Our work not only clarifies the critical role of amine ligands in modulating NW growth dynamics but also provides a robust framework for designing stable, high-performance, one-dimensional perovskite optoelectronic materials.

ID knee osteoarthritis; muscle mass; pain; management; sarcopenia; fracture; people; impact; injury; drugs
AB The prevalence of musculoskeletal diseases such as osteoarthritis, osteoporosis, sarcopenia, and rheumatoid arthritis is rising sharply with global ageing, increasing disability rates among older adults (aged >= 60 years), diminishing quality of life, and burdening health-care systems. Current musculoskeletal care for older adults faces multiple limitations, including comorbidities, frailty, and fragmented care. High osteoarthritis prevalence in individuals older than 55 years, the mounting

economic burden of osteoporotic fractures, the growing concern of muscle mass decline, and insufficient guideline implementation collectively underscore these challenges. In the USA, musculoskeletal diseases affect over 121 million people and account for the highest rate of disability among all disease groups, underscoring the need for targeted strategies. Although promising solutions encompassing advanced pharmacological therapies, regenerative medicine, and digital health technologies (including artificial intelligence) are available, they remain underutilised in existing care models. This Personal View discusses the need for personalised, multidisciplinary approaches to address these issues, advocating for collaboration among the orthopaedic, geriatric, and health-care sectors in the USA. We propose that prevention of musculoskeletal diseases is key to its effective management in ageing populations, alongside a holistic, scalable approach that integrates diagnostics, therapy, and telemedicine. Early intervention, interdisciplinary collaboration, and personalised care are essential to improving patient outcomes and addressing the growing musculoskeletal disease burden in the USA.

DT Article
DE cortical bone trajectory screw; 3D-printing navigation molds; free-hand isthmus method; lumbar internal fixation surgery; retrospective study
ID pedicle screw; biomechanical evaluation; part i; insertion; fixation; strength; spine; template; fusion; osteoarthritis
AB Objectives: Traditional cortical bone trajectory (CBT) screws in the lumbar spine offer greater holding strength and are well-suited for patients with osteoporosis. However, the screw implantation procedure is challenging and associated with significant risk. This study aimed to assess whether individualized 3D-printing navigation technology provides higher accuracy and better clinical outcomes compared to the free-hand isthmus method for lumbar CBT screw implantation. Methods: From September 2020 to August 2023, a total of 41 patients who underwent CBT screw surgery were retrospectively collected. Among them, 23 patients underwent the free-hand isthmus method (Group A), while 18 patients underwent the individualized 3D-printing navigation technique (Group B). All imaging and clinical data for these patients were collected in a blinded manner. Results: During the surgery, 185 CBT screws were implanted into the lumbar spines of 41 patients-78 in Group A and 107 in Group B. After the surgery, the majority of implanted screws (86.5%) were classified as grade 0, indicating satisfactory implantation. Compared to Group A, Group B had fewer screws classified as grade 1 or grade 2 ($p = 0.045$), indicating higher accuracy in screw implantation. Additionally, Group B also had a shorter operation duration ($p = 0.02$), fewer fluoroscopy exposures ($p < 0.01$), and less blood loss ($p = 0.03$). In addition, compared to Group A, individuals in Group B showed significant improvement in back pain symptoms at both 3 and 6 months ($p = 0.01$ and <0.01), as well as in physical activity at 3 months ($p = 0.02$) postoperatively. No significant difference in postoperative complications was observed between the two groups. Conclusion: Compared to the free-hand isthmus method, lumbar CBT screw implantation with individualized 3D-printing navigation technology shows higher accuracy, shorter operative time, reduced intraoperative fluoroscopy and blood loss, and better clinical outcomes at three months post-surgery.

TI Is physical activity in polluted environments beneficial or detrimental to osteoporosis and osteoarthritis? A prospective cohort study
SO INTERNATIONAL JOURNAL OF SURGERY
LA English
DT Article
DE environmental pollutants; osteoarthritis; osteoporosis; physical activity
ID air-pollution; health; exercise; europe
AB Background:Although physical activity and environmental pollutants may influence the risk of osteoporosis and osteoarthritis, their combined effects remain poorly understood. Therefore, we aimed to evaluate the independent associations of environmental pollutants and physical activity with these risks and to explore their interaction.Methods:We conducted a prospective cohort study of 400949 UK Biobank participants. Environmental pollutants comprised particulate matter (PM2.5, PM10, and PM2.5-10), nitrogen oxides (NOx, NO2, and NO), air pollutant score, and 24-hour noise. Physical activity was classified by intensity (low, moderate, and high) and by type [walking for pleasure, strenuous sports, light DIY (do it yourself) heavy DIY and other sports]. We used multivariable Cox models to estimate the independent associations of each exposure with disease risk. Interaction analyses between pollutants and physical activity were then performed on both the additive scale (relative excess risk due to interaction) and the multiplicative scale (interaction term P value).Results:During follow-up, 9667 and 46 782 participants developed osteoporosis and osteoarthritis, respectively. Air

pollutants were generally associated with an increased risk of osteoporosis and osteoarthritis. Physical activity (regardless of intensity and type) reduced osteoporosis risk, while a high level of physical activity increased osteoarthritis risk. Additionally, strenuous sports increased osteoarthritis risk, while walking for pleasure decreased it. Under most conditions, we observed neither additive nor multiplicative interaction between pollutants and physical activity.Conclusions:Caution is warranted for the increased osteoarthritis risk with high intensity of physical activity. However, effects of physical activity (whether beneficial or harmful) on osteoporosis and osteoarthritis are not markedly altered by pollutants.

TI Complement C3 deficiency inhibits osteoclast differentiation and prevents ovariectomy-induced osteoporosis
SO JOURNAL OF IMMUNOLOGY
LA English
DT Article
DE osteoclasts; complement proteins; osteoimmunology; bone biology; osteoblasts
ID 3rd component; bone; cells; proteins
AB The pathomechanistic role of the complement system is well recognized in various pathological conditions affecting bone tissues and the bone microenvironment, including rheumatoid arthritis, osteoarthritis, bone fractures, and periodontitis. The homeostasis of the bone is maintained by continuous remodeling, in which bone-resorbing or demineralizing osteoclast cells remove bone calcification, and osteoblast cells deposit new bone matrix. Major complement protein C3 is reported to control endochondral ossification, cartilage-to-bone transition, and longitudinal bone growth. The role of the

complement protein C3 in differentiating multinucleated osteoclast cells (bone-resorbing cells) from osteoclast precursor cells (OCPs) and its contribution to long bone microarchitecture and strength are unclear. We demonstrated that C3 promotes the differentiation of osteoclasts and the formation of multinucleated osteoclasts from bone marrow-derived OCPs. C3-/- mice OCPs had reduced osteoclast-associated gene expression of TRAP (tartrate-resistant acid phosphatase), cathepsin K, calcitonin receptor, and RANK (receptor activator of nuclear factor kappa B) molecules compared with osteoclasts derived from wild-type (WT) OCPs. C3-/- mice had significantly increased bone mineral density and other bone parameters of the femur compared with WT mice. Furthermore, compared with WT mice, C3-/- mice were protected from ovariectomy-induced osteoporosis, characterized by significantly increased Foxp3+CD4+ T cells in the spleen and interleukin-10-producing B cells in both the spleen and the bone marrow. Intriguingly, C3 knockout mice exhibit reduced differentiation of functional osteoclast cells, which promotes a strong bone microarchitecture, suggesting that complement pathways may be explored as a therapeutic target in bone inflammatory diseases.

TI Natural Products in the Prevention of Degenerative Bone and Joint Diseases: Mechanisms Based on the Regulation of Ferroptosis
SO PHYTOTHERAPY RESEARCH
LA English
DT Review
DE degenerative bone and joint diseases; ferroptosis; intervertebral disc degeneration; natural products; osteoarthritis; osteoporosis
ID intervertebral disc degeneration; mesenchymal stem-cells; lipid-peroxidation; oxidative stress; nucleus pulposus; osteoarthritis; differentiation; expression; ferritinophagy; inhibition
AB Degenerative bone and joint diseases (DBJDs), characterized by osteoporosis, osteoarthritis, and chronic inflammation of surrounding soft tissues, are systemic conditions primarily affecting the skeletal system. Ferroptosis, a programmed cell death pathway distinct from apoptosis, autophagy, and necroptosis. Accumulating evidence suggests that ferroptosis is intricately linked to the pathogenesis of DBJDs, and targeting its regulation could be beneficial in managing these conditions. Natural products, known for their anti-inflammatory and antioxidant properties, have shown unique advantages in preventing DBJDs, potentially through modulating ferroptosis. This article provides an overview of the latest research on ferroptosis, with a focus on its role in the pathogenesis of DBJDs and the therapeutic potential of natural products targeting this cell death pathway, offering novel insights for the prevention and treatment of DBJDs.

TI Influence of pre-operative co-morbidities on pain and function outcomes at 1 year after primary total knee arthroplasty
SO KNEE
LA English
DT Article
DE Total knee replacement; Arthroplasty; Western Ontario and McMaster Universities; Osteoarthritis Index (WOMAC); Patient-reported outcome measures; (PROMS); Co-morbidities; Multi-morbidity
ID patient-reported outcm; replacement surgery; comorbidity index; hip; predictors; satisfaction
AB Introduction: Multimorbidity has been found to be associated with more pain and poorer function following total knee arthroplasty (TKA). We describe the relationship between both the total number of pre-operative co-morbidities, and individual co-morbidities, with the Western Ontario and McMaster Universities

Osteoarthritis Index (WOMAC) score at 12 months after TKR. Methods: We performed a secondary analysis on 290 participants from the Arthroplasty Pain Experience (APEX) trial, with seventeen imputations by Chained Equations. Using multivariable adjusted linear regression models, we analysed the relationship between total number of pre-operative co-morbidities, followed by individual co-morbidities, with WOMAC score at 12 months after randomisation. Results: Patients with >= 5 co-morbidities have worse outcomes compared to patients with 3 co-morbidities, scoring -9.6 points for function (95% CI -15.3 to -3.8), and -9.8 points for pain (95%CI -15.9 to -3.8). Patients reported worse pain with osteoporosis (-7.8 95% CI -14.1 to -1.6), peripheral vascular disease (-17.8 95%CI -34 to -1.8), depression (-9.8 95%CI -18.1 to -1.4), anxiety (-9.7 95%CI -18 to -1.4) or degenerative disc disease (-7.5 95%CI -13.3 to -1.7). Worse function was associated with osteoporosis (-7.1 95%CI -12.9 to -1.4), diabetes mellitus (-9.1 95%CI -15.6 to -2.6), anxiety (-8.1 95%CI -16 to -0.2) and degenerative disc disease (-8.6 95%CI -14.1 to -3.2). Conclusion: Pre-operative multimorbidity is associated with worse outcomes after TKA. Patients with pre-operative osteoporosis, anxiety and degenerative disc disease had worse pain and function at 12-months. Surgeons may use these results during discussion with patients about their potential outcome after TKA. (c) 2025 The Authors. Published by Elsevier B.V. TI Autophagy: regulating the seesaw of bone-fat balance
SO FRONTIERS IN CELL AND DEVELOPMENTAL BIOLOGY
LA English
DT Review
DE autophagy; metabolism; lipid metabolism; bone metabolism; bone diseases
ID mesenchymal stem-cells; marrow adipose-tissue; diet-induced obesity; alpha-lipoic acid; factor c/ebp-beta; ppar-gamma; oxidative stress; osteogenic differentiation; osteoclast differentiation; transcription factor
AB The interrelationship between bone and fat can be described as a seesaw in bone homeostasis, in which both osteogenesis and adipogenesis occur in a delicate balance. Osteoblasts and adipocytes share a common origin and play key roles in osteogenesis and adipogenesis. Bone-fat balance indicates osteogenesis and adipogenesis keeps a balance for concordant distribution of trabecular bone and bone marrow adipose tissue in bone, thereby leading to the balance between bone metabolism and lipid metabolism. Bone-fat balance is crucial for metabolic health. When disrupted by various factors, this balance can lead to several bone-related metabolic diseases and systemic disorders, such as obesity, osteoporosis, and osteoarthritis. Recent research highlights the role of autophagy dysfunction in these metabolic conditions. Restoring autophagic function can help restore metabolic homeostasis and re-establish the bone-fat balance. The current review explores the factors that regulate bone-fat balance, the consequences of imbalance under pathological conditions, and the potential of autophagy modulation as a therapeutic approach. Overall, it can be concluded that targeting autophagy presents a promising strategy for treating metabolic disorders and restoring bone-fat balance.

TI Therapeutic Potential of Bioactive Peptides Derived from Natural Products of Tortoiseshell and Antler in Alleviating Osteoporosis and Osteoarthritis
SO INTERNATIONAL JOURNAL OF MOLECULAR SCIENCES
LA English
DT Article
DE traditional Chinese medicines; tortoiseshell; antler; bioactive peptides; osteoporosis; osteoarthritis; natural products
AB Tortoiseshell and antler, the main components of Guilu Erxian Jiao, are natural products that can be used as traditional Chinese medicine (TCM) to alleviate osteoporosis and osteoarthritis. However, research on the active ingredients in tortoiseshell and antler for alleviating osteoporosis and osteoarthritis remains insufficient. This study primarily compares the antioxidant capacity of tortoiseshell gelatin and antler gelatin and their bioactive peptides, as well as their effects on the cell viability of MC3T3-E1 osteoblasts and HIG-82 chondrocytes. Our results indicate that when tortoiseshell and antler are combined with their respective bioactive peptides, the antioxidant capacity and cell viability of osteoblasts and chondrocytes are superior to the effects of either used alone. Comparing the antioxidant capacity and cell viability of osteoblasts and chondrocytes of tortoiseshell and antler and their respective bioactive peptides when used alone, we found that tortoiseshell and its bioactive peptides have better cell viability and calcium deposition for osteoblasts compared to the antler and its bioactive peptides. Conversely, antler and its bioactive peptides exhibit stronger antioxidant

capacity and better cell viability for chondrocytes than tortoiseshell and its bioactive peptides. These results suggest that the alleviation of osteoporosis may mainly be attributed to tortoiseshell and its bioactive peptides, while the alleviation of osteoarthritis may mainly be attributed to antler and its bioactive peptides. When tortoiseshell and antler are used together, they can provide the best therapeutic effects for both osteoporosis and osteoarthritis.

TI Health among Retired Great Britain's Olympic Athletes: A cross-sectional Study of Disease and Multimorbidity
SO SPORTS MEDICINE-OPEN
LA English
DT Article
DE Prevalence; Olympic Athletes; Multimorbidity; Chronic Diseases; Melanoma
ID physical-activity; osteoarthritis; prevalence; cohort; risk; knee; hip
AB Background: Currently, there is a paucity of long-term health data for retired athletes. This study describes the prevalence of common morbidities and multimorbidity among retired Great Britain's (GB) Olympic athletes, compared to a general population comparator group. Methods: A cross-sectional study of retired athletes was undertaken. The English Longitudinal Study of Ageing (ELSA) served as the reference population. Age- and sex-standardized morbidity ratios (SMRs) and

odd ratios (ORs) determined where morbidity and multimorbidity prevalence amongst retired athletes exceeded or were inferior to those of the reference population. Results: Retired athletes (n = 493) were less likely (SMR < 1) than controls (n = 8024) to report diabetes (0.43, 99% CI 0.22, 0.74), stroke (0.39, 99% CI 0.12, 0.90), obesity (0.35, 99% CI 0.23, 0.50), asthma (0.29, 99% CI 0.12, 0.59), lung disease (0.29, 99% CI 0.06, 0.81), angina (0.18, 99% CI 0.05, 0.46), and eye disorders (0.06, 99% CI 0.01, 0.18). In addition, abnormal heart rhythm (0.45, 99% CI 0.40, 0.54) and osteoporosis (0.46, 99% CI 0.42, 0.51) were lower in female athletes. Retired athletes were more likely (SMR > 1) than controls to report melanoma or other skin cancer (5.64, 99% CI 2.80, 10.06) and osteoarthritis (1.44, 99% CI 1.18, 1.75). There were no differences detected in cancers of the breast, prostate, colon, bowel or bladder. Multimorbidity was less prevalent among retired athletes (OR 0.50, 99% CI 0.38, 0.67). Conclusions: Retired athletes had superior cardiovascular health and a lower risk of multimorbidity, but were more at risk of melanoma or other skin cancer and osteoarthritis.

TI A Systematic Review of the Potential of Acmella Genus Plants for the Treatment of Musculoskeletal Disorders
SO INTERNATIONAL JOURNAL OF MOLECULAR SCIENCES
LA English
DT Review
DE <italic>Acmella</italic> genus plant; musculoskeletal disorders; osteoporosis; muscle strains; tendonitis; osteoarthritis
ID spilanthes-acmella; postmenopausal women; global burden; osteoporosis; osteoarthritis; epidemiology; pain; mass; hip
AB The genus Acmella has received growing attention for its pharmacological properties, including its potential applications in musculoskeletal disorders (MSDs).

Plants in this genus, such as Spilanthes acmella, Blainvillea acmella, Acmella uliginosa, and Acmella oleracea contain various bioactive compounds which have demonstrated anti-inflammatory, analgesic, and anti-arthritic properties. This systematic review evaluates the clinical and preclinical evidence supporting the use of plants from Acmella genus for the treatment of MSD, such as arthritis, osteoporosis, muscle injuries, joint inflammation, and other related pathologies. The methodology used in this study involved a systematic literature review, following the Preferred Reporting Items for Systematic Reviews and Meta-Analysis (PRISMA) guidelines, along with synthesis analysis and quality appraisal. The articles were retrieved from Scopus, Google Scholar, and PubMed databases. Eleven articles were further analyzed to determine the therapeutic potential of Acmella genus plants for musculoskeletal disorders. The plants included were Spilanthes acmella, Blainvillea acmella, Acmella uliginosa, and Acmella olerecia. The musculoskeletal disorders investigated were osteoporosis, osteoarthritis, and myopathies. The extracts from these plants were shown to decrease inflammation, enhance joint health, relieve pain, and stimulate osteogenic activity. These effects may be attributed to several active compounds found in these plants. The available evidence suggests that Spilanthes acmella and Blainvillea acmella have the potential to treat osteoporosis. Acmella oleracea and Acmella uliginosa have the potential to be used for the treatment of osteoarthritis, while Spilanthes acmella is used to treat myopathies. Further research is needed to establish the efficacy, optimal dosing, and safety of these plants.

DT Review
DE Plant deprivative; exosome-like nanovesicles; osteoporosis; osteoarthritis; bone
ID mesenchymal stem-cells; rankl
AB Osteoporosis (OP) and osteoarthritis (OA) are clinically common chronic orthopedic diseases. With the aging of the global population, OP and OA pose a serious threat to human health. Exosomes are nanoscale vesicles secreted by cells and can mediate inter-cell communication. Recent research has shown that plant-derived exosomes-like nanovesicles (PELNs) can affect the proliferation and differentiation of osteoclasts, osteoblasts, bone marrow mesenchymal stem cells (BMSCs) and chondrocytes, regulate the immune system and inhibit inflammatory responses, and have potential value in treating OP and OA. This article summarizes the basic concepts, formation and components, separation and characterization methods of PELNs, and focuses on discussing the impact of PELNs on OP and OA, aiming to provide new ideas for the research of OP and OA.

DT Review
DE cellular senescence; aging; musculoskeletal disease; degenerative diseases; senotherapy
ID marrow stromal cells; secretory phenotype; bone-marrow; stem-cells; intervertebral-disk; protein-kinase; osteoarthritis; mitochondrial; homeostasis; mechanisms
AB Aging is typically associated with decreased musculoskeletal function, leading to reduced mobility and increased frailty. As a hallmark of aging, cellular senescence plays a crucial role in various age-related musculoskeletal diseases, including osteoporosis, osteoarthritis, intervertebral disc degeneration, and sarcopenia. The detrimental effects of senescence are primarily due to impaired regenerative capacity of stem cells and the pro-inflammatory environment created by accumulated senescent cells. The secreted senescence-associated secretory phenotype (SASP) can induce senescence in neighboring cells, further amplifying senescent signals. Although the removal of senescent cells and the suppression of SASP factors have shown promise in alleviating disease progression and restoring musculoskeletal health in mouse models, clinical trials have yet to demonstrate significant efficacy. This review summarizes the mechanisms of cellular senescence

in age-related musculoskeletal diseases and discusses potential therapeutic strategies targeting cellular senescence.

TI Clinical implications of teleradiology in rheumatic and musculoskeletal diseases: improving rheumatic care

SO RHEUMATOLOGY INTERNATIONAL
LA English
DT Review
DE Telemedicine; Teleradiology; Osteoarthritis; Osteoporosis; Rheumatoid arthritis; Spondyloarthritis; Rheumatic diseases; Surveys and questionnaires
ID challenges
AB Teleradiology, the transmission of radiologic images for remote assessment and consultation, has transformed modern medical care by mitigating geographical inequities and improving diagnostic accuracy. This technology employs telecommunications, digital imaging, and data-sharing systems developments to deliver swift and precise image analysis across various healthcare environments. Teleradiology has been essential in identifying and controlling diseases, including osteoarthritis, osteoporosis, rheumatoid arthritis, and spondyloarthritis, especially in musculoskeletal radiology and rheumatology. The combination of teleradiology and telemedicine has transformed multidisciplinary cooperation, enhancing communication among radiologists, rheumatologists, and other healthcare practitioners to provide patient-centered treatment. It has markedly enhanced access to highly specialized knowledge, especially in rural and disadvantaged areas, facilitating prompt consultations and alleviating patient travel constraints. However, despite its benefits, teleradiology encounters several challenges, including standardization issues, ethical dilemmas, and infrastructure constraints. The absence of uniform standards and inequalities in access to high-speed Internet and digital health records impede extensive implementation. Addressing these constraints is crucial to fully utilizing teleradiology's potential in musculoskeletal and rheumatic care. This article highlights the transformational potential of teleradiology and its incorporation into telemedicine for musculoskeletal and rheumatological treatment. Teleradiology is set to enhance global healthcare delivery by addressing disparities in healthcare access, fostering multidisciplinary cooperation, and utilizing advanced technologies. It underscores the necessity for ongoing innovation and investment in infrastructure, education, and standards to optimize the advantages of this crucial technology and guarantee equitable, efficient, and high-quality care for all patients.

TI A novel hypothesis on the pathogenesis of knee osteoarthritis: the muscle weakness-joint instability and stress overload - uneven bone settlement cascade
SO MEDICAL HYPOTHESES
LA English
DT Article
DE Knee osteoarthritis; Muscle weakness; Uneven bone settlement; Stress overload
ID biomechanics; kinematics; complaints; density; disease; women; gait
AB The pathogenesis of knee osteoarthritis (KOA) remains incompletely elucidated. Traditional perspectives emphasize the roles of articular cartilage degeneration and soft tissue laxity. This article synthesizes recent research to propose an integrated musculoskeletal biomechanical hypothesis: weakness of muscles is the initiating factor in KOA development, leading to diminished dynamic joint stability, this instability triggers abnormal distribution of contact stresses and excessive loading within the joint. Coupled with the unique anatomical features of the tibia and fibula (such as fibular support and the abundance of trabecular bone in the medial tibia) and underlying osteoporosis, this process ultimately results in "uneven bone settlement" of tibial plateau changes. This settlement further exacerbates varus deformity, joint space narrowing, soft tissue imbalance, and pain, establishing a

vicious cycle of KOA progression. The clinical efficacy of the currently employed Proximal Fibular Osteotomy (PFO) and the researches related of knee Joint periarticular muscle strength training provides support for this theory. This hypothesis emphasizes the central importance of muscle strengthening to restore joint stability and early intervention in bone metabolism for the prevention and management of KOA.

TI Association between bone mineral density and lower back pain in the general United States population using the NHANES of 1999-2004
SO FRONTIERS IN SURGERY
LA English
DT Article
DE lower back pain; bone mineral density; osteoporosis; economic impact; U-shaped relationship
ID modic changes; risk; osteoporosis; osteoarthritis; disorders; fracture
AB Objectives Lower back pain (LBP) is a prevalent health issue that has substantial effects on individuals and society. However, the association between bone mineral density (BMD) and LBP remains controversial. In this study we aimed to ascertain whether a relationship exists between BMD and LBP in the United States population. Methods Data from the National Health and Nutrition Examination Survey (NHANES) spanning 1999-2004 were analyzed using a cross-sectional approach. BMD and LBP were assessed using multivariate logistic regression, smoothing curves, and generalized additive models. Subgroup analyses were also performed to ensure data stability and mitigate confounding factors. Results In this population-based study, the data of 107,570 adults were analyzed (mean age: 47.13 +/- 18.38 years) and 36.74% of them had LBP. After controlling for all covariates, a positive correlation was established between BMD and LBP [odds ratio (OR) = 1.87, 95% confidence interval (CI) = (1.00, 3.50)]. The two-segment linear

regression model revealed a U-shaped relationship between BMD and LBP with a 1.14 g/cm2 inflection point. BMD values <1.14 g/cm2 were linked to a lower likelihood of experiencing LBP [OR = 0.55, 95% CI = (0.45, 0.68)]. However, a BMD >1.14 g/cm2 increased the risk of LBP [OR = 6.15, 95% CI = (4.51, 8.39)]. Conclusions BMP was significantly and positively correlated with LBP. A U-shaped relationship was observed between BMD and LBP, indicating that both insufficient and excessive BMD may increase the risk of LBP.

TI Is bone mineral density a risk factor for femoral stem subsidence in primary cementless total hip arthroplasty: a prospective study
SO BMC MUSCULOSKELETAL DISORDERS
LA English
DT Article
DE Subsidence; Total hip arthroplasty; Bone density; Osseointegration; Dorr classification; Prospective study
ID osteoporosis; replacement; stability; women
AB Background The success of primary total hip arthroplasty (THA) in patiens with primary osteoarthritis (OA) of the hip is significantly influenced by stem osseointegration, migration and implantation. Additionally, the bone mineral density (BMD) of the proximal femur, the femoral morphology and stem design play important roles in these outcomes. This study aimed to evaluate the effect of BMD on subsidence who underwent primary cementless THA with a fit-and-fill stem design for primary OA of the hip, assuming that subsidence is not influenced by BMD. Methods This prospective study included 72 hips from 67 patients who underwent primary cementless THA for OA between May 2019 and March 2022. Two patients were excluded due to intraoperative complications, and the final analysis was conducted on 70 hips. Patients were grouped according to preoperative BMD and proximal femur anatomy based on Dorr classification. Harris Hip Score (HHS), radiological subsidence and Engh score values were used for postoperative clinical evaluation. Results The mean age was 65.99 +/- 8.10 years (range 52 to 83 years). The mean follow-up was 24.6 +/- 5.8 months (range, 12 to 34 months). Amongst 70 OA of the hip cases, 22 (31.43%) were Dorr type A, 44 (62.86%) type B, and 4 (5.71%) type C. Forty-three patients (61.43%) had normal BMD, while 27 patients (38.57%) were osteopenic or osteoporotic. The mean axial migration at the latest follow-up was 1.04 +/- 0.69 mm (range 0 to 3.1 mm). Total Engh score was 22.89 +/- 3.28 (range 14 to 27), and in terms of stabilization bone ingrowth was seen in all of the femoral stems. There was no statistically significant effect of femoral T-score levels ($p = 0.853$) or femoral morphologies ($p = 0.763$) on femoral stem subsidence. Conclusions No statistically significant differences were observed in clinical or radiological outcomes between patients with normal and low BMD. These findings suggest that early stem migration and osseointegration are more closely related to initial mechanical stability than to BMD. Cementless femoral stems can therefore be considered reliable across different bone qualities, offering an innovative perspective that challenges the conventional emphasis on bone density in implant selection.

TI Molecular mechanisms and targeted therapy of progranulin in metabolic diseases
SO FRONTIERS IN ENDOCRINOLOGY
LA English
DT Review
DE PGRN; metabolic diseases; inflammation; cartilage repair; bone homeostasis; targeted therapy
ID tnf-alpha; serum progranulin; osteoarthritis; bone; periodontitis; inflammation; suppresses; apoptosis; roles; pgrn
AB Progranulin (PGRN) is a secreted glycoprotein with cytokine-like properties, exerting tripartite mechanisms of inflammation suppression, tissue repair promotion, and metabolic regulation. This multifaceted functionality positions PGRN as a potential "multi-effect therapeutic strategy" for metabolic disorders characterised by cartilage degradation and imbalanced bone remodelling, potentially establishing it as a novel therapeutic target for such conditions. Osteoarthritis, rheumatoid arthritis, intervertebral disc degeneration, osteoporosis, periodontitis, and diabetes-related complications-representing the most prevalent metabolic diseases-currently lack effective treatments due to incomplete understanding of their precise pathogenic mechanisms. Recent studies have revealed that PGRN expression levels are closely associated with the onset and progression of these metabolic disorders. However, the exact regulatory role of

PGRN in these diseases remains elusive, partly owing to its tissue-specific actions and context-dependent dual roles (anti-inflammatory vs. pro-inflammatory). In this review, we summarise the structure and functions of PGRN, explore its involvement in neurological disorders, immune-inflammatory diseases, and metabolic conditions, and specifically focus on its molecular mechanisms in metabolic diseases. Furthermore, we consolidate advances in targeting PGRN and the application of its engineered derivative, Atsttrin, in metabolic bone disorders. We also discuss potential unexplored mechanisms through which PGRN may exert influence within this field or other therapeutic domains. Collectively, this work aims to provide a new framework for elucidating PGRN's role in disease pathogenesis and advancing strategies for the prevention and treatment of metabolic disorders.

TI Factors contributing to clinical misdiagnosis of fetal head position: an ultrasound based cohort study from Tanzania
SO JOURNAL OF MATERNAL-FETAL & NEONATAL MEDICINE
LA English
DT Article
DE Ultrasound; labor; fetal position; misdiagnosis; cesarean section
ID transvaginal digital examination; persistent occiput posterior; 2nd-stage; delivery; labor; sonography
AB Objectives: Accurate determination of fetal head position is essential for managing labor, particularly in cases of slow progress or before operative vaginal interventions. Several studies have shown that ultrasound examinations are more accurate than clinical examinations, but few ultrasound studies are done in sub-Saharan Africa. Clinical vaginal assessment of fetal position remains the standard in most African settings, but its accuracy is limited by examiner skills and labor conditions. This study aimed to compare clinical and ultrasound assessments of fetal position during active labor, to identify factors contributing to clinical misdiagnosis, and to evaluate the impact of misdiagnosis on delivery mode. Methodology: An observational cohort study was conducted at Kilimanjaro Christian Medical Centre in Moshi, Tanzania, from 19(th) November 2023 to 13(th) April 2024. Fetal position was categorized as a clock; 10 to 2 o'clock as occiput anterior (OA) position, 3 o'clock as left occiput transverse (LOT) position, 4 to 8 o'clock as occiput posterior (OP) position, and 9 o'clock as right occiput transverse (ROT) position. Three trained doctors conducted ultrasound examinations, while midwives performed clinical assessments recording position, station, cervical dilatation, caput succedaneum, and molding. Fetal station ranged from -5 to +5. Caput succedaneum was first graded as 0, +1, +2, or +3 and recategorized as none (0), slight (grade +1), and huge (grade +2 and +3). Molding was categorized as absent or present. Clinical misdiagnosis of position was defined as any discrepancy between clinical and ultrasound assessments using ultrasound examinations as the gold standard. Misdiagnosis included cases where the fetal head position could not be determined clinically, as well as those that were incorrectly assessed through vaginal examination. Blinded comparisons evaluated agreement and clinical misdiagnosis. Factors contributing to clinical misdiagnosis were assessed using logistic regression and potential confounders included maternal age, gestational age, body mass index (BMI), station during the second stage, caput succedaneum, and molding. Results: The final study population comprised 215 women, 204 were examined in the active first labor stage and 210 in the second stage. Fetal position could not be determined clinically in 40/204 (19.6%) women in the active first

stage, but ultrasound successfully determined position in all cases. The overall agreement rate in the active first stage was 101/164 (61.6%), with 60/76 (78.9%) agreement in OA position and 41/88 (46.6%) agreement in non-OA positions. Agreement in classifying position into four categories (OA, LOT, OP, and ROT) was moderate (Cohen's kappa, k = 0.41, 95% CI 0.31-0.52). In the second stage, clinical assessment failed in 11/210 (5.2%) cases, while ultrasound failed in 5/210 (2.4%). The overall agreement rate was 155/194 (79.9%), with 133/152 (87.5%) agreement in OA position and 22/42 (52.4%) agreement in non-OA positions. Cohen's kappa in classifying position into four categories showed moderate agreement (k = 0.46, 95% CI 0.32-0.59). Presence of molding showed a strong association with clinical misdiagnosis, adjusted OR 5.81 (95% CI 1.95-17.30). Slight caput succedaneum was not associated; however, a huge caput succedaneum was significantly associated with clinical misdiagnosis, adjusted OR 5.95 (95% CI 1.85-19.13). Fetal station showed a significant inverse association in unadjusted analysis, where a lower fetal station reduced the likelihood of clinical misdiagnosis, unadjusted OR 0.63 (95% CI 0.41-0.96), but this association was not significant in the adjusted analysis, OR 0.64 (95% CI 0.39-1.06). Maternal age, gestational age, and BMI were not associated with clinical misdiagnosis in either model. The cesarean section (CS) rate among parturients with misdiagnosed positions was 19/50 (38.0%), compared to 14/155 (9.0%) in women with correctly assessed positions ($p < .001$). Conclusions: Clinical and ultrasound assessments showed moderate agreement. Caput succedaneum and molding influenced clinical misdiagnosis, and misdiagnosed positions were associated with higher CS rates.

TI The Role of PGE2 in Age-related Diseases
SO CURRENT DRUG TARGETS
LA English
DT Review
DE Prostaglandin E2; aging; inflammation; prostaglandin E receptors
ID prostaglandin e-2 receptor; alzheimers-disease; mouse model; alveolar macrophages; dopaminergic-neurons; parkinsons-disease; e synthase-1; fatty-acids; bone loss; expression
AB In the past several years, human life expectancy has increased dramatically, and the global aging process is accelerating at an unprecedented rate. Impaired organ functions and systemic inflammation increase the risk of aging-related diseases. It seriously affects the quality of life in older adults and places a heavy burden on the global economy and public health. Inflammation is the cornerstone of many age-related diseases, and among various inflammatory mediators, Prostaglandin E2 (PGE2) has emerged as a key player. For example, PGE2 could participate in the progression of Alzheimer's disease (AD) by modulating neuroinflammation. Plasma PGE2 is regarded as a potential and specific diagnostic biomarker, and higher initial PGE2 levels are positively correlated with longer survival in AD. PGE2 also mediates bone and muscle metabolism to affect age-related musculoskeletal diseases, including sarcopenia, osteoporosis, and osteoarthritis. It activates the EP4 receptor on sensory nerves to inhibit sympathetic nerve activity and modulate bone formation. Moreover, the PGE2/EP4 axis positively regulates muscle mass and strength. In diabetes, increased Cox-2 and m-PGES2 promote PGE2 production. The activated PGE2/EP3 axis exacerbates the progression of type 2 diabetes (T2D) by impairing glucose metabolism and accelerating beta-cell senescence. Therefore, the role of PGE2 in age-related diseases deserves greater attention. Its involvement is driven by the dysregulation of its biosynthesis, metabolism, and receptor-mediated signaling. Regulating the concentration of PGE2 or modulating receptor activity represents a promising therapeutic strategy for managing

age-related diseases.

TI Higher frequency of public hospital utilisation for rheumatological conditions by First Nations people in Western Sydney
SO INTERNAL MEDICINE JOURNAL
LA English
DT Article
DE aboriginal Australian; arthritis; first nations; osteoporosis; Rheumatology
ID systemic-lupus-erythematosus; body-composition; australians; aborigines; sle
AB Objectives There is limited research on the burden of rheumatologic disease affecting First Nations people in Australia. We sought to characterise public

hospital utilisation by First Nations people for a 6-year period (2014-2019) for gout, systemic lupus erythematosus (SLE), rheumatoid arthritis (RA), osteoarthritis (OA) and osteoporosis (OP) in Western Sydney, New South Wales. Design A cross-sectional medical records review. Setting All patients who presented to the emergency departments (EDs) of, or who were admitted to, any of the four Western Sydney Local Health District hospitals with a primary diagnosis of gout, SLE, RA, OA or OP between 1 January 2014 and 31 December 2019.Main outcome measures Description of ED presentations and hospital admissions for the five conditions among First Nations and non-First Nations people. The hospital utilization rate was calculated for both First Nations and non-First Nations people. Results There was a higher likelihood of First Nations people accessing public hospital healthcare for gout compared to the non-First Nations population (73.3% vs 62.4%, P < 0.030). The public hospital utilisation rate for First Nations people with rheumatological conditions was almost three times that of the non-First Nations population for those aged >= 45 years (13.1 per 1000 people vs 5.0 per 1000 people respectively). Conclusions This study suggests First Nations people living in Western Sydney access public hospital care for rheumatological conditions at a higher rate than the general population.

TI Molecular insights and emerging therapeutic perspectives of the lncRNA GAS5/miR-21 axis in cancer, fibrosis, cardiovascular, and immune disorders
SO MUTATION RESEARCH-REVIEWS IN MUTATION RESEARCH
LA English
DT Article
DE LncRNA GAS5; MiR-21; Cancer progression; Fibrosis; Cardiovascular disease; Immune disorders
ID long noncoding rna; systemic-lupus-erythematosus; signaling pathway; gas5; mir-21; osteoporosis; cell; radiosensitivity; mechanisms; expression
AB Non-coding RNAs (ncRNAs) have redefined the complexity of gene regulation, with the long non-coding (lncRNA) GAS5/miR-21 axis emerging as a critical determinant of cell fate across diverse pathological contexts. This review examines the molecular mechanisms by which GAS5 regulates miR-21 activity, thereby restoring tumor suppressor networks and controlling key pathways, including the PI3K/AKT, MAPK/ERK, and Wnt/beta-catenin pathways. We detail how dysregulation of this axis fuels cancer progression, metastasis, therapy resistance, fibrosis, cardiovascular diseases, osteoporosis, osteoarthritis, and autoimmune conditions like systemic lupus erythematosus. Beyond its role as a master regulator of apoptosis, proliferation, and EMT, the GAS5/ miR-21 interaction holds immense promise as a therapeutic target and a liquid biopsy biomarker. However, clinical translation demands solutions to major challenges, including RNA delivery barriers, context-dependent effects, and adaptive resistance. Leveraging multi-omics integration, gene-editing technologies, and personalized RNA therapeutics will be pivotal to overcoming these obstacles. By critically integrating current knowledge and outlining future directions, this review positions the GAS5/miR-21 axis at the forefront of next-generation ncRNA therapeutics. Harnessing its full potential could not only revolutionize treatment paradigms but also transform our understanding of RNA-driven disease networks.

TI Cadmium exposure and its role in joint disease: A brief review of experimental and population-based evidence
SO JOURNAL OF TRACE ELEMENTS IN MEDICINE AND BIOLOGY
LA English
DT Review
DE Cadmium; oxidative stress; inflammation; osteoporosis; osteoarthritis; rheumatic and metabolic diseases
ID rheumatoid-arthritis; induction; toxicity; risk
AB Cadmium is a toxic metal released into the environment mainly by mining and industrial activities, posing health risks through inhalation and ingestion. Smoking is a major source of exposure, followed by consuming contaminated foods such as vegetables and offal. Due to its long half-life, Cadmium accumulates in the body and contributes to chronic diseases, including rheumatic and metabolic disorders such as osteoporosis, osteoarthritis, rheumatoid arthritis, systemic lupus erythematosus, gout, and hyperuricemia. The impact of Cadmium on bone health was first documented in Japan in 1955 when contaminated rice consumption caused significant bone mineral loss and severe pain. Recent studies suggest that Cadmium concentrations above 1 mu g/L have osteotoxic effects, likely due to impaired Calcio absorption or its replacement in bone tissue. Cadmium accumulation also disrupts joint homeostasis, promoting cartilage degradation, osteophyte formation, and synovitis. This may result from its interference with essential metals such as Zinc, Iron, Manganese, and Chromium, which are critical for the extracellular matrix. Cadmium has also been linked to rheumatoid arthritis by disrupting immune function, promoting oxidative stress, and increasing inflammatory mediators like TNF-alpha, IL-6, and COX-2. It may contribute to systemic lupus erythematosus by increasing antinuclear antibodies and altering cytokine profiles. Additionally, Cadmium exposure raises the risk of hyperuricemia and gout by interfering with urate metabolism, renal transport, and inducing oxidative stress. This article highlights Cadmium's toxic effects and underscores the need for public health strategies to monitor and reduce exposure, ultimately preventing musculoskeletal, rheumatic, and metabolic diseases while improving quality of life.

TI Prediction of joint deformity after MIPPO with double reverse traction repositor based on Hounsfield units derived from CT scans
SO JOURNAL OF ORTHOPAEDIC SURGERY AND RESEARCH
LA English
DT Article
DE Tibial plateau fracture; Post-traumatic osteoarthritis; Hounsfield units; BMD; Alignment
ID bone-mineral density; tibial plateau fractures; knee osteoarthritis; osteoporosis; femur; women
AB Background Tibial plateau fractures (TPFs) account for approximately 1% of all fractures and notably 8% of fractures among the elderly. While both surgical and non-surgical interventions can yield promising short-term results, the long-term

implications, particularly the risk of post-traumatic osteoarthritis (PTOA), necessitate further investigation. Although osteoarthritis (OA) and osteoporosis (OP) share common risk factors, including age and gender, yet the interaction between PTOA and OP remains unclear, thereby warranting in-depth exploration. Methods This study involved a cohort of 103 patients with TPFs who underwent minimally invasive percutaneous plate osteosynthesis (MIPPO) combined with double reverse traction reposition (DRTR) from December 2015 to July 2018. We analyzed the relationship between Bone Mineral Density(BMD), knee alignment, PTOA grading, and joint function. Differences in BMD and knee alignment were compared between patients with HKA < 177 degrees (varus group) and those with HKA >= 177 degrees (non-varus group). BMD was evaluated using computed tomography-derived Hounsfield Units (HUs). Alignment and joint deformation were quantified via hip-knee-ankle angle (HKA), medial proximal tibial angle (MPTA), lateral distal femoral angle (LDFA), joint line convergence angle (JLCA), and posterior tibial slope (PTS), while OA stages were assessed via Kellgren-Lawrence (K-L) classification. The functional outcome was assessed via SF-36 and HSS score. Results There were 30 cases (29.1.0% %) in the varus group and 73 cases (70.9%) in the non-varus group. The K-L classification showed a positive correlation with PTS(r = 0.339, p < 0.001). The SF-36 score was negatively correlated with tibial BMD(medial tibia: r = - 0.235, P = 0.050; lateral tibia: r = - 0.260, P = 0.036; mean tibial BMD: r = - 0.285, P = 0.021). The HSS score was negatively correlated with femoral BMD (medial femur: r = - 0.320, P = 0.017; lateral femur: r = - 0.236, P = 0.050; mean femoral BMD: r = - 0.300, P = 0.018). Among patients with high BMI, the K-L classification was positively correlated with femoral BMD, with stronger associations observed Additionally, HKA demonstrated a negative correlation with the BMD of the medial femur and the mean femoral BMD. Significant differences were observed in medial femoral BMD and MPTA between the varus and non-varus groups. Conclusion BMD in the distal femur and proximal tibia is significantly associated with knee function and quality of life, particularly in patients with elevated BMI. Increased BMD correlates with poorer joint function, reduced quality of life, and greater varus deformity, contributing to the progression of PTOA. Notably, patients with knee varus exhibit increased medial femoral BMD and aggravated tibial varus. These findings suggest that postoperative assessment and management of periarticular BMD may help optimize joint alignment, reduce abnormal stress distribution, and delay PTOA progression, thereby improving clinical outcomes.

TI Prevalence of osteoporosis in patients with knee osteoarthritis awaiting total knee arthroplasty is similar to that in the general population
SO BMC MUSCULOSKELETAL DISORDERS
LA English
DT Article
DE Bone mineral density; Prevalence of osteoporosis; Osteoarthritis of knee; Arthroplasty
ID bone-mineral density; health; hip
AB Background Osteoporosis is common in patients with knee osteoarthritis (KOA) awaiting total knee arthroplasty (TKA) and varies in different regional and ethnic. However, it is unclear whether the prevalence of osteoporosis and osteopenia in these patients is different from that in the general population. This study aims to investigate the prevalence of osteoporosis and osteopenia in both populations to help exploring the relationship between the osteoporosis and osteoarthritis, and to explore whether knee function and radiological assessments of KOA are associated with osteoporosis. Methods In total, 249 patients diagnosed with KOA awaiting TKA were investigated in this cross-sectional study. The mean age was 70.9 +/- 6.4 years. Bone mineral density (BMD) and T scores at the hip and lumbar spine were used to assess bone status using dual X-ray absorptiometry. A matched cohort

from 2448 individuals in the Health Examination Center of our hospital was set as controls by matching sex, age (+/- 3.0 years) and BMI (+/- 1.0). The Kellgren-Lawrence grades (K-L grades), mechanical femorotibial angle (mFTA), Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) score and range of motion (ROM) of the knee were measured to evaluate radiological assessments and knee function in patients awaiting TKA and used to explore the association between KOA and BMD or T score. Prevalence of osteoporosis and osteopenia were investigated in the two cohorts, and inferential statistical analyses were undertaken. The chi-squared test or Fisher's exact test was used for categorical variables while comparisons of scores were examined by ANOVA with/without Bonferroni correction or the Kruskal-Wallis test. Results The prevalence of osteoporosis and osteopenia in patients awaiting TKA was 30.5% (76/249) and 44.2% (110/249), respectively. In the matched cohort, 72/249 (28.9%) had osteoporosis, while 98/249 (39.4%) had osteopenia. There was no significant difference in the prevalence of osteoporosis or osteopenia between the two groups (chi 2 = 2.603, P = 0.272). mFTA was significantly correlated with BMD and T score (P < 0.05), while no correlation was found between K-L grade, ROM or WOMAC and BMD or T score (P > 0.05). Conclusions The prevalence of osteoporosis in patients awaiting TKA was similar to that in the general population. BMD and T score were not correlated with WOMAC score or K-L grade but were correlated with mFTA.

TI Associations of osteoarthritis with risk of future fracture events: prospective study in UK Biobank
SO INTERNATIONAL JOURNAL OF SURGERY
LA English
DT Article
DE fall; fracture; osteoarthritis
ID bone loss; rheumatoid-arthritis; knee osteoarthritis; trabecular bone; femoral-neck; falls; pain; hip; acetaminophen; osteoporosis
AB Background: Researchers have long been interested in the potential relationship

between osteoarthritis (OA), falls, and fractures; however, the evidence supporting this relationship has been conflicting. This study aimed to investigate the association between osteoarthritis and future fracture events. Materials and methods: This study was designed as a prospective cohort study. We recruited a total of 440 476 individuals from the UK Biobank to investigate the impact of OA on the incidence of fracture. Among the total population, there were 54 581 participants diagnosed with OA. Cox proportional hazard models were used to calculate hazard ratios (HRs) and 95% confidence intervals (95% CIs). Results: A total of 26 083 fracture events were documented over a median follow-up period of 13.5 years. After multivariable adjustment, participants with osteoarthritis had an HR (95% CI) of 1.11 (1.08, 1.15) for future fracture events compared to participants without osteoarthritis ($P < 0.0001$). Falls explained 16.34% of the association between osteoarthritis and fracture events and 14.15% of the association between knee osteoarthritis and fracture events. The association was not substantially altered across the series of sensitivity analyses. Conclusion: Osteoarthritis was associated with a greater risk of future fracture events. This finding highlights the importance of preventing future fracture events in people with osteoarthritis.

TI Clinical Progress in Mesenchymal Stem Cell Therapy: A Focus on Rheumatic Diseases
SO IMMUNITY INFLAMMATION AND DISEASE
LA English
DT Review
DE mesenchymal stem cells; osteoarthritis; rheumatic diseases; rheumatoid arthritis; systemic lupus erythematosus; systemic sclerosis
ID ankylosing-spondylitis patients; systemic-lupus-erythematosus; regulatory t-cells; bone-marrow; stromal cells; crohns-disease; osteogenic differentiation; classification criteria; extracellular vesicles; regenerative medicine
AB BackgroundRheumatic diseases are chronic immune-mediated disorders affecting multiple organ systems and significantly impairing patients' quality of life. Current treatments primarily provide symptomatic relief without offering a cure. Mesenchymal stem cells (MSCs) have emerged as a promising therapeutic option due to their ability to differentiate into various cell types and their immunomodulatory, anti-inflammatory, and regenerative properties. This review aims to summarize the clinical progress of MSC therapy in rheumatic diseases, highlight key findings from preclinical and clinical studies, and discuss challenges and future directions.MethodologyA comprehensive review of preclinical and clinical studies on MSC therapy in rheumatic diseases, including systemic lupus erythematosus, rheumatoid arthritis, ankylosing spondylitis, osteoarthritis, osteoporosis, Sj ögren's syndrome, Crohn's disease, fibromyalgia, systemic sclerosis, dermatomyositis, and polymyositis, was conducted. Emerging strategies to enhance MSC efficacy and overcome current limitations were also analyzed.Results and DiscussionEvidence from preclinical and clinical studies suggests that MSC therapy can reduce inflammation, modulate immune responses, and promote tissue repair in various rheumatic diseases. Clinical trials have demonstrated potential benefits, including symptom relief and disease progression delay. However, challenges such as variability in treatment response, optimal cell source and dosing, long-term safety concerns, and regulatory hurdles remain significant barriers to clinical translation. Standardized protocols and further research are required to optimize MSC application.ConclusionMSC therapy holds promise for managing rheumatic diseases, offering potential disease-modifying effects beyond conventional treatments. However, large-scale, well-controlled clinical trials are essential to establish efficacy, safety, and long-term therapeutic

potential. Addressing current limitations through optimized treatment protocols and regulatory frameworks will be key to its successful integration into clinical practice.

TI Postoperative Physical Therapy Utilization for Anterior Cervical Discectomy and Fusion An Analysis of Practice Patterns in the United States
SO SPINE
LA English
DT Article
DE rehabilitation; cervical spine; spine surgery; radiculopathy; myelopathy; timing; usage; patterns; fusion; visits
ID predictive factors; spine surgery; decompression; management; trends
AB Study Design/Setting. Retrospective Cohort study. Objective. To describe postoperative physical therapy (PostopPT) utilization patterns and evaluate predictors of utilization after anterior cervical discectomy and fusion (ACDF). Background Context. ACDF is the most common cervical spine procedure. PostopPT may improve outcomes, but current usage and program characteristics are unknown. Materials and Methods. PearlDiver Database identified patients who underwent ACDF between 2010 and April 2023. PostopPT utilization was assessed 7 to 365 days postoperatively. Demographics, comorbidities, and procedural characteristics were analyzed. Univariate and multivariate logistic regression identified predictors of PostopPT utilization. Results. Of 309,230 ACDF patients, 17.16% utilized PostopPT within one year. Among users, the average number of visits was 7.4, with mean initiation at 88 days (median: 61 d). PostopPT users were younger, had higher comorbidity burden, higher income, were more often female, and more likely to present with combined radiculopathy and myelopathy (P<0.001).Demographic predictors included commercial insurance (OR: 1.37), residence in the Northeast (OR: 1.35) or Midwest (OR: 1.31), income >$75,000 (OR: 1.17), female gender (OR: 1.14), and age below 50 (OR: 1.10) (all P<0.001). Comorbidity predictors included fibromyalgia (OR: 1.37), osteoarthritis (OR: 1.30), obesity (OR: 1.29), depression (OR: 1.26), osteoporosis (OR: 1.19), ECI >= 4 (OR: 1.13), diabetes (OR: 1.08), and tobacco use (OR: 1.07) (all P<0.001). Procedural predictors included mixed myelopathy/radiculopathy (OR: 1.29), fusion >= 3 levels (OR: 1.22), orthopedic surgeon as provider (OR: 1.10), inpatient surgery (OR: 1.09), and two-level fusion (OR: 1.08) (all P<0.001).Patients with myelopathy alone were more likely to receive gait training, aquatic therapy, and group training, but less

likely to receive manual therapy, electrical stimulation, hot/cold therapy, or ultrasound (all P<0.001). Conclusions. PostopPT usage following ACDF is limited. Distinct demographic, comorbidity, and procedural factors predicted usage. PostopPT programs varied in timing, frequency, and intervention type.

TI Implication of bone marrow adipose tissue in bone homeostasis during osteoarthritis
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE Osteoarthritis; Bone marrow adipose tissue; Subchondral bone; Mineralization; Epiphysis
ID infrapatellar fat pad; osteoporosis; differentiation; proliferation; model; pain
AB Objective: To explore the role of bone marrow adipocytes (BMAds) in osteoarthritis (OA). Methods: Male and female C57BL/6 mice (n=4/group) underwent meniscectomy (MNX) or SHAM surgery. OA was determined using Osteoarthritis Research Society International (OARSI) score, and the number of perilipin+ adipocytes was quantified. Mesenchymal Stromal Cells (MSCs) from MNX and SHAM mice were differentiated into osteoblasts and adipocytes. Human adipocytes and MSCs (n=8) were enzymatically isolated from epiphyseal and metaphyseal marrow, and from subcutaneous adipose tissue (SCAT) of hip OA patients. Human OA MSCs were differentiated into osteoblasts and adipocytes

(OA-Diff-hAdipo). Gene expression patterns of epiphyseal and metaphyseal BMAds, SCAT adipocytes and OA-Diff-hAdipo were evaluated by RNAseq (n=4). The effect conditioned media from OA epiphyseal bone (n=5) on the alkaline phosphatase (ALP) activity and mineralization kinetics was assessed in vitro. Results: Increase in BMAd density was positively correlated with cartilage degradation in MNX mice. OA modified the differentiation capacity of MSCs, accelerating adipocyte differentiation and failing to produce osteoblasts in both human and mice. Human epiphyseal, metaphyseal and SCAT adipocytes from the same OA patients each displayed a specific transcriptome, suggesting different functions. Enrichment analysis defined metaphyseal OA-BMAds as cells implicated in hematopoietic stem cell differentiation. On the other hand, epiphyseal OA-BMAds were considered as osteogenic cells showing an up-regulation of genes related to bone mineralization and remodeling. Specifically, OA epiphysis-secreted molecules decreased ALP activity and altered in vitro the mineralization process. Conclusion: All these results support the emergence of BMAds as new cell partners in OA, opening new venues for therapeutic approaches. (c) 2025 The Authors. TI Clinical, imaging, and histopathological characteristics of Vietnamese patients with late-stage avascular necrosis of the femoral head
SO BMC MUSCULOSKELETAL DISORDERS
LA English
DT Article
DE Avascular necrosis of the femoral head (AVNFH); AVNFH stages; Femoral head collapse; Hip joint movement; Histopathology of AVNFH
ID total hip-arthroplasty; nontraumatic osteonecrosis; proximal femur; bone; classification; reliability
AB Introduction Avascular necrosis of the femoral head (AVNFH) causes femoral head (FH) collapse and hip osteoarthritis due to various factors. Objective The purpose of this study is to report on clinical features, MRI imaging, and histopathology of AVNFH in Vietnamese patients. Methods One hundred fifty patients diagnosed with AVNFH (stage IV,V, orVI according to Steinberg's classification) were evaluated for clinical symptoms, blood tests, X-rays, and hip MRI. Histopathological was performed on cancellous bone samples from the neck, greater trochanter, and lesser trochanter of the femur. Results Patients revealed rapid, persistent onset of pain in all three stages, with 100% exhibiting quadriceps atrophy, gluteal atrophy, and shortened limbs. Risk factors for AVNFH include alcohol/smoking (> 70%). Imaging injuries include bone defects/osteoporosis, femoral neck collapse, and joint space constriction (100%). Synovial edema, congestion, and cartilage separation were prevalent in phases V and VI (76.7-100%). Stage IV showed a wrinkled FH cartilage surface (80%) and partial FH collapse (100%), while stages V and VI revealed a jagged cartilage surface and total FH collapse (80-100%). Bone marrow necrosis, marrow edema, subchondral fractures, dead bone trabeculae, and thickening bone trabeculae occurred in all AVNFH patients. Furthermore, articular cartilage had fewer elastic fibers (stages IV and V), but complete articular cartilage degradation occurs only in stage VI. Conclusions Bone defects/osteophytes, FH collapse, and joint space narrowing are common markers for AVNFH in Vietnamese patients. Hip joint effusion, bone

marrow necrosis, edema, subchondral fracture, dead bone trabeculae, and thickening bone trabeculae are common.

TI Associations between bone mineral density and WOMAC scores in healthy individuals: Insights from the Qatar Biobank

SO JOURNAL OF CLINICAL DENSITOMETRY
LA English
DT Article
DE Bone mineral density; WOMAC scores; Healthy Individuals; Pain and stiffness; Physical function
ID mcmaster universities osteoarthritis; body-mass index; western ontario; smoking; osteoporosis; progression; burden; bmd
AB Background: Bone mineral density (BMD) is an indicator of bone health that predicts future bone fractures. The Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) is used to assess the severity of symptoms related to pain, stiffness, and function in diseased hip and knee joints. Here we assessed whether BMD measured at specific sites predicts WOMAC scores in healthy individuals whilst controlling for sociodemographic variables. Methodology: BMD, sociodemographic, and WOMAC data were collected from 1764 healthy adult individuals attending the Qatar Biobank (QBB). Multiple linear regression was used to examine associations between sociodemographic factors, total body BMD and BMD related to specific skeletal sites (including femoral (femoral neck and trochanter), trunk, pelvis and total spine), and the three WOMAC subscales (pain, stiffness, and physical function). Results: After controlling for sociodemographic variables, total body and specific BMD measures did not predict pain. However, BMD measures significantly contributed to predicting stiffness after controlling for sociodemographic variables ($R^2 = 0.065$, $\Delta F(7, 1724) = 3.34$, $p = 0.002$), with a higher total body BMD associated with increased stiffness and a higher trunk BMD associated with decreased stiffness. Total body BMD measures also significantly contributed to predicting compromised physical function ($R^2 = 0.091$, $\Delta F(7, 1724) = 3.762$, $p < 0.001$) after controlling for sociodemographic variables, with a higher total body BMD associated with an increase in compromised physical function. Conclusion: Total body BMD seems to be a more important predictor of stiffness and physical function than specific skeletal sites BMD measures. Monitoring BMD may have important implications for osteoarthritis patients.

TI Osteo-F, a Newly Developed Herbal Formula, Ameliorates Osteoarthritis Through the NF-κB/IκB/JNK Pathway Based on Network Pharmacology
SO FOOD SCIENCE & NUTRITION
LA English
DT Article
DE functional foods; inflammation; network pharmacology; NF-kappa B/I kappa B/JNK pathway; osteoarthritis
ID osteoporosis; inflammation
AB Osteoarthritis (OA) is a painful joint condition primarily caused by cartilage degradation, leading to pain and reduced mobility. Given the side effects of current treatments, this study investigates Osteo-F, a novel herbal-based functional ingredient formulated with Schizandra chinensis, Lycium chinense, and Eucommia ulmoides, traditionally valued for their bioactive and health-promoting properties. Network pharmacology analysis identified significant interactions involving Osteo-F within the TNF signaling pathway, highlighting its role in modulating key inflammatory processes in OA. In vivo experiments using a monosodium iodoacetate-induced OA rat model demonstrated significant improvements in arthritis scores, bone mineral content, and bone mineral density, alongside preservation of cartilage integrity, as confirmed by histological analyses. In vitro studies further revealed that this formulation reduced the activation of JNK and NF-kappa B pathways, decreasing inflammatory cytokines and matrix metalloproteinases critical in cartilage breakdown. These findings underscore the potential of Osteo-F as a functional food candidate to reduce inflammation and support cartilage preservation in OA. Future clinical trials are required to validate these findings and explore its dietary integration in OA management.

TI Patients with periprosthetic femoral fractures are older adults who are commonly diagnosed with osteoporosis
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE Bone mineral density; Fracture liaison service; Osteoporosis; Periprosthetic femoral fractures; Periprosthetic fractures
ID density; femur
AB This study focused on individuals aged >= 50 years with periprosthetic femoral fractures (PFF). When compared to those with native hip fractures, patients with PFF were older, had a higher BMI, and demonstrated a greater number of comorbidities. Given the high frequency of osteoporosis risk factors and the BMD results, PFF should be classified as osteoporotic fractures. Introduction To compare patients presenting with periprosthetic femoral fractures (PFF) to patients with native hip fractures with a special focus on bone mineral density (BMD) measurements, in order to reinforce the hypothesis that PFF are osteoporotic fractures. Methods A retrospective, single-centre, observational study of all patients aged >= 50 years with low-energy PFF identified at the Lille University Hospital from January 1, 2016, to December 31, 2022, was conducted. The PFF group was compared to a group of patients with native hip fractures hospitalized during the same period. To compare the T-score data, we used a linear mixed model that considered a predefined adjustment for age, sex, and BMI. Adjusted means +/- standard error of the mean (SEM) are derived from the mixed model. Results Among 71 patients with PFF (78.9% female, median (IQR) age 81 (72-88) years), osteoarthritis (57.8%) was the primary indication for hip surgery. Compared with the native hip fracture group (n = 117), patients in the PFF group were significantly older (p = 0.002), had a significantly greater BMI (p = 0.043), and had a higher history of multiple falls (54.3% vs. 26.1%, p < 0.001). A greater frequency of previous low-energy fractures (69.0% vs. 44.0%, p < 0.001) and an increased prescription of anti-osteoporosis medications (26.8% vs. 11.1%, p = 0.006) in patients with PFF were found. Adjusted T-scores differed between the two groups at the lumbar spine (mean adjusted +/- SEM, - 0.5 +/- 0.2 (PFF group) vs. - 1.2 +/- 0.2 (comparator group), p = 0.008) but not at the femoral neck or at the total hip. Conclusion Low-energy PFF should be considered as an osteoporotic fracture and treated accordingly.

TI A Scoping Review of Interventions Aimed at Reducing Fear of Falling in Older Adults With Orthopedic Conditions
SO JOURNAL OF GERIATRIC PHYSICAL THERAPY
LA English
DT Review
DE fear of falling; orthopedic conditions; interventions; older adults
ID knee osteoarthritis; exercise programs; physical function; self-efficacy; elderly-women; balance; community; people; gait; osteoporosis
AB Background and Purpose:Fear of falling (FoF) is a persistent anxiety regarding the risk of falling, which can even impact individuals without a history of falls. Fear of falling has been associated with decreased physical functioning and increased risk of falls. Most interventions have focused on reducing FoF in healthy older adults. This study aimed to review the literature's scope, nature, and content related to FoF interventions in older adults with orthopedic conditions.Methods:A scoping literature review was conducted. The method steps included identifying the research question, identifying relevant studies, selecting the studies, charting the data, and synthesizing, summarizing, and reporting the results. Cochrane Library, Medline, PsycINFO, Embase, ProQuest, and Google Scholar were searched. The search strategy used a set of key concepts, including "Fear of Falling," "Orthopedic conditions," "Interventions," and "Older adults."Results and Discussion:Out of the 33 articles that fulfilled the inclusion criteria, 21 were randomized control trials (RCTs), 5 were RCT protocols, 3 were quasi-experimental studies, 2 employed pre-post designs, 1 was a prospective cohort study, and 1 was an experimental study. The review revealed 7 distinct categories of interventions: exercise training, cognitive behavioral therapy, enhanced occupational or physical therapy (OT or PT), motivational interviews, interdisciplinary interventions, education, and mind-body intervention. The Falls Efficacy Scale (FES) was the most frequently used outcome measure for assessing FoF. Other measures were the Fear of Falling Questionnaire (FoFQ), the International Physical Activity Questionnaire

(IPAQ), and the Perceived Ability to Manage Fall (PAMF). The studies varied in their reasoning, content, and how they reported findings, posing challenges for healthcare professionals in choosing and applying FoF intervention programs specific to various orthopedic conditions.Conclusion:This review highlighted the need for adopting more comprehensive approaches for assessing and addressing FoF in older adults with orthopedic conditions.

AB The crosstalk between H-type endothelial cells (ECs) and macrophages is critical for maintaining angiogenesis and osteogenesis in bone homeostasis. As core components of type H vessels, ECs respond to various pro-angiogenic signals, forming specialized vascular structures characterized by high expression of platelet-endothelial cell adhesion molecule-1 (CD31) and endothelial mucin (EMCN), thereby facilitating angiogenesis-osteogenesis coupling during bone formation. Macrophages, as key immune cells in the perivascular region, are primarily classified into the classically activated pro-inflammatory M1 phenotype and the selectively activated anti-inflammatory M2 phenotype, thereby performing dual functions in regulating local tissue homeostasis and innate immunity. In recent years, the complex crosstalk between type H vessel ECs and macrophages has garnered significant interest in the context of bone-related diseases. Orderly regulation of angiogenesis and bone immunity provides a new direction for preventing bone metabolic disorders such as osteoporosis and osteoarthritis. However, their interactions in bone homeostasis remain insufficiently understood, with limited clinical data available. This review comprehensively examines the intricate interactions between type H vessel ECs and macrophages with diverse phenotypes, and Insights into the signaling pathways that regulate their crosstalk, focusing on their roles in angiogenesis and osteogenesis. Furthermore, the review discusses recent interventions targeting this crosstalk and the challenges that remain. These insights may offer new perspectives on bone homeostasis and provide a theoretical foundation for developing novel therapeutic strategies.

TI Spontaneous facet fusion following lateral lumbar interbody fusion supplemented with percutaneous pedicle screw fixation in degenerative lumbar disease
SO EUROPEAN SPINE JOURNAL
LA English
DT Article
DE Minimally invasive surgery; Lateral lumbar interbody fusion; Spontaneous facet fusion; Facet osteoarthritis
ID mechanical-behavior; spine; instrumentation; osteoarthritis; flexibility; disc
AB PurposeTo identify factors contributing to spontaneous facet fusion (SFF) after lateral lumbar interbody fusion (LLIF) with percutaneous pedicle screw fixation and evaluate its clinical significance.MethodsWe analyzed 43 patients (150 facet joints) who underwent LLIF with percutaneous pedicle screw fixation without posterior decompression and had at least one year of follow-up. Factors associated with SFF included patient-related factors (age, BMI, diabetes, smoking, osteoporosis), lumbar spinal factors (preoperative diagnosis, number of fused segments), and radiologic factors (facet osteoarthritis, interbody fusion status, cage position, and subsidence). Clinical outcomes were assessed using VAS for lower back pain (LBP) and radiating pain (RP) and the Oswestry Disability Index (ODI). Patients were categorized into three groups based on facet and interbody fusion status.ResultsSFF was observed in 65.3% (98/150) of facet joints, and in 52.0% of cases, SFF preceded interbody fusion. Preoperative facet osteoarthritis (p = 0.009, OR = 9.951) and solid interbody fusion (p = 0.048, OR = 9.837) were significant predictors of SFF. Clinical analysis showed significantly lower VAS for LBP in fused segments (p = 0.023), though no difference between facet fusion-only and interbody fusion groups.ConclusionsSFF frequently occurs after LLIF with percutaneous pedicle screw fixation, often before interbody fusion. It was more common in preoperative facet joint osteoarthritis and was frequently seen with solid interbody fusion. SFF correlates with improved LBP outcomes.

TI Postoperative rehabilitation training adherence and influencing factors in adults with traumatic fractures in China: a cross-sectional study
SO BMJ OPEN

LA English
DT Article
DE Pain management; Cross-Sectional Studies; Fractures, Bone; REHABILITATION MEDICINE
ID exercise adherence; prescribed exercise; home exercise; health-care; patient; people; osteoarthritis; reconstruction; intervention; osteoporosis
AB Objective To explore rehabilitation training adherence as well as its related influencing factors among adult patients with traumatic limb fractures to provide a basis for clinical intervention strategies. Design Cross-sectional study. Setting Department of Rehabilitation Medicine. Participants Adults within 1 year postoperative for traumatic limb fractures and who underwent rehabilitation training were included in this study. Interventions Not applicable. Main outcome measures Patient information was collected using a self-designed general information form. Rehabilitation training adherence was evaluated using the Exercise Adherence Rating Scale (0/64, higher values=higher adherence). Barriers to and facilitators of rehabilitation were assessed using sociodemographic data, ability to perform daily life (ADL), General Self-Efficacy Scale (GSES) and Visual Analogue Scale. Pearson's (r) and determination (R-2) correlation coefficients were calculated to determine the strength of associations between variables. Potential correlates were explored using multiple linear regression analysis. Results Between December 2022 and December 2023, 180 subjects were recruited. The age of the participants ranged from 18 to 93 years, with a mean age of 41.5 years (SD 15.6). The mean Exercise Adherence score was 30.31 (SD 5.8). Adherence to postoperative rehabilitation training tended to be lower in participants of older age (-1.30; 95% CI -2.14 to -0.46; p=0.003), and those who had higher pain scores on the movement (moderate pain (-3.25; 95% CI -4.56 to -1.95; p<0.001) to severe pain (-5.42; 95% CI -7.31 to -3.54; p<0.001)), less education (-2.90; 95% CI -4.17 to -1.64; p<0.001), fewer family income (-1.82; 95% CI -2.77 to -0.87; p<0.001), treated at home (-1.90; 95% CI -3.35 to -0.45; p=0.011) and with lower GSES scores (0.25; 95% CI 0.16 to 0.34; p<0.001). Conclusions Patients with limb fractures require rehabilitation but often struggle with adherence to interventions. Strategies that focus on targeted education programmes, pain management and self-efficacy improvement may be considered to guide future research and programmatic approaches to enhance adherence to rehabilitation training.

TI Maternal and neonatal outcomes of occiput posterior vaginal delivery
SO JOURNAL OF OBSTETRICS AND GYNAECOLOGY RESEARCH
LA English
DT Article
DE delivery; malpresentation; occiput posterior position
ID fetal head position; anal-sphincter injury; impact; risk
AB AimThe occiput posterior (OP) position is the most common fetal malposition associated with poorer maternal outcomes compared to the occiput anterior (OA) position. However, there are no equivalent reports for women in Japan. This study aimed to investigate the maternal and neonatal outcomes of OP delivery in Japan.MethodsThis retrospective study was conducted at a tertiary hospital in Japan. Singleton pregnant women who delivered vaginally at and after 37 weeks of gestation between January 2000 and May 2023 were included. Participants were divided into OA and OP groups and pregnancy outcomes were compared. Multivariable analysis was performed to adjust for background.ResultsIn total, 13 852 eligible participants were divided into OA (13 633, 98.4%) and OP (218, 1.6%) groups. Maternal weights were significantly higher in the OP group than in the OA group, but there were no significant differences in maternal age, height, BMI, and parity. The incidence of assisted vaginal delivery (6.0% vs. 25.2%, adjusted odds ratios [aOR] 6.97), third- or fourth-degree perineal laceration (0.9% vs. 2.8%, aOR 3.52), postpartum hemorrhage (4.3% vs. 8.7%, aOR 2.17), and prolonged second stage of labor (11.3% vs. 29.4%, aOR 4.75) were significantly higher in the OP group. On the other hand, there were no significant differences in neonatal outcomes.ConclusionThe present study showed that OP vaginal deliveries require more time, and the increased number of assisted vaginal deliveries resulted in more maternal lacerations and hemorrhage. Maternal complications should be noted in the management of OP deliveries.

TI The role of lactylation modifications in musculoskeletal diseases: From mechanism to clinical application
SO PHARMACOLOGICAL RESEARCH
LA English
DT Article
DE Lactylation; Musculoskeletal diseases; Post-translational modification;

Epigenetic regulation; Therapeutic approaches
ID lactate; metabolism; cell
AB Lactylation, a recently discovered histone and non-histone modification driven by lactate, has redefined the understanding of how metabolic by-products regulate gene expression. Beyond its conventional role as an energy substrate, lactate emerges as a pivotal signaling mediator that couples cellular metabolism with epigenetic regulation. In musculoskeletal disorders, aberrant lactylation has been implicated in the disruption of osteogenic-osteoclastic balance, extracellular matrix homeostasis, and regenerative capacity, thereby linking cellular metabolic stress to pathological tissue remodeling. These findings position lactylation as a unifying mechanism across osteoporosis, osteoarthritis, intervertebral disc degeneration, and sarcopenia. Yet, the field remains in its infancy: the enzymatic machinery of lactylation is incompletely characterized, context-specific functions are poorly defined, and translation to human pathology is scarce. Conceptualizing lactylation as a metabolic-epigenetic nexus not only reframes our understanding of musculoskeletal biology but also highlights new opportunities for biomarker discovery and targeted epigenetic therapies. Addressing these challenges will be essential to harness the clinical potential of this emerging regulatory paradigm.

TI Study on Bone Mineral Density Around the Knee in Postmenopausal Women with Osteoarthritis and Osteoporosis
SO INTERNATIONAL JOURNAL OF WOMENS HEALTH
LA English
DT Article
DE bone mineral density; osteoarthritis; osteoporosis; dual-energy computed tomography; subchondral bone
ID subchondral bone; proximal tibia; fracture; individuals; injury
AB Background: Osteoporosis (OP) and knee osteoarthritis (KOA) are common comorbidities in postmenopausal women, yet the relationship between OP and localized bone mineral density (BMD) around the knee remains unclear. This study investigated the effect of concomitant OP on periarticular BMD and its associations

with the Western Ontario and McMaster University Osteoarthritis Index (WOMAC), radiographic severity, and hip-knee-ankle (HKA) angle in postmenopausal women with KOA.
 Methods: In this cross-sectional study, 117 postmenopausal women were classified into a KOA combined with OP group (n=59) and a KOA-only group (n=58) based on dual-energy X-ray absorptiometry (DXA) T-scores. All participants underwent dual-energy computed tomography (DECT) to quantify BMD around the distal femur, proximal tibia, and patella; weight-bearing radiographs to assess Kellgren-Lawrence (K&L) grade and HKA angle; and the WOMAC questionnaire to evaluate pain and joint function.
 Results: Patients with KOA combined with OP demonstrated significantly lower knee BMD than those with KOA alone ($P < 0.001$). This reduction in BMD was more pronounced with increasing OP severity. Notably, even after adjusting for pain levels, BMD remained significantly lower in the KOA combined with OP group ($P < 0.05$). Furthermore, medial knee BMD in the KOA combined with OP group exhibited an inverted U-shaped relationship with K&L grade, peaking at grade III before declining. In contrast, BMD increased progressively with K&L grade in the KOA group. A significant inverse correlation was also observed between the HKA angle and medial knee BMD in the KOA combined with OP group, suggesting greater bone loss with increasing valgus deformity.
 Conclusion: Postmenopausal women with KOA combined with OP have markedly lower periarticular BMD, associated with more severe pain, distinctive radiographic changes, and poorer alignment. These findings highlight the need for active bone preservation and OP management in KOA patients to alleviate symptoms and potentially slow disease progression.

TI Effects of E2F Family on Musculoskeletal System Development and Related Diseases
SO PROGRESS IN BIOCHEMISTRY AND BIOPHYSICS
LA English
DT Article
DE E2F family; bone; muscle; osteosarcoma; osteoarthritis
ID blocks terminal differentiation; duchenne muscular-dystrophy; cell-cycle progression; transcription factor; stem-cells; bone-formation; dna-repair; muscle; proliferation; expression
AB The E2F family consists of transcription factors that mediate the induction of the E2 gene by adenovirus E1a and play a vital role in regulating cell cycle progression, cell proliferation, and cell apoptosis. Given its primary functions in cell proliferation and differentiation, early studies on the E2F family focused on its relationship with cancer. However, as research has expanded, the E2F family has been found to play an independent role in the development of the musculoskeletal system and the mechanisms of related diseases. The E2F family can influence the progression of musculoskeletal diseases by regulating the cell cycle and proliferation of stem cells, osteoblasts, osteoclasts, chondrocytes, and myoblasts, acting as a target gene for various downstream pathways and microRNAs. This review is divided into two parts: the first elaborates on the physiological roles of the E2F family in bone

metabolism, skeletal muscle, and cartilage development, while the second summarizes its roles in the pathological processes of osteosarcoma, rheumatoid arthritis, osteoporosis, and muscle-related diseases. During musculoskeletal system development, the E2F family affects bone metabolism by regulating stem cell differentiation, promoting osteoclast differentiation and metabolism, and increasing osteoblast activity or inhibiting osteoblast differentiation. It also regulates mitosis in cartilage, influencing chondrocyte proliferation and differentiation. Additionally, the E2F family is essential for skeletal muscle development, controlling muscle differentiation and myogenesis. In the pathological mechanisms of musculoskeletal diseases, most E2F family members act as downstream targets of various microRNAs, regulating osteosarcoma progression. Some members function independently through their ability to control cell proliferation. The E2F family also contributes to osteoporosis progression by promoting pathological increases in osteoclast activity and affecting osteoblast function. In rheumatoid arthritis and osteoarthritis, E2F family members aggravate inflammation by increasing inflammatory factors through multiple pathways. Moreover, the E2F family plays a crucial role in muscle-related diseases, influencing skeletal muscle regeneration after injury and affecting symptoms of muscular dystrophies. This review provides a comprehensive overview of the physiological roles of the E2F family in the musculoskeletal system and its mechanisms of action in related diseases. By offering a systematic summary and analysis, this article aims to provide a foundation for future research as well as insights for disease diagnosis and treatment.

DT Article
DE WISP-1; Musculoskeletal disorders; Sarcopenia; Osteoporosis; Osteoarthritis
ID nf-kappa-b; ccn family proteins; signaling pathway; skeletal-muscle; chondrocyte apoptosis; wnt; expression; osteoarthritis; proliferation; cartilage
AB As the global population ages, the incidence of age-related musculoskeletal diseases continues to increase, driven by numerous complex and poorly understood factors. WNT-1 inducible secreted protein 1 (WISP-1), a secreted matrix protein, plays a critical role in the growth and development of the musculoskeletal system, including chondrogenesis, osteogenesis, and myogenesis. Numerous in vivo and in vitro studies have demonstrated that WISP-1 is significantly upregulated in age-related musculoskeletal conditions, such as osteoarthritis, osteoporosis, and sarcopenia, suggesting its involvement in the pathogenesis of these diseases. Regulating WISP-1 expression holds promise as a therapeutic strategy for improving musculoskeletal function, potentially offering new avenues for treating age-related musculoskeletal diseases in clinical practice. This review highlights the signaling pathways associated with WISP-1, its physiological roles within the musculoskeletal system, and its therapeutic potential in treating age-related musculoskeletal disorders.

TI The 2024 UK clinical guideline for the prevention and treatment of osteoporosis
SO ARCHIVES OF OSTEOPOROSIS
LA English
DT Article
DE Osteoporosis; Fracture; NOGG; Guideline
ID bone-mineral density; glucocorticoid-induced osteoporosis; corticosteroid-induced osteoporosis; vertebral compression fractures; yearly zoledronic acid; post hoc analysis; quality-of-life; aged 50 years; postmenopausal

women; hip fracture
AB The National Osteoporosis Guideline Group (NOGG) has updated the revised UK guideline for the assessment and management of osteoporosis and the prevention of fragility fractures in postmenopausal women, and men age 50 years and older. This guideline is relevant for all healthcare professionals involved in osteoporosis management.IntroductionThe UK National Osteoporosis Guideline Group (NOGG) first produced a guideline on the prevention and treatment of osteoporosis in 2008, with updates in 2013, 2017 and 2021. This paper presents a minor update of the 2021 guideline, the scope of which is to review the assessment and management of osteoporosis and the prevention of fragility fractures in postmenopausal women and men aged 50 years and older.MethodsWhere available, systematic reviews, meta-analyses and randomised controlled trials have been used to provide the evidence base. Conclusions and recommendations have been systematically graded according to the strength of the available evidence.ResultsReview of the evidence and recommendations are provided for the diagnosis of osteoporosis, fracture-risk assessment and intervention thresholds, management of vertebral fractures, non-pharmacological and pharmacological treatments, including duration and monitoring of anti-resorptive therapy, glucocorticoid-induced osteoporosis, as well as models of care for fracture prevention. Recommendations are made for training, service leads and commissioners of healthcare, and for review criteria for audit and quality improvement. Specific 2024 updates include guidance on fracture risk assessment by ethnicity, Parkinson's disease, Down's syndrome and lower-limb amputation; furthermore, the definition of very high fracture risk has been clarified. Hormone replacement therapy (HRT) is now recommended as a first-line treatment option in younger postmenopausal women with high fracture risk and low baseline risk for adverse events; recommendations regarding abaloparatide are included; additional training resources have been added.ConclusionThe guideline provides a comprehensive overview of the assessment and management of osteoporosis for all healthcare professionals involved in its management. This position paper has been endorsed by the International Osteoporosis Foundation and the European Society for Clinical and Economic Aspects of Osteoporosis, Osteoarthritis and Musculoskeletal Diseases (ESCEO).

DE Aging; Epigenetic clocks; Degenerative musculoskeletal diseases; DNA methylation; Epigenetic age acceleration
ID dna methylation; age; osteoarthritis; pain; biomarker
AB Objective: Epigenetic clocks have emerged as powerful tools for quantifying biological aging. Degenerative musculoskeletal disorders (e.g., osteoarthritis [OA], osteoporosis) represent a group of age-related conditions characterized by progressive tissue deterioration. While their epidemiological association with aging is well-established, the precise relationship with epigenetic aging markers remains to be systematically elucidated. This review synthesizes current evidence on the application of epigenetic clocks as biomarkers and their clinical potential in managing these conditions. Methods: We systematically searched four major biomedical databases (PubMed, PMC, Web of Science, ScienceDirect) from inception through December 2024 for observational studies examining the association between the epigenetic clock and degenerative musculoskeletal diseases using controlled vocabulary (e.g., DNA methylation age) combined with disease-specific terms. The protocol was registered with PROSPERO (CRD42024623554). Results: After screening, 14 studies (case-control, cross-sectional, cohort) were included. We identified eight epigenetic clocks (based on cartilage, bone, and blood biomarkers) for assessing degenerative musculoskeletal diseases. DunedinPACE showed significant associations with chronic low back pain severity (r = 0.39-0.45) and functional impairment, while Horvath's clock revealed tissue-specific epigenetic aging in OA cartilage (Delta Age = 3.7 years). GrimAge exhibited the strongest correlations with chronic pain (rho = 0.47) and mediated socioeconomic influences (beta = 0.81). Conclusions: This systematic review of 14 clinical studies establishes epigenetic clocks as promising biomarkers for degenerative musculoskeletal diseases. The differential associations observed across epigenetic metrics highlight the need for disease-specific algorithm development. Future research should prioritize longitudinal validation and mechanistic investigations into socioeconomic influences on epigenetic aging.

TI Feasibility of ballistic vs conventional resistance training in healthy postmenopausal women: A three-arm parallel randomised controlled trial
SO MATURITAS
LA English
DT Article
DE Adverse events; Satisfaction; Osteoarthritis; Osteoporosis; Strength training
ID older-adults; strength; osteoporosis
AB Objectives: Power training has gained attention as a method for enhancing functional performance and mitigating fall risk in older adults, yet its long-term feasibility and safety, particularly in ballistic resistance training, remain underexplored in postmenopausal women. We evaluated the feasibility of 8-month

ballistic resistance training compared with conventional resistance training in postmenopausal women. Study design: The Resistance Exercise Programme on Risk of Osteoporosis and Osteoarthritis in Females (REPROOF) study was a three-arm parallel group randomised controlled trial at a university lab in the UK. Healthy postmenopausal women (n = 109) were randomised to 30 weeks (2 sessions/week) of lower-body ballistic resistance training, conventional resistance training, or a non-exercising control group. Main outcome measures: The primary outcomes, collected by questionnaire, were process feasibility, acceptability, perceived exercise efficacy, and adverse events. Results: Eighty-two participants completed the trial (75.2 % retention). Both ballistic resistance training and conventional resistance training were well accepted, with most participants rating the intervention positively. No differences in the perceived improvements in physical function and psychological well-being were found between the resistance training groups. Similarly, there was no significant difference in the rate of muscle-related adverse events between the resistance training groups (ballistic, 2.7 per 100 person-weeks; conventional, 2.3 cases per 100 person-weeks), but the rate was significantly lower in the control group (0.9 cases per 100 personweeks). No serious adverse events occurred during or within 24 h of exercise sessions. Conclusions: The absence of serious adverse events and the observed positive outcomes confirm the safety, satisfaction, and perceived effectiveness of ballistic resistance training, suggesting its potential for broader application in healthy postmenopausal women. ClinicalTrials.gov registry ID NCT05889598

TI Bibliometric analysis of the application of artificial intelligence in orthopedic imaging
SO QUANTITATIVE IMAGING IN MEDICINE AND SURGERY
LA English
DT Article
DE Bibliometric analysis; artificial intelligence (AI); orthopedic; image
ID convolutional neural-networks; classification; segmentation; bone; impact; tissue; joint; hip
AB Background: With the development of artificial intelligence (AI) and the increasing significance of imaging in orthopedics, the application of AI in the field of orthopedic imaging is becoming increasingly extensive. Previous studies show that the application of AI-based orthopedic imaging may break the traditional model of the field. As a result, relevant research has received attention, and numerous articles have been published. Through bibliometric analysis, this study summarized the knowledge structure of AI-based orthopedic imaging and explored its potential research trends and focal points. Methods: In this study, literature on AI in the field of orthopedic imaging available in the Web of Science Core Collection (WoSCC) database from 1 January 2007 to 31 December 2024 was analyzed. In order to identify the main research topics and generate visual charts of countries, institutions, authors, and keyword networks, the search results were imported into VOSviewer and CiteSpace. Results: A total of 3,147 publications were analyzed, revealing a rapid increase in AI research in orthopedic imaging since 2007, with over 90% of studies published after 2017. The United States (US) and China dominate this field, with the US leading in citations and academic influence, and China demonstrating significant growth in productivity. Institutional analysis highlighted Harvard University and Stanford University as key contributors, reflecting their strong academic influence. Keyword analysis identified three main convolutional neural networks (CNNs); (II) applications in orthopedic disease imaging, including osteoarthritis, osteoporosis, and total knee arthroplasty; and (III) innovations in multimodal fusion and three-dimensional (3D) imaging techniques. Emerging trends emphasize integrating imaging data with clinical biomarkers to improve diagnostic accuracy and therapeutic decision-making. These findings provide a comprehensive overview of AI's role in orthopedic imaging, emphasizing areas of high impact and potential future directions for research. Conclusions: The research on the application of AI in orthopedic imaging is a hot topic and indicates broad research prospects in the future. However, this study suggests that research teams should strengthen collaboration, especially international cooperation. Based on comprehensive analysis, the development of DL algorithms (especially CNNs), the use of AI in processing image data related to orthopedic diseases

(segmentation, classification, and feature map extraction), and the expansion of AI imaging applications in different diseases are expected to become hotspots in future research on the application of AI in orthopedic imaging.

TI Comparative Analysis of Knee Biomechanics in Total Knee Arthroplasty Patients Across Daily Activities
SO BIOENGINEERING-BASEL
LA English
DT Article
DE knee biomechanics index; motion analysis; stair ambulation; gait analysis
AB Total knee arthroplasty (TKA) is a commonly conducted surgery to relieve pain and enhance mobility in patients with end-stage knee osteoarthritis. Patient-reported outcome measures are often used whereas biomechanical variables are too complicated for clinicians and patients to assess functional improvement. There is a need for a simplified integrated knee biomechanics index (KBI) to compare improvements in TKA patients across various daily activities and examine the relationships between clinical functional tests and daily activities. Age-, gender-, and BMI-matched three groups (20 each in posterior stabilized TKA, bi-cruciate stabilized TKA, and healthy controls) were recruited and tested pre-op and 6-month post-op to perform walking on level, slope, and stairs, and two clinical tests (timed-up-go, 10-time sit-to-stand). Knee joint kinematics and kinetics variables were calculated from motion data and ground reactions captured at 120 Hz and 1200 Hz, respectively. KBI was developed based on these variables relative to healthy controls. The longitude comparison of KBI and the differences of KBI across various daily activities were identified using repeated-measure ANOVA. Pearson correlation analysis was used to compare clinical tests and KBI of daily

activities. KBIs of five daily activities were significantly increased following TKA follow-up. KBI improvement during level walking was significantly higher than those during stair ascending and descending. Significant correlations were found between timed-up-go test time and KBIs for stair ascending and descending.

TI The role of the infrapatellar fat pad in osteoporotic knee osteoarthritis: bone-fat crosstalk: cross-sectional studies
SO JOURNAL OF ORTHOPAEDIC SURGERY AND RESEARCH
LA English
DT Article
DE Knee osteoarthritis; Osteoporosis; Obesity; Infrapatellar fat pad; Triglycerides
ID whole joint assessment; body-mass index; articular-cartilage; obesity; mri; association; progression; risk; inflammation; effusion
AB Backgrounds Osteoporosis (OP) and osteoarthritis (OA) of the knee are common and serious human health problems. However, the relationship between

knee OP and the progression of OA, and the potential association between knee OP and adipose tissue within the knee, is not well understood. This study aims to characterize differences in IPFP morphology and lipid metabolism markers, bone metabolism profiles between patients with isolated knee OA and those with concurrent OA and OP, to explore potential mechanisms linking adipose tissue dysfunction to OA-OP comorbidity. Methods This study enrolled 402 participants (89 healthy volunteers, 100 knee OA patients, 108 OP patients, and 105 OA + OP patients) from September 2011 to January 2023. Synovial inflammation markers (effusion grading: 0-3; IPFP abnormalities: 0-3; synovial proliferation: 0-2) and structural knee abnormalities (Whole-Organ Magnetic Resonance Imaging Score [WORMS]: cartilage, bone marrow edema, meniscus sub-scores) were assessed via MRI. Pathological analysis of IPFP tissue (fibrosis: 0-3; vascularization: 0-2) was performed by two blinded pathologists in OA patients undergoing arthroplasty. Clinical outcomes (WOMAC, Oxford Knee Score, Anterior Knee Pain Score) were evaluated preoperatively and at 1-year follow-up. Risk factors (triglycerides, hip BMD, IPFP abnormalities) were analyzed using LASSO regression with 10-fold cross-validation. Results The OA + OP group exhibited higher grades of synovial effusion (mean +/- SD: 2.1 +/- 0.7 vs. 1.3 +/- 0.5, $p < 0.01$), IPFP abnormalities (2.4 +/- 0.6 vs. 1.8 +/- 0.4), and synovial proliferation scores (1.9 +/- 0.5 vs. 1.2 +/- 0.3) compared to the OA group. Total WORMS scores were significantly elevated in OA + OP (32.5 +/- 8.2 vs. 24.1 +/- 6.5, $p < 0.001$), driven by higher cartilage degradation, increase of bone marrow edema, and meniscus damage sub-scores. Pathological analysis confirmed increased fibrosis (2.7 +/- 0.4 vs. 1.9 +/- 0.3) and vascularization (1.8 +/- 0.5 vs. 1.1 +/- 0.2) in OA + OP. At 1-year follow-up, OA + OP patients had worse WOMAC (45.2 +/- 10.1 vs. 33.5 +/- 8.7) and OKS (22.1 +/- 5.3 vs. 28.4 +/- 4.9). LASSO regression identified TG, total hip BMD, and IPFP abnormalities as key risk factors. Conclusion Our results identify a pathophysiological triad of (1) IPFP fibrosis/hypervascularization, (2) systemic hypertriglyceridemia, and (3) low BMD that collectively accelerates structural degeneration and symptom progression in knee OA. While genetic and biomechanical factors initiate OA pathogenesis, these acquired metabolic-inflammatory mechanisms represent tractable therapeutic targets for modifying disease evolution in established OA, particularly with OP comorbidity.

TI Insights into bone and cartilage responses to pulsed electromagnetic field stimulation: a review with quantitative comparisons
SO FRONTIERS IN BIOENGINEERING AND BIOTECHNOLOGY
LA English
DT Review
DE pulsed electromagnetic field (PEMF); bone; cartilage; bone fractures; osteoporosis; osteoarthritis; fracture healing; quantitative comparison
ID mesenchymal stem-cells; subchondral trabecular bone; osteoblast-like cells; osteogenic differentiation; knee osteoarthritis; double-blind; mechanical-property; extracellular-matrix; engineered bone; magnetic-fields
AB Bone fractures and cartilage pathologies represent a heavy socioeconomic burden for the national healthcare systems worldwide. Pulsed electromagnetic field (PEMF) stimulation has become a widely recognized treatment for enhancing bone fracture healing and reducing tissue inflammation, thereby supporting bone tissue regeneration. More recently, its effectiveness in treating cartilage degeneration and osteoarthritis has also been demonstrated. However, the effects of PEMF, particularly the underlying mechanisms related to the activation of specific signaling pathways, are not yet fully known neither correlated with the specific PEMF parameters applied. As a result, standardized protocols for PEMF treatment are lacking in clinical practice, leading to empirical application of PEMF stimulation and heterogeneity in treatment protocols. For these reasons, over the past three decades, the biological effects of PEMF on bone and cartilage tissues have been extensively investigated through both in vitro and in vivo experiments. The aim of this review is to provide a detailed overview of the performed studies, focusing on the applied PEMF stimulation parameters and the induced effects on bone and cartilage tissues. Furthermore, to enable comparisons across various published protocols and to aid in understanding the correlation between applied PEMF parameters and their resulting biological effects, we propose, for the first time, a quantitative descriptor for PEMF stimulation, termed PEMF dose, which accounts for magnetic field intensity, stimulation waveform, and exposure duration. The use of this comprehensive descriptor enabled the identification of common features across different studies and, in the future, it could serve as a valuable tool for refining PEMF stimulation protocols and establishing standardized guidelines to support bone and cartilage repair.

TI Growth Hormone and Bone: Preclinical and Clinical Perspectives
SO ENDOCRINE PRACTICE
LA English
DT Review
DE growth hormone; bone; insulin-like growth factor; growth hormone deficiency; growth hormone excess; acromegaly
ID radiological spinal deformity; morphometric vertebral fractures; term biochemical control; gh-deficient patients; factor-i; mineral density; adult patients; igf-i; replacement therapy; postmenopausal osteoporosis
AB Objective: Growth hormone (GH) is essential for growth and bone metabolism. This article reviews preclinical data that has shaped our understanding of the mechanisms underpinning the effects of GH on bone beyond the downstream activation of insulin-like growth factor-I (IGF-I) generation and summarizes the clinical data of GH deficiency (GHD) and acromegaly on bone health parameters and fracture risk. Methods: A literature search was conducted on PubMed using the following key words: GH, IGF-I, bone, GHD, and acromegaly. The discussion of therapy in GHD and patients with acromegaly, and their fracture risk assessment was based on evidence derived from previously published preclinical and clinical studies. Results: Preclinical and clinical data have demonstrated important pleiotropic effects of GH and IGFI on bone formation and resorption. GH exerts direct and IGF-dependent and independent effects on bone, while IGF-I acts in an endocrine and autocrine/paracrine manner. In GHD, decreased bone turnover, delayed statural growth, low bone mass, and increased fracture risk are observed, whereas acromegaly is associated with increased bone turnover but decreased lumbar bone mineral density and increased vertebral fracture and osteoarthritis risk. Treatment aimed at normalizing the GH/IGF-I axis decreases the fracture risk in GHD, but not acromegaly. Conclusion: Preclinical and clinical studies have improved our understanding of the role of GH in bone in healthy individuals and in disease states. More research is needed to identify the effects of GH on bone and to determine how best to treat patients with GHD and acromegaly, so that their bone health is optimized. (c) 2025 AACE. TI Evaluation of osteogenic activity of Plaksha (Ficus lacor Buch. Ham.) stem bark on human dental pulp derived mesenchymal stem cells
SO INDIAN JOURNAL OF BIOCHEMISTRY & BIOPHYSICS
LA English
DT Article
DE Alkaline phosphatase; Ficus lacor; Human dental pulp stem cells; Mesenchymal stem cells; Osteogenesis; Osteonectin; Plaksha
AB The adverse effects and lower efficacy of synthetic drugs have increased scientists' interest in traditional medicine for managing chronic diseases like osteoporosis and osteoarthritis, which raise the risk of bone fractures. Herbal

medications are increasingly used for joint disorders due to their potential benefits in reducing pain, inflammation, and stiffness, as well as their safety when used correctly. Plaksha (Ficus lacor Buch. Ham) possess a great potential in treating bone disorders. The purpose of the study is to determine the osteogenic effect of stem bark extract of Plaksha on mesenchymal stem cells. Aqueous extract of Plaksha obtained via Soxhlet Apparatus. Mesenchymal stem cells were obtained from human dental pulp; Characterized using Cell Surface Antigen Expression Analysis via FluorescenceActivated Cell Sorting (FACS). Cytotoxicity assessed with MTT. Osteogenic potential evaluated through trilineage differentiation and gene expression analysis (RT-PCR) for Alkaline Phosphatase (ALP) and Osteonectin (OSN). Viability assay revealed that the 10 mu g/mL concentration helps for trilineage differentiation of cells. Upregulation of ALP and OSN genes via RT-PCR in treated group showed the osteogenic differentiation of cells. This demonstrates the aq. Extract of FL promotes the osteogenic differentiation of MSCs and facilitate the osteogenesis. Hence the drug can be used in various bone disorders.

TI High prevalence and underdiagnosis of osteoporosis in total hip arthroplasty candidates: a comprehensive assessment using bone mineral density, trabecular bone score, and bone turnover markers
SO JOURNAL OF ORTHOPAEDIC SURGERY AND RESEARCH
LA English
DT Article
DE Total hip arthroplasty; Osteoporosis; Bone mineral density; Trabecular bone score; Bone turnover markers; Patient-reported outcome measures
ID vitamin-d deficiency; postmenopausal women; fracture risk; osteoarthritis; metaanalysis; replacement; prediction; diagnosis; therapy; bmd
AB Background Total hip arthroplasty (THA) effectively alleviates symptoms in individuals with hip osteoarthritis. However, some candidates may have undiagnosed osteoporosis, and bone mineral density (BMD) alone may not sufficiently reflect bone fragility. The trabecular bone score (TBS) and bone turnover markers (BTMs) provide additional information on bone quality and metabolism. This study aimed to comprehensively evaluate osteoporosis prevalence using BMD, TBS, and BTMs, and to assess whether preoperative osteoporosis affects postoperative pain and patient-reported outcome measures (PROMs). Methods This retrospective study included 357 patients who underwent primary THA. Comprehensive evaluation involved dual-energy X-ray absorptiometry to assess BMD and lumbar TBS, along with serum levels of tartrate-resistant acid phosphatase 5b (TRACP-5b), and 25-hydroxyvitamin D (25(OH)D). The subsequent analysis excluded patients receiving preoperative osteoporosis treatment (n = 33) to avoid treatment-related confounding. Patients (n = 324) were initially stratified by sex, and then classified as normal, osteopenia, or osteoporosis group based on total hip BMD. Postoperative outcomes were assessed using the Numerical Rating Scale for pain and the Hip Disability and Osteoarthritis Outcome Score for Joint Replacement for PROMs at preoperatively and 12 months postoperatively. Results Osteoporosis and osteopenia were identified in 23.8% and 37.5% of all patients, respectively. TBS revealed

compromised bone microarchitecture (Low TBS) in 25.7% of patients. Elevated TRACP-5b and vitamin D deficiency were observed in 15.6% and 72.3% of patients, respectively. Only 9.2% received osteoporosis pharmacologic treatment. No complications were observed within 12 months postoperatively. In only female patients, the osteopenia and osteoporosis groups, compared with the normal group, showed significantly lower TBS and 25(OH)D levels, and significantly higher TRACP-5b levels ($p < 0.05$); however, no significant differences were observed between the osteopenia and osteoporosis groups for these parameters. Furthermore, the improvement in HOOS JR scores from baseline to 12 months was significantly lower in the osteoporosis group compared with the normal and osteopenia groups ($p = 0.02$). Conclusion This comprehensive assessment, which included BMD, TBS and BTMs, revealed that female patients exhibited abnormalities in bone microarchitecture and bone turnover starting from the osteopenia stage. Furthermore, the osteoporosis group showed a significantly lower improvement in PROMs 12 months postoperatively.

TI Targeting type H vessels with bioactive metabolites from traditional Chinese botanical drugs: a therapeutic strategy for skeletal disorders
SO FRONTIERS IN PHARMACOLOGY
LA English
DT Review
DE bioactive metabolites; type H vessels; osteoporosis; osteoarthritis; bone defects; fracture; osteonecrosis of the femoral head
ID endothelial-cells; attenuates osteoarthritis; femoral-head; bone; angiogenesis; osteogenesis; mechanisms; differentiation; subtype
AB Type H vessels are a specialized subtype of bone capillaries, first identified in 2014, characterized by high co-expression of CD31 and Endomucin. These vessels play a key regulatory role in bone development, repair, and remodeling through angiogenesis-osteogenesis coupling, which is essential for maintaining skeletal homeostasis. Type H vessels are abundant in the bones of young individuals but gradually decline with age, and their dysregulation is closely associated with skeletal disorders, including osteoporosis, osteoarthritis, bone defects, fractures, and osteonecrosis of the femoral head. Previous studies have identified the molecular mechanisms underlying the regulation of type H vessels, and recent investigations have examined pharmacological strategies to modulate these pathways. Among these, bioactive metabolites derived from traditional Chinese botanical drugs have attracted attention for their ability to regulate type H vessel formation and improve skeletal health. This review summarizes the molecular mechanisms by which these bioactive metabolites target type H vessels, highlighting their therapeutic potential in skeletal disorders and suggesting that modulation of type H vessel formation represents a promising strategy for intervention. Future studies are needed to further clarify the mechanisms of action of these metabolites and to assess their safety and clinical efficacy for translation into human therapy.

TI Synthetic Nanopillars for Stimulating Osteoblast Activity and Osteointegration in Bone-Related Disorders
SO INTERNATIONAL JOURNAL OF NANOMEDICINE
LA English
DT Review
DE synthetic polymers; nanopillars; bone repair; osteoblast activity;

osteointegration
ID surface; arrays; nanotopography; nanoparticles; particles; therapy; scaffolds; adhesion; disease; cells
AB Osteoporosis, osteoarthritis, and fractures are bone-related disorders that have a huge impact on the quality of life and healthcare systems worldwide. Traditional treatments, including bone grafts, have their limitations, with bone grafts often being rejected by the immune system and infected, making new treatments necessary. Nanopillars based on synthetic polymers have been demonstrated to be promising tools for bone regeneration and repair, showing to emulate the extracellular matrix composition, stimulate osteoblast activity and induce osteointegration. In this review, nanopillars fabrication techniques, such as electrospinning, nanoimprint lithography and self-assembly, also the state of the art of nanopillars technology are presented. Their role in modulating cellular responses via both physical and biochemical means, to enhance mineralization and to stabilize implants is also discussed. Additionally, their applications in treating bone-related disorders, eg promotion of fracture healing, augmentation of dental or orthopedic implants, and improvement of bone tissue engineering are discussed in the review. Using these focuses, each section examines opportunities and challenges (eg optimizing fabrication processes, improving biocompatibility, and investigating the integration of nanopillars with upcoming therapies like gene and stem cell therapy) for the potential of nanopillar technology. Finally, this review points out the requirement of scalable fabrication techniques, long term biocompatibility studies and multifunctional therapeutic strategies to fully employ the therapeutic applications of nanopillars in clinical scenarios. This review seeks to consolidate current knowledge of synthetic polymer based nanopillars and identify future directions for their use in bone related disorders through a comprehensive synthetic polymer nanopillar review.

DT Article
DE data-limited fisheries; demersal and pelagic fish; generalized additive models (GAMs); K-nearest neighbors; otolith morphometry; random forest

ID size; shape; growth; body; identification; north; stock; width; coast; city
AB Accurate estimation of fish length from otoliths is essential for stock assessment, bycatch monitoring, and automated length reconstruction workflows. However, the strength and consistency of otolith-somatic scaling can vary across species and environments. This study examined the predictive performance of otolith morphometric variables for estimating fish length across six pelagic and demersal species from major Philippine fishing grounds. We evaluated 11 otolith morphometric and shape metrics using linear and nonlinear regressions, generalized additive models (GAMs), and machine learning (ML) algorithms. Model performance was compared across species to identify both the most informative predictors and ecological factors influencing otolith-length relationships. Otolith length (OL) and otolith area (OA) consistently produced the highest predictive power, whereas otolith perimeter (OP) showed the weakest performance. Demersal species and the midwater schooling Decapterus kurroides exhibited highly predictable otolith-length relationships (R-2 > 0.95), reflecting relatively stable habitats and uniform growth dynamics. In contrast, Selar crumenophthalmus and Thunnus albacares displayed lower predictability (R-2 <= 0.70), likely due to exposure to dynamic thermal regimes, variable prey fields, and ontogenetic shifts that increase plasticity in otolith accretion. ML models, particularly Random Forest, outperformed classical approaches for species with heterogeneous growth patterns by capturing nonlinearities and interactions among morphometric variables. Our findings demonstrate that OL and OA are robust and broadly transferable predictors of fish length in tropical multispecies fisheries, while species inhabiting variable pelagic environments benefit from more flexible ML frameworks. Integrating ecological context with advanced modeling tools can significantly improve otolith-based size estimation. The study highlights the value of expanding sampling coverage and refining ML approaches to enhance future applications in fisheries monitoring and assessment.

TI Identifying key components from Melastoma dodecandrum in TNF-α-induced osteoblast injury model through a combination of cell membrane chromatography and mass spectrometry
SO JOURNAL OF ETHNOPHARMACOLOGY
LA English
DT Article
DE Melastoma dodecandrum; Isovitexin; TNF-alpha; Cell membrane chromatography; Key component
ID bone; activation
AB Ethnopharmacological relevance: Melastoma dodecandrum (MD), a traditional ethnomedicine, has been widely used for the treatment of fractures, osteoarthritis, and osteoporosis due to its remarkable anti-inflammatory activity. However, the specific active components responsible for its therapeutic effects on orthopedic conditions remain unidentified. Aim of the study: This study aimed to screen and identify key active components in MD using a combination of cell membrane chromatography and mass spectrometry, followed by cellular validation. Materials

and methods: A TNF-alpha-induced osteoblast injury model and an osteoblast membrane chromatography screening system were established to select and identify chemical components of MD that directly act on osteoblasts. The protective effects of MD on osteoblasts were assessed by evaluating cell viability, alkaline phosphatase (ALP) activity, cell mineralization and the expression of osteogenesis-related proteins OCN, RUNX2, and the TNF-alpha receptor protein TNFR1. Validation of the activity of individual components was also conducted. Results: MD significantly improved the viability of osteoblasts under TNF-alpha-induced injury, enhanced ALP activity, stimulated the expression of OCN and RUNX2 proteins, and decreased the expression of TNFR1. Cell membrane chromatography screening identified 32 chemical components, including 21 flavonoids, 6 organic acids, 2 phenylpropanoids, 2 terpenes, and 1 nucleotide. Molecular docking revealed that isovitexin could bind to the specific receptor TNFR1 on the cell membrane. Furthermore, cellular validation demonstrated that isovitexin significantly protected osteoblasts. Conclusions: MD and its pharmacologically active component, isovitexin, exhibit protective effects against TNF alpha-induced inflammatory injury in osteoblasts, laying a solid foundation for future drug development.

TI Influencing factors of flexion contracture among patients with knee

osteoarthritis: a multi-center retrospective cross-sectional study
SO SCIENTIFIC REPORTS
LA English
DT Article
DE Knee osteoarthritis; Flexion contracture; Risk factors; Protective factors
ID articular-cartilage; arthroplasty; joint
AB Knee osteoarthritis (KOA) is a chronic disease with a high prevalence and disability rate. Alterations in lower limb alignment and reduction in lower limb muscle strength are important factors in the progression of KOA. Although pain is the main reason for KOA patients to seek medical treatment, the presence or absence of joint deformity is one of the crucial factors influencing the prognosis and recurrence of the disease. Approximately half of KOA patients may become disabled due to the development of joint deformity. To investigate the prevalence, characteristics, and influencing factors of knee flexion contracture in patients with KOA, providing a basis for preventing and delaying the occurrence of knee joint deformities in such patients. From January 2022 to June 2022, a survey was conducted on 870 patients with KOA visiting 7 community hospitals. Patients whose knees could fully extend to 0 degrees were categorized as the none flexion contracture (NFC) Group, while those whose knees could not fully extend to 0 degrees were categorized as the flexion contracture (FC) Group. Data were collected on patients' demographic characteristics, work and lifestyle habits, dietary preferences, and clinical evaluations. Compare the results of the two groups, and perform a Logistic regression analysis on the influencing factors that show differences to identify the risk factors and protective factors for joint deformity. A total of 853 patients with KOA were included in the study, with a questionnaire recovery rate of 98.05%. Among them, 308 patients were in the FC Group, with a prevalence of knee flexion contracture at 36.11%, and 545 patients were in the NFC Group. The risk factors (OR > 1) included being female, older age, higher Body Mass Index (BMI), history of knee trauma, history of osteoporosis, physically demanding occupations, living in high-rise buildings without elevators, squatting posture during defecation, disease duration, and Kellgren-Lawrence (KL) III-IV grade. Protective factors (OR < 1) included commuting by cycling or driving, regular knee exercises, and calcium supplementation. Standing occupational posture, mountain climbing or hiking activities, and KL II grade were not associated with the occurrence of joint deformity (P > 0.05). Among patients with KOA, KL III-IV grade, living in high-rise buildings without elevators, history of knee injury, and squatting posture during defecation were identified as risk factors for knee joint deformity, which should be prevented early to delay joint deformity.

TI Role and mechanism of Actein on condylar bone metabolism in APOE deletion-induced osteoporotic mice
SO BONE
LA English
DT Article
DE Actein; APOE; Osteochondral; Condylar; Bone lipid metabolism
ID mineral density; progression; growth
AB Aims: To investigate the effects of Actein from Cimicifugae Rhizoma on condylar bone and cartilage in APOE deletion-induced osteoporotic mice, and to preliminarily explore the underlying mechanism. Methods: Sixty 8-week-old female mice were used, which underwent APOE-/- and ovariectomy procedures, followed by oral administration of Actein (15 mg/kg) and Atorvastatin Calcium (AC, 3 mg/kg) for eight weeks. Body weight, uterine weight, and systemic indexes related to bone metabolism and lipid metabolism were assessed in each group. Changes in condylar bone histomorphometric parameters were evaluated using Micro- CT. Morphological changes in the condyle were observed with Hematoxylin-Eosin (H&E), Safranin O/Fast Green, and Alcian Blue Hematoxylin/Orange G (ABH/OG)

staining, with OARSI pathology scoring performed. Sirius red staining and immunofluorescence were used to determine the expression levels of Collagen I (Col I) and Collagen III (Col III) in bone matrix, and Col II in cartilage matrix. Immunohistochemistry assessed the relative expression levels of ALP and proteins associated with the Wnt/(3-catenin/RUNX2 signaling pathway. Results: APOE- /- exacerbates ovariectomy-induced osteoporosis (OP) in condylar of mice. Actein and AC significantly reversed OP, improved bone mineral density (BMD), increased bone microarchitecture, and restored abnormal calcium and phosphorus metabolism in the blood and urine. Morphologically, APOE- /- and ovariectomy reduced condylar cartilage thickness, disrupted chondrocyte arrangement, chondrocyte cleavage, and clustered aggregation, resembling osteoarthritis (OA)-like changes. Actein and AC partially restored the disrupted chondrocyte arrangement, smoothed chondrocyte cleavage, and up-regulated the levels of chondrocyte matrix (Col II, aggrecan) and bone matrix (Col III, ALP). Actein reversed the OA process, potentially through the Wnt/(3-catenin/RUNX2 signaling pathway. Conclusion: APOE- /- and ovariectomy induced OP, leading to OA-like lesions in condylar of mice. Actein promoted cartilage repair and trabecular bone recovery by increasing extracellular matrix synthesis (Col II, Col III, aggrecan), reversing the OA process, possibly through the Wnt/(3-catenin/RUNX2 signaling pathway.

TI The Roles of Forkhead Box O3a (FOXO3a) in Bone and Cartilage Diseases - A Narrative Review
SO DRUG DESIGN DEVELOPMENT AND THERAPY
LA English
DT Review
DE FOXO3a; osteoporosis; osteoarthritis; rheumatoid arthritis; ankylosing spondylitis; intervertebral disc degeneration
ID mesenchymal stem-cells; nf-kappa-b; transcription factor foxo3a; oxidative stress; rheumatoid-arthritis; promotes tumorigenesis; articular-cartilage; survival signals; inhibition; proliferation
AB Bone and cartilage diseases are significantly associated with musculoskeletal disability. However, no effective drugs are available to cure them. FOXO3a, a member of the FOXO family, has been implicated in cell proliferation, ROS detoxification, autophagy, and apoptosis. The biological functions of FOXO3a can be modulated by post-translational modifications (PTMs), such as phosphorylation and acetylation. Several signaling pathways, such as MAPK, NF-kappa B, PI3K/AKT, and AMPK/Sirt1 pathways, have been implicated in the development of bone and cartilage diseases by mediating the expression of FOXO3a. In particular, FOXO3a acts as a transcriptional factor in mediating the expression of various genes, such as MnSOD, CAT, BIM, BBC3, and CDK6. FOXO3a plays a critical role in the metabolism of bone and cartilage. In this article, we mainly discussed the biological

functions of FOXO3a in bone and cartilage diseases, such as osteoporosis (OP), osteoarthritis (OA), rheumatoid arthritis (RA), ankylosing spondylitis (AS), and intervertebral disc degeneration (IDD). FOXO3a can promote osteogenic differentiation, induce osteoblast proliferation, inhibit osteoclast activity, suppress chondrocyte apoptosis, and reduce inflammatory responses. Collectively, up-regulation of FOXO3a expression shows beneficial effects, and FOXO3a has become a potential target for bone and cartilage diseases.

TI Risk Factors for Subchondral Insufficiency Fracture of the Knee in the Setting of Medial Meniscus Posterior Root Tear
SO AMERICAN JOURNAL OF SPORTS MEDICINE
LA English
DT Article
DE SIFK; SONK; spontaneous osteonecrosis; subchondral insufficiency; joint space; meniscus root; meniscal tear; osteoarthritis; risk factors
ID spontaneous osteonecrosis; tibial slope; radiological assessment; femoral condyle; osteoarthritis; injury; osteoporosis; reliability; conversion; extrusion
AB Background: Subchondral insufficiency fracture of the knee (SIFK) is commonly associated with medial meniscus posterior root tears (MMPRTs). However, there is limited research investigating risk factors for SIFK in patients with MMPRTs. Purpose/Hypothesis: The purpose of this investigation was to identify the risk factors for SIFK in patients with MMPRTs. It was hypothesized that age, body mass index, and extent of meniscal extrusion would emerge as significant risk factors for SIFK. Study Design: Case series; Level of evidence, 4. Methods: Patients with a primary isolated MMPRT confirmed via magnetic resonance imaging were included. Data on patient demographics, medical and surgical history, and imaging parameters were assessed for associations with SIFK. Imaging parameters included mechanical axis, medial tibial slope, tibiofemoral joint space, and meniscal extrusion. Patients were identified and divided into 2 groups based on the presence or absence of findings of SIFK on magnetic resonance imaging. Continuous variable distribution normality was assessed using the Shapiro-Wilk test. Demographic comparisons were made by t tests and chi-square tests. Multivariable logistic regression was used to identify SIFK risk factors. The threshold of joint space for predicting SIFK was determined through receiver operating characteristic analysis. The optimal threshold was determined with the Youden index. Results: A total of 153 patients were included (mean +/- SD age, 56.2 +/- 9.1 years): 90 patients (26 male, 64 female) in the non-SIFK group and 63 patients (16 male, 47 female) in the SIFK group. There were no differences in patient demographics between the cohorts. Patients with SIFK had a greater incidence of previous knee injections (P = .047), a significantly smaller tibiofemoral joint space (P < .001), and a significantly greater degree of meniscal extrusion (P = .041). Multivariable logistic regression analysis identified diminished joint space as

the only independent predictor of SIFK (odds ratio, 0.41; P = .017). Receiver operating characteristic analysis determined a predictive threshold for joint space <3.93 mm, yielding an acceptable area under the curve of 0.766. Conclusion: The development of SIFK is likely multifactorial; however, decreased tibiofemoral joint space is a significant independent risk factor for SIFK in patients with MMPRTs, with a greater risk in patients with a tibiofemoral joint space <3.93 mm.

TI Identification of Schizothorax species in Yarkand River, (Xinjiang, China) based on otolith morphology
SO JOURNAL OF OCEANOLOGY AND LIMNOLOGY
LA English
DT Article
DE <italic>Schizothorax</italic>; otolith morphological analysis; elliptic Fourier transform; species discrimination
ID sagittal otolith; somatic growth; shape-analysis; mackerel; atlantic; marmara; stocks; tool
AB This study explored the morphological characteristics and differences of the otoliths in three native species, Schizothorax biddulphi, S. eurystomus and S. curvifrons, in the Yarkand River of the Tarim River, Xinjiang, China. A total of 93 specimens (27 S. biddulphi, 39 S. eurystomus, and 27 S. curvifrons) were analyzed using six basic otolith morphological parameters (OA, Rmax, Rmin, OP, OL, OW) to derive six factors (F1, F2, F3, F4, F5, F6) and seven indices (RO, FF, CI, RE, EL, RR, AR) for morphological assessment. A discriminant analysis incorporating 77 Fourier coefficients of the otoliths revealed distinct morphological differences among the species. A significant power function relationship between otolith morphology and standard length was observed across the species, with R2 values ranging from 0.409 to 0.749. Principal component analysis (PCA) of 7 traditional otolith morphological indicators explained 81.243% of the variance, yielding an overall

species discrimination rate of 81.65%. Further PCA of 77 Fourier harmonic values enhanced the discrimination accuracy, with the first 3 components accounting for 77.49% of the total variation and an improved discrimination rate of 100.00%. Cluster analysis resulted in the grouping of S. biddulphi and S. curvifrons together and revealed their association with S. eurystomus, indicating notable morphological distinctions. Both otolith shape indices and elliptical Fourier analysis have been useful in distinguishing the phenotypic units of different fish species. In this study, otolith morphology was applied for the first time to identify Schizothorax species, providing an in-depth description of species distribution and evolutionary history. This study provides a reference for the identification and systematic classification of Schizothorax species and a scientific basis for formulating effective species protection measures, for promoting the sustainable management of species and important habitats.

TI Emerging roles of the metabolite succinate in bone-related diseases
SO JOURNAL OF ZHEJIANG UNIVERSITY-SCIENCE B
LA English
DT Review
DE Succinate; Osteoarthritis; Rheumatoid arthritis; Osteoporosis; Fracture; Periodontitis
ID receptor gpr91; sdh mutations; reperfusion; cancer; fumarate; hypoxia; dicarboxylate; transporters; metabolomics; macrophages
AB Bone-related diseases, including osteoporosis (OP), osteoarthritis (OA), rheumatoid arthritis (RA), fracture, and periodontitis, significantly impact human health. Succinate, primarily known as a metabolic intermediate in the tricarboxylic acid (TCA) cycle, has emerged as a regulator of cellular functions beyond its metabolic role. Under stress, succinate accumulates in mitochondria and acts as a signaling molecule, modulating cellular processes. Notably, succinate activates angiogenesis and inflammation by stabilizing hypoxia-inducible factor-1 alpha (HIF-1 alpha). Moreover, it influences various pathophysiological processes by interacting with the succinate receptor 1 (SUCNR1), thereby impacting immune response, inflammation, cancer metastasis, and bone homeostasis. The multifaceted roles of succinate as a signaling molecule vary depending on its cellular location and concentration. Recent metabolomic analyses have revealed elevated succinate levels in bone-related diseases, indicating its potential association with these conditions. The objective of this review is to elucidate the impacts of succinate on different bone-related diseases and to discuss potential therapeutic targets and drug molecules based on its mechanisms of action.

TI Current status of nano-embedded growth factors and stem cells delivery to bone for targeted repair and regeneration
SO JOURNAL OF ORTHOPAEDIC TRANSLATION
LA English
DT Review
DE Bone regeneration; Growth factors; Osteoporosis; Stem cells; Targeted delivery
ID platelet-rich plasma; bmp-2-induced osteogenic differentiation; drug-delivery; tissue regeneration; endothelial-cells; fracture; scaffolds; nanoparticles; expression; cartilage
AB Bone-related diseases like osteoarthritis and osteoporosis impact millions globally, affecting quality of life. Osteoporosis considerably enhances the probability of bone fractures of the wrist, hip, and spine. Enhancement and acceleration of functional bone development can be achieved through the sustained delivery of growth factors (GFs) and cells in biomaterial carriers. The delivery of bioactive compounds in a targeted, spatiotemporal way that most closely resembles the natural defect repair process can be achieved by designing the carrier system with established release kinetics. Furthermore, the carrier can serve as a substrate that mimics the extracellular matrix, facilitating osteoprogenitor cell infiltration and growth for integrative tissue healing. In this report, we explore the significance of GFs within the realm of bone and cartilage tissue engineering, encompassing their encapsulation and delivery methodologies, the kinetics of release, and their amalgamation with biomaterials and stem cells (SCs) to facilitate the mending of bone fractures. Moreover, the significance of GFs in evaluating the microenvironment of bone tissue through reciprocal signaling with cells and biomaterial scaffolds is emphasized which will serve as the foundation for prospective advances in bone and cartilage tissue engineering as well as therapeutic equipment. Nanoparticles are being used in regenerative medicine to promote bone regeneration and repair by delivering osteoinductive

growth factors like BMP-2, VEGF, TGF-(3. These nanocarriers allow controlled release, minimizing adverse effects and ensuring growth factors are concentrated at the injury site. They are also mixed with mesenchymal stem cells (MSCs) to improve their engraftment, differentiation, and survival. This approach is a key step in developing multi-model systems that more efficiently facilitate bone regeneration. Researchers are exploring smart nanoparticles with immunomodulatory qualities to improve bonre regeneration and reduce inflammation in injury site. Despite promising preclinical results, challenges include cost manage- ment, regulatory approval, and long term safety. However, incorporating stem cell transport and growth factors in nanoparticles could revolutionize bone regeneration and offer more personalized therapies for complex bone disorders and accidents. The translational potential of this article: Stem cell transport and growth factors encapsulated in nanoparticles are becoming revolutionary methods for bone regeneration and repair. By encouraging stem cells to develop into osteoblasts, osteoinductive GFs like BMP-2, VEGF, and TGF-(3 can be delivered under control due to nano- materials like nanoparticles, nanofibers, and nanotubes. By ensuring sustained release, these nanocarriers lessen adverse effects and enhance therapeutic results. In order to prove their survival and development, MCSs, which are essential for bone regeneration, are mixed with nanoparticles, frequently using scaffolds that resemble the ECM of bone. Furthermore, by adjusting to the injured environment and lowering inflammation, immunomodulatory nanostructures and stimuli-responsive nanomaterials can further maximize. While there are still shotcomings to overcome, including managing expenses, negotiating regulatory processes, and guaranteeing long-term safety, this method promises to outperform traditional bone grafting by providing quicker, more individualized, and more efficient treatments. Nano-embedded growth factors and stem cell technologies have the potential to revolutionize orthopedic therapy and significantly enhance patient outcomes with further research.

TI A bibliometric and visualized analysis of extracellular vesicles in degenerative musculoskeletal diseases (from 2006 to 2024)
SO FRONTIERS IN PHARMACOLOGY
LA English
DT Article
DE degenerative musculoskeletal diseases; bibliometric analysis; extracellular vesicles; senescence; cell-free therapy
ID exosm; osteoarthritis; osteoporosis; delivery; therapy; diagnosis; knowledge
AB Background With the rapid development of extracellular vesicles (EVs) in regenerative medicine research, they have become a promising new direction in the mechanistic, diagnosis and treatment studies of degenerative musculoskeletal diseases (DMDs), and has attracted increasing attention. However, there is currently a lack of comprehensive and objective summary analysis to help researchers quickly and conveniently understand the development trajectory and future trends of this field.Method This study collected articles and reviews published from 2006 to 2024 on EVs in DMDs from the Web of Science database. Bibliometric and visual analysis was conducted using several tools, including Microsoft Excel Office, VOSviewer, CiteSpace, Pajek, and R packages.Results 1,182 publications were included in the analysis from 2006 to 2024. Notably, there was a rapid increase in the number of publications starting in 2016, suggesting that this field remains in a developmental stage. Co-authorship analysis revealed that China ranked first in terms of publications, whereas the United States led in citations. The journal with the highest number of publications was International Journal of Molecular Sciences (INT J MOL SCI). The most prolific authors were Ragni, E with 23 publications, while the most cited author was Toh, WS. Additionally, nine of the top 10 institutions were from China, with Shanghai Jiao Tong University leading in the number of publications. The most cited article was "MSC exosomes mediate cartilage repair by enhancing proliferation, attenuating apoptosis and modulating immune reactivity", authored by Zhang, S, and published in BIOMATERIALS in 2018.Conclusion This study, through bibliometric and visual analysis, clearly illustrates the collaborative relationships among countries, authors, institutions, and journals, providing valuable insights for researchers seeking academic collaboration opportunities. Moreover, the analysis of keywords and citations allows researchers to better understand key research hotspots and frontiers in this field, and points toward

promising directions for future research. The growing interest in EV research in DMDs over recent years indicates increasing attention and a dynamic progression in this field.

TI Prevalence and predictors of bone mineral density testing after distal radius fracture in menopausal women
SO INJURY-INTERNATIONAL JOURNAL OF THE CARE OF THE INJURED
LA English
DT Article
DE Bone mineral density; Distal radius fracture; DEXA scan; Fragility; Osteoporosis
ID osteoporosis; health
AB Background: Osteoporosis screening guidelines recommend bone mineral density (BMD) testing following fragility fractures. Nevertheless, previous studies have demonstrated low rates of osteoporosis screening. Diagnosis and treatment of osteoporosis is essential for prevention of future fractures, however not much is known about the factors associated with receiving BMD testing in this patient population. The purpose of this study was to evaluate the prevalence, timing, and predictors of BMD testing following distal radius fractures (DRF) in menopausal women. Methods: We queried a national insurance database to identify menopausal women aged 45-64 years with a DRF between years 2013 and 2020. The rate of BMD testing within 1 year of injury was calculated. Multivariable logistic regression analysis was used to evaluate the effect of patient- and injury-related variables on the likelihood of undergoing BMD testing following DRF. Results: Among 31,728 patients meeting inclusion criteria (mean +/- SD age: 57.5 +/- 4.3), 3,886 (12.2 %) received a BMD test within 1 year following DRF. The rate of BMD tests decreased with the highest rate of 14.5 % in 2015 and the lowest rate of 10.5 % in 2020. Mean time from DRF to BMD testing was 143 +/- 102 days. Patients aged 60-64 had the highest adjusted odds of receiving BMD testing (OR 2.85 [95 % CI: 2.26 to 3.64]). Factors associated with increased likelihood of BMD testing included surgical intervention (OR 1.38 [1.28-1.48]), rheumatoid arthritis (OR 1.22 [1.06-1.40]), osteoarthritis (OR 1.28 [1.19-1.37]), breast cancer (OR 1.35 [1.16-1.56]), and vitamin D deficiency (OR 1.29 [1.17-1.43]). Factors associated with decreased likelihood of testing included tobacco use (OR 0.90 [0.84-0.97]), patients with Medicaid (OR 0.73 [0.61-0.86]) or Medicare (OR 0.76 [0.65-0.88]) insurance, and living in Southern (OR 0.67 [0.62-0.73]) or Western (OR 0.69 [0.62-0.77]) regions of the United States. Obesity, diabetes, renal disease, and early menopause were not

associated with BMD testing. Conclusions: Despite guidelines recommending BMD testing after low-energy fractures, rates of BMD testing were low and decreased among menopausal women with DRF. Mean time to BMD testing was 4.7 months, indicating substantial delays in workup. Known risk factors for osteoporosis did not reliably predict likelihood of BMD testing. Level of Evidence: Level III, prognostic

TI Stress Analysis in Conversion Total Hip Arthroplasty: A Finite Element Analysis on Stem Length and Distal Screw Hole
SO JOURNAL OF CLINICAL MEDICINE
LA English
DT Article
DE osteoporosis; femoral trochanteric fracture; conversion total hip arthroplasty; periprosthetic fracture; stress distribution
ID failed internal-fixation; periprosthetic fractures; intertrochanteric fracture; surgical-treatment; cortical defects; femoral-neck; salvage; complications; management; femur
AB Background/Objectives: Proximal femoral fractures are particularly common in older adults, and cases requiring conversion to total hip arthroplasty may arise because of treatment failure or osteoarthritis. Fractures around the distal screw removal holes can be problematic. This study aimed to analyze the relationship between stem length and femoral stress distribution to determine the optimal stem length. Methods: A finite element analysis simulation was conducted using pre-existing femoral computed tomography data, an intramedullary nail, and three types of stems of varying lengths. Loads simulating normal walking and stair climbing were applied, and the average and maximum equivalent stresses were measured on both the medial and lateral sides of the distal screw removal hole for each stem length. Statistical analysis was then performed to evaluate the stress distributions. Results: The average stress around the distal screw removal hole tended to decrease as stem length increased. The maximum stress was significantly lower with the 160-mm stem, which provides a 40-mm bridging length, compared to the 120-mm and 130-mm stems, where the stem tip aligned with or only slightly extended past the distal screw removal hole (bridging lengths of 0 mm and 10 mm, respectively). Conclusions: In conversion hip total arthroplasty following proximal

femoral fractures, using a sufficiently long stem can help avoid stress concentration around the distal screw removal hole, thereby potentially reducing the risk of periprosthetic fractures.

TI Targeting oxidative stress, iron overload and ferroptosis in bone-degenerative conditions
SO TURKISH JOURNAL OF BIOCHEMISTRY-TURK BIYOKIMYA DERGISI
LA English
DT Review
DE oxidative stress; iron overload; ferroptosis; bone-degenerative conditions; homeostasis
ID mesenchymal stem-cells; plasma-membrane; differentiation; expression; transport; metabolism; osteoclastogenesis; transferrin; mechanisms; inhibitor
AB Introduction Bone-degenerative conditions, including osteoporosis, rheumatoid arthritis, and osteoarthritis, are major public health concerns worldwide, associated with oxidative stress and iron overload that disrupts bone homeostasis. Ferroptosis, an iron-mediated form of cell death, has emerged as a critical factor in bone degeneration, necessitating a comprehensive review of its role in these conditions.Content This review comprehensively examined the latest research on oxidative stress, iron metabolism, and ferroptosis related to bone biology and degeneration, focusing on their interconnections and potential therapeutic implications. The review revealed that oxidative stress affects various bone cell types, including osteoclasts, osteoblasts, and chondrocytes, contributing to bone loss and cartilage degradation. Iron homeostasis was found to be crucial for bone cell function, with both iron overload and deficiency potentially leading to pathological conditions. Ferroptosis regulation involves a complex interplay between iron metabolism, lipid peroxidation, and antioxidant systems, including the SLC7A11-GSH-GPX4 network and the FSP1-CoQ10H2 pathway. Different bone cell lineages, including mesenchymal stem cells, osteoblasts, osteoclasts, and chondrocytes, exhibit varied responses to ferroptosis induction and regulation.Summary Understanding the molecular mechanisms underlying ferroptosis regulation in bone cells offers promising avenues for developing targeted therapies for bone-degenerative conditions.Outlook Future research should focus on elucidating the specific roles of ferroptosis in different bone disorders and exploring potential therapeutic interventions targeting oxidative stress, iron overload, and ferroptosis pathways to improve the management of these debilitating conditions.

DT Review
DE cinnamon; cinnamaldehyde; analytical methods; pharmacokinetics; chronic disease prevention
ID trans-cinnamaldehyde; in-vitro; oxidative stress; diabetic mice; brain-injury; cinnamon; cells; model; nanoparticles; inflammation
AB Natural antioxidants isolated from fruits, vegetables, herbs and spices have drawn great attention owing to their numerous health-promoting effects. Cinnamaldehyde (CA), an abundant antioxidant in cinnamon spice, has been explored more intensely over the last decade as it has been demonstrated to be effective and safe in the treatment of various diseases. Structurally, a substituted aldehyde group with an unsaturated carbon-carbon double bond with two electrophilic sites for reaction with receptors and enzymes can exert diverse biological effects. Although cinnamon has been traditionally used as a spice and herbal remedy, many studies investigating the most dominant functional compound, CA, and its biological activities have been reported in recent years. This review article intends to present an overview of recent advances in analytical methods and the application of cinnamon extract/oil, CA and its derivatives, CA-polymer/biomolecule conjugates and CA micro/nanosystems in alleviating various chronic diseases including cancer, diabetes, obesity, cardiovascular disease,

neurological disorders, osteoarthritis and osteoporosis. Both in vitro and in vivo studies have demonstrated the improved pharmacological efficiency of CA and its derivatives as well as their polymer/drug/biomolecule conjugates and micro/nanoencapsulated forms, suggesting a possible alternative natural therapy and adjuvant therapy with conventional drugs via a synergistic process.

TI Vitamin D Alleviates Osteoarthritis Progression by Targeting Cartilage and

Subchondral Bone via Myd88-TAK1-ERK Axis Suppression
SO DRUG DESIGN DEVELOPMENT AND THERAPY
LA English
DT Article
DE vitamin D; bone; cartilage; osteoarthritis; rat
ID nf-kappa-b; d supplementation; inflammatory response; knee osteoarthritis; deficiency; volume; drug; pain
AB Background: Osteoarthritis (OA) causes irreversible joint damage, but current treatments fail to fully address its complex pathology. Emerging evidence suggests subchondral bone metabolic dysfunction may initiate OA. While vitamin D (VitD) is well-established for bone metabolism regulation in osteoporosis, its therapeutic potential in OA remains unclear despite observational studies suggesting protective effects. Our integrated in vivo/in vitro study demonstrates VitD's dual chondroprotective and osteogenic actions in OA. Methods: Sprague-Dawley rats (n=24) were divided into three groups: sham operation (Sham), OA model (OA), and OA+VitD treatment, with 8 rats in each group. Oral cholecalciferol (2.34 mu g/kg/day) was administered for 6 weeks post-Monosodium iodoacetate (MIA) induction. The therapeutic potential of vitamin D was evaluated through a series of in vivo experiments. Human chondrocyte C28 cells were pretreated with TNF alpha (1ng/mL) to model inflammatory injury, followed by 1,25(OH)2 D3 (10-2 mu M) exposure for 72 hours to assess the VitD's effects of chondrogenesis and further investigate its underlying mechanism. Results: In OA rats, VitD suppressed femoral cartilage degradation (evidenced by 567.76% increased cartilage area, and 39.13% decreased Osteoarthritis Cartilage Histopathology (OACH) score and enhanced subchondral bone mass (61.81% higher BV/TV). At the molecular level, VitD downregulated the expression of cartilage matrix metalloproteinase 13 (MMP13), with a reduction of 74.72% compared to OA group. Additionally, VitD inhibit inflammatory signaling pathways, particularly through the MyD88-TAK1ERK axis in chondrocytes, and decrease serum IL-6 level. Mechanistic validation of these findings was demonstrated by protein expression reduction of Myd88 (31.22%), phospho-ERK1/2 (66.11%), AP-1 (61.43%) and NF kappa B (34.36%) compared to OA group. In vitro, VitD also rescued ethanol-induced C28 cell viability loss while significantly upregulating cartilage anabolic markers. Conclusion: These findings establish VitD as a multimodal OA therapeutic agent targeting both cartilage catabolism and subchondral bone remodeling through Myd88-TAK1-ERK axis.

TI Effects of nonstationary system blur on radiomic texture features of trabecular bone in normal and ultra-high resolution CT
SO MEDICAL PHYSICS
LA English
DT Article
DE CT spatial resolution; reproducibility; texture analysis
ID image noise uniformity; subchondral bone; position; number
AB Background CT image texture features (TFs) of trabecular bone are being investigated as predictive markers in osteoporosis (OP) and osteoarthritis (OA). To support the development of such radiomic approaches, the reproducibility of bone TFs to CT system factors needs to be characterized. We hypothesize that, in addition to the well-established inter- and intra-scanner effects (e.g., changes in reconstruction algorithm), the non-stationarity of CT spatial resolution may introduce inconsistencies in TFs of morphologically similar bone regions placed in different locations within the scanner field-of-view (FOV).Purpose To characterize the impact of spatially-variant CT blur on the reproducibility of trabecular bone TFs to radial shift within the FOV for a conventional normal resolution (NR) protocol with similar to 0.5 mm slice thickness, and an ultra-high resolution (UHR) protocol representative of the new generation of high-resolution CT (0.25 mm slice thickness).Methods Canon Aquilion Precision CT (Canon Medical Systems, Japan) was used to scan four human femora placed at 0, 9, and 18 cm radial shifts from the isocenter. NR (similar to 0.26 mm in-plane voxel size) and UHR (similar to 0.13 mm in-plane voxel) images were obtained at 1.5 s rotation. At each CT resolution, a total of 377 spherical regions of interest (ROIs) of 2.5 mm radius were seeded within the trabecular bone of the femora at 0 cm shift and transported via rigid registration to the images at 9 cm and 18 cm shift. TFs of the Gray Level Co-Occurrence and Run Length matrices (GLCM and GLRLM) were obtained for all ROIs. Reproducibility across radial shifts was evaluated (separately in NR and UHR) in terms of the concordance correlation coefficient (CCC) between the registered ROIs. Support vector machine (SVM) classifiers were applied to evaluate whether the radial shift of an ROI can be predicted from its TFs.Results In NR, the median CCCs for 0 cm vs. 9 cm radial shifts were similar to 0.9 for both GLCM and GLRLM

TFs, dropping to similar to 0.6 for 0 cm vs. 18 cm shifts. In UHR CT, the median CCCs of GLCM TFs were 0.92 for 0 cm vs. 9 cm and 0.52 for 0 cm vs. 18 cm; for GLRLM, the median CCCs were 0.88 for 0 cm vs. 9 cm and 0.53 for 0 cm vs. 18 cm. In a separate analysis on only high contrast ROIs (upper quartiles of voxel value variance at 0 cm), we found an additional 20% (for 0 cm vs. 9 cm) to 40% (for 0 cm vs. 18 cm) reduction in CCC in both UHR and NR. The somewhat worse reproducibility in UHR CT is attributed to more pronounced effects of gantry motion blur. The classification models were able to discriminate ROIs at 0 cm from the other radial shifts with median accuracy of 0.54 (0.67 in high contrast ROIs) in NR and 0.46 (0.67 in high contrast ROIs) in UHR. The ROIs at 9 cm were identified with 0.31 (0.5) accuracy in NR and 0.46 (0.58) accuracy in UHR; the ROIs at 18 cm were identified with 0.60 (0.83) accuracy in NR and 0.77 (0.83) accuracy in UHR.Conclusions Nonstationary CT spatial resolution leads to a loss of reproducibility of trabecular bone TFs between different regions of the scan FOV, potentially confounding radiomic predictors in clinical data where the lateral shift of the skeletal site of interest changes with patient size.

TI Epigenetic roles of chromatin remodeling complexes in bone biology and the pathogenesis of bone-related disease (Review)
SO INTERNATIONAL JOURNAL OF MOLECULAR MEDICINE
LA English
DT Review
DE chromatin remodeling complexes; epigenetic regulation; bone biology; bone development; bone-related diseases
ID mesenchymal stem-cells; self-renewal; osteoblast differentiation; swi/snf complex; gene-expression; brg1; transcription; pluripotency; protein; chd7

AB Chromatin remodeling complexes are essential regulators of chromatin architecture, facilitating critical processes such as nucleosome sliding, eviction, histone exchange and post-translational modifications. By providing an additional layer of epigenetic regulation beyond the canonical genetic code, these complexes significantly influence bone biology and health. Epigenetic regulation through chromatin remodeling complexes is crucial in modulating gene expression and cellular behavior in bone cells. However, alterations in the activity of chromatin remodeling complexes can also contribute to the progression of various bone diseases. Emerging evidence suggests that specific chromatin remodeling factors may serve as potential biomarkers for diagnosing bone-related conditions and as therapeutic targets for intervention. The present review aims to elucidate the intricate relationship between chromatin remodeling complexes and bone-related diseases, including osteoporosis, osteoarthritis and osteosarcoma. The present review discusses the diverse subunits of these complexes and their multifaceted roles in regulating key cellular processes such as stemness, differentiation, proliferation, senescence and apoptosis in bone cells. Notably, the present review provides a comprehensive overview of the roles of various chromatin remodeling subunits, such as BRG1, BAF47 and chromodomain-helicase-DNA binding 7 (CHD7), in bone metabolism, highlighting their disease-specific mechanisms, including bromodomain-containing protein (BRD)9-mediated pyroptosis in intervertebral disc degeneration and CHD7-driven bone-fat imbalance. Furthermore, the present review highlights the therapeutic potential of targeting dysfunctional subunits (such as BRD7 in osteosarcoma and SS18 in synovial sarcoma) and propose AI-driven structural biology approaches to design chemical modulators. The understudied impact of aging on chromatin remodeling activity in bone homeostasis is also underscored, advocating for longitudinal studies to address this gap. Finally, the distinct functions of each chromatin remodeling complex and its specific subunits in the context of bone-related diseases were also explored, providing a comprehensive understanding of their contributions to both normal bone physiology and pathological conditions.

DT Review
DE anthocyanins; osteoporosis; rheumatoid arthritis; osteoarthritis; osteosarcoma; inflammatory; oxidative stress

ID nf-kappa-b; rheumatoid-arthritis; gene-expression; bone loss; cartilage degradation; osteosarcoma cells; signaling pathway; clinical scores; global burden; rankl
AB Background Musculoskeletal diseases (MSDs) are a common group of conditions involving bones, muscles, cartilage, ligaments, and nerves, which significantly impact patients' quality of life and ability to participate in society. Anthocyanins (ACNs), as phytochemicals, possess various pharmacological and biological activities, including anti-apoptotic, antioxidant, anti-inflammatory, and immunosuppressive properties. In recent years, ACNs have shown remarkable potential in improving MSDs. This review article aims to recapitulate the therapeutic potential of ACNs and its mechanism of action in treating MSDs.Methods Extensive literature was searched and reviewed through online electronic databases (PubMed, Embase, and Web of Science), focusing on analysing the specific roles and molecular mechanisms of ACNs in in vivo and in vitro studies.Results ACNs exert protective effects on MSDs by targeting multiple key signaling pathways, including mitogen-activated protein kinase (MAPK), nuclear factor-kappaB (NF-kappa B), Wingless-related integration site (Wnt)/beta-catenin, phosphatidylinositol 3-kinase/protein kinase B (PI3K/Akt), adenosyl monophosphate-dependent protein kinase (AMPK), receptor activator of nuclear factor-kappa Beta/receptor activator of nuclear factor-kappaB ligand/osteoprotegerin (RANK/RANKL/OPG) and oxidative stress signaling. In addition, ACNs exhibited anti-inflammatory, anti-apoptotic, and immunosuppressive properties. This article reviews the mechanisms and potential therapeutic applications of ACNs in the prevention and alleviation of MSDs, providing valuable reference points for further research and development of ACNs.Conclusion ACNs improve the prevention of MSDs through multiple actions such as antioxidant, anti-inflammatory, immunomodulatory and bone metabolism homeostasis regulation. However, results from in vitro and in vivo studies still need to be further validated by human clinical trials.

DT Article
DE alendronate; bone remodeling; cartilage; osteoarthritis; osteoporosis
ID subchondral bone; knee osteoarthritis; articular-cartilage; risedronate; markers
AB ObjectiveOsteoarthritis (OA) and osteoporosis (OP) are highly prevalent in postmenopausal women; however, their relationship remains complex and controversial. This study aimed to investigate whether anti-OP treatment alleviates osteoarthritis symptoms and reverses disease progression.MethodsThis prospective clinical study enrolled 30 postmenopausal women diagnosed with OP and concomitant knee OA who visited our outpatient clinic between January and June 2023. Patients received anti-osteoporotic treatment comprising calcium carbonate, vitamin D3, and alendronate (ALN). BMD, WOMAC, and VAS scores were assessed at 6 and 12 months. In animal studies, OP was induced in rats by ovariectomy, followed by OA induction via anterior cruciate ligament sectioning and meniscectomy. ALN treatment was administered for 8 weeks, and evaluations of behavior, macroscopic appearance, pathology, and subchondral bone microstructure were performed 8 weeks after OA induction. One-way ANOVA was used for multiple group comparisons, and Spearman's rank correlation was used to assess associations.ResultsClinical outcomes demonstrated that one-year anti-OP therapy achieved dual therapeutic benefits: a 9.3% increase in bone mineral density (BMD) was accompanied by a 36.54% reduction in knee OA symptoms. Statistical analysis revealed a strong positive correlation between BMD improvement and symptomatic relief ($r = 0.76$, $p < 0.05$). In the animal model, OP markedly accelerated OA progression, leading to more severe cartilage damage, as confirmed by symptoms, macroscopic cartilage appearance, and histological

evaluations. Micro-CT analysis revealed abnormal subchondral bone microarchitecture in OP animals. Notably, ALN treatment partially reversed OA progression, as evidenced by reduced cartilage degeneration, improved subchondral bone microstructure, and enhanced bone remodeling.ConclusionAnti-OP treatment alleviates knee OA symptoms in OP patients. Postmenopausal OP accelerates OA progression, while anti-OP therapy can partially reverse this effect. These findings highlights the importance of anti-OP treatment in managing both conditions.

TI Knee joint mechanics during gait after anterior cruciate ligament reconstruction using a partial or full thickness quadriceps tendon autograft at 2 years after surgery
SO PM&R
LA English
DT Article
ID osteoarthritis; walking; strength; predictors; criteria; sports; injury; return
AB BackgroundDespite quadriceps weakness in individuals after quadriceps tendon anterior cruciate ligament reconstruction (QT-ACLR), and its association with knee joint mechanics, no studies have addressed gait mechanics in both partial-thickness

(PT-Q) and full-thickness (FT-Q) options for QT-ACLR.ObjectiveTo assess gait mechanics across a QT-ACLR cohort. We hypothesized that QT-ACLR would show changes in knee joint mechanics compared to control participants (CON) and nonoperated limbs. Additionally, we hypothesized that FT-Q operated limbs would show greater changes compared to PT-Q and CON.DesignRetrospective cohort study.SettingUniversity-affiliated sports medicine institute.ParticipantsSixteen patients who underwent QT-ACLR (7 FT-Q: Age (years) = 28.6 +/- 7.3, post-op (months) = 23.5 +/- 10.7, 9 PT-Q: Age = 25.2 +/- 4.3, post-op = 24.4 +/- 11.7) were recruited and compared to 11 CON (age = 23.4 +/- 4.8).InterventionParticipants underwent gait testing with force plate integrated motion capture.Main Outcome MeasuresMixed repeated-measures analyses of covariance, adjusted for gait speed, were used to determine significant main effects or interactions in peak knee flexion angle, sagittal knee range of motion, peak internal knee extension moment (KEM), and peak internal knee flexion moment.ResultsWhen measured an average of 2 years after surgery, no main effect for limb or limb by depth interaction were detected. A significant effect by group was observed for peak KEM (p = .03, eta 2 = .27) and peak knee flexion angle (p = .04, eta 2 = .24) in the loading response phase. FT-Q (p = .02) and PT-Q (p = .03) showed lower KEM compared to the CON group in both limbs. The FT-Q group showed lower peak knee flexion angle compared to the CON group (p = .01).ConclusionsKnee joint symmetry may be recovered 2 years following QT-ACLR, but lower KEM compared to CON for both graft options and lower peak knee flexion angle than CON for the FT-Q group may indicate a need for further investigation in QT-ACLR.

TI Diurnal aging of biomass burning emissions: impacts on secondary organic aerosol formation and oxidative potential
SO ATMOSPHERIC CHEMISTRY AND PHYSICS
LA English
DT Article
ID residential wood combustion; oxygen species ros; particulate-matter; mass-spectrometry; nighttime chemistry; wide variety; urban areas; fuels; particles; photooxidation
AB Residential biomass burning is an important wintertime source of aerosols. These particles are subjected to complex diurnal aging processes in the atmosphere, contributing to urban and regional air pollution. The cumulative impact of these aging cycles on aerosol composition and oxidative potential, a key toxicity metric, remains unclear. This study examined the oxidation cycles of biomass burning emissions during day-to-night and night-to-day transitions in the FORTH (Foundation for Research and Technology - Hellas) atmospheric simulation chamber, focusing on emissions from burning of olive wood. The final high-resolution AMS spectra of biomass burning organic aerosol (bbOA) after either oxidation cycle were almost identical (R-2 > 0.99, theta= 3 degrees). This indicates transformation into similar biomass burning secondary organic aerosol (bbSOA) regardless of the initial step of the diurnal cycle. A 56 % average increase in the bbOA oxygen-to-carbon (O:C) ratio was observed during both cycle cases (from 0.38 +/- 0.06 for the fresh to 0.59 +/- 0.07 after aging). Additional OA mass was produced after the two cycles, varying from 35 % to 90 % of the initial OA. The aging of the emissions led to a final water-soluble oxidative potential (WS-OP) increase of 60 % to 68 +/- 18 pmol min(-1) mu g(-1) for both cycles, but with notably different transient values that depend on the order of the oxidation regimes. The effect of each oxidation regime on the WS-OP of the bbOA depends on the airmass history. The evolution of the WS-OP was not well correlated with that of the O:C.

TI The impact of uric acid on musculoskeletal diseases: clinical associations and underlying mechanisms
SO FRONTIERS IN ENDOCRINOLOGY
LA English
DT Review
DE uric acid; musculoskeletal diseases; sarcopenia; osteoarthritis; intervertebral disc degeneration; gout; osteoporosis
ID skeletal-muscle; knee osteoarthritis; oxidative stress; mitochondrial dysfunction; xanthine-oxidase; blood-pressure; gout; hyperuricemia; risk; insulin
AB Serum urate (SU) levels are significantly elevated in conditions such as gout, type 2 diabetes (T2D), obesity, and other metabolic syndromes. Recently, due to the high prevalence of hyperuricemia (HUA), numerous clinical connections between SU and musculoskeletal disorders like sarcopenia, osteoarthritis (OA), rheumatoid arthritis (RA), intervertebral disc degeneration (IDD), and osteoporosis (OP) have been identified. This review discusses the mechanisms linking SU to musculoskeletal disorders, as well as the clinical associations of SU with conditions such as sarcopenia, T2D with sarcopenia, McArdle disease, heart failure, gout, OA, IDD, OP and exercise-induced acute kidney injury (EIAKI), offering valuable insights for improved prevention and treatment strategies. Mechanisms linking SU to musculoskeletal disorders include oxidative stress, MSU (monosodium urate) crystal deposition, inflammation, and other factors. In adults, both age and SU levels should be considered for preventing sarcopenia, while gender and SU may directly impact muscle mass in children and adolescents. HUA and gout may be risk factors for OA progression, although some reports suggest otherwise. A U-shaped relationship between SU and IDD has been reported, particularly in Chinese men, indicating lower or higher SU level may be risk factors for IDD. Maintaining SU levels within a certain range may help prevent OP and fractures. Future research, including epidemiological studies and new pathogenesis findings, will further clarify the relationship between musculoskeletal diseases and SU.

TI Current Applications and Development of Radiomics in Osteoporosis: A Narrative Review

SO APPLIED SCIENCES-BASEL
LA English
DT Review
DE osteoporosis; radiomics; bone strength assessment; diagnosis; fracture risk prediction
ID machine learning analysis; texture analysis; trabecular bone; computed-tomography; plain radiograph; proximal femur; fracture load; prediction; diagnosis; strength
AB Osteoporosis is a prevalent disease among the elderly, with fractures being one of the most serious consequences. Early diagnosis and accurate assessment of fracture risk could help prevent fractures. Radiomics employs advanced image analysis techniques for the development of diagnostic tools, thereby improving the accuracy of disease diagnosis and treatment strategies. Specifically, in the application of bone diseases, radiomics has proven effective in the diagnosis and prognostic evaluation of osteoporosis, osteoarthritis, and bone tumors. Radiomics allowed for quantitative characterization of bone geometry, material distribution, and microstructure, making it applicable to osteoporosis as well. In this review, an overview was provided regarding the current progress of radiomics based on clinical bone imaging in osteoporosis, including bone strength assessment, osteoporosis diagnosis, and fracture risk prediction. Additionally, the potential and challenges for their clinical application were summarized.

TI A ZnCl2-based pH-responsive low-melting mixture solvent for extracting psoralen from Ficus carica L. leaves: Insights from experimental and mechanism investigation
SO CHEMICAL ENGINEERING RESEARCH & DESIGN
LA English
DT Article
DE Low-melting mixture solvent; Metal salt; Sustainability; Extraction mechanism; Psoralen
ID purification; biomass; bond
AB Ficus carica L. is one of the most ancient fruit crops which is being cultivated in sub-tropical regions worldwide. Ficus carica L. leaves, which are considered

agricultural by-products, are frequently discarded, leading to the wastage of biological resources. However, Ficus carica L. leaves are valuable source of psoralen (PSO) that displays multiple bioactive properties beneficial for the treatment of osteoporosis, viruses, bacteria, and inflammation. Therefore, enhancing the efficient isolation of PSO from Ficus carica L. leaves using sustainable solvents has been a focus. In this study, a switchable ZnCl2-based pH-responsive low-melting mixture solvent (LoMMSZnCl2) for sustainable extraction of PSO from Ficus carica L. leaves was developed. The LoMMS-ZnCl2 system, consisting of ZnCl2, DL-menthol, and octanoic acid (OA), demonstrates exceptional performance with an extraction yield of 30.68 mg & sdot;g- 1 for PSO. After removing ZnCl2 from the LoMMS-ZnCl2 system using reverse extraction, the polarity of LoMMS was changed rapidly by pH stimulus, resulting in in-situ separation and enrichment of PSO. The extraction mechanism was further investigated by DFT simulation and nuclear magnetic resonance analysis, revealing that hydrogen bonding, halogen bonding, coordination bonding, and Van der Waals forces are the primary intermolecular interactions between LoMMS-ZnCl2 and PSO. This strategy highlights the potential of LoMMS-ZnCl2 for efficient and sustainable extraction of PSO from Ficus carica L. leaves. Furthermore, it also offers a valuable reference for utilizing LoMMS-ZnCl2 in the extraction of natural bioactive compounds from various plant materials.

TI Urinary 4-pyridoxic acid as a non-invasive biomarker for evaluating osteoarthritis severity: findings from the ROAD study
SO AGING CLINICAL AND EXPERIMENTAL RESEARCH
LA English
DT Article
DE 4-pyridoxic acid; Knee osteoarthritis; Lumbar spondylosis; Population-based cohort ROAD; Predictive biomarker
ID plasma; vitamin-b-6; pyridoxal
AB Background The early detection of osteoarthritis (OA) requires reliable biomarkers; however, reports identifying such biomarkers remain limited. Aims This study aimed to evaluate the potential of urinary 4-pyridoxic acid (4PA) as a biomarker for the severity of knee osteoarthritis (KOA) and lumbar spondylosis (LS) in Japanese adults, using data from the population-based cohort study. Methods Data were analysed from 1566 participants (510 men and 1,056 women) aged >= 40 years, who were enrolled in the Research on Osteoarthritis/Osteoporosis against Disability (ROAD) cohort, a population-based study initiated in 2005. Participants underwent radiographic assessments of the knees and lumbar spine, and urinary

4PA levels were measured using high-performance liquid chromatography. Logistic regression analyses were performed to evaluate the association between urinary 4PA levels and the Kellgren-Lawrence (KL) grade of KOA and LS, adjusting for age, sex, body mass index (BMI), and lifestyle factors. Results Urinary 4PA levels were significantly higher in participants with KL grade 4 KOA compared to those with lower KL grades ($p < 0.001$). This association remained significant after adjusting for confounding factors. In contrast, no significant differences in 4PA levels were observed across the KL grades for LS, although a slight increase in 4PA levels was noted in KL grade 4 cases. Discussion and conclusions These findings suggest that urinary 4PA could serve as a biomarker for assessing KOA severity, particularly in advanced stages. While the detection of early OA using 4PA remains challenging, the significant increase in KL grade 4 cases highlights its potential role in guiding treatment decisions, such as surgical intervention.

TI High prevalence and multifactorial risks of sarcopenia in knee osteoarthritis: a systematic review and meta-analysis
SO JOURNAL OF ORTHOPAEDIC SURGERY AND RESEARCH
LA English
DT Review
DE Knee osteoarthritis; Sarcopenia; Prevalence; Risk factors; Meta-analysis
ID smoking; obesity; classification; hip
AB ObjectiveThis study aimed to evaluate the prevalence and risk factors of sarcopenia in patients with knee osteoarthritis (KOA) through a systematic review and meta-analysis.MethodsA comprehensive search was conducted in PubMed, Web of Science, Cochrane Library, Scopus, China National Knowledge Infrastructure, and WanFang databases for studies published between January 2000 and June 2025. Eligible studies were screened according to predefined inclusion and exclusion criteria. Data were extracted, study quality was assessed, and meta-analyses were performed using Stata 17.0.ResultsA total of 35 studies involving 13,528 KOA patients were included, of whom 3597 were diagnosed with sarcopenia. The pooled prevalence of sarcopenia and sarcopenic obesity was 25.07% (95% CI 18.85-31.29%) and 12.06% (95% CI 8.24-15.87%), respectively. Subgroup analyses revealed that sarcopenia prevalence increased with disease severity, reaching 26.01% (95% CI 16.27-35.75%) in patients with Kellgren-Lawrence grade 4 KOA. Prevalence was 25.65% (95% CI 20.30-31.00%) among female and 25.85% (95% CI 18.64-33.06%) among Asian populations. Among patients with osteoporosis and diabetes mellitus, prevalence rates were 21.68% (95% CI 8.84-34.53%) and 28.36% (95% CI 17.43-39.29%), respectively. Additionally, sarcopenia was more common among alcohol consumers (30.72%, 95% CI 15.58-45.86%) and smokers (29.82%, 95% CI 18.87-40.77%), with the prevalence being notably higher at 35.20% (95% CI 28.09-42.31%) among patients with irregular physical activity.ConclusionSarcopenia and sarcopenic obesity are highly prevalent in patients with KOA and are significantly associated with disease severity, gender, geographic region, comorbidities, and lifestyle factors. These findings highlight the clinical importance of assessing sarcopenia in KOA management. Early screening and timely interventions may improve patient outcomes and quality of life.

TI Advancements in High-Resolution Computed Tomography: Revolutionising Bone Health Micro-Research

SO BIOENGINEERING-BASEL
LA English
DT Article
DE bone health; micro-computed tomography; high-resolution peripheral quantitative computed tomography; finite element analysis; machine learning
AB Bone disorders such as osteoporosis, osteopenia, and osteoarthritis affect millions worldwide, creating an urgent need for earlier and more accurate assessment of bone health. High-resolution imaging has transformed this field: micro-computed tomography remains the research gold standard for ex vivo and preclinical studies, while high-resolution peripheral quantitative computed tomography enables in vivo clinical assessment of trabecular and cortical bone microarchitecture. Combined with finite element analysis and machine learning, these modalities enable biomechanical modelling, predictive risk stratification, and progress toward personalised treatment. Remaining challenges include cost, limited availability, motion artefacts, and lack of standardisation. This review summarises current advances in imaging and computational methods, highlights their respective strengths and limitations, and outlines future directions required to translate these technologies into routine clinical practice.

TI ZBTB16 exerts anti-angiogenic effects in rheumatoid arthritis by regulating HIF-1 α pathway
SO ALLERGOLOGIA ET IMMUNOPATHOLOGIA
LA English
DT Article
DE GRK2/HIF-1 alpha pathway; rheumatoid arthritis; ZBTB16
ID differentiation
AB Background: Rheumatoid arthritis (RA) is one complex chronic autoimmune disease, resulting body pain and badly affect the health of RA patients. Zinc finger and BTB domain containing 16 (ZBTB16) has been reported to participate into many diseases including osteoarthritis and osteoporosis. Objective: To verify the regulatory functions of ZBTB16 in RA progression keep dimness. Methods: The mRNA expressions were tested through RT-qPCR. The protein expressions were evaluated through western blot. The pathological changes of synovial tissues were determined through HE staining. The erosion and destruction of bone tissues were examined through safranin-O/fast green staining. The levels of TNF-alpha, IL-1 beta, IL-6 and MMP-3 were testified through ELISA. The fluorescence intensity of proteins was assessed through IF assay. Results: Firstly, it was uncovered that ZBTB16 expression was markedly reduced in the synovium tissues of RA patients through analyzing GSE55235 expression profile by GEO2R online tool. Next, ZBTB16 expression was down-regulated in synovial tissues of RA patients. Moreover, ZBTB16 can alleviate the degree of paw swelling in CIA mice. ZBTB16 improved the pathological changes of synovial tissues in CIA mice. The levels of inflammatory factors and matrix metalloproteinase were increased in CIA mice, but these impacts were reversed after ZBTB16 amplification. ZBTB16 can relieve pannus in CIA mice. Besides, the triggered GRK2/ HIF-1 alpha pathway in CIA mice can be retarded after ZBTB16 overexpression. Conclusion: ZBTB16 exerted anti-angiogenic effects in RA by blocking GRK2/HIF-1 alpha pathway. This work hinted that ZBTB16 may be one useful target for RA treatment. (c) 2025 Codon Publications. TI The Association Between Serum Ergothioneine Concentration and Japanese Dietary Habits: The Third Survey of the ROAD Study
SO NUTRIENTS
LA English
DT Article
DE ergothioneine; ROAD study; dietary habit; fish
ID 3-year follow-up; lower back-pain; knee osteoarthritis; risk-factors; lumbar spondylosis; men; women; biosynthesis; accumulation; history
AB Background/Objectives: As a result of aging societies, the increasing number of older adults requiring nursing care has become a serious issue and the extension of healthy life expectancy has become an urgent priority. Ergothioneine (EGT) is a sulfur-containing amino acid found in foods such as mushrooms. Low EGT blood concentrations have been reported to be associated with the risk of onset and progression of various diseases. However, the distribution of EGT blood concentrations and their association with dietary habits in the Japanese general population remains unclear. Methods: This cross-sectional study was conducted using data from the third survey of the Research on Osteoarthritis/osteoporosis Against Disability (ROAD) study, which analyzed 1457 participants (474 men and 983 women) aged >= 40 years. Serum EGT concentrations and their association with dietary habits were analyzed. Results: Serum EGT concentrations (1) peaked in the 70s in men and the 60s in women, (2) were higher in women than in men, and (3) showed a significant positive correlation with fish intake and nutrients

commonly found in fish. Conclusions: In the present study, we report for the first time an age- and sex-specific serum EGT distribution in a Japanese population and its association with dietary habits, particularly fish intake. These findings help define normal and abnormal EGT levels and suggest new potential sources of EGT.

TI Gait stability improves following unilateral total ankle arthroplasty
SO JOURNAL OF ORTHOPAEDIC RESEARCH
LA English
DT Article

DE gait; gait stability; margin of stability (MoS); total ankle arthroplasty
ID clinical-outcm; dynamic stability; walking; falls; osteoarthritis; arthrodesis; balance; margin; performance; arthritis
AB End-stage ankle arthritis is often treated surgically by total ankle arthroplasty (TAA) due to its potential to improve gait through increased joint range of motion and reduce pain. However, TAA's effect on gait stability is not well understood. This study explores the impact of TAA on gait stability, measured by Margin of Stability (MoS), in 148 patients with end-stage ankle arthritis. Kinematic data were collected pre-operatively, at 1-year post-op, and at 2-years post-op and the MoS was determined at heel strike and midstance for the anteroposterior (MoSAP) and mediolateral (MoSML) directions. A linear mixed effects model including gait speed as a factor was used to assess the effects of limb, session, and their interaction on outcome measures. A significant interaction ($p < 0.002$) between limb (surgical, nonsurgical) and session (pre-op, 1-year post-op, 2-years post-op) was identified for each MoS variable of interest. Cumulatively, our results suggest that the nonsurgical limb, MoSAP at heel strike and MoSML at midstance improved (increased) as time from surgery increased. These results suggest patients developed a compensatory movement pattern to navigate surgical limb single support. TAA reduces this compensation improving side-to-side symmetry, while not fully restoring symmetry by 2-years post-op. These results indicate that TAA could improve gait stability in patients with end-stage ankle arthritis, but further work is needed to understand the impact of TAA on altering fall risk.

TI DNA-Based Hydrogels for Musculoskeletal Reconstruction: Harnessing Dynamic Programmability and Multimodal Therapeutic Integration
SO ADVANCED SCIENCE
LA English
DT Review
DE DNA-based hydrogel; dynamic crosslinking; musculoskeletal regeneration; therapeutic delivery; tissue engineering
ID mesenchymal stem-cells; articular-cartilage; plasmid dna; osteogenic differentiation; induced osteoporosis; muscle injury; nucleic-acids; bone; tissue; delivery
AB Musculoskeletal disorders, including bone fractures, osteoarthritis, and muscle injuries, represent a leading cause of global disability, revealing the urgency for advanced therapeutic solutions. However, current therapies face limitations including donor-site morbidity, immune rejection, and inadequate mimicry of dynamic tissue repair processes. DNA-based hydrogels emerge as transformative platforms for musculoskeletal reconstruction, with their sequence programmability, dynamic adaptability, and biocompatibility to balance structural support and biological functions. These hydrogels are classified into two categories: 1) DNA hydrogels, where DNA serves as the structural backbone; 2) DNA component-loaded hydrogels, integrating functional DNA elements like aptamers and therapeutic genes into non-DNA matrices. Through dynamic crosslinking strategies, primarily Watson-Crick base pairing, DNA networks achieve shear-thinning injectability and self-healing behaviors while providing binding sites for bioactive DNA components. Hybrid systems further enhance functionality by incorporating diverse materials to improve mechanical strength, drug delivery, and cellular guidance. This review systematically examines molecular design principles, classification frameworks, and preclinical applications of DNA-based hydrogels, aiming to bridge gaps between material innovation and clinical translation. Finally, current challenges are highlighted, and future directions to advance these intelligent biomaterials toward next-generation musculoskeletal therapies are proposed.

ID circular rna; stem-cells; osteogenic differentiation; osteoclast differentiation; doxorubicin resistance; osteosarcoma cells; expression; osteoporosis; contributes; promotes
AB Circular RNAs (circRNAs) are non-coding RNAs that exist naturally in various eukaryotic organisms. The majority of circRNAs are produced through the splicing of exons, although there are a limited number that are generated through the circularization of introns. Studies have shown that circRNAs play an irreplaceable role in the pathogenesis, disease progression, diagnosis, and targeted therapy of motor system tumors (osteosarcoma), metabolic diseases (osteoporosis), and degenerative diseases (osteonecrosis of the femoral head, osteoarthritis,

intervertebral disc degeneration). This review summarizes the advancements in circRNA detection techniques and the research progress of circRNAs in orthopedic diseases.

TI Development and validation of the BPDKC model for predicting sarcopenic knee osteoarthritis in community-dwelling older adults: a cross-sectional study
SO BMC MUSCULOSKELETAL DISORDERS
LA English
DT Article
ID guidelines; management
AB Background Sarcopenia and knee osteoarthritis frequently coexist as sarcopenic knee osteoarthritis (SPKOA), a clinically significant and burdensome condition among older adults. Despite its high prevalence and functional impact, no validated, practical tool exists for early identification of SPKOA in community settings. This study aimed to develop and internally validate a parsimonious, clinically applicable prediction model for SPKOA risk stratification in community-dwelling older adults. Methods We conducted a cross-sectional

analysis of 640 community-dwelling adults aged 65-85 years, recruited between March and October 2024 from the Yuyuan Community Health Service Center in Shanghai, China (median age: 71 years; 57% female). SPKOA was diagnosed using established criteria for both sarcopenia and knee osteoarthritis. Participants were randomly split (7:3) into training (n = 448) and internal test (n = 192) sets. In the training set, we employed a hybrid variable selection strategy: age, gender, BMI, physical activity (PA), diabetes mellitus (DM), Knee Visual Analog Scale(KVAS), and calf circumference (CC) were prespecified based on clinical relevance; remaining candidate variables underwent univariate screening ($P < 0.05$), followed by forward stepwise logistic regression (entry: $P < 0.05$; removal: $P > 0.10$). Three candidate models were derived and compared: Model 1 (7 predictors: CC, KVAS, BMI, DM, PA, osteoporosis, age); Model 2 - the BPDKC model (5 predictors: BMI, PA, DM, KVAS, CC); and Model 3 (5 predictors: DM, PA, KVAS, CC, age). Model performance was evaluated using discrimination (AUC with 95% CI), calibration (Brier score, calibration plots), clinical utility (decision curve analysis). The optimal model was translated into a nomogram and an interactive web-based calculator. Results Among 640 participants, 12.5% (n = 80) met SPKOA criteria, with balanced prevalence across training (12.5%, n = 56) and test sets (12.5%, n = 24). In the training set, all models showed strong discrimination (Model 1 AUC = 0.953; Model 2 AUC = 0.951; Model 3 AUC = 0.934) and excellent calibration (Brier scores: 0.053-0.062). However, in the internal test set, Model 2 (BPDKC) demonstrated the best generalizability and balance of performance: AUC = 0.861 (95% CI: 0.795-0.926), specificity = 94.6% (95% CI: 90.1-97.5%), precision = 50.0% (95% CI: 26.0-74.0%), F1-score = 0.429 (95% CI: 0.243-0.618), and Brier score = 0.1038 (95% CI: 0.068-0.139). Although sensitivity remained modest (37.5%, 95% CI: 18.8-59.4%), calibration curves and decision curve analysis confirmed robust risk estimation and superior net clinical benefit across clinically relevant risk thresholds (10-40%). Model 2 also achieved the best trade-off between performance and parsimony (AIC = 178.41 vs. Model 3 AIC = 194.79). A user-friendly web calculator implementing the BPDKC model is freely accessible at (https://lgmyyyy.shinyapps.io/bpdkc_spkoa_app/) . Conclusion The BPDKC model is a simple, internally validated, and clinically practical tool for SPKOA risk prediction in community-dwelling older adults. Its high specificity and calibration support its utility in ruling out low-risk individuals, while its web-based implementation facilitates integration into primary care workflows. Although sensitivity remains limited-reflecting the challenge of case-finding in low-prevalence settings-the model offers meaningful clinical value for targeted screening and early intervention. External validation in diverse populations is recommended prior to broader implementation.

TI Weaker subchondral bone and thinner articular cartilage of the knee are associated with elevated baseline fracture risk independently of osteoarthritis risk factors
SO ARCHIVES OF OSTEOPOROSIS
LA English
DT Article
DE Fracture risk; FRAX; Knee osteoarthritis; MRI; Bone marrow lesion; Cartilage morphometry; Subchondral bone structure; BMD
ID mineral density; osteoporosis; prediction; frax; prevalence; parameters; falls; pain
AB Objectives To examine how well fracture risk predicts subchondral bone and cartilage morphometry independently of osteoarthritis (OA) clinical risk factors. Methods Male and female participants in the Osteoarthritis Initiative (OAI) at visit 5 (36 months) were evaluated for fracture risk using FRAX and categorized into low-, moderate-, or high-risk groups. These groups were compared for bone marrow lesion (BML) size, number and effusion, subchondral bone structure, density, and cartilage morphometry in the most affected knee at either same time point, 1 or 2 years later, using general linear models. Sex interactions were examined in each

case and probed if significant. Results Among 1240 participants (58.8% female, age: 63.7 +/- 8.8 years, and BMI: 30.1 +/- 4.9 kg/m(2)), 20.32% had moderate or high FRAX and showed lower subchondral bone density (- 0.12 to - 0.25 g/cm(2)), less intact trabeculae, and thinner cartilage (- 0.14 to - 0.47 mm) compared to low FRAX ($p < 0.05$). Males showed larger positive FRAX correlations with bone density, and females had protective effects of FRAX against BML numbers, although the effects were small (sex interaction, $p < 0.05$). All FRAX models adjusting for OA risk factors yielded better model fit than OA risk factors alone. Having moderate/high versus low FRAX at baseline predicted a 1.36 (1.00, 1.86)-fold higher odds of reaching a Kellgren-Lawrence score of 3 or 4 within a year. Conclusions High FRAX predicts thinner cartilage and weaker subchondral bone within a year. Complementing standard OA clinical risk factors with FRAX calculation could help identify individuals likely to develop worse knee OA radiologic outcomes.

TI The Role of the Immune Microenvironment on Osteoblast Differentiation
SO IMMUNOLOGICAL INVESTIGATIONS
LA English
DT Review
DE Immune microenvironment; osteoblast differentiation; cytokine; immune cell; osteoimmunology
ID mesenchymal stem-cells; regulatory t-cells; tgf-beta; bone-formation; rheumatoid-arthritis; knee osteoarthritis; in-vitro; growth; osteogenesis; expression
AB Background: Osteoblasts, derived from mesenchymal stem cells (MSCs) in the bone marrow, are responsible for bone formation. Osteoblast differentiation is orchestrated by a spectrum of biological signals, with immune-derived components serving as indispensable regulators in this network. Dysfunctional osteoblast differentiation underlies bone-related pathologies such as osteoarthritis, rheumatoid arthritis, and osteoporosis, where immune dysregulation drives inflammatory cascades that disrupt the osteoblast-osteoclast equilibrium. This bidirectional crosstalk has propelled the emergence of osteoimmunology as a pivotal discipline.Methods: By analyzing immune cells and cytokines in the immune microenvironment, we synthesize evidence on their roles in regulating osteoblast differentiation, with focus on inflammatory bone disorders, particularly in

osteoarthritis.Results: Thus, bone growth, development, and healing are intrinsically coupled with the dynamics of the immune microenvironment, which contributes to subchondral bone sclerosis and disease progression in osteoarthritis. Therefore, targeting immune-osteoblast crosstalk offers therapeutic potential for bone pathologies.Conclusion: This review consolidates recent advances in understanding how the immune microenvironment impacts osteoblast differentiation, aiming to provide novel insights for clinical strategies targeting bone repair and disease mitigation.

TI Intermuscular adipose tissue and lean muscle mass assessed with MRI in people with chronic back pain in Germany: a retrospective observational study
SO LANCET REGIONAL HEALTH-EUROPE
LA English
DT Article
DE Chronic back pain; Muscle composition; Body composition; German national cohort; Physical activity
ID health; force; time
AB Background Chronic back pain (CBP) affects over 80 million people in Europe, contributing to substantial healthcare costs and disability. Understanding modifiable risk factors, such as muscle composition, may aid in prevention and treatment. This study investigates the association between lean muscle mass (LMM) and intermuscular adipose tissue (InterMAT) with CBP using noninvasive whole-body magnetic resonance imaging (MRI). Methods This cross-sectional analysis used whole-body MRI data from 30,868 participants in the German National Cohort (NAKO), collected between 1 May 2014 and 1 September 2019. CBP was defined as back pain persisting >3 months. LMM and InterMAT were quantified via MRI-based muscle segmentations using a validated deep learning

model. Associations were analyzed using mixed logistic regression, adjusting for age, sex, diabetes, dyslipidemia, osteoporosis, osteoarthritis, physical activity, and study site. Findings Among 27,518 participants (n = 12,193/44.3% female, n = 14,605/55.7% male; median age 49 years IQR 41; 57), 21.8% (n = 6003; n = 2999/50.0% female, n = 3004/50% male; median age 53 years IQR 46; 60) reported CBP, compared to 78.2% (n = 21,515; n = 9194/42.7% female, n = 12,321/57.3% male; median age 48 years IQR 39; 56) who did not. CBP prevalence was highest in those with low (<500 MET min/week) or high (>5000 MET min/week) self-reported physical activity levels (24.6% (n = 10,892) and 22.0% (n = 3800), respectively) compared to moderate (500-5000 MET min/week) levels (19.4% (n = 12,826); p < 0.0001). Adjusted analyses revealed that a higher InterMAT (OR 1.22 per 2-unit Z-score; 95% CI 1.13-1.30; p < 0.0001) was associated with an increased likelihood of chronic back pain (CBP), whereas higher lean muscle mass (LMM) (OR 0.87 per 2-unit Z-score; 95% CI 0.79-0.95; p = 0.003) was associated with a reduced likelihood of CBP. Stratified analyses confirmed these associations persisted in individuals with osteoarthritis (OA-CBP LMM: 22.9 cm3/kg/m; InterMAT: 7.53% vs OA-No CBP LMM: 24.3 cm3/kg/m; InterMAT: 6.96% both p < 0.0001) and osteoporosis (OP-CBP LMM: 20.9 cm3/ kg/m; InterMAT: 8.43% vs OP-No CBP LMM: 21.3 cm3/kg/m; InterMAT: 7.9% p = 0.16 and p = 0.0019). Higher pain intensity (Pain Intensity Numerical Rating Scale >= 4) correlated with lower LMM (2-unit Z-score deviation = OR, 0.63; 95% CI, 0.57-0.70; p < 0.0001) and higher InterMAT (2-unit Z-score deviation = OR, 1.22; 95% CI, 1.13-1.30; p < 0.0001), independent of physical activity, osteoporosis and osteoarthritis. Interpretation This large, population-based study highlights the associations of InterMAT and LMM with CBP. Given the limitations of the cross-sectional design, our findings can be seen as an impetus for further causal investigations within a broader, multidisciplinary framework to guide future research toward improved prevention and treatment.

TI The causal role of homocysteine in multiple diseases: a systematic review of

Mendelian randomization studies
SO NUTRITION & METABOLISM
LA English
DT Review
DE Homocysteine; Mendelian randomization; Nervous system diseases; Cardiovascular diseases; Musculoskeletal system diseases
ID oxidative stress; hyperhomocysteinemia; pathogenesis; risk
AB BackgroundHomocysteine (Hcy) has been implicated in the development of multiple diseases; however, its causal role remains unclear. Mendelian randomization (MR) studies provide a robust approach to assessing causality by minimizing confounding and reverse causation.ObjectiveThis study aimed to evaluate the causal role of Hcy in various diseases by synthesizing evidence from MR studies.MethodsWe performed a comprehensive literature search in PubMed, the Cochrane Library, Embase, and Web of Science for MR studies published up to May 30, 2024. Studies investigating the association between genetic predisposition to Hcy levels and specific diseases were included.ResultsFindings from 33 MR studies (covering 31 distinct primary outcomes) suggest that genetically elevated Hcy levels are associated with an increased risk of several health conditions, including: Five cardiovascular diseases: small vessel stroke, small artery occlusion stroke, stroke, subarachnoid hemorrhage, and ischemic stroke. Six musculoskeletal diseases: soft tissue disorders, osteoporosis with pathological fractures, hospital-diagnosed osteoarthritis (OA), overall OA, knee OA, and hip OA. One musculoskeletal biomarker: waist-to-hip ratio (WHR) adjusted for BMI. Two digestive system diseases: gastric cancer and non-alcoholic fatty liver disease. Three digestive biomarkers: alkaline phosphatase (ALP), alanine aminotransferase (ALT), and aspartate aminotransferase (AST). One urogenital system disease: chronic kidney disease. Two mental disorders: schizophrenia and bipolar disorder type I. One metabolic disorder: metabolic syndrome. Conversely, elevated Hcy levels are associated with a reduced risk of: One neurological disorder: multiple sclerosis. Two neurological biomarkers: gray matter volume and total brain volume. Five musculoskeletal biomarkers: heel bone mineral density (BMD), right/left grip strength, walking pace, and appendicular lean mass. One urogenital system biomarker: estimated glomerular filtration rate. Additionally, genetically reduced plasma Hcy levels correlated with higher forearm BMD.ConclusionThese findings provide significant evidence for the role of Hcy in disease causation and may contribute to the development of future preventive measures or therapeutic strategies.

TI Analysis of Risk Factors for Lumbar Spondylolisthesis: A Logistic Regression Study
SO WORLD NEUROSURGERY
LA English
DT Article
DE Age; Body mass index; Facet joint osteoarthritis; Logistic regression; Lumbar spondylolisthesis
ID natural-history; prevalence
AB <black square> OBJECTIVE: Lumbar spondylolisthesis is the forward displacement of one vertebra over another, commonly occurring at the L4/5 or L5/S1 levels. The condition is influenced by various risk factors, including age, body

mass index (BMI), long-term physical labor, pelvic incidence (PI), and facet joint osteoarthritis. This study aims to identify the significant risk factors associated with lumbar spondylolisthesis through univariate and multivariate logistic regression analyses. <black square> METHODS: A retrospective analysis of 531 patients diagnosed with lumbar spondylolisthesis between September 2019 and September 2024 was conducted. Data were collected on age, BMI, PI, history of lumbar trauma, long-term physical labor, congenital pedicle dysplasia, osteoporosis, intervertebral disc degeneration, and facet joint osteoarthritis. Univariate logistic regression was used to screen for significant variables, followed by multivariate logistic regression to adjust for confounding factors. Receiver operating characteristic curve analysis was performed to assess the sensitivity of significant factors. <black square> RESULTS: Univariate analysis identified age, BMI, longterm physical labor, PI, and facet joint osteoarthritis as significant risk factors. Multivariate analysis confirmed that age (P = 0.035), BMI (P = 0.005), and facet joint osteoarthritis (P = 0.002) remained statistically significant. Interaction effect analysis did not reveal any significant interactions between variables. Receiver operating characteristic curve analysis showed that age, BMI, and facet joint osteoarthritis were key predictors of lumbar spondylolisthesis. CONCLUSIONS: Age, BMI, and facet joint osteoarthritis (Grade III or above) were observed as potential risk factors for lumbar spondylolisthesis, with facet joint osteoarthritis showing the highest odds ratio. These findings indicate that degenerative changes in the spine, particularly those involving the facet joints, may contribute significantly to the development of lumbar instability, although further research is needed to establish causal relationships.

TI Lower osteoporotic-like vertebral fractural deformity (OLVF) prevalence and severity among older Thais and Indonesians than among older Chinese
SO QUANTITATIVE IMAGING IN MEDICINE AND SURGERY
LA English
DT Article
DE Osteoporotic vertebral fracture; osteoporosis; Chinese; Thais; Indonesians
ID united-states; risk-factors; end-plate; hong-kong; men; women; osteoarthritis
AB Background: Chinese are known to have a lower vertebral fragility fracture risk than Caucasians. This study evaluates radiographic osteoporotic-like vertebral fractural deformity (OLVF) prevalence and severity among Chinese, Thai, Indonesian women and men. Methods: In an epidemiological study with community subjects, spine radiographs (T4-L5) were sampled for 195 Thai women (mean: 73.6 years), 202 Thai men (mean: 73.7 years), 236 Indonesian women (mean: 70.4 years), and 174 Indonesian men (mean: 70.2 years). Spine radiographs of age-matched subjects were also sampled for Chinese. OLVF classification included no OLVF (grade 0), and OLVFs with <20% (grade 0.5, minimal grade), >= 20-25% (grade 1, mild grade), >= 25%-1/3 (grade 1.5, moderate grade), >= 1/3-40% (grade 2, marked grade), >= 40%-2/3 (grade 2.5, severe grade), and >= 2/3 height loss (grade 3, collapsed grade). OLVF sum score (OLVFss) was calculated with each vertebra assigned a score of 0, -0.5, -1, -1.5, -2, -2.5, and -3 for no OLVF or OLVF grades 0.5-3. Osteoporosis prevalences were estimated based on OLVFss. For a woman, OLVFss <=-1.0 and OLVFss <=-1.5 were the thresholds to classify the case being osteoporotic according to the lowest T-score or femoral neck T-score respectively. For men, these thresholds were OLVFss <=-2.5 and OLVFss <=-3.0. Results: Compared with Southeast Asians, Chinese had overall higher prevalences of all-inclusive OLVF, apparent OLVF, and OLVF among Chinese were more likely to be multiple. A trend was noted that Chinese women were more likely to have severe and collapsed grades OLVFs than Southeast Asian women, while such a trend was not noted for Chinese men vs. Southeast Asian men comparison. For men, the Chinese vs. Southeast Asians difference was that Chinese had a higher prevalence of milder OLVFs. For the Thais vs. Indonesians comparison, OLVFss (mean +/- standard deviation) was -0.62 +/- 1.43 for Thai men, -0.47 +/- 0.98 for Indonesian men, -0.82 +/- 2.39 for Thai women, and -0.76 +/- 2.18 for Indonesian women. The lowest T-score based osteoporosis prevalence and femoral neck

T-score based osteoporosis prevalence was 9.4% and 6.9% respectively for Thai men, and 6.9% and 2.9% for respectively Indonesian men; 19.5% and 14.9% respectively for Thai women, 18.9% and 14.5% respectively for Indonesian women. Conclusions:<bold> </bold>The prevalence and severity of radiographic OLVF show a weak trend of 'Chinese > Thais > Indonesians', both for older women and for older men. The results of the current study support the notion that 'populations from a warmer climate have better spine health'.

TI The Impact of Total Hip Arthroplasty on the Incidence of Hip Fractures in Romania
SO JOURNAL OF CLINICAL MEDICINE
LA English
DT Article
DE total hip arthroplasty; hip fracture; orthopedics surgery; osteoporosis; public health; epidemiology; implants
ID osteoarthritis; trends
AB Background/Objectives: The increase in life expectancy and the share of the elderly population has the effect of increasing the number of osteoporotic hip fractures. At the same time, the number of total hip arthroplasty (THA) interventions is continuously increasing. The objective of this study is to investigate the incidence rates of hip fractures during the period 2008-2019, in Romania, among people who are at least 40 years old, as well as to determine the extent to which the increase in the prevalence of people who have undergone THA has affected the incidence of hip fractures, given that the operated hip no longer presents a risk of fracture. Methods: We extracted the information, between 2008 and 2019, from nationwide retrospective studies about the incidence and time trend of hip fractures in Romania. Information on primary THA interventions during the period 2001-2019 was obtained from the Romanian Arthroplasty Register (RAR). We obtained the population size, by gender and age groups, from the reports of the National Institute of Statistics. For the period 2008-2019, we calculated the standardized annual hip fracture incidence rates by sex and by age. Given that each person has two hips at risk of fracture, we calculated hip fracture rates in a scenario without THA interventions. For this, we subtracted 0.5 people from the at-risk population for each prevalent hip prosthesis. Thus, we revealed the effects of decreasing fracture rates due to having hip prostheses. Results: From 2008 to 2019, age-standardized incidence rates of hip fractures increased by 10.8% in women, and by 2.8% in men. By excluding hips being replaced with prostheses in the at-risk population, we obtained higher hip fracture incidence rates. These recorded values were considerably higher for the elderly population. The variation in hip fracture rates during the observed period was 10.16% (9.76% in women and 11.68% in men) lower due to the increased prevalence of hip prostheses. Conclusions: Although the incidence of hip fractures has continued to rise, the growing number of people who have undergone THA and are living with hip prostheses has helped to blunt this increase.

TI IL-34 as a Novel Mediator Linking Vitamin D Deficiency with Osteoporosis and Knee Osteoarthritis
SO INTERNATIONAL JOURNAL OF MOLECULAR SCIENCES
LA English
DT Article
DE body composition; fat mass; inflammation; cytokines; structural equation modeling
ID d supplementation; adipose-tissue; d metabolism; cross-talk; inflammation; association; expression; bone; interleukin-34; mechanism
AB Vitamin D deficiency (VDD) is a widespread human condition closely associated with musculoskeletal disorders, involving alterations in body composition and systemic inflammation. In this cross-sectional study, 1075 adults were classified into a VDD (n = 304) group and a VD sufficient (VDS) group (n = 771). Body composition measurements, including the fat mass-to-weight ratio (FM/WT), were assessed using bioelectrical impedance analysis. Plasma levels of IL-9, IL-34, and MCP-1 were also measured. Data on osteoporosis (OP) and knee osteoarthritis (KOA) were collected. Regression analyses indicated that FM/WT was independently associated with VDD, which in turn was linked to elevated IL-34 levels. Individuals with VDD had a significantly higher prevalence of OP and KOA compared with those with VDS. Structural equation modeling confirmed and quantified these associations, suggesting that FM/WT is a significant predictor of VDD status (beta = 0.305, 95% CI: 0.231-0.367). VDD is directly associated with elevated IL-34 levels (beta = 0.353, 95% CI: 0.308-0.398), while IL-34 levels, in turn, are a possible cause of KOA (beta = 0.573, 95% CI: 0.460-0.687) and OP (beta = 0.433, 95% CI: 0.329-0.536). Our data clearly demonstrate existence of a physiological-pathological continuum: obesity-VDD-IL-34 and both OP and KOA.

TI Independent association between sarcopenic obesity and knee osteoarthritis: A cross-sectional study
SO JOURNAL OF SPORTS SCIENCES
LA English
DT Article
DE Muscle ultrasonography; older adults; osteoarthritis; sarcopenic obesity
ID older-adults; muscle mass; reliability; ultrasound; strength; validity
AB Although obesity is a known risk factor for knee osteoarthritis (OA), the impact of sarcopenic obesity (SO) on OA remains unclear. This study aimed to investigate the association between SO and knee OA in older adults. This cross-sectional study included 101 obese outpatients, of whom 61 (60.3%) had knee OA. SO was diagnosed using ESPEN/EASO criteria. OA presence was determined by two specialists based on bilateral standing knee radiographs and Kellgren-Lawrence (KL) grading (0-4). Joint cartilage was assessed via ultrasonography. Frailty was evaluated using the Clinical Frailty Scale. Osteoporosis (OP) was defined by bone mineral density measurements and confirmed fragility fractures. The study participants comprised 74 (73%) females and 27 (27%) males with a median age of 72.0 [8.0] years. The patients were divided into two groups: patients with OA (60.3%, n = 61) and those without OA (39.7%, n = 40). In regression analysis, the

presence of SO increased the risk of OA independent of age, sex, body mass index (BMI), frailty, and OP (OR = 5.82, 95% CI = 1.55-21.94 and p = 0.009). The study results highlight the independent role of SO in OA development, suggesting that body composition assessment should be integrated into OA risk evaluation.

TI Prevalence and risk factors of musculoskeletal symptoms among treated coeliac disease patients
SO SCANDINAVIAN JOURNAL OF GASTROENTEROLOGY
LA English
DT Article
DE Coeliac disease; adults; extraintestinal; musculoskeletal; gluten-free diet
ID extraintestinal manifestations; premenopausal women; arthritis; children; pattern; mass
AB Objective: Varying musculoskeletal symptoms, such as joint pain and myalgia, are recognized as possible extraintestinal complaints of coeliac disease (CeD), but little is known about the prevalence and risk factors of these symptoms. In this study the aim was to evaluate the prevalence of and factors associated with self-reported musculoskeletal symptoms among adult CeD patients on a gluten-free diet (GFD). Materials and methods: The presence of current musculoskeletal symptoms was studied in 614 CeD patients on a GFD and 539 of their non-CeD relatives by a systematic interview. The association between musculoskeletal symptoms and various patient-related factors was investigated using logistic regression. Results: CeD patients reported more often current musculoskeletal symptoms than controls (37.8% vs. 22.8%, $p < 0.001$). CeD was an independent risk factor for musculoskeletal symptoms even after adjusting for age, gender and previously diagnosed co-morbidities, including autoimmune thyroid disease, osteoarthritis and osteoporosis/osteopenia (odds ratio 1.95, 95% confidence interval 1.48-2.59). Factors associated with these symptoms were female sex, higher age at present, long duration of any CeD-related symptoms before diagnosis and presence of autoimmune thyroid diseases and osteoarthritis.

Conclusion: CeD is associated with musculoskeletal symptoms even on a strict GFD. Possible susceptibility to current musculoskeletal complaints should be kept in mind, especially among certain risk patients such as those with long diagnostic delay and osteoarthritis.

TI Investigating multimorbidity patterns and associated risk factors in the fasa

adults cohort study (FACS): A latent class analysis
SO PLOS ONE
LA English
DT Article
ID physical-activity; sleep duration; health-care; prevalence; mortality
AB Background Multimorbidity, defined as the co-occurrence of multiple health conditions, is a major global public health concern. This study aimed to identify latent classes of multimorbidity and associated risk factors in Iranian adults.Method This cross-sectional study analyzed baseline data from 10,131 adults who participated in the Fasa Adults Cohort Study (FACS) in southern Iran. Multimorbidity was defined as the presence of two or more of 11 chronic diseases, including hypertension, dyslipidemia, stroke, osteoarthritis, depression, type two diabetes mellitus, obesity, osteoporosis, cardiovascular disease, thyroid disease, and respiratory disease. Latent class analysis (LCA) was used for cluster participants, and multinomial logistic regression was conducted to investigate the association between age, sex, education level, socioeconomic status, daily sleep duration, physical activity, and multimorbidity.Result The prevalence of multimorbidity was 40.3%. Three latent classes were identified: healthy (66.8%), dyslipidemia (14.1%), and cardio-metabolic conditions (19.1%). Older age increased the odds of belonging to dyslipidemia (odds ratio (OR) = 1.04 [95% confidence interval (CI): 1.03-1.05]) and cardio-metabolic conditions (OR = 1.10 [95% CI: 1.09-1.11]) classes. Similarly, women were at higher odds than men of being in dyslipidemia (OR = 2.49 [95% CI: 2.05-3.02]) and cardio-metabolic conditions (OR = 3.35, 95% CI: 2.79-4.03]) classes. Employed participants showed decreased odds of having cardio-metabolic conditions (OR = 0.66 [95% CI: 0.55-0.80]). However, very high socioeconomic status was a risk factor for cardio-metabolic conditions (OR = 1.44 [95% CI: 1.16-1.78]) and dyslipidemia (OR = 1.35 [95% CI: 1.10-1.65]). Higher physical activity and sleeping for 8 hours or more were protective factors against cardio-metabolic conditions (OR = 0.74 [95% CI: 0.63-0.87]). Moreover, medium or high dietary intake increased the odds of belonging to the dyslipidemia class (OR = 1.46 [95% CI: 1.09-1.94] and OR = 1.57 [95% CI: 1.16-2.11], respectively).Conclusion Using LCA, we identified distinct subgroups of chronic diseases, showing hidden patterns of multimorbidity associated with several risk factors. This approach offers deeper knowledge of disease clustering, contributes to a more comprehensive understanding of multimorbidity, and shows the importance of regional health challenges in designing targeted public health interventions.

TI Characterizing therapeutic effects of velvet antler using different omics strategies
SO JOURNAL OF TRADITIONAL AND COMPLEMENTARY MEDICINE
LA English
DT Article
DE Velvet antler; Therapeutic effects; Microbiomics; Proteomics; Transcriptomics
ID formosan sambar deer; pilose antler; rna-seq; polypeptides; tip; transcriptome; expression; components; stress
AB Velvet antler (VA) has been widely used in traditional Chinese medicine more than thousand years. Several pharmacological properties of VA have been demonstrated, such as anti-osteoporosis, anti-osteoarthritis, anti-aging, and anti-ischemia-hypoxia effects. Recently, many studies applied different omics in VA studies to illustrate biological pathways or processes, identify bioactive compounds, and discover pharmacological properties. This mini-review article summarizes the application of different omics for investigating therapeutic effects of VA. The limitation and future challenges facing the application of multi-omics in VA is also briefly discussed.

ID mesenchymal stem-cells; promotes osteogenic differentiation; rheumatoid-arthritis; inhibiting inflammation; synovial fibroblasts; osteosarcoma cells; global burden; osteoclastogenesis; osteoarthritis; expression
AB Bone and cartilage diseases have become the leading causes of joint disability due to the destruction of bone and cartilage. No effective drugs are available to cure bone and cartilage diseases. Exploring natural compounds as therapeutic alternatives shows promise. Apigenin, a naturally occurring flavonoid, exhibits various pharmacological activities, such as anti-inflammation, antioxidant, and immune modulation. Apigenin acts as a phytoestrogen and mediates the balance of bone remodeling by inducing osteogenic differentiation, promoting osteoblast-associated bone formation, and inhibiting osteoclast-related bone resorption. In addition, apigenin exhibits protective effects against osteoporosis (OP), rheumatoid arthritis (RA), osteoarthritis (OA), gouty arthritis (GA), and intervertebral disc degeneration (IDD). Apigenin can be a promising agent in treating bone and cartilage. However, the application of apigenin is limited due to its low water solubility and bioavailability. More efforts are still needed.

TI Genetic analysis of comorbidities between osteoarthritis, sarcopenia, and osteoporosis
SO EXPERIMENTAL GERONTOLOGY
LA English
DT Article
DE Osteoarthritis; Sarcopenia; Osteoporosis; Genetic correlation; Shared genetic structure; Causal association
ID hand osteoarthritis; common variants; metaanalysis; traits
AB Background: Osteoarthritis (OA), sarcopenia (SCP), and osteoporosis (OP) pose a substantial global morbidity and mortality burden, and previous studies have

observed potential associations among them. This study aims to comprehensively characterize the common genetic structure, biological basis, and underlying causal relationship among OA, SCP, and OP. Methods: We used pooled statistics from the largest European genome-wide association study to investigate the genetic overlap and underlying causal relationships among OA, SCP, and OP. LD Score Regression (LDSC) was first used for estimating global and local genetic associations, cross-trait meta-analysis was then conducted to identify shared loci, and mendelian randomization (MR) analysis was performed to test causal association. Results: In global and local genetic correlation analysis, we found strong positive correlations among OA, SCP, and OP. Cross-trait meta-analysis revealed 9 novel pleiotropic loci for HandOA_SCP trait-pairs, 1 for ThumbOA_SCP (females), and 6 for KneeOA_SCP (males)0.10 novel pleiotropic loci were also identified for HipOA_TBMD, while none for WLM_FinOP. Bidirectional MR analyses indicated significant causal associations between HandOA and SCP(Forward: OR: 1.41, 95 % CI: 1.25-1.60, p < 0.01,Reverse: OR: 1.77, 95 % CI: 1.34-2.35, p < 0.01). Reverse analyses suggested that ThumbOA.female (OR: 1.92, 95 % CI:1.18-3.13, p < 0.01) and KneeOA.male (OR: 1.58, 95 % CI: 1.13-2.12, p < 0.01) were positively correlated with SCP, while TBMD was positively correlated with HipOA (OR: 1.23, 95 % CI: 1.16-1.31, p < 0.01). Conclusions: Our work demonstrates a shared genetic basis, pleiotropic loci, and putative causal relationships among OA, SCP, and OP, highlighting the intrinsic links behind these three complex skeletal diseases.

TI Non-coding RNAs in osteoarthritis and osteoporosis-related hip fractures: molecular biomarkers for precision diagnosis and prognosis

SO FRONTIERS IN ENDOCRINOLOGY
LA English
DT Review
DE hip fracture; osteoporosis; osteoarthritis; non-coding RNAs; biomarkers; diagnostics
ID osteoblast differentiation; circular rna; bone loss; promotes; expression; osteogenesis; delivery
AB As individuals age, bone density declines and the likelihood of fractures increases, particularly in women experiencing menopause. Hip fractures, the most severe consequence of osteoporosis, are becoming more common due to the aging global population and a 1-3% annual increase in hip fractures in most regions. The specific epigenetic mechanisms underlying the onset of osteoporosis and its related fractures remain predominantly unexamined. Research indicates that epigenetic modifications can elevate the risk of osteoarthritis, osteoporosis and bone fractures, especially hip fractures, by linking genetic predispositions with environmental factors. Essential regulatory components in these factors encompass microRNAs, lncRNAs, and circular RNAs. This review examines the function of miRNAs, lncRNAs, and circRNAs in the advancement of osteoporosis, with an emphasis on osteoblasts and osteoclasts. The objective is to enhance comprehension of RNA classes in osteoporotic hip fractures, which may facilitate early detection and prognosis, as well as clarify cellular interactions, potentially resulting in innovative diagnostic techniques and targeted therapies.

TI Multimodal analysis investigating the shared pathogenic mechanisms of osteoporosis and osteoarthritis with an initial exploration of the role of ferroptosis
SO PLOS ONE
LA English
DT Article
AB Background Osteoarthritis (OA) and osteoporosis (OP) are prevalent conditions with overlapping molecular mechanisms. Recent studies have brought attention to ferroptosis, a type of cell death that relies on iron, as a possible connection between these diseases.Methods We performed a comprehensive analysis with datasets obtained from the Gene Expression Omnibus (GEO), focusing on differentially expressed genes (DEGs) in OA and OP. Functional enrichment and integrated analyses identified ferroptosis-related pathways. The role of ferroptosis in OP was further explored through in vivo studies using an ovariectomy-induced OP mouse model.Results The analysis revealed significant overlaps in DEGs related to ferroptosis pathways in both OA and OP. Key genes like TXNIP and SLC2A3 were implicated in the regulation of ferroptosis and associated with disease mechanisms. In vivo results confirmed increased ferroptosis markers in bone marrow stromal cells (BMSCs) from OP mice, supporting the hypothesis that ferroptosis contributes to bone density reduction and structural deterioration.Conclusion Our findings highlight ferroptosis as a critical pathway in the pathogenesis of both OA and OP. Targeting ferroptosis-related genes and pathways could provide new therapeutic opportunities for managing these musculoskeletal diseases.

TI Relationships between Otolith Morphometrics and Fish Size in an Economically Important Fish, Boops Boops (Linnaeus, 1758) from Aegean and Mediterranean Seas (Türkiye)
SO THALASSAS
LA English
DT Article

DE Otolith morphometrics; Fish size; Linear and non-linear regressions; Boops boops; T & uuml;rkiye
ID shape-analysis; stock discrimination; body-size; growth; bogue; age; sparidae; south
AB The present study was conducted to investigate the comparative biometric relationship between fish size and otolith morphometrics in bogue, Boops boops collected from Aegean and Mediterranean Seas in T & uuml;rkiye. Linear and non-linear regression equations between otolith morphometrics and fish size were established in the fish samples of both the ecosystems. The values of "R2" of regression analysis between TL to otolith morphometrics (OL, OH, OP and OA) showed the positive relationships and all data were well fitted in the regression model where a greater degree of fit was recorded in the stocks of bogue fish in Aegean Sea and Mediterranean Sea. The highest correlations were observed between TL-OL and TL-OA, with both regression coefficients (R-2) reaching 0.765 to 0.900 in Aegean Sea Mediterranea Sea, respectively. In addition, all relationships were found statistically important ($p < 0.001$). The results obtained from this examination were the first to address the relationship between otolith measurements and total length for B.boops collected from Aegean Sea and Mediterranean Sea.

TI Methyltransferase-Like 3-Mediated N6-Methyladenosine Modification on RNAs: A Novel Perspective for the Pathogenesis and Treatment of Bone Diseases
SO JOURNAL OF CELLULAR AND MOLECULAR MEDICINE
LA English
DT Review
DE diagnosis; methyltransferase-like 3; osteoarthritis; osteoporosis; osteosarcoma; RNA N-6-methyladenosine modification; treatment
ID osteosarcoma; osteoarthritis; osteoporosis
AB Osteoarthritis, osteoporosis, and osteosarcoma are prevalent osseous pathologies associated with the aberrant functionality of chondrocytes, osteoclasts, and osteoblasts, respectively. These conditions frequently exhibit therapeutic resistance and possess a high mortality risk, thus representing substantial health threats. To mitigate these concerns, it is imperative to investigate novel mechanistic insights. Methyltransferase-like 3 (METTL3) is pivotal in these disorders by modulating gene expression via N-6-methyladenosine (m(6)A) modifications on RNA, thereby impacting cellular processes. Although considerable research has elucidated METTL3's involvement in these diseases, a systematic review is essential to summarise these findings and evaluate METTL3's significance. This review endeavours to aggregate and examine contemporary studies to elucidate METTL3's role in bone pathologies and its clinical implications. We propose that METTL3 constitutes a risk gene in these conditions by mediating m(6)A modifications on both mRNAs and non-coding RNAs, suggesting that METTL3 may serve as a critical diagnostic biomarker and therapeutic target. In conclusion, this review provides an extensive analysis of METTL3 and its correlation with osteoarthritis, osteoporosis, and osteosarcoma, offering valuable perspectives on extant research and serving as a valuable reference for researchers engaged in both basic and translational studies.

TI Age-related bone mass and body composition dynamics in female cynomolgus monkeys: dual-energy X-ray absorptiometry insights for osteoporosis etiology
SO QUANTITATIVE IMAGING IN MEDICINE AND SURGERY
LA English
DT Article
DE Female cynomolgus monkeys; dual-energy X-ray absorptiometry (DXA); bone mineral density (BMD); body composition
ID mineral density; primate model; menopausal; difference; children; cycle; fat; sex
AB Background: Osteoporosis, characterized by reduced bone mass and increased fracture risk, is a major global health burden. Nonhuman primates, particularly female cynomolgus monkeys, are critical preclinical models due to their skeletal and hormonal similarity to humans. Dual-energy X-ray absorptiometry (DXA) is the gold standard for measuring bone mineral density (BMD) and body composition. However, data on age-related changes in these metrics in cynomolgus monkeys are inconsistent, and the relationship between body composition and BMD remains debated and understudied in this model. The objectives of this study were to delineate the age-dependent trends in bone mass and body composition and to evaluate the impact of body composition on bone mass. This study aims to furnish a data reference for experiments involving bone mass and body composition in cynomolgus monkeys as a disease model. Methods: A cohort of 112 healthy female cynomolgus monkeys was stratified into four age-based groups. DXA scans were conducted to ascertain total body bone mass, subcranial bone mass, spine BMD (BMDs), central region-of-interest bone mineral density (BMDCROI), and body

composition metrics. A generalized additive model (GAM) was utilized for non-linear regression analysis of the aging trends in bone mass and body composition parameters. Spearman's rank correlation and multiple linear regression analyses were conducted to investigate the interplay between body composition and bone mass. Results: In female cynomolgus monkeys <= 10 years of age, bone mass parameters showed a significant increase with age. Beyond the age of 10 years, BMDs remained stable with age, while total body BMD (BMDTB) and subcranial BMD exhibited a slight increasing trend in advanced age. A relative decline in BMDCROI was observed in the elderly cohort, with a higher cumulative bone loss rate compared to BMDs (-10.0% vs. 1.8%). BMDTB demonstrated a strong positive correlation with subcranial BMD, with correlation coefficients ranging from 0.947 to 0.990 (P<0.001). Similarly, total body bone mineral content (BMCTB) was highly correlated with subcranial BMC, with correlation coefficients ranging from 0.961 to 0.996 (P<0.001). In the correlation analysis of bone mass and body composition in female cynomolgus monkeys prior to peak age (<= 10 years old), both lean mass (LM) and fat mass (FM) positively influenced BMD, with LM contributing more significantly. Post-peak age (>10 years), FM had a more pronounced effect on total body bone mass. Conclusions: The bone mass and body composition data of female cynomolgus monkeys across different age groups serve as a valuable reference for studies employing female cynomolgus monkeys as animal models. BMDCROI is a sensitive indicator for detecting spinal bone mass loss, minimizing the confounding effects of osteoarthritis (OA). The variable contributions of LM and FM to bone mass in female cynomolgus monkeys at different ages offer significant insights for investigating the etiological factors of osteoporosis.

TI Interactions between the gut microbiota and immune cell dynamics: novel insights into the gut-bone axis
SO GUT MICROBES
LA English
DT Review
DE Gut microbiota; bone homeostasis; bone-related diseases; gut-immune-bone axis
ID aryl-hydrocarbon receptor; b-cells; dendritic cells; t-cells; arthritis; osteoporosis; osteoarthritis; inflammation; activation; acid
AB Over the past few decades, accumulating evidence has demonstrated that gut microbiota engages in a sustained dialog with the immune system, leading to microbiota-driven immune responses that mediate the regulation of bone-related diseases. Despite the complexity of the dynamic interactions within the gut-immune-bone axis, advancements in high-throughput multi-omics sequencing have significantly facilitated the detailed exploration of this intricate network, thereby providing the potential to develop novel therapeutic strategies for bone-related diseases. In this review, we first summarize the variations in gut microbiota composition observed in patients with bone-related diseases, such as rheumatoid arthritis (RA), osteoarthritis (OA), and osteoporosis (OP), in comparison to healthy controls, along with the factors influencing these changes. The review that follows synthesize evidences highlighting the profound effects of gut microbial dysbiosis on immune homeostasis and bone microenvironment, respectively. We further elaborate that the gut-immune axis and gut-bone axis are not independent but three-dimensional networks, emphasizing gut microbial dysbiosis as a pivotal driver of immune dysregulation and subsequent bone homeostasis imbalance. Therapeutic strategies to manipulate the gut-immune-bone axis based on the use of probiotics as well as prebiotics, fecal microbiota transplantation, dietary modifications, and pharmacological interventions are also discussed. Finally, we discuss the challenges of current research on the gut-immune-bone axis and propose future directions for identifying novel therapeutic targets based on this axis to treat these diseases.

TI Exploring the Four-Dimensional Impact of Pain-Related and/or Intra-Articular Temporomandibular Disorder Symptoms on Oral Health-Related Quality of Life Among Young Adults
SO JOURNAL OF ORAL REHABILITATION
LA English
DT Article
DE intra-articular; oral health-related quality of life; pain; symptoms; temporomandibular disorders
ID malocclusion; prevalence; severity; tmd
AB Objectives A four-dimensional structure for oral health-related quality of life (OHRQoL) was recently proposed, comprising oral function (OF), orofacial pain (OP), orofacial appearance (OA) and psychosocial impact (PI). This study examined the impact of different temporomandibular disorder (TMD) symptoms on the four OHRQoL dimensions in young adults. It also correlated the four dimensions with the seven Oral Health Impact Profile (OHIP) domains. Methods Young adults were recruited from a large university. The quintessential five TMD symptoms (5Ts) and OHIP-14 were used to assess TMD symptoms and OHRQoL. Participants were categorised into no (NT), pain-related (PT), intra-articular (IT) and combined (CT) TMD groups, and total, dimension and domain OHIP scores were computed. Data were evaluated using the chi-square test and non-parametric analyses (alpha = 0.05). Results Among the 1097 eligible participants (mean age 19.9 years [SD = 1.3]; 69.7% women), 47.2% reported no TMD symptoms, while 20.5%, 14.9% and 17.4% had PT, IT and CT TMD symptoms, respectively. Significant differences in OHIP

scores were noted between individuals with and without TMD symptoms across all dimensions and domains (CT, PT, IT > NT). Additionally, notable distinctions in normalised dimension scores were evident in all participant groups (OP, OA > OF, PI). Moderate to strong correlations were discerned between OHIP dimensions and domain, except for OA with functional limitation (rs = 0.35). Conclusions Adopting the four dimensions as the standard metric for assessing OHRQoL can improve study comparability and enhance understanding of TMD impacts.

DT Article
DE aging; osteoporosis; hip fracture; inflammaging; osteoimmunology; immunoporosis
ID c-reactive protein; osteoporosis; association
AB Inflammaging has been implicated in age-related bone loss and fragility fractures through immune-mediated effects on bone turnover. We aimed to explore the relationship between systemic inflammatory markers and bone health in older adults, focusing on the differences between patients with osteoporotic fractures and non-fractured controls. We retrospectively analyzed 40 older patients (20 with hip fractures and 20 with osteoarthritis without prior fragility fractures). We compared routine inflammatory markers, including red cell distribution width (RDW), C-reactive protein (CRP), neutrophil-to-lymphocyte ratio (NLR), systemic immune-inflammation index (SII), and the composite CRP-albumin-lymphocyte index (CALLY), between groups. Bone mineral density (BMD) at the hip, lumbar spine, and wrist, as well as the FRAX score, were assessed. Correlations between inflammatory markers, BMD, and FRAX scores were evaluated using Spearman's coefficient. Patients with fractures exhibited significantly elevated CRP (66.2 +/- 70.3 vs. 3.8 +/- 4.0 mg/L, p = 0.0008) and SII (1399.7 +/- 1143.4 vs. 751.4 +/- 400.8, p = 0.025) compared to controls. RDW, NLR, and CALLY scores did not differ significantly between the groups. Higher CRP levels were associated with lower BMD at all sites (hip: r approximate to -0.63, p = 0.002; spine: r approximate to -0.60, p = 0.005; wrist: r approximate to -0.60, p = 0.005). No significant correlations were observed between the SII and BMD or FRAX values. Elevated systemic inflammation, particularly indicated by CRP and SII, was associated with osteoporotic fracture status and low bone density in our cohort. These findings support the concept that inflammatory pathways may contribute to osteoporosis and fracture risk and suggest that inflammatory markers could serve as adjunctive tools in fracture risk assessment. Further studies are required to clarify the causality and evaluate whether targeting chronic inflammation can improve bone health in older adults.

AB As a type of epigenetic modifications, mRNA modifications regulate the metabolism of mRNAs, thereby influencing gene expression. Previous studies have indicated that dysregulation of mRNA modifications is closely associated with the occurrence and progression of bone diseases (BDs). In this study, we first introduced the dynamic regulatory processes of five major mRNA modifications and their effects on the nucleus export, stability, and translation of mRNAs. We then summarized the mechanisms of mRNA modifications involved in the development of osteoporosis, osteoarthritis, rheumatoid arthritis, ankylosing spondylitis, fractures, osteomyelitis, and osteosarcoma. Finally, we reviewed therapeutic strategies for BDs based on the above mechanisms, focusing on regulating osteoblast and osteoclast differentiation, inhibiting cellular senescence and injury, and alleviating inflammation. This review identified mRNA modifications as potential targets for treating BDs and proposes perspectives on the diversity, targetability, and safety of mRNA-modifying therapies.

TI Quality by design strategy of human mesenchymal stem/stromal cell drug products for the treatment of knee osteoarthritis
SO WORLD JOURNAL OF STEM CELLS
LA English
DT Review
DE Mesenchymal stem/stromal cells; Knee osteoarthritis; Quality by design; Critical quality attributes; Critical material attributes
ID stem-cells; stromal cells; therapy; differentiation; heterogeneity; proliferation; osteoporosis; expression; expansion; criteria
AB Knee osteoarthritis (KOA), characterized by heterogeneous arthritic manifestations and complex peripheral joint disorder, is one of the leading causes of disability worldwide, which has become a high burden due to the multifactorial nature and the deficiency of available disease-modifying treatments. The application of mesenchymal stem/stromal cells (MSCs) as therapeutic drugs has provided novel treatment options for diverse degenerative and chronic diseases including KOA. However, the complexity and specificity of the "live" cells have posed challenges for MSC-based drug development and the concomitant scale-up preparation from laboratory to industrialization. For instance, despite the considerable progress in ex vivo cell culture technology for fulfilling the robust development of drug conversion and clinical trials, yet significant challenges remain in obtaining regulatory approvals. Thus, there's an urgent need for the research and development of MSC drugs for KOA. In this review, we provide alternative solution strategies for the preparation of MSC drugs on the basis of the principle of quality by design, including designing the cell production processes, quality control, and clinical applications. In detail, we mainly focus on the quality by design method for MSC manufacturing in standard cell-culturing factories for the treatment of KOA by using the Quality Target Product Profile as a starting point to determine potential critical quality attributes and to establish relationships between critical material attributes and critical process parameters. Collectively, this

review aims to meet product performance and robust process design, and should help to reduce the gap between compliant products and the production of compliant good manufacturing practice.

TI Targeting chemokine signaling networks for therapeutics in skeletal disorders
SO FRONTIERS IN ENDOCRINOLOGY
LA English
DT Review
DE chemokine networks; bone remodeling; osteoimmunology; osteoporosis; osteoarthritis; bone regeneration; targeted therapy
ID cancer; axis; osteoclasts; inhibition; activation; expression; migration; cells
AB Chemokine signaling networks have emerged as pivotal regulators of skeletal homeostasis, integrating inflammation, angiogenesis, and immune activation with the processes of bone remodeling and regeneration. Recent evidence demonstrates that dysregulated chemokine-receptor interactions, including CCL2/CCR2, CCL5/CCR5, and CX3CL1/CX3CR1, disrupt the equilibrium between osteogenesis and osteoclastogenesis, thereby contributing to the pathogenesis of osteoporosis, osteoarthritis, multiple myeloma, and bone metastasis. This review synthesizes current insights into how chemokine-mediated signaling cascades intersect with canonical pathways such as JAK/STAT3, NF-kappa B, PI3K/Akt, and Wnt/beta-catenin to coordinate cellular communication within the bone microenvironment. Furthermore, it highlights recent progress in therapeutic

strategies targeting chemokine axes to mitigate inflammatory bone loss and promote tissue regeneration, while addressing translational barriers including receptor redundancy, context-dependent specificity, and limited in vivo validation. By positioning chemokines as dynamic mediators at the interface of the immune and skeletal systems, this review establishes a conceptual foundation for the development of precision therapeutics aimed at restoring bone homeostasis and treating skeletal disorders.

TI Expressions of insulin-like growth factor-1, interleukin-1β, and matrix metalloproteinase-13 in patients with knee osteoarthritis and their associations with the severity

SO REVISTA ROMANA DE MEDICINA DE LABORATOR
LA English
DT Article
DE expression; insulin-like growth factor; interleukin; knee osteoarthritis; matrix metalloproteinase
AB Background A key factor in the pathogenesis of osteoarthritis is an imbalance in cytokines, favoring proinflammatory activity. This study aimed to explore the expressions of insulin-like growth factor-1 (IGF-1), interleukin-1 beta (IL-beta) and matrix metalloproteinase-13 (MMP-13) in patients with knee osteoarthritis (KOA), as well as their associations with the severity. Methods Subjects (166 in total) were recruited from KOA patients treated between January 2021 and June 2023. Their clinical data were collected, disease severity was assessed by Kellgren-Lawrence (K-L) grades, and venous blood was drawn to measure the serum levels of IGF-1, MMP-13, and IL-1 beta. Factors affecting the severity of KOA were analyzed by multivariate logistic regression model incorporating the aforementioned information. Results There were more cases of disease course >1 year, body mass index (BMI) >25 kg/m2, heavy physical labor, and osteoporosis in the severe group ($P<0.05$). Multivariate logistic regression analysis revealed that disease course >1 year, BMI >25 kg/m2, heavy physical labor, osteoporosis, lowly expressed MMP-13, and lowly expressed IL-1 beta were risk factors for the severity of KOA [odds ratio (OR) >1, $P<0.05$], while highly expressed IGF-1 was a protective factor ($OR<1$, $P<0.05$). The areas under the receiver operating characteristic (ROC) curves (95% confidence interval) of IGF-1, MMP-13, and IL-1 beta levels and their combination for assessing the severity of KOA were 0.883 (0.823-0.942), 0.880 (0.827-0.934), 0.895 (0.847-0.943), and 0.923 (0.877-0.968), respectively. Conclusions IGF-1 is lowly expressed, whereas MMP-13 and IL-1 beta are highly expressed. The combined application of the three indicators has the highest value for assessing the severity of KOA.

TI RANKL-mediated osteoclastic subchondral bone loss at a very early stage precedes subsequent cartilage degeneration and uncoupled bone remodeling in a mouse knee osteoarthritis model
SO JOURNAL OF ORTHOPAEDIC SURGERY AND RESEARCH
LA English
DT Article
DE Subchondral bone loss; Early stage; Knee osteoarthritis; Mouse destabilization of the medial meniscus (DMM) model; Tsukuba hypertensive mice; High-turnover bone metabolism; Osteoporosis
ID mineral density; hypertrophic differentiation; osteoporosis; resorption; progression; inhibition; activation; apoptosis; renin; mice
AB IntroductionUncoupled bone remodeling in the subchondral bone (SB) has recently been considered as an important process in the progression of knee osteoarthritis (KOA). In this study, we aimed to investigate changes in SB and articular cartilage using a mouse model of destabilization of the medial meniscus (DMM) and determine the effects of bone metabolism on KOA progression.MethodsDMM or sham surgery was performed on the left knees of 40-week-old male wild-type (WT) mice and Tsukuba hypertensive mice (THM), which exhibit high-turnover bone metabolism. Bone volume/tissue volume (BV/TV) and bone mineral density (BMD) in the medial tibial SB were measured longitudinally in vivo using mu CT at 0 (immediately after surgery), 1, 2, 4, 8, and 12 weeks postoperatively. Concurrently, histological evaluations of the articular

cartilage in the medial tibial plateau were conducted. Furthermore, the number of endo-periosteal tartrate-resistant acid phosphatase-positive osteoclasts, trabecular RANKL-positive osteocytes, and osteocytes in the trabeculae were measured at 0, 1, 2, and 4 weeks.ResultsIn the WT + DMM group, BV/TV and BMD in the SB significantly decreased with time, whereas cartilage degeneration significantly increased. In the THM + DMM group, these changes in BMD and cartilage degeneration were significantly pronounced. Interestingly, in the THM + DMM group, BV/TV significantly decreased up to 4 weeks but then began to increase, although BMD continued to decrease until the 12-week mark. The number of osteoclasts and the percentage of RANKL-positive osteocytes per total number of osteocytes within the total trabecular bone area (%) in the WT + DMM group significantly increased with time, with a significant difference between the WT + DMM and WT + sham groups at 4 weeks. The number of osteocytes in the WT + DMM group significantly decreased with time, and the difference between the WT + DMM and WT + sham groups was significant at 4 weeks postoperatively. These histological changes were significantly enhanced in the THM + DMM group.ConclusionsThe results indicate that early-stage osteocyte death in the SB and RANKL-mediated osteoclastic SB loss precede histological cartilage degeneration and contribute to uncoupled bone remodeling at the later stage. Acceleration of disease processes in the THM + DMM group suggests that high-turnover bone metabolism is a potential risk factor for KOA. Maintaining SB integrity and avoiding continuous SB overload may be key strategies for mitigating disease progression.

TI The role of RGS12 in tissue repair and human diseases
SO GENES & DISEASES
LA English
DT Review
DE Cancer; Nervous disorders; Osteoporosis; RGS12; Tissue repair
ID protein signaling 12; goloco motif; regulators; osteoclastogenesis; osteoporosis; cancer; osteoarthritis; periodontitis; inflammation; receptors
AB Regulator of G protein signaling 12 (RGS12) belongs to the superfamily of RGS proteins defined by a conserved RGS domain that canonically binds and deactivates heterotrimeric G-proteins. As the largest family member, RGS12 is widely expressed in many cells and tissues. In the past few decades, it has been found that RGS12 affects the activity of various cells in the human body, participates in many physiological and pathological processes, and plays an important role in the pathogenesis of many diseases. Here, we set out to comprehensively review the role of RGS12 in human diseases and its mechanisms, highlighting the possibility of RGS12 as a therapeutic target for the treatment of human diseases. <feminine ordinal indicator> 2024 The Authors. DT Article

ID older-adults; skeletal-muscle; atrial-fibrillation; stroke prevention; heart-failure; resistance; metformin; people; falls; anticholinergics
AB Integrating exercise prescriptions with medication management represents a novel approach for enhancing health and function, optimising medication effectiveness, and reducing adverse drug reactions and polypharmacy in older adults (ie, those aged >= 60 years). This Personal View highlights the need for a comprehensive assessment of lifestyle, diagnoses, geriatric syndromes, and medications with an emphasis on fully incorporating exercise treatment into geriatric care. Exercise is an alternative to less effective or unsafe medications for many conditions, including depression, anxiety, insomnia, osteoarthritis, and dementia. Exercise is an important adjunct to pharmacotherapy for many common chronic conditions such as coronary artery disease, heart failure, diabetes, osteoporosis, cancer, and chronic obstructive pulmonary disease. Adding exercise to drug management can mitigate adverse drug reactions, enhance medication compliance, and reduce the adverse effects of sedentary behaviour and ageing processes on chronic disease expression. Targeted exercise programmes have also been shown to ameliorate drug-induced sideeffects, including anorexia, falls, sarcopenia, osteoporosis, and orthostatic hypotension, and to overcome constraints such as reduced aerobic fitness, balance impairment, and muscle atrophy due to some medications. Health-care professionals require additional training and support to ensure that exercise assumes a key, central role in older adults with multimorbidity and polypharmacy, as supported by the current literature. This Personal View describes practical approaches to incorporating exercise into clinical practice as a step towards an integrated geriatric care model, with the ultimate aim of increasing health span and minimising disability.

TI Differential Pattern of Obesity in Total Hip and Knee Arthroplasty Candidates
SO PHYSIOTHERAPY CANADA
LA English
DT Article
DE creatinine; hip and knee; obesity; osteoarthritis; sex
ID body-mass index; osteoarthritis; men; risk; associations; mortality; gender; women; hand; oa

AB Purpose: This study examined the differential pattern of obesity between men and women with severe OA of the knee or hip joint. The relationship between creatinine, a pro-inflammatory parameter and obesity, sex, and site of joint involvement was examined.Design: This study involved a secondary analysis of prospectively collected data of patients who underwent hip or knee arthroplasty.Results: Data of 5,130 patients (1,989 males, 39%, 3,141 females, 62%), mean age: 66 (11) were used for data analysis. Of these patients, 2,038 patients underwent hip and 3,092 patients underwent knee arthroplasty. Prevalence of obesity (grade I and II) was higher in the TKA group as compared with THA group (55% vs. 38%) with the prevalence of morbid obesity (Grade II) being twice as many in the TKA group (27% vs. 14%), $p < 0.001$. There was a statistically significant association between obesity and site of joint involvement ($p < 0.001$) and for the interaction between sex of the patient and site of arthritis ($p < 0.001$). In the TKA group, the sex factor was the only factor that was related to the pre-op creatinine level ($p < 0.001$). In THA group, both sex ($p < 0.001$) and obesity ($p = 0.002$) showed an association with pre-op creatinine.Conclusion: This study provides further evidence that obesity has a multifaceted interaction with osteoarthritis with a differential pattern in hip and knee joints. Creatinine considered as a pro-inflammatory factor appears to have a differential role in hip and knee OA.

TI Interoceptive regulation of bone homeostasis: The interplay between the nervous and skeletal systems in pathophysiology
SO PHARMACOLOGICAL RESEARCH
LA English
DT Article
DE Skeletal interoception; Nervous system; Neuropeptides; Skeletal tissue homeostasis; Therapeutic strategies for skeletal diseases
ID gene-related peptide; serotonin reuptake inhibitors; nicotinic acetylcholine-receptors; osteoblast-like cells; neuropeptide-y; substance-p; osteoclast differentiation; neurons contribute; leptin regulation; mineral density
AB Studies have demonstrated that the nervous system can perceive and respond to signaling from bone tissue, a process termed interoception, which plays a crucial role in the homeostasis of bone tissue. Sensory nerves extensively innervate bone tissue and transmit interoceptive signals to the central nervous system (CNS). The hypothalamus, located within the CNS, is instrumental in processing these interoceptive signals and regulating bone homeostasis through the autonomic nervous system, the release of neuropeptides, and neuroendocrine mechanisms. Although CNS regulation of bone has been recognized for decades, the specific interoceptive mechanisms governing skeletal homeostasis remain an emerging research focus. This review explores the latest advancements in interoceptive regulation of bone homeostasis, highlighting its role in skeletal diseases such as osteoporosis and osteoarthritis(OA). Furthermore, we discuss potential therapeutic strategies targeting interoceptive pathways, including biomaterials, pharmacological interventions, and non-pharmacological approaches. By elucidating the interplay between the nervous and skeletal systems, this review provides new insights into the regulation of bone health and its implications for future treatments of skeletal disorders.

TI Total Body PET/CT: A Role in Musculoskeletal Diseases
SO SEMINARS IN NUCLEAR MEDICINE
LA English
DT Review
ID regional bone metabolism; lumbar spine; risedronate; f-18-fdg; pain
AB Recent advancements in PET technology have culminated in the development

of total-body PET (TB-PET) systems, which overcome many limitations of traditional scanners. These TB- PET scanners, while still becoming widely available, represent the forefront of clinical imaging across numerous medical institutions worldwide. Early clinical applications have demonstrated their enhanced image quality, precise lesion quantification, and overall superior performance relative to conventional scanners. The capabilities of TB-PET technology, including extended scan range, ultrahigh sensitivity, exceptional temporal resolution, and dynamic imaging, offer significant potential to tackle unresolved clinical challenges in medical imaging. In this discussion, we aim to explore the emerging applications, opportunities, and future perspectives of TB-PET/CT in musculoskeletal disorders (MSDs). Clinical applications for both oncologic and non-oncologic musculoskeletal diseases are discussed, including inflammatory arthritis, infections, osteoarthritis, osteoporosis, and skeletal muscle disorders. From the ability to visualize small musculoskeletal structures and the entire axial and appendicular skeleton, TB-PET shows significant potential in the diagnosis and management of MSD conditions as it becomes more widely available. TI Overview of biomembrane-derived nanoparticles as emerging drug delivery

systems for treating bone aging diseases
SO INTERNATIONAL JOURNAL OF PHARMACEUTICS
LA English
DT Review
DE Biomembrane; Bone aging diseases; Nanoparticles; Osteoporosis; Osteoarthritis
ID mesenchymal stem-cells; red-blood-cell; responsive nanoparticles; engineered exosome; membrane; cartilage; osteoporosis; therapy; cancer; osteoarthritis
AB Bone aging diseases, including osteoporosis and osteoarthritis, present significant global health challenges, particularly in countries experiencing demographic aging. Conventional treatment strategies such as pharmacotherapy and lifestyle adjustments frequently yield suboptimal therapeutic outcomes and are carry risks of longterm adverse effects. In recent years, biomembrane-derived nanoparticles have emerged as promising candidates for advanced drug delivery systems to overcome these limitations. By encapsulating therapeutic agents within biomembranes (cell membrane, extracellular vesicles), these systems enhance biocompatibility, prolong circulation time, and enable targeted delivery to pathological sites. Moreover, biomembranes can be functionally modified to optimize their therapeutic performance. In this review, we explore the pathophysiology of bone aging diseases, current treatment approaches, and the development of biomembrane-derived nanoparticles, with a focus on their potential applications in osteoporosis and osteoarthritis. These innovative delivery systems offer the potential to improve treatment efficacy and minimize side effects, thereby laying the foundation for clinical translation in the future.

TI Age-related prevalence of radiographic lumbar spondylolisthesis and its associations with low back pain, walking speed, and muscle index: findings from the second survey of the ROAD study
SO EUROPEAN SPINE JOURNAL
LA English
DT Article
DE Lumbar spondylolisthesis; Low back pain; Prevalence; Walking speed; Appendicular lean mass
ID bioelectrical-impedance analysis; dwelling elderly subjects; degenerative spondylolisthesis; natural course; risk-factors; sarcopenia; cohort; mass; men
AB ObjectivesTo determine the prevalence of lumbar spondylolisthesis (LS) and its association with low back pain, walking speed, grip strength, and muscle mass in the general population.MethodsParticipants included 1551 members of the general population from the 2nd ROAD (Research on Osteoarthritis/osteoporosis Against Disability) study conducted in Wakayama Prefecture, Japan, between 2008 and 2010. Lumbar radiography diagnosed LS when the slip was >= 3 mm in the lateral views. Logistic regression analysis (adjusted for sex, age, area, and BMI) assessed the association between LS and low back pain, walking speed, grip strength, and appendicular lean mass.ResultsComplete data from 1522 participants (510 men, 1012 women, mean age 65.7 +/- 12.2 years) were analyzed. The prevalence of LS increases with age, with an estimated one in five men aged 80 years or older and one in four women aged 70-79 years affected. Logistic regression showed LS was significantly associated with low back pain (OR: 1.36, CI: 1.03-1.80). Walking speed, grip strength, and appendicular lean mass were not significantly associated with LS. The prevalence of LS at any level was 17.4% in the total sample, 13.3% in men, and 19.5% in women (P = 0.005).ConclusionLS was prevalent in 17.4% of the general population, with a higher prevalence in women. Patients with LS had more low back pain than those without LS.

TI A modified minimally invasive subvastus approach shows superior early postoperative clinical outcomes compared to the medial parapatellar approach in total knee arthroplasty for osteoarthritis patients: a comparative study
SO BMC MUSCULOSKELETAL DISORDERS
LA English
DT Article
DE Modified minimally invasive subvastus approach; Total knee arthroplasty; Osteoarthritis
ID femoral nerve block; mini-subvastus; surgical approach; analgesia; efficacy; anatomy
AB ObjectiveThis study compared the modified minimally invasive subvastus approach (MMSA) versus the medial parapatellar approach (MPA) in total knee arthroplasty (TKA) for osteoarthritis, focusing on perioperative blood loss, postoperative pain, quadriceps strength, and knee mobility.MethodsIn this retrospective cohort study, we enrolled patients undergoing TKA from June 2020 to June 2022. Inclusion criteria were adults aged 40-80 with end-stage knee osteoarthritis undergoing primary TKA. Exclusion criteria included neuromuscular disorders, active infections, severe osteoporosis, prior knee surgery, and rheumatoid arthritis. We compared the MMSA group (n = 36) with the MPA group (n = 57) for primary outcomes including blood loss, postoperative pain, quadriceps strength, knee range of motion, and clinical scores including Oxford Knee Score (OKS) and Western Ontario and McMaster Universities (WOMAC) score.ResultsThe MMSA group showed reduced blood loss, less pain on day 3, and better quadriceps strength and knee mobility compared to the MPA group. Clinical scores (WOMAC and OKS) were significantly better in the MMSA group in the early postoperative period, indicating improved function and reduced pain. However, the MMSA group had longer operation times. Long-term recovery and prosthesis placement accuracy, including prosthesis angles, were similar in both groups.ConclusionThe MMSA offers superior short-term outcomes post-TKA without compromising long-term recovery, indicating its potential as a preferred approach for patients aiming to minimize postoperative complications and expedite recovery. This study provides evidence for the clinical superiority of MMSA in the early postoperative period.

TI From neuromodulation to bone homeostasis: therapeutic targets of nerve growth factor in skeletal diseases
SO FRONTIERS IN PHARMACOLOGY
LA English
DT Review
DE nerve growth factor; bone homeostasis; bone formation; bone resorption; skeletal diseases
ID mesenchymal stem-cells; mouse model; pain; ngf; expression; kinase; trka; blockade; immunoreactivity; differentiation
AB The skeletal system is an important support structure in the human body, and

its homeostatic state is highly relevant to the development of a wide range of orthopaedic diseases. The search for key regulatory factors associated with skeletal development is essential for exploring potential therapeutic targets for bone diseases. Nerve Growth Factor (NGF), the first neurotrophic factor to be discovered, plays an important role in regulating immune cell function, influencing angiogenesis and participating in the physiological and pathological processes of bone homeostasis. Here, we mainly review the biological functions of NGF in the skeletal system and its molecular mechanisms, analyse the pathophysiological roles of the NGF signaling pathway in skeletal diseases such as osteoporosis, osteoarthritis, and fracture healing, and summarize the progress and challenges of the current clinical research on therapeutic strategies targeting NGF. In addition, we provide an overview of NGF and highlight the role of NGF in the regulation of bone formation and bone resorption. Therefore, by reviewing the literature related to NGF and bone diseases, this paper summarises the specific regulatory mechanisms of NGF in various bone diseases, which provides new perspectives and intervention targets for the treatment of skeletal diseases, especially in the field of diseases in which the effects of traditional treatments are limited. The therapeutic strategies targeting neurotrophic factors show broad prospects for clinical application.

TI Update on the role of bone turnover markers in the diagnosis and management of osteoporosis: a consensus paper from The European Society for Clinical and Economic Aspects of Osteoporosis, Osteoarthritis and Musculoskeletal Diseases (ESCEO), International Osteoporosis Foundation (IOF), and International Federation of Clinical Chemistry and Laboratory Medicine (IFCC)

AB Purpose The International Osteoporosis Foundation (IOF) and the International Federation of Clinical Chemistry and Laboratory Medicine (IFCC) have proposed procollagen type I N propeptide (PINP) and beta isomerized C-terminal telopeptide of type I collagen (beta-CTX-I) as reference bone turnover markers (BTMs) for osteoporosis. This report examines the published literature since the 2011 IOF-IFCC position paper in order to determine the clinical potential of the reference BTMs and newer markers for the prediction of fracture risk and monitoring the treatment of osteoporosis. Methods Evidence for the relationship between BTMs and subsequent fractures was gathered from prospective studies through literature

review of the Medline database from years 2011 to May 2024. The impact of treatment on BTMs was also studied by examining publications in that period. Studies of the accuracy of BTMs in the assessment of bone turnover in the setting of advanced chronic kidney disease were also examined. Results Increased BTM concentrations are associated with higher fracture risk in postmenopausal women. PINP and beta-CTX-I measured in blood are associated with fracture risk but their interaction with other risk factors has not been sufficiently studied limiting their incorporation into fracture risk algorithms. Treatment-induced changes in PINP and beta-CTX-I account for a substantial proportion of fracture risk reduction and are useful for improving adherence; they are recommended for inclusion in studies to examine adherence in individual patients. However, total PINP (tPINP) and beta-CTX-I may be elevated in CKD due to renal retention. Bone alkaline phosphatase (BALP), intact PINP (iPINP), and tartrate resistant acid phosphatase 5b (TRACP5b) show the most promise in discriminating high and low turnover bone diseases in patients with advanced CKD and for predicting fracture risk, monitoring treatment response, and assessing the risk of treatment-related complications. Conclusion We re-affirm the use of serum/plasma tPINP and plasma beta-CTX-I as reference BTMs with appropriate patient preparation and sample handling and measurement by standardized/harmonized assays in clinical studies to accumulate further data, and for monitoring treatment of osteoporosis in the setting of normal renal function in clinical practice. BALP and TRACP5b, measured by standardized assays, are recommended as reference BTMs for CKD-associated osteoporosis and should be included in observational and intervention studies to ascertain their utility for risk-evaluation, treatment initiation, and assessment of treatment response in CKD-associated osteoporosis.

TI Hospital-Treated Infections and 15-year Incidence of Musculoskeletal Disorders: A Large Population-Based Cohort Study
SO CLINICAL EPIDEMIOLOGY
LA English
DT Article
DE infectious disease; osteoarthritis; rheumatoid arthritis; osteoporosis; gout; low back pain
ID rheumatoid-arthritis; bacterial-infection; risk; disease; periodontitis; osteoporosis; association; databases
AB Background: Basic science evidence reveals interactions between the immune and bone systems. However, population studies linking infectious diseases and musculoskeletal (MSK) disorders are limited and inconsistent. We aimed to examine the risk of six main MSK disorders (osteoarthritis, rheumatoid arthritis, osteoporosis, gout, low back pain, and neck pain) following hospital-treated infections in a large cohort with long follow-up periods. Methods: We analysed data from 502,409 UK Biobank participants. Participants free of specific MSK disorders at baseline were included in each analysis. Hospital-treated infections before baseline were identified using national inpatient data, while incident MSK outcomes were ascertained from inpatient records, primary care, and death registers. Participants with prior infections were propensity score matched (1:5) with those without. Hazard ratios (HRs) and absolute rate differences (ARDs) with 95% confidence intervals (CIs) were calculated using Cox proportional hazards

models. To assess potential reverse causality due to delayed diagnosis of preexisting illness, analyses were repeated excluding MSK disorder cases that occurred within the first 5 and 10 years post-baseline. Results: A hospital-treated infection was associated with increased risks of all six MSK disorders, with particularly strong associations for osteoporosis (HR, 1.55 [1.48-1.63]; ARD, 1.48 [95% CI 1.29-1.68] per 1000 person-years) and rheumatoid arthritis (HR, 1.53 [1.41-1.65]; ARD, 0.58 [0.46-0.71] per 1000 person-years), while other disorders showed HRs of 1.28-1.32. Bacterial and viral infections showed similar associations, with MSK infections (generally stronger risk) and other locations both linked to increased risks. Associations remained significant even for incident cases that occurred more than 10 years postbaseline. Conclusion: Hospital-treated infections are associated with long-term MSK disorder risks, regardless of pathogen type or disorder nature (inflammatory or degenerative). Long-term monitoring and care for MSK health in patients with prior hospital-treated infections are recommended. frequent and severe infections, suggesting a systemic rather than pathogen-specific effect. The risk persists beyond 10 years, highlighting the need for long-term MSK care for individuals with a history of severe infections.

TI Fetal rotation examined with ultrasound in a sub-Saharan population: A longitudinal cohort study
SO ACTA OBSTETRICIA ET GYNECOLOGICA SCANDINAVICA
LA English
DT Article
DE birth; cesarean; maternity care; obstetrics; ultrasound
ID occiput posterior position; head position; intrapartum sonography; labor; 2nd-stage; delivery; association; duration; outcm; 1st
AB Introduction Occiput posterior (OP) position rates at birth are 5%-8% in studies mainly comprising white European women. The anthropoid pelvis is common in black African women. This pelvic shape has a narrow anterior segment and an ample room posteriorly. The fetal head is wider posteriorly, and the OP position may be favorable in women with an anthropoid pelvic shape. We aimed to examine the fetal rotation with ultrasound longitudinally during the active phase of labor in a sub-Saharan population. We also aimed to examine associations between fetal position, delivery mode, and duration of labor. Material and Methods The study was conducted at Kilimanjaro Christian Medical Centre in Moshi, Tanzania from the 19th of November 2023 to 13th of April 2024. Women with a single fetus in cephalic presentation, gestational age >37 weeks, without previous or pre-labor cesarean section were eligible. Fetal position was classified as occiput anterior (OA) from 10 to 2 o'clock, occiput transverse (OT) at 3 or 9 o'clock, and OP position from 4 to 8 o'clock. Results The study participants comprised 215 women. Fetal positions at admission, in the first and second stage of labor and at birth are presented in the graphical figure. In all, 65/215 (30.2%) fetuses were in OP position at admission, 59/204 (28.9%) in the first stage, 38/210 (18.1%) in the second stage and 35/215 (16.3%) were delivered in OP position. The OP rates at birth were 25/92 (27.2%) in nulliparous and 10/123 (8.1%) in parous women. The operative delivery rate was 10/157 (6.4%) in women with ultrasound assessed fetal position as OA in the second stage (six cesarean section and four vacuum extractions), and 28/48 (58.3%) in the non-OA group (27 cesarean section and one vacuum extraction) ($p < 0.01$). The hazard ratio for delivery in the second stage was 0.26 (95% CI 0.13-0.52) for the non-OA versus the OA group in nulliparous women and 0.25 (95% CI 0.12-0.52) in parous women. Conclusions The persistent OP position rate at birth was higher than previously reported, and the operative intervention rate was nine time higher

in women with the fetus in non-OA versus OA position in the second stage.

TI Research progress on mesenchymal stem cell-derived exosomes in the treatment of osteoporosis induced by knee osteoarthritis (Review)
SO INTERNATIONAL JOURNAL OF MOLECULAR MEDICINE
LA English
DT Review
DE exosomes; mesenchymal stem cells; knee osteoarthritis; osteoporosis
ID bone-mineral density; epigenetic regulation; differentiation; polymorphisms; angiogenesis; mechanisms; arthritis; repair; susceptibility; regeneration
AB Knee osteoarthritis (KOA) and osteoporosis (OP) are closely related, age-related, degenerative orthopedic conditions. Elderly patients with OP frequently develop concurrent KOA, with high co-occurrence rates. Studies indicate that OP significantly increases KOA risk and that these conditions mutually exacerbate each other. Anti-OP therapies show significant efficacy in KOA management, substantially delaying disease progression. Mesenchymal stem cell-derived exosomes (MSC-Exos) have significant therapeutic potential for both KOA and OP. These exosomes enhance chondrocyte proliferation, modulate cartilage matrix synthesis and degradation, and suppress synovial inflammation, suggesting a novel therapeutic approach for KOA. However, their OP mechanisms remain unclear but may involve disrupted bone metabolic signaling, amplified inflammation, and dysregulated intercellular communication in the bone microenvironment. The present review summarizes MSC-Exos research advances in KOA and OP, providing a foundation for future studies and clinical applications.

TI Risk of dementia in patients with age-related medical conditions: a retrospective cohort study
SO PSYCHOGERIATRICS
LA English
DT Article
DE ageing; comorbidity; dementia; retrospective studies; risk factors
ID mild cognitive impairment; obstructive pulmonary-disease; midlife blood-pressure; alzheimers-disease; heart-disease; follow-up; association; decline
AB ObjectiveThis retrospective cohort study aimed to investigate the impact of age-related medical conditions on the incidence of dementia, considering factors such as hypertension, diabetes mellitus, cerebrovascular disease, cardiovascular disease, chronic kidney disease, osteoarthritis, osteoporosis, chronic obstructive pulmonary disease, and hearing difficulties.MethodsData from 513 640 patients at Keimyung University Dongsan Hospital were analyzed using the Observational Medical Outcomes Partnership Common Data Model. Patients with and without age-related medical conditions were assigned to experimental and control groups, respectively, with propensity score matching. Cox proportional hazards models assessed the association between each condition and dementia

incidence.ResultsHypertension, diabetes mellitus, cerebrovascular disease, cardiovascular disease, chronic kidney disease, osteoarthritis, osteoporosis, and hearing difficulties were associated with increased dementia risk. Chronic obstructive pulmonary disease showed no significant association with increased risk of dementia. Incidence rates ranged from 4.52 to 8.05 per 1000 person-years in the control group and 7.46 to 14.99 per 1000 person-years in the experimental group. Hazard ratios ranged from 1.38 to 2.36.ConclusionsThe study highlights the importance of managing age-related medical conditions to mitigate dementia risk. Understanding these risk factors can inform preventive strategies and improve cognitive health outcomes. Problems with deidentification data analysis and the need for further multicentred studies are among the limitations of this study.

TI Runners with osteoarthritis sustain more injuries than healthy runners: An observational cohort study
SO PHYSICAL THERAPY IN SPORT
LA English
DT Article
DE Running; Risk factors; Comorbidity
ID risk; prevention; distance
AB Objective: Examine whether runners with specific diseases, including osteoarthritis, osteoporosis, rheumatoid arthritis, diabetes, multiple sclerosis (MS), cancer, or multiple diseases, sustain more running-related injuries (RRI) compared with healthy runners in the Garmin-RUNSAFE Running Health Study. Design: 18-month cohort study. Setting/participants: Participants were runners >= 18 years, proficient in English, and using a Garmin watch. Exposure included having one of the following diseases: osteoarthritis, osteoporosis, rheumatoid arthritis, diabetes type 1 or 2, multiple sclerosis (MS), cancer, or multiple diseases. Main outcome measures: Outcome was sustaining an RRI and was reported through weekly questionnaires. Appropriate censoring methods were applied for discontinued participation. Time-to-event analysis assessed after 1000 km running. Results: Of 7038 included runners, 6207 had no disease and 831 had at least one of the specified diseases. After 1000 km, 64.4 % of runners with a disease and 56.7 % of healthy runners sustained an RRI, yielding a cumulative incidence risk difference (cIRD) of 8.0 % (95 %CI: 4.0-12.0 %). Among separate diseases, a significant risk

difference was observed between the osteoarthritis group and the healthy group, with a cIRD of 14.7 % (95 %CI: 9.0-20.4 %). Conclusions: A significantly higher incidence of running-related injuries was observed among adult runners reporting a disease. Runners with osteoarthritis is a particularly vulnerable sub-group.

TI Raloxifene Is Associated with Total Knee Arthroplasty in Postmenopausal Women: A Comparative Cohort Study
SO LIFE-BASEL
LA English
DT Article
DE post-traumatic knee osteoarthritis; raloxifene; total knee replacement; postmenopausal women; anti-osteoporotic medications; bisphosphonates; denosumab
ID osteoporosis; bisphosphonates; denosumab; risk
AB Post-traumatic osteoarthritis (PTOA) is a distinct form of knee osteoarthritis

characterized by accelerated joint degeneration following injury. It poses unique challenges in post-menopausal women due to hormonal changes and altered bone metabolism that create complex pathophysiological environments. This retrospective cohort study compared the effectiveness of different anti-osteoporotic medications in preventing total knee replacement (TKR) in 6155 postmenopausal women with PTOA treated between 2011 and 2021. We compared raloxifene and denosumab with bisphosphonates serving as the reference group. The primary outcome was TKR occurrence. Cox proportional hazards regression and inverse probability of treatment weighting (IPTW) were performed to estimate hazard ratios, with Kaplan-Meier survival analysis for time-to-event assessment. Participants' mean (SD) age was 69.4 (10.0) years. Given the retrospective nature and typical delayed presentation of PTOA symptoms, cohort entry was defined as the concurrent diagnosis of PTOA and osteoporosis requiring anti-resorptive therapy. Over a mean follow-up of 5.47 years, 99 patients (1.6%) underwent TKR. Raloxifene was associated with a significantly reduced TKR risk compared to bisphosphonates (IPTW-HR 0.81, 95% CI 0.67-0.99, p = 0.040), representing a 19% relative risk reduction. Kaplan-Meier analysis demonstrated raloxifene maintained the lowest cumulative TKR incidence compared to bisphosphonates and denosumab over time, particularly beyond 5 years. These findings suggest that raloxifene may offer superior joint protection compared with bisphosphonates and denosumab in postmenopausal women with PTOA, supporting its potential as a disease-modifying therapeutic option for this vulnerable population.

TI Muscle Atrophy Around the Hip Joint in Patients with Femoral Neck Fracture is Associated with Postoperative Walking Ability
SO GERIATRIC ORTHOPAEDIC SURGERY & REHABILITATION
LA English
DT Article
DE femoral neck fractures; osteoarthritis; muscle weakness; muscle volume; walking ability; computer tomography; rehabilitation
AB Introduction: Patients with femoral neck fractures (FNF) have reduced walking ability owing to muscle weakness. Preoperative muscle volume and quality may have an association with prolonged rehabilitation and can be useful to predict the postoperative walking ability in patients with FNF. This study aimed to compare the muscle volume and computed tomography (CT)-assessed density around the hip joint in patients with FNF with patients having hip osteoarthritis (HOA) and assess the association of these measurement with postoperative walking ability. Materials and Methods: This retrospective observational study included 15 patients with FNF and 15 with unilateral HOA who were matched for age, sex, and osteoporosis medication. Muscle volume and CT-assessed density of the gluteus maximus, gluteus medius, gluteus minimus, iliacus, psoas major, rectus femoris, and rectus abdominis on the unaffected side were measured three-dimensionally using 3D Slicer software with preoperative CT data. The associations of muscle measurement with patient background, load to FNF (measured using the finite element method), and pre- or postoperative walking ability were assessed. Results: Muscle volume of gluteus maximus, CT-assessed density of all muscles, and femoral strength were significantly lower in the FNF group than in the OA group ($P < .01$, $P < .01$, and $P = .04$, respectively). Muscle volume showed a moderate-to-strong correlation with body mass index ($r = 0.66$-0.81) and FNF load ($r = 0.51$-0.70), and CT-assessed density showed a moderate correlation with serum nutritional markers ($r = 0.33$-0.60). Postoperative walking ability was significantly correlated with the muscle volumes of iliacus and gluteus maximus ($r = 0.40$ and 0.49) and CT-assessed density of all muscles ($r = 0.47$-0.64). Conclusion: Muscle volume and CT-assessed density significantly correlated with femoral bone strength, serum total protein levels, and pre- and postoperative walking ability. These findings suggest that muscle CT analysis around the hip joint may serve as a valuable tool for assessing musculoskeletal status in patients with FNF.

DT Review
DE flavonoid glycoside; linarin; molecular mechanism; pharmacological effects
ID cytochrome-c release; expression in-vitro; natural-products; drug discovery; cytokine production; daflon 500mg; risk-factors; apoptosis; disease; pharmacokinetics
AB Linarin, a flavonoid glycoside found in the Asteraceae, Lamiaceae, and Scrophulariaceae families, shows diverse therapeutic benefits in laboratory studies. This study aims to evaluate the pharmacological effects of linarin through clinical and preclinical experiments, investigating its mechanisms against different diseases. To achieve this, data collection and search operations were carried out (current as of April 09, 2024) in several reliable online databases, such as PubMed/Medline, Scopus, Springer Link, ScienceDirect, Wiley Online, Web of Science, and Google Scholar, as part of this research. Studies revealed that linarin provides benefits against inflammation and various diseases, including osteoporosis, osteoarthritis, liver injuries, diabetes, hypertension, and neurodegenerative conditions, such as Alzheimer's, ischemia-reperfusion, convulsions, and depression. Our results further reveal that linarin displays remarkable anticancer potentials through multiple molecular pathways, including apoptotic cell death, oxidative stress induction, cytotoxic effect, antiproliferative effect, genotoxic effect, and mitigation of cancer cell migration and invasion and migration against a range of malignancies, including lung, brain, prostate, and glioma cell cancers. Database reports and the current literature-based study suggest that linarin might be a prospective lead chemical for treating a range of illnesses and ailments. For linarin to be proven as a medicine, further clinical and preclinical trials are required.

TI Nanotechnology in Orthopedic Care: Advances in Drug Delivery, Implants, and Biocompatibility Considerations
SO INTERNATIONAL JOURNAL OF NANOMEDICINE
LA English
DT Review
DE orthopedics; nanomaterials; toxicity of nanomaterials; biocompatibility; orthopedic implants; drug delivery; diagnostics; rheumatoid arthritis; osteoporosis; osteoarthritis
ID in-vivo; targeted delivery; oxide nanoparticles; bone; arthritis; cartilage; cells; osteoporosis; titanium; release
AB Nanotechnology has profoundly transformed medical science, with orthopedics experiencing significant advancements diagnostic techniques, drug delivery systems, and tissue regeneration. The complex nature of orthopedic tissues presents substantial challenges for conventional therapeutic interventions, but the development of nanomaterials with specialized chemical, physical, biological properties has facilitated the creation of novel treatment modalities. Nanotechnology has significantly advanced orthopedic care by enabling targeted drug delivery, enhanced implant performance, and improved diagnostic tools. This review uniquely integrates recent breakthroughs in biocompatible nanomaterials, focusing on their clinical translation and regulatory challenges. highlights the complexity of orthopedic tissues and the limitations of conventional therapies, emphasizing how nanomaterials address these through controlled drug release, and improved tissue regeneration. Key sections address advancements in drug delivery systems, innovative implant technologies, toxicity issues, and biocompatibility considerations. It also explores the existing regulatory landscape, challenges in clinical approval, and future directions for the successful translation of nanotechnologies in orthopedic care.

TI Effects of regional variations and occupation on hand osteoarthritis: Insights from the research on osteoarthritis/osteoporosis against disability study
SO MODERN RHEUMATOLOGY
LA English
DT Article
DE Hand osteoarthritis; occupational workload; population-based; prevalence; regional variation
ID knee osteoarthritis; elderly-patients; japanese women; grip strength; united-states; finger joints; prevalence; association; population; determinants
AB Objectives This study aimed to investigate the prevalence of radiographic hand osteoarthritis (HOA) in older Japanese individuals in three distinct regions with unique geographic and occupational characteristics and explore the regional variations and factors, including occupational workload, that affect HOA.Methods We analysed the radiographic images and data of 1642 participants aged >= 60 years (mean, 75.6 years). After grading the radiographs of both hands using the modified Kellgren-Lawrence (KL) classification, HOA was defined as at least one joint with a KL grade >= 2, and severe HOA was defined as at least one joint with a KL grade >= 3.Results The overall prevalence rates of HOA and severe HOA were 95.9% and 54.2%, respectively. Regional differences were observed: residence in the mountainous region was associated with HOA and severe HOA, whereas residence in the coastal region was associated with only HOA. Occupational workload was associated with severe HOA in a dose-dependent manner, and heavy work was associated with a higher number of osteoarthritis-affected joints.Conclusion The present study revealed a high prevalence of HOA in older Japanese individuals and highlighted regional variations in HOA prevalence. A higher occupational workload was associated with a higher risk of severe HOA.

TI Plumbagin alleviates muscle atrophy in female mice through inhibiting the DANCR/NF-κB axis
SO PHYTOMEDICINE
LA English
DT Article
DE Plumbagin; DANCR; NF-kappa B pathway; myogenic differentiation; muscle atrophy
ID protein; pathway
AB Background: Muscle atrophy is a condition of the skeletal muscular system

closely related to inflammation and significantly affects a person's quality of life and physical activity. It is characterized primarily by the progressive loss of muscle mass, strength, and function. Plumbagin (PB), the main bioactive component of the traditional Chinese medicine Plumbago zeylanica L., has bFeen shown to treat various inflammatory diseases, such as osteoporosis, osteoarthritis, and sepsis. Furthermore, many biological processes, including inflammation, involve differentiation antagonistic nonprotein-coding RNA (DANCR). However, their role and clinical importance in myogenesis and amyotrophy are not well understood. Purpose: This study aimed to explore the role of DANCR and the inflammatory response in the anti-muscle atrophy effects of PB. Methods: The expression of DANCR in muscle atrophic mice and during myogenic differentiation was examined using quantitative reverse transcription PCR (RT-qPCR). The mechanism of DANCR in muscle atrophy was confirmed through gene knockdown, RNA sequencing (RNA-seq), RNA pull-down, RNA immunoprecipitation (RIP), immunofluorescence (IF), and luciferase reporter gene assays. Bioinformatics was utilized to investigate the mechanism by which PB treatment affects muscle atrophy. The relationship between PB and DANCR was verified by surface plasmon resonance (SPR) and RT-qPCR. Additionally, the role of PB in muscle atrophy was explored through its control of DANCR-mediated regulation of the NF-kappa B pathway. Finally, the effect of PB on the myogenic differentiation of human skeletal muscle cells (HsKMCs) was investigated. Results: DANCR expression was upregulated in the muscle tissues of mice with muscle atrophy and downregulated during myogenic differentiation. Knockout of DANCR promoted myogenic differentiation and significantly alleviated the loss of muscle mass, strength, and function in mice with muscle atrophy. The primary mechanism involved DANCR directly binding to the p65 protein to regulate NF-kappa B pathway activity. Experiments revealed that PB could target the degradation of DANCR, reduce the nuclear entry of p65, and inhibit the activation of the NF-kappa B pathway. Consequently, PB significantly inhibited myotube atrophy and the inflammatory response in HsKMCs and promoted their myogenic differentiation by regulating the NF-kappa B pathway. Conclusions: Our results suggest that PB regulates myogenesis and prevents amyotrophy by targeting the degradation of DANCR and inhibiting the activation of the NF-kappa B pathway. This study reveals the crucial role of DANCR in maintaining muscle physiology during muscle atrophy and identifies PB as an effective drug that can target DANCR degradation to alleviate muscle atrophy.

TI O-GlcNAcylation: Sagacious Orchestrator of Bone-, Joint-, and Spine-Related Diseases
SO JOURNAL OF PROTEOME RESEARCH
LA English
DT Review
DE O-GlcNAcylation; intervertebral disc degeneration; osteoarthritis; osteoporosis; osteosarcoma
ID n-acetylglucosamine modification; mesenchymal stem-cells; kinase-c isozymes; glcnac transferase; in-vitro; posttranslational modifications; transcription factor;

protein modification; chondrogenesis; differentiation
AB O-linked beta-N-acetylglucosamine glycosylation (O-GlcNAcylation), a post-translational modification of proteins, occurs in multiple physiological and pathological processes. Despite comprehensive study of protein modifications, such as phosphorylation, acetylation, and ubiquitination in musculoskeletal diseases, the role of O-GlcNAcylation in this field has been largely overlooked. However, in recent years, several studies have initially elucidated the biological mechanisms through which O-GlcNAcylation regulates the development and progress of musculoskeletal diseases, including osteoarthritis, osteoporosis, osteosarcoma, and intervertebral disc degeneration. This review aims to systematically and comprehensively summarize the existing evidence, sketching the contours of the underlying mechanisms and related signaling pathways, discussing the limitations and controversies, and providing guidance for future studies on the role of O-GlcNAcylation modifications in musculoskeletal diseases.

TI Radiofrequency Echographic Multi Spectrometry-A Novel Tool in the Diagnosis of Osteoporosis and Prediction of Fragility Fractures: A Systematic Review
SO DIAGNOSTICS
LA English
DT Review
DE REMS; DXA; comparison; accuracy; fracture risk; osteoporosis
ID x-ray absorptiometry; bone-mineral density; osteoarthritis; spine; score
AB Background/Objectives: Given the significant economic and social burden of osteoporosis, there is growing interest in developing an efficient alternative to the traditional dual-energy X-ray absorptiometry (DXA). Radiofrequency Echographic Multi Spectrometry (REMS) is an innovative, non-ionizing imaging technique that recently emerged as a viable tool to diagnose osteoporosis and estimate the fragility fracture risk. Nevertheless, its clinical use is still limited due to its novelty and continuing uncertainty of long-term performance. Methods: In order to evaluate the accuracy of the REMS, a systematic review of the English-language literature was conducted. Three databases were searched for relevant publications from 1 January 2015 until 1 December 2024 using the keyword combinations "(radiofrequency echographic multi spectrometry OR REMS) AND (dual-energy X-ray absorptiometry OR DXA)". The initial search yielded 602 candidate articles. After screening the titles and abstracts following the eligibility criteria, 17

publications remained for full-text evaluation. Results: The reviewed studies demonstrated strong diagnostic agreement between REMS and DXA. Additionally, REMS showed enhanced diagnostic capabilities in cases where lumbar bone mineral density measurements by DXA were impaired by artifacts such as vertebral fractures, deformities, osteoarthritis, or vascular calcifications. REMS exhibited excellent intra-operator repeatability and precision, comparable to or exceeding the reported performance of DXA. The fragility score (FS), a parameter reflecting bone quality and structural integrity, effectively discriminated between fractured and non-fractured patients. Moreover, REMS proved to be a radiation-free option for bone health monitoring in radiation-sensitive populations or patients requiring frequent imaging to assess fracture risk. Conclusions: This current study underscores the robustness of REMS as a reliable method for diagnosing and monitoring osteoporosis and evaluating bone fragility via the FS. It also identifies critical knowledge gaps and emphasizes the need for further prospective studies to validate and expand the clinical applications of REMS across diverse patient populations.

TI Which Approach to Choose to Counteract Musculoskeletal Aging? A Comprehensive Review on the Multiple Effects of Exercise
SO INTERNATIONAL JOURNAL OF MOLECULAR SCIENCES
LA English
DT Review
DE aging; musculoskeletal system; physiology; senescence; senotherapeutic; physical exercise; prevention
ID mesenchymal stem-cells; skeletal-muscle; osteoblast differentiation; senescent cells; resveratrol; sirt1; bone; quercetin; expression; bioavailability
AB Aging is a complex physiological process that profoundly affects the functionality of the musculoskeletal system, contributing to an increase in the incidence of diseases such as osteoporosis, osteoarthritis, and sarcopenia. Cellular senescence plays a crucial role in these degenerative processes, promoting chronic inflammation and tissue dysfunction through the senescence-associated secretory phenotype (SASP). Recently, senotherapeutics have shown promising results in improving musculoskeletal health. Natural compounds such as resveratrol, rapamycin, quercetin, curcumin, vitamin E, genistein, fisetin, and epicatechin act on key signaling pathways, offering protective effects against musculoskeletal decline. On the other hand, molecules such as dasatinib, navitoclax, UBX0101, panobinostat, and metformin have been shown to be effective in eliminating or modulating senescent cells. However, understanding the mechanisms of action, long-term safety, and bioavailability remain areas for further investigation. In this context, physical exercise emerges as an effective non-pharmacological countermeasure, capable of directly modulating cellular senescence and promoting tissue regeneration, representing an integrated strategy to combat age-related diseases. Therefore, we have provided an overview of the main anti-aging compounds and examined the potential of physical exercise as a strategy in the management of age-related musculoskeletal disorders. Further studies should focus on identifying synergistic combinations of pharmacological and non-pharmacological interventions to optimize the effectiveness of anti-aging strategies and promoting healthier musculoskeletal aging.

TI Musculoskeletal diseases, infections and vaccines: state of the art, research perspectives and educational needs
SO AGING CLINICAL AND EXPERIMENTAL RESEARCH
LA English
DT Review
DE Musculoskeletal disease; Infection; Vaccination; Older adults
ID rheumatoid-arthritis; influenza; frailty; risk
AB Musculoskeletal disorders are a significant public health burden concern, projected to increase in the coming decades, and will substantially contribute to the rising prevalence of functional impairment, frailty and disability in a growing global population. Since persons with musculoskeletal disorders tend to have immune dysfunction, inflammation or be taking immunosuppressive medication, prevention of vaccine-preventable diseases (VPDs) in this group is particularly important. The European Interdisciplinary Council for Aging (EICA) and the European Society for Clinical and Economic Aspects of Osteoporosis, Osteoarthritis and Musculoskeletal Diseases (ESCEO) jointly convened a 2-day in-person and virtual meeting on 26-27 September 2023, to review the state of the evidence on the link between musculoskeletal diseases, infections and vaccines. We present here the Executive Summary of the proceedings of this meeting. We review the importance of physical activity in preventing or mitigating both musculoskeletal diseases and risk of infection. We summarize current knowledge of the impact of common VPDs on the development and progression of musculoskeletal diseases, and the role of selected vaccines in preventing onset and worsening of frailty and disability in these individuals. This report summarizes the evidence presented at the two-day meeting, highlighting the need to raise awareness among scientists, healthcare professionals, decision-makers, civil society and the general public about the long-term sequelae of VPDs, with focus on the health status of older patients with musculoskeletal diseases.

TI Nucleic acid aptamers in orthopedic diseases: promising therapeutic agents for bone disorders
SO BONE RESEARCH
LA English
DT Review
ID necrosis-factor-alpha; mesenchymal stem-cells; factor-kappa-b; macrophage inflammatory protein-1-alpha; human osteoarthritic chondrocytes; osteoclast-associated receptor; human articular chondrocytes; parathyroid-hormone 1-34; nitric-oxide production; affinity dna aptamers
AB Precision medicine has become a cornerstone in modern therapeutic strategies, with nucleic acid aptamers emerging as pivotal tools due to their unique properties. These oligonucleotide fragments, selected through the Systematic Evolution of Ligands by Exponential Enrichment process, exhibit high affinity and specificity toward their targets, such as DNA, RNA, proteins, and other biomolecules. Nucleic acid aptamers offer significant advantages over traditional therapeutic agents, including superior biological stability, minimal immunogenicity, and the capacity for universal chemical modifications that enhance their in vivo performance and targeting precision. In the realm of osseous tissue repair and regeneration, a complex physiological process essential for maintaining skeletal integrity, aptamers have shown remarkable potential in influencing molecular pathways crucial for bone regeneration, promoting osteogenic differentiation and supporting osteoblast survival. By engineering aptamers to regulate inflammatory responses and facilitate the proliferation and differentiation of fibroblasts, these oligonucleotides can be integrated into advanced drug delivery systems,

significantly improving bone repair efficacy while minimizing adverse effects. Aptamer-mediated strategies, including the use of siRNA and miRNA mimics or inhibitors, have shown efficacy in enhancing bone mass and microstructure. These approaches hold transformative potential for treating a range of orthopedic conditions like osteoporosis, osteosarcoma, and osteoarthritis. This review synthesizes the molecular mechanisms and biological roles of aptamers in orthopedic diseases, emphasizing their potential to drive innovative and effective therapeutic interventions.

TI Trends in the prevalence of hypovitaminosis D over a 10-year period in Japan: the research on osteoarthritis/osteoporosis against disability study 2005-2015
SO ARCHIVES OF OSTEOPOROSIS
LA English
DT Article
DE Vitamin D deficiency; Vitamin D insufficiency; Prevalence; Secular trend; Population-based cohort ROAD study
ID vitamin-d deficiency; bone; osteoporosis; association; criteria
AB The Summary We examined the trends in vitamin D insufficiency and deficiency over a 10-year period in the general population. The prevalence of deficiency significantly decreased (29.5% vs. 21.6%), whereas mean serum levels increased (23.3 ng/mL vs. 25.1 ng/mL). These trends may reduce the incidence of osteoporosis and osteoporotic fractures. Purpose: We aimed to clarify the trends in the prevalence of vitamin D insufficiency and deficiency in the general population using population-based cohort data from a baseline survey and a follow-up survey conducted 10 years later. Methods: A baseline survey of the Research on Osteoarthritis/Osteoporosis Against Disability (ROAD) study was conducted from 2005 to 2007. Blood samples were collected to measure serum 25-hydroxyvitamin D (25D) and intact parathyroid hormone levels from 1,683 participants (595 men, 1,088 women). Participants also completed an interviewer-administered questionnaire, and underwent bone mineral density measurements and radiographic examinations. The fourth survey was conducted from 2015 to 2016 with 1,906 individuals (637 men, 1,269 women), including both follow-up participants from the baseline survey and newly recruited individuals to increase the sample size for future longitudinal analyses. All participants completed assessments identical to those in the baseline survey. Vitamin D deficiency and insufficiency were defined as serum 25D levels of < 20 ng/mL and >= 20 ng/mL but < 30 ng/mL, respectively. Results: The mean serum vitamin D levels were 23.3 ng/mL at baseline and 25.1 ng/mL at the fourth survey, indicating a significant increase ($p < 0.001$). The prevalences of vitamin D insufficiency and deficiency were 52.9% and 29.5%, respectively, at baseline, and 54.8% and 21.6%, respectively, in the fourth survey, indicating a significant decrease in vitamin D deficiency ($p <$

0.001). Conclusions: In this population-based survey with a 10-year interval, the prevalence of hypovitaminosis D significantly decreased. This favourable trend may contribute to future reductions in the incidence of osteoporosis and osteoporotic fractures.

DT Review
ID vertebral end-plate; bone-marrow; intervertebral disc; beta-galactosidase; stem-cell; rheumatoid-arthritis; senile osteoporosis; articular-cartilage; oxidative stress; nucleus pulposus
AB Cellular senescence and its senescence-associated secretory phenotype (SASP) represent a pivotal role in the development of skeletal diseases. Targeted elimination or rejuvenation of senescent cells has shown potential as a therapeutic strategy to reverse age-related skeletal senescence and promote bone regeneration. Meanwhile, other age-related mechanisms, involving altered cellular functions, impaired intercellular crosstalk, disturbed tissue microenvironment, and decreased regenerative capacity, synergistically contribute to the pathogenesis. In this review, we outline the cellular senescence and other age-related mechanisms in developing skeletal diseases, including osteoporosis, intervertebral disc degeneration, osteoarthritis, rheumatoid arthritis, bone tumors and ankylosing spondylitis, with the aim of comprehensively understanding their detrimental effects on the aged skeleton and screening the potential targets for anti-aging therapy within the skeletal system.

ID spermidine; autophagy; metabolism; risk; eflornithine; inhibition; muscle; cells
AB Age-related bone diseases such as osteoporosis, osteoarthritis, and sarcopenia present complex pathogenesis. These conditions are associated with high morbidity, disability, and mortality rates, underscoring the urgent need for effective prevention and treatment strategies. Polyamines, a group of small-molecule compounds, regulate critical biological processes, including cell proliferation, differentiation, and apoptosis, and show potential bone-protective effects. Following the elucidation of polyamines' therapeutic effects in cancer and neurodegenerative diseases, growing research attention has been directed toward their role in age-related bone disorders. This review synthesizes the current understanding of polyamines' mechanisms in age-related bone diseases, analyzing their biological functions and bone-protective effects to explore the therapeutic potential for these conditions, thereby offering valuable perspectives to guide future investigations and clinical applications in this emerging field.

DT Review
DE ginseng; ginsenoside; polysaccharide; extract; osteosarcoma; osteoporosis; osteoarthritis
ID inhibits osteoclast differentiation; glucocorticoid-induced osteoporosis; panax-quinquefolius l.; korean red ginseng; cell-cycle arrest; inflammatory mediators; mg-63 cells; dna-damage; compound k; ginsenosides
AB Ginseng phytochemicals have attracted considerable attention for their potential therapeutic applications in bone-related diseases including osteosarcoma, osteoporosis, and osteoarthritis. Recent research has highlighted the promising effects of ginsenosides and polysaccharides from ginseng by studying multi-target effects and combination therapies in osteosarcoma progression. Beyond osteosarcoma, ginseng phytochemicals have been explored for their effects on osteoporosis. Various ginsenosides and ginseng extract were shown to regulate signaling pathways involved in activating osteoblast and inhibiting osteoclast in vitro and in vivo models. Ginseng ginsenosides have also demonstrated potential anti-osteoarthritic properties. Recent studies discussed how ginsenoside reduced inflammation and cartilage degradation as a therapeutic candidate for osteoarthritis management. In this review, we examine the anti-osteosarcoma, anti-osteoporotic, and anti-osteoarthritic activities of ginseng-derived phytochemicals reported in studies published between 2014 and 2024. This review also provides a comprehensive overview of the working mechanisms of these compounds in various model systems. Furthermore, we address the limitations of current research approaches and outline future directions to maximize the therapeutic application of ginseng phytochemicals in the management of bone-related diseases.

TI Exploring the Role of Exercise and the Lysosomal Cathepsin Family in the Regulation of Vascular-Musculoskeletal Degenerative Diseases
SO FASEB JOURNAL
LA English
DT Review
DE exercise; lysosomal cathepsin family; musculoskeletal degenerative diseases; vascular aging
ID skeletal-muscle; older-adults; endochondral ossification; knee osteoarthritis; bone loss; cells; women; expression; gene; osteoporosis
AB Musculoskeletal degenerative diseases significantly compromise patient quality of life through muscle loss, bone fragility, and cartilage degeneration. Given the established link between vascular aging and musculoskeletal disorders, the vascular-skeletomuscular axis represents a complex network wherein conditions interact via mechanisms including impaired blood flow, inflammation, oxidative stress, and hormonal imbalances. As pharmacological interventions targeting lysosomal cathepsins face developmental and application challenges, exploring non-pharmacological alternatives becomes imperative. This review investigates the regulatory roles of the lysosomal cathepsin family, especially cathepsins B, K, and L, in musculoskeletal degenerative diseases and evaluates how exercise interventions modulate their activities. It proposes exercise as a viable non-pharmacological strategy to selectively influence lysosomal cathepsin functions, thereby offering therapeutic potential in managing vascular-musculoskeletal degenerative diseases.

The review elucidates several key concepts: the intricate interaction between vascular aging and musculoskeletal degenerative pathologies; the pivotal roles of lysosomal cathepsins in disease progression through metabolic regulation, inflammatory modulation, macrophage polarization, and autophagy dysfunction; and the multifaceted mechanisms by which exercise influences cathepsin activity, including calcium homeostasis, cellular energy metabolism enhancement, inflammatory response reduction, autophagy stimulation, myokine secretion, and vascular function improvement. This comprehensive analysis provides novel insights into exercise as a selective modulator of lysosomal cathepsin activity, highlighting its significant potential for advancing diagnostic and clinical therapeutic approaches.

TI The Multifaceted Role of p53 in Musculoskeletal Diseases: A Comprehensive Review
SO INTERNATIONAL JOURNAL OF RHEUMATIC DISEASES
LA English
DT Review
DE gout; lower back pain; musculoskeletal diseases; osteoarthritis; osteoporosis; p53; rheumatoid arthritis; scoliosis
ID nucleus pulposus cells; chondrocyte apoptosis; oxidative stress; rheumatoid-arthritis; cellular senescence; bone; osteoarthritis; gene; degeneration; pathogenesis
AB Background While extensively studied for its central role in tumor suppression (regulating cell cycle, DNA repair, and apoptosis), the p53 gene is now recognized for its significant involvement in musculoskeletal diseases. Aberrant p53 expression and function are key factors in the pathogenesis and progression, although the specific mechanisms and clinical change potential remain incompletely defined.Objective This review systematically summarizes the multifaceted roles of p53 in major musculoskeletal diseases, analyzes the molecular mechanisms driving disease progression, and evaluates its potential as a therapeutic target.Methods A comprehensive literature search was conducted in PubMed January 2008 to March 2025 using keywords including P53, osteoporosis, osteoarthritis, rheumatoid arthritis, gout, low back pain, and scoliosis. Original research, reviews, and clinical trials focusing on p53 mechanisms were included. 90 relevant articles were selected for analysis.Results & Conclusion p53 critically influences the development and progression of musculoskeletal diseases (osteoporosis, osteoarthritis, rheumatoid arthritis, low back pain, gout, and scoliosis) through diverse mechanisms: Disrupting bone formation/resorption balance (via the p53-Nedd4-Runx2 axis in osteoporosis). Promoting chondrocyte apoptosis (via the miR-34a-SIRT1-p53 pathway in osteoarthritis). Modulating inflammatory mediators (TNF-alpha, IL-6 in rheumatoid arthritis). Regulating oxidative stress responses (p53-SLC2A9 axis in gout). p53 exhibits dual roles (pro-apoptotic vs. anti-inflammatory), necessitating precise targeting strategies. Promising therapeutic interventions include p53-focused gene editing (CRISPR/Cas9), small-molecule inhibitors (PFT-alpha), and natural products (naringin). However, further clinical validation is essential. Future research requires multidisciplinary approaches to deepen understanding of p53 mechanisms and advance clinical applications in musculoskeletal disorders.

TI Advances in copper-containing biomaterials for managing bone-related diseases
SO REGENERATIVE BIOMATERIALS
LA English
DT Review
DE bone-related diseases; copper; bone regeneration; copper-containing biomaterials

ID calcium-phosphate cement; mesenchymal stem-cells; in-vitro; cartilage repair; bioactive glass; antibacterial activity; antimicrobial activity; cu; alloy; osteonecrosis
AB Bone-related diseases pose a major challenge in contemporary society, with significant implications for both health and economy. Copper, a vital trace metal in the human body, facilitates a wide range of physiological processes by being crucial for the function of proteins and enzymes. Numerous studies have validated copper's role in bone regeneration and protection, particularly in the development and expansion of bone collagen. Owing to copper's numerous biological advantages, an increasing number of scientists are endeavoring to fabricate novel, multifunctional copper-containing biomaterials as an effective treatment strategy for bone disorders. This review integrates the current understanding regarding the biological functions of copper from the molecular and cellular levels, highlighting its potential for bone regeneration and protection. It also reviews the novel fabrication techniques for developing copper-containing biomaterials, including copper-modified metals, calcium phosphate bioceramics, bioactive glasses, bone cements, hydrogels and biocomposites. The fabrication strategies and various applications of these biomaterials in addressing conditions such as fractures, bone tumors, osteomyelitis, osteoporosis, osteoarthritis and osteonecrosis are carefully elaborated. Moreover, the long-term safety and toxicity assessments of these biomaterials are also presented. Finally, the review addresses current challenges and future prospects, in particular the regulatory challenges and safety issues faced in clinical implementation, with the aim of guiding the strategic design of multifunctional copper-based biomaterials to effectively manage bone-related diseases.

TI Direct observation of the strong thermal non-equilibrium between optical and acoustic phonons in monolayered 2D materials

ID hot-carrier diffusion; transport; graphene; raman
AB Quantifying thermal non-equilibrium between different phonon branches in supported monolayered two-dimensional materials remains a significant challenge due to complex substrate interactions and optical interference in Raman measurements. Here, we report on the direct quantification of optical-acoustic phonon thermal non-equilibrium in supported monolayered WS2 materials by leveraging the distinct thermal response of optical phonons (OPs) and acoustic phonons (APs) under modulated laser excitation of different frequencies. The temperature response of different phonon branches is separated based on the measured Raman shift power coefficient (psi) with high precision. The reduction of the laser spot radius from similar to 1.7 to similar to 0.4 mu m increases the psi(OA)/psi(AP) ratio by over 2.5 times, revealing a pronounced enhancement of optical-acoustic phonon thermal non-equilibrium. Comparisons between transferred monolayered WS2 and hetero-bilayered WS2/WSe2 show that the heterogeneous interface strongly strengthens optical to acoustic phonon scattering. In addition, smaller laser spots intensify the hot carrier diffusion effect, reducing the associated OP-AP temperature difference by over 60%. Our method establishes a powerful experimental platform for probing phonon transport in nanoscale materials.

TI Targeting osteosarcopenia and multimorbidity for frailty prevention through identification and deep phenotyping methods in healthy ageing and high-burden disease cohorts (OPTIMA-C): a longitudinal observational cohort study protocol for neuromusculoskeletal muscle health
SO BMJ OPEN
LA English
DT Article
DE Frailty; Stroke; Brain Injuries; Knee; Breast tumours; Physical Fitness
ID older-adults; sarcopenia; ultrasound; osteoporosis; validity; architecture; reliability; consensus; people; stroke
AB Introduction Sarcopenia and frailty have been identified as negative predictors of health outcomes. Patients with stroke, traumatic brain injury (TBI), knee osteoarthritis (OA) and breast cancer commonly experience low physical activity levels in the chronic phase of recovery. This prospective study aims to explore the feasibility of multimodal screening and longitudinal tracking of various biomarkers from the acute to chronic phase of disease to determine the relationship with frailty outcomes.Methods and analysis A prospective longitudinal observational cohort study involving Asian populations is planned over 3 years. Enrolled participants with index conditions of acute stroke, TBI, knee OA and breast cancer will be recruited from rehabilitation hospitals and clinics and followed longitudinally. Reference thresholds from the Asian Working Group on Sarcopenia will be used. Variables include self-reported questionnaires, disease and comorbidity characteristics, anthropometric measurements, appetite questionnaires, muscle ultrasound (MUS), muscle/bone mass, blood biomarkers and markerless gait motion systems. In particular, physical performance (short physical performance battery and hand grip strength), sarcopenia (SARC-F questionnaire) and frailty assessment (FRAIL score, clinical frailty scale), four-region MUS, body composition analysis, dual X-ray absorptiometry, bone mineral densitometry, physical activity levels (International Physical Activity Questionnaire for the elderly [IPAQ-E], fitness trackers) and health-related quality of life assessment (EuroQoL-5D questionnaire five level [EQ5D-5L]) will be used. Blood biomarkers measuring metabolic health (eg, glycated haemoglobin, cholesterol, fasting glucose and 25-OH vitamin D) and inflammation (eg, Tumor Necrosis Factor-alpha [TNF-alpha] and Monocyte Chemoattractant Protein-1 [MCP-1]) will be measured at baseline. Data collection will take place at postrecruitment baseline (hospital admission), 1, 6 months, 12 months and 2 years postrecruitment (inpatient) and at postrecruitment baseline, 6 months, 12 months and 2 years postrecruitment (outpatient).Ethics and dissemination Ethical approval has been obtained from the National Healthcare Group Domain Specific Review Board

(2023/00105). Findings will be disseminated through conference presentations and publication in scientific journals.Trial registeration number NCT06073106.

TI Deciphering the toxicological mechanisms of per-and polyfluoroalkyl substances (PFAS) in musculoskeletal disorders via integrated network toxicology and molecular docking
SO ENVIRONMENT INTERNATIONAL
LA English
DT Article
DE PFAS; Musculoskeletal disorders; Network toxicology; Molecular docking
ID perfluoroalkyl substances; growth-factor; association; osteoarthritis; proteins
AB Per-and polyfluoroalkyl substances (PFAS) have been extensively used in everyday products; however, their effects on human health remain largely unknown. This study aimed to investigate the potential mechanisms by which PFAS may contribute to functional disorders in the human musculoskeletal system. Four representative musculoskeletal disorders were selected, which included intervertebral disc degeneration, myositis, osteoarthritis, and osteoporosis. Advanced network toxicology approaches integrating data from the Comparative Toxicogenomics Database (CTD) and GeneCards identified potential PFAS-associated targets for each disorder. Molecular docking simulations were employed to assess interactions between PFAS and target proteins. Molecular docking of a series of PFAS molecules against multiple protein targets revealed strong binding affinities. Prioritization based on average binding energies highlighted the targets with the greatest PFAS-binding potential. A subsequent comprehensive analysis further discussed these findings by integrating the functional roles of the targets and the classification of the various PFAS compounds. Evidence synthesis confirmed that these core targets are critically involved in key pathological processes common to musculoskeletal diseases, including chronic inflammation, oxidative stress, apoptosis, extracellular matrix degradation, and impaired bone remodeling. This study provides innovative insights into the mechanisms by which environmental pollutants contribute to human diseases, thereby establishing a theoretical foundation for disease prevention and therapeutic strategies.

TI Calcium pyrophosphate deposition disease is associated with increased risk of fractures: A retrospective cohort study using electronic health record data
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE Calcium pyrophosphate deposition; Pseudogout; Osteoarthritis; Fracture; Osteoporosis; Bone mineral density
ID chondrocalcinosis
AB Objective: To evaluate the risk of fractures in older adults with calcium pyrophosphate deposition (CPPD) disease and osteoarthritis (OA) compared to those with OA alone, and to assess site-and gender-specific fracture risk. Methods: Using predominantly North American electronic health record data from 2005-2025, we defined CPPD as patients aged >= 60 years with >= 2 administrative codes for CPPD plus OA, excluding other inflammatory arthritides. Comparators were defined analogously with >= 2 OA codes but without CPPD. The primary outcome was any fracture of spine, upper limb, lower limb. We used Cox proportional hazards models 1:1 propensity score-matched for demographics, comorbidities, and medications. Subgroup analyses assessed gender-specific outcomes and site-specific fractures. Sensitivity analyses excluded individuals with prior exposure to glucocorticoids or anti-osteoporosis medications or prior fracture history. Results: Among 20,176 matched pairs (mean age 73 years, 59% female) with 4015 and 3349 fracture events over 81,291 and 85,802 patient-years, CPPD was associated with 29% increased hazard of any fracture (HR 1.29, 95%CI 1.23, 1.35) which was consistent in males (HR 1.36, 95%CI 1.23, 1.49) and females (HR 1.30, 95%CI 1.23, 1.38). Site-specific analyses similarly showed elevated fracture risks at the upper limb (HR 1.37; 1.28, 1.46), lower limb (HR 1.31; 1.23, 1.39), and spine (HR 1.18; 1.11, 1.26). Results were similar across all sensitivity analyses. Conclusion: CPPD disease is associated with increased fracture risk across gender and fracture sites. Clinicians should consider screening for bone health in these patients. Future research should clarify underlying mechanisms and refine targeted interventions. TI Biomedical Applications of Functionalized Composites Based on Metal-Organic Frameworks in Bone Diseases
SO PHARMACEUTICS
LA English
DT Review
DE metal-organic frameworks; bone diseases; bone regeneration; biomedical applications
ID drug-delivery-system; osteogenic differentiation; therapy; nanoparticles; osteosarcoma; scaffolds; membrane; release; mofs; ag
AB Every year, millions of people worldwide suffer from bone tissue damage caused by bone trauma and surgical operations, as well as diseases such as osteoporosis, osteoarthritis, osteomyelitis, and periodontitis. Bone defect repair is one of the major challenges in the field of regenerative medicine. Although bone grafts are the gold standard for treating bone defects, factors such as donor

sources and immune responses limit their application. Functionalized nanomaterials have become an effective means of treating bone diseases due to their good biocompatibility and osteoinductivity, anti-inflammatory, and antibacterial properties. Metal-organic frameworks (MOFs) are porous coordination polymers composed of metal ions and organic ligands, featuring unique physical properties, including a high surface area-volume ratio and porosity. In regenerative medicine, MOFs function as the functions of drug carriers, metal ion donors, nanozymes, and photosensitizers. When combined with other functional materials, they regulate cellular reactive oxygen species, macrophage phenotypic transformation, bone resorption, osteogenesis, and mineralization, providing a new paradigm for bone tissue engineering. This study reviews the classification of functionalized MOF composites in biomedicine and the application of their synthesis techniques in bone diseases. The unique in vivo and in vitro applications of MOFs in bone diseases, including osteoarthritis, osteoporosis, bone tumors, osteomyelitis, and periodontitis, are explored. Their properties include excellent drug loading and sustained release abilities, high antibacterial activity, and bone induction abilities. This review enables readers to better understand the cutting-edge progress of MOFs in bone regeneration applications, which is crucial for the design of and functional research on MOF-related nanomaterials.

ID osteogenic differentiation; rat model; network pharmacology; osteoporosis; cells; epimedium; apoptosis; osteoarthritis; cytotoxicity; metabolism
AB Icariin (ICA) is a bioactive flavonoid compound extracted from Epimedium plants. In recent years, it has attracted significant research interest in the field of bone tissue repair due to its pharmacological effects via multiple targets and pathways. Studies have shown that ICA promotes the osteogenic differentiation of mesenchymal stem cells (MSCs) and enhances bone matrix formation by regulating signaling pathways such as Akt and Wnt/beta-catenin. It concurrently inhibits osteoclast activity to maintain the balance of bone remodeling, thereby simultaneously stimulating new bone regeneration and suppressing bone resorption. At the same time, ICA exerts potent anti-inflammatory and antioxidant effects and promotes angiogenesis, improving the local microenvironment of bone injury and significantly facilitating the regeneration of bone and cartilage tissues. Additionally, ICA exhibits notable protective effects in multiple organ systems including the cardiovascular, hepatic, renal, and nervous systems. Specifically, ICA reduces cardiomyocyte apoptosis and fibrosis to preserve cardiac function, improves hepatic metabolic function and alleviates oxidative stress, attenuates renal inflammation and fibrosis, and-through neuroprotective actions-reduces neuroinflammation and promotes neuronal survival. These multi-organ effects help optimize the systemic environment for bone healing. However, ICA faces significant pharmacokinetic challenges. It has low oral bioavailability (due to poor absorption and extensive first-pass metabolism) as well as a short half-life. Consequently, maintaining effective drug concentrations in vivo is difficult, which limits its therapeutic efficacy and impedes clinical translation. To fully realize its regenerative potential, advanced drug delivery strategies (e.g., nanocarrier-based delivery systems) are being explored to enhance ICA's bioavailability and prolong its duration of action. Overall, ICA's multi-modal actions on bone cells, the immune microenvironment, and systemic factors make it a promising multi-target agent for bone regeneration. Addressing its pharmacokinetic limitations through optimized delivery and conducting further clinical studies will be crucial to realize its full therapeutic potential. This review provides a comprehensive overview of recent advances and challenges in translating ICA's benefits into orthopedic therapy.

TI The Role of Oral and Gut Microbiota in Bone Health: Insights from Bacterial Extracellular Vesicles
SO MICROORGANISMS
LA English
DT Review
DE bacterial extracellular vesicles; microbiota; dysbiosis; osteoporosis; osteoarthritis; neuroinflammation
ID outer-membrane vesicles; porphyromonas-gingivalis; osteoclast differentiation; periodontal-disease; tgf-beta; biogenesis; infection; system; mass; pathogenesis
AB Bone health is critically influenced by the oral and gut microbiota, which are

among the largest microbial reservoirs in the human body. These microbiota play essential roles in maintaining bone mass through immune modulation, metabolite production, and nutrient resorption. Recent observations have underscored that extracellular vesicles (EVs) derived from oral and gut microbiota may circulate to the brain and bone marrow, suggesting their integral roles in the gut-brain-bone axis and oral-brain-bone axis. This review outlines the current research status of bacterial extracellular vesicles (BEVs), including their biogenesis, classification, structural features, and cargo composition, with emphasis on factors influencing cargo heterogeneity and the consequences of cellular uptake and presentation. Oral-microbiota-derived BEVs and their cargo associated with bone health are highlighted, along with recent evidence linking BEVs to systemic dis-eases and the potential integration into the oral-gut-bone axis. Preclinical animal studies on BEV dosage, routes of administration, and disease models are summarized, together with the limitations of current approaches and strategies for engineering BEVs. Finally, an overview of translational applications and future therapeutic prospects is provided, aiming to advance the understanding of BEVs as innovative tools for the treatment and prevention of bone-related diseases.

TI Recent advances in targeting the cGAS-STING pathway for immunotherapy in orthopedic diseases
SO FRONTIERS IN IMMUNOLOGY
LA English
DT Review
DE cGAS-STING pathway; orthopedic diseases; innate immunity; bone remodeling; immunotherapy
ID cyclic gmp-amp; innate immune-response; cytosolic dna; 2nd-messenger; inflammation; combination; mechanism
AB With increasing evidence highlighting the role of immune dysregulation in orthopedic diseases such as osteoarthritis, osteoporosis, intervertebral disc degeneration, delayed fracture healing, and bone tumors, the cyclic GMP-AMP synthase-stimulator of interferon genes (cGAS-STING) pathway has emerged as a central mediator of innate immune sensing and sterile inflammation. This review summarizes the core mechanisms of cGAS-STING activation and its involvement in regulating inflammatory responses, bone remodeling, cell death, and immune cell polarization in musculoskeletal tissues. In particular, we discuss recent findings on how aberrant cGAS-STING signaling contributes not only to chronic inflammatory bone loss but also to the tumor immune microenvironment in primary bone cancers and bone metastases. Furthermore, we highlight the therapeutic prospects of targeting this pathway using agonists or inhibitors, which show promise for novel immunomodulatory approaches in the treatment of orthopedic diseases, including skeletal malignancies.

TI Weight-Adjusted Waist Index (WWI)-A Promising Anthropometric Indicator of Depressive Symptoms in Hospitalized Older Patients
SO NUTRIENTS
LA English
DT Article
DE WWI; BMI; depressive symptoms; older adults
ID body-mass index; instrumental activity; obesity; association; risk; people; dyslipidemia; hypertension; osteoporosis
AB Objectives: The aim of this study was to evaluate which anthropometric index, either body mass index (BMI) or weight-adjusted waist index (WWI), is more accurately associated with the prevalence of the most common chronic diseases and components of geriatric assessment in hospitalized older adults. Methods: The study included a total of 2945 hospitalized older adults (median age 82 years). The associations between the presence of chronic diseases and Comprehensive Geriatric Assessment (CGA) results were compared with WWI and BMI values. Results: The WWI was significantly higher in both sex groups suffering from hypertension, diabetes, osteoarthritis, and depression. In women, the parameter was increased among individuals with previous myocardial infarction, who presented heart failure symptoms or had chronic kidney disease diagnosed, whereas in men, among those with pulmonary diseases and osteoporosis, WWI was related to many CGA parameters oftentimes where BMI proved to fail. There was a positive correlation of WWI with the presence of depressive symptoms assessed with the geriatric depression scale (GDS) but no significant correlation with BMI. In multiple logistic regression models, WWI was a stronger predictor of depression as compared to waist circumference or the waist-to-height ratio. Conclusions: There is an association between a higher WWI and depression diagnosis as well as the presence of depressive symptoms according to the GDS in hospitalized older adults, both women and men. There is no such correlation between depression and BMI. Both high BMI and high WWI values seem to identify older patients with cardiometabolic diseases such as hypertension and diabetes. According to this study, WWI seems to be a promising indicator of depression risk and, similarly to BMI, a useful parameter for the assessment of cardiometabolic risk in older hospitalized adults.

TI Osteoarthritis progression pattern based on patient specific characteristics using machine learning
SO NPJ DIGITAL MEDICINE
LA English
DT Article
ID individual radiographic features; bone-mineral density; knee osteoarthritis; disease; risk; mass; phenotypes; incident; atlas; hip
AB This study aimed to identify key factors associated with different progression patterns of early osteoarthritis (OA) by developing a predictive model using patient-specific characteristics. From 2003 to 2017, data from 833 knees were analyzed. Demographic factors included age, body mass index, bone mineral density (BMD), metabolic diseases, and other comorbidities. Radiographic factors included joint space narrowing (JSN) and osteophyte formation grades. Three classification models were developed using logistic regression and a light gradient boosting machine: unicompartmental/tricompartmental OA, tricompartmental JSN-dominant OA, and tricompartmental osteophyte-dominant OA. Feature importance was evaluated using SHapley Additive exPlanations feature explanations. Patients with osteoporosis were likely to progress to tricompartmental OA with JSN, while those with a high BMD were likely to progress to unicompartmental OA. Metabolic disease-related OA was associated with tricompartmental OA involving large osteophytes. Identifying OA progression patterns and patient information may enable more effective personalized treatment and prevention strategies in the future.

TI The association between glycemic indicators and bone mineral density and osteoporosis: a cross-sectional study
SO SCIENTIFIC REPORTS
LA English
DT Article
DE HbA1c; Bone mineral density; Osteoarthritis; Fasting plasma glucose; Cross-sectional study
ID fracture risk; older white; complications; pentosidine; glucose; adults; dxa; qus
AB To investigate the relationship between glycemic indicators (HbA1c and FPG) and bone mineral density (BMD) as well as osteoporosis in adults. A total of 1445 participants from the "The longitudinal investigation of osteoarthritis and cardiovascular health status" cohort were recruited and classified into normal BMD, osteopenia, and osteoporosis groups based on BMD. Data on sociodemographic factors, anthropometric measurements, medical history, and FPG samples were collected. BMD was measured by tibial ultrasound. Logistic regression analysis was performed to calculate the Odds Ratio (OR) and 95% confidence interval (CI), with adjustments for confounding factors. Participants in the osteopenia and osteoporosis groups were older, had higher triglycerides and body mass index, and fewer smokers and alcohol consumers compared to the normal BMD group. HbA1c levels were significantly lower in the osteopenia and osteoporosis groups than in the normal BMD group, while FPG showed no significant differences. Logistic regression indicated a significant negative correlation between HbA1c and the risk of osteoporosis (OR (95% CI) 0.914 (0.838, 0.997)) and osteopenia (OR (95% CI) 0.904 (0.826, 0.989)). After adjusting for confounding factors, a significant positive correlation exists between HbA1c and BMD, and higher HbA1c levels are associated with a relatively lower risk of osteoporosis. These findings highlight the importance of considering long-term blood glucose control in clinical practice for bone health management.

TI Role of SOST in Response to Mechanical Stimulation in Bone and Extraosseous Organs
SO BIOMOLECULES
LA English
DT Review
DE SOST; extra-skeletal organs; osteoporosis; exercise; mechanical stimulation
ID serum sclerostin increases; articular-cartilage; disease; expression; decreases; men
AB Sclerostin (SOST) is a specific osteocyte protein. During the differentiation and proliferation of osteoblasts and osteoclasts, the high expression of SOST can inhibit bone formation and contribute to osteoporosis and the bone metastasis of malignant tumors. Most of the research on SOST has focused on bone cells, but studies have found that SOST is not a specific product of bone cells but that it is also expressed by articular chondrocytes. SOST can regulate the progression of osteoarthritis in bone and cartilage, promote subchondral bone sclerosis, and inhibit cartilage degeneration. A review of the literature found that SOST can not only regulate bone metabolism, but it is also expressed in cardiovascular, kidney, liver, and other tissues, influencing the occurrence and development of diseases in these organs and tissues. Studies have found that diseases of extra-bone organs, such as atherosclerosis, aneurysm, chronic kidney disease, and cirrhosis, may be related to the expression of SOST. Simultaneously, long-term exercise can reduce SOST levels, especially in areas of high bone strain. Prolonged exercise induces bone adaptation to mechanical stress, resulting in diminished responsiveness of bone cells to exercise and a reduction in serum SOST levels. Short-term acute exercise can elevate serum SOST levels, but these results are often limited by age, gender, and energy status. In general, serum SOST rises immediately after

short-term acute exercise, returning to baseline or even decreasing after exercise.

TI Does the fetal head station and position affect the pelvic floor muscles in labour? A prospective study using 3 dimensional transperineal ultrasound
SO EUROPEAN JOURNAL OF OBSTETRICS & GYNECOLOGY AND REPRODUCTIVE BIOLOGY
LA English
DT Article
DE Levator ani muscle avulsion; Fetal head position; Fetal head station; Transperineal ultrasound

ID levator ani muscle; reliability; 2nd-stage; diagnosis; avulsion; delivery; stretch; hiatus; impact
AB Aims: The passage of the fetus through the birth canal, stretches the soft tissues of the pelvic floor, in particular the levator ani muscle. Excessive distension of the levator ani muscle (LAM) hiatus and LAM avulsions are associated with pelvic organ prolapse. Our aim was to evaluate the impact of the fetal head position and station on the LAM. Methods: A prospective cross-sectional observational study of women undergoing their first vaginal birth. Women were examined vaginally by a doctor or midwife to assess the fetal head station in relation to the ischial spines. Three dimensional transperineal ultrasound (3D TPUS) was performed on these women in the second stage of labour when they had a vaginal examination. The 3D TPUS was done to identify LAM avulsion and measure the anteroposterior (AP) diameter and the hiatal area. In addition, transabdominal ultrasound (TAUS) was used to determine the fetal head position. A Kruskal-Wallis test was performed to compare non-parametric variables. Results: 274 women were invited and 264 (95 %) agreed to participate. 52 women had a TPUS performed during the second stage of labour. The fetal head position was occiput anterior (OA) 32 (62 %), occiput posterior (OP) 9 (17 %), and occiput transverse (OT) 11 (21 %). There was a significant increase in the AP diameter and hiatal area as the fetal head descended from-1 to +2. (AP diameter: 6.1 vs 8.1 cm, p = 0.002; hiatal area: 16.3 vs 30.3 cm2, p = 0.01). The fetal head position did not affect the AP diameter or hiatal area measurements. No LAM avulsions were diagnosed in the second stage of labour before birth. No LAM avulsions were found following caesarean section (n = 7). Women who gave birth vaginally were invited to have a repeat scan after three months, and 35/45 (78 %) came for follow-up. LAM avulsions were diagnosed three months postpartum in 10/35 (29 %) women following their vaginal birth. Conclusions: This is the first study to evaluate how the fetal head station and position affect the LAM after active second stage of labour. There is a 25 % increase in AP diameter and a doubling of the hiatal area as the head descends from station-1 to +2. LAM avulsions are known to occur following a vaginal birth, and this study demonstrates that LAM avulsions do not occur until the birth of the head. It also highlights that despite pushing in the active second stage of labour, an unsuccessful vaginal delivery followed by CS is not associated with a LAM avulsion. This information will be useful to counsel women regarding mode of delivery.

TI Targeting mitochondria in bone and cartilage diseases: A narrative review
SO REDOX BIOLOGY
LA English
DT Review
DE Mitochondria; Bone; Cartilage; Mitochondrial dynamics; Osteoarthritis; Osteoporosis; Osteomyelitis
ID transplantation; metabolism; chondrocytes; apoptosis; differentiation; osteoclast; activation; mechanisms; phosphate; autophagy
AB Mitochondria are essential regulators of bone health, controlling cell differentiation, cellular energy production, immune function, osteogenesis, and osteoclast activity. Their dysfunction is linked to orthopedic disorders such as osteoporosis, osteoarthritis, and osteomyelitis, contributing to impaired bone homeostasis and increased fracture risk. While mitochondrial research has been more advanced in fields such as cardiology and neurology, emerging therapeutic strategies from these areas are beginning to show potential for translation into orthopedics. These include mitochondrial biogenesis stimulation, mitochondrial fission inhibition, antioxidant therapies, mitochondrial transplantation, and photobiomodulation, which have demonstrated success in enhancing tissue repair, reducing oxidative stress, and improving overall cellular function in non-orthopedic applications. The novel inhibitor of mitochondrial fission and accumulation of reactive oxygen species Mdivi-1 offers potential to improve clinical outcomes of bone diseases by alleviating cellular dysfunction and preventing bone loss. While these treatments are still in the developmental phase, they present innovative approaches to address mitochondrial dysfunction in orthopedic conditions, potentially transforming bone disease management and enhancing patient outcomes. This report explores research regarding the involvement of mitochondrial health in bone and joint function and discusses possible future

treatment strategies targeting mitochondria in orthopedic conditions.

TI Pyroptosis: candidate key targets for mesenchymal stem cell-derived exosomes for the treatment of bone-related diseases
SO STEM CELL RESEARCH & THERAPY
LA English
DT Review
DE Pyroptosis; Mesenchymal stem cells; Exosomes; Osteoarthritis; Spinal cord injury; Disc herniation; Osteoporosis
ID inflammasome activation; extracellular vesicles; rheumatoid-arthritis; nlrp3 inflammasome; spinal-cord; injury; osteoarthritis; communication; osteoporosis; diagnosis
AB Bone-related diseases impact a large portion of the global population and, due to their high disability rates and limited treatment options, pose significant medical and economic challenges. Mesenchymal stem cells (MSCs) can differentiate into multiple cell types and offer strong regenerative potential, making them promising for treating various diseases. However, issues with the immune response and cell survival limit the effectiveness of cell transplantation. This has led to increased interest in cell-free stem cell therapy, particularly the use of exosomes, which is the most studied form of this approach. Exosomes are extracellular vesicles that contain proteins, lipids, and nucleic acids and play a key role in cell communication and material exchange. Pyroptosis, a form of cell death involved in innate immunity, is also associated with many diseases. Studies have shown that MSC-derived exosomes have therapeutic potential for treating a range of conditions by regulating inflammation and pyroptosis. This study explored the role of MSC-derived exosomes in modulating pyroptosis to improve the treatment of bone-related diseases.

TI Tourniquet-less total knee arthroplasty does not negatively affect cement penetration: a double-blinded randomized controlled trial
SO INTERNATIONAL ORTHOPAEDICS
LA English
DT Article
DE Total knee arthroplasty; Tourniquet; Cement penetration; Bone mineral density; Randomized controlled trial
ID soft-tissue damage; blood-loss; society; mantle; pain; hip
AB Background The use of tourniquets in total knee arthroplasty (TKA) remains controversial, with growing interest in tourniquet-less techniques to improve patient outcomes. However, concerns persist regarding the adequacy of cement penetration and long-term implant stability. This study evaluated whether tourniquet-less TKA compromises cement penetration compared to conventional tourniquet-assisted procedures. Methods A double-blind randomized controlled trial included 120 patients with end-stage osteoarthritis undergoing cemented TKA. Patients were randomized into two groups: tourniquet (n = 60) and tourniquet-less (n = 60). All patients received standardized protocols including tranexamic acid, spinal anaesthesia with controlled hypotension, and identical cementing techniques. The primary outcome was cement penetration depth measured on standardized radiographs at 60 days. Secondary analysis assessed the impact of bone mineral density on cement penetration. Results Both groups achieved optimal cement penetration (2-3 mm) across the measured zones, with no clinically significant differences in average penetration depth. Bone mineral density did not affect penetration in either group, with 28.9% of patients having osteoporosis. Statistically significant differences in select zones (0.06-0.5 mm) were not clinically meaningful. Conclusions Tourniquet-less TKA achieves equivalent cement

penetration to tourniquet-assisted procedures when performed with modern standardized techniques. These findings support surgical decision-making for tourniquet-less approaches without compromising implant fixation quality, potentially enabling improved patient-centered outcomes.

TI Effect of Antiresorptive Therapy on Development of Posttraumatic Osteoarthritis after Intra-articular Distal Radius Fracture in Female Patients
SO CLINICS IN ORTHOPEDIC SURGERY
LA English
DT Article
DE Radius fractures; Osteoarthritis; Bisphosphonates; Denosumab; Osteoporosis
ID bisphosphonate use; bone; alendronate; cartilage; damage; model
AB Background: Subchondral bone is a potential target for osteoarthritis (OA) prevention. Antiresorptive therapy has been demonstrated to be chondroprotective in surgically induced OA animal models, but results were mixed in clinical studies. We aimed to determine whether patients with traumatic joint injury could benefit from antiresorptive therapy and whether the osteoporosis status might affect the chondroprotective effect, if any, of the therapy. Methods: We retrospectively reviewed 299 women (mean age, 64.7 +/- 8.6 years) who underwent surgery for an intra-articular distal radius fracture (DRF). We evaluated radiographic and symptomatic OA development at 1 year postoperatively. The odds ratio (OR) for the OA development was analyzed using logistic regression for factors including age, lowest T score, bone mineral density, presence of osteoporosis, residual intra-articular step-off, and antiresorptive therapy. To delineate the effect of the

osteoporosis status, subgroup analyses were performed. Results: Development of radiographic OA was identified in 80 patients (27%), and the mean pain score on a visual analog scale was 2.2 +/- 1.1. In the regression analysis, radiographic OA was associated with the presence of osteoporosis (OR, 3.97; 95% CI, 1.89-8.32), residual intra-articular step-off (OR, 3.68; 95% CI, 1.45-9.39), and not starting antiresorptive therapy (OR, 0.29; 95% CI, 0.14-0.61). In subgroup analysis, radiographic OA was associated with not starting antiresorptive therapy (OR, 0.24; 95% CI, 0.07-0.93) for patients without osteoporosis. However, for patients with osteoporosis, no association was found between radiographic OA and the evaluated factors. Conclusions: Initiation of antiresorptive therapy was associated with a lower incidence of radiographic OA after an intra-articular DRF, especially in those without osteoporosis. This study suggests that attempts to decrease bone remodeling might be effective for OA prevention in a joint at risk.

TI The therapeutic potential of icariin in the intervention of bone and joint diseases through multiple pathways: a narrative review
SO FRONTIERS IN PHARMACOLOGY
LA English
DT Review
DE icariin; natural flavonoids; Osteometabolic balance; inflammation; oxidativestress; mechanisms
ID intervertebral disc degeneration; osteogenic differentiation; stem-cells; udp-glucuronosyltransferases; ankylosing-spondylitis; articular-cartilage; controlled-release; signaling pathway; oxidative stress; herbal fufang
AB The prevalence of bone and joint diseases is projected to increase owing to rapidly aging populations, sedentary lifestyles, and unhealthy diets. This poses a significant challenge for the global healthcare system. In recent years, natural herbal medicines have been used to treat various types of orthopedic diseases, opening new frontiers in new drug research. Epimedium is a traditional Chinese herb with a long history of medicinal use. It is commonly used to treat osteoporosis, joint disorders, cardiovascular diseases, sexual dysfunction and aging.

The primary active component of Epimedium is icariin (ICA), an isoprenylated flavonoid. Recent studies have demonstrated its significant positive effects on bone metabolism and remodeling, including promoting osteoblast proliferation and mineralization, reducing osteoclast activity, and inhibiting inflammation and oxidative stress. Thus, ICA represents a potential compound for treating bone and joint diseases. However, the specific mechanisms underlying these effects have not yet been fully elucidated. This paper focuses on the latest advances in the use of ICA for the treatment of skeletal and joint diseases, covering a range of conditions including osteoporosis, osteoarthritis, rheumatoid arthritis, intervertebral disc degeneration and fractures. Building on this, we have systematically integrated its multi-target pharmacological mechanism network for the first time, elucidating its multi-pathway synergistic effects mediated by regulating the balance of the bone microenvironment. In summary, as a multi-target natural compound, ICA demonstrates significant translational medicine potential in the comprehensive treatment of bone and joint diseases, providing a critical theoretical foundation for the development of novel therapeutic strategies.

TI Exploring new therapeutic drugs for osteoarthritis and osteoporosis: Glucagon-like peptide-1 receptor agonists: A review
SO MEDICINE
LA English
DT Article
DE bone; cartilage; glucagon-like peptide-1 receptor agonist; osteoarthritis; osteoclasis; osteogenesis; osteoporosis
ID bone-mineral density; extracellular-matrix; glp-1 receptor; liraglutide; exendin-4; degradation; fracture; cells; risk; differentiation
AB As the 2 most common diseases of bone and joint, osteoarthritis (OA) and osteoporosis (OP) have a high incidence. The two diseases are often accompanied in clinical practice, affecting the health and quality of life of patients, but the relationship is complex. So far, there are no very effective drugs for the treatment of both diseases, so it is very meaningful to search for drugs that are suitable for OA and OP. Glucagon-like peptide-1 (GLP-1), as a type of enterotropic insulin, has hypoglycemic and weight loss effects. Recently, the effects of GLP-1 receptor agonists (GLP-1RA) on OA and OP have attracted more and more attention. This review aims to summarize the mechanism of GLP-1RA affecting bone metabolism in OA and OP, such as anti-inflammatory, affecting chondrocyte matrix metabolism, analgesia, promoting bone formation, inhibiting bone resorption, and reducing fracture incidence, to provide new methods for drug treatment of OA and OP.

TI Recent Advances in pH-Responsive Coatings for Orthopedic and Dental Implants: Tackling Infection and Inflammation and Enhancing Bone Regeneration
SO COATINGS
LA English
DT Review
DE pH-sensitive materials; bone implants; coating; antibiotic resistance; bone healing
ID mesoporous silica nanoparticles; controlled drug-release; delivery-system; osteogenic differentiation; surface-roughness; titania nanotubes; ti implants; antibacterial; polymers; chitosan
AB Bone is a structurally complex and dynamic tissue that plays a crucial role in mobility and skeletal stability. However, conditions such as osteoporosis, osteoarthritis, trauma-induced fractures, infections, and malignancies often necessitate the use of orthopedic and dental implants. Despite significant progress in implant biomaterials, challenges such as bacterial infection, inflammation, and loosening continue to compromise implant longevity, frequently leading to revision surgeries and extended recovery times. Smart coatings have emerged as a next-generation solution to these problems by providing on-demand, localized therapeutic responses to microenvironmental changes around implants and promoting bone regeneration. Such coatings can minimize antibiotic resistance by enabling controlled, stimulus-triggered drug release. Although the idea of using pH-sensitivity as a tool to make smart coatings is not a new thought, there are no options currently good enough to enter clinical studies. This review provides a comprehensive overview of recent advances in pH-sensitive polymers, hybrid composites, porous architectures, and bioactive linkers designed to dynamically respond to pathological pH variations at implant sites. By investigating the mechanisms of action, antibacterial and anti-inflammatory effects, and roles in bone regeneration, it is shown that the ability to provide time-dependent drug release for both short-term and long-term infections, as well as keeping the environment welcoming to the bone cell growth and replacement, is not an easy goal to reach, even with a fully biocompatable, non-toxic, and semi-biodegradable (one that releases the drug, but does not fade away) coating material compound. Reviewing all available options, including their functions and failures, finally,

emerging trends, translational barriers, and future opportunities for clinical implementation are highlighted, underscoring the transformative potential of bioresponsive coatings in orthopedic and dental implant technologies.

TI The potential role of GLP-1 receptor agonists in the management of psoriatic disease: a scoping review
SO INFLAMMATION RESEARCH
LA English
DT Review
DE Psoriatic disease; Psoriasis; Glucagon-like peptide-1 receptor agonists; Obesity; Type 2 diabetes mellitus; Cardiovascular disease
ID peptide-1 analog therapy; bone-mineral density; once-weekly semaglutide; adipose-tissue; body-weight; collagen vi; cardiovascular events; extracellular-matrix; human macrophages; controlled-trial
AB BackgroundPsoriatic disease (PsD) is a chronic systemic inflammatory condition associated with significant cardiometabolic comorbidities, including obesity, type 2 diabetes mellitus (T2DM), and cardiovascular (CV) disease. These comorbidities are interlinked via shared immunopathogenic mechanisms, notably chronic low-grade inflammation driven by Th1/Th17 cytokines such as TNF, IL-6, and IL-17. Obesity, in particular, exacerbates PsD severity and treatment resistance, underscoring the need for integrated therapeutic strategies. This scoping review investigates the biological rationale and evidence for the use of glucagon-like peptide-1 receptor agonists (GLP-1RAs) in PsD.FindingsOriginally developed for T2DM, GLP-1RAs have demonstrated efficacy in reducing weight and improving glycemic control and CV outcomes. Evidence also suggests immunomodulatory properties through modulation of key inflammatory pathways and immune cell activity. We examined studies addressing: (1) the impact of obesity, T2DM, and CV disease on PsD; (2) outcomes of GLP-1RAs in these comorbidities; and (3) their potential in related rheumatologic and dermatologic diseases. GLP-1RAs show promise in reducing PsD burden by improving metabolic parameters and reducing systemic inflammation. Early clinical and preclinical data suggest benefits also in rheumatoid

arthritis, osteoarthritis, osteoporosis, psoriasis, and hidradenitis suppurativa.ImplicationsGLP-1RAs represent a novel, multifaceted therapeutic option in PsD, targeting both metabolic and inflammatory components. Further clinical trials are warranted to define their role in comprehensive PsD management and validate their disease-modifying potential.

TI Depressive Symptoms and Osteoporosis in Middle-Aged and Older Adults: A Cross-Sectional Analysis of NHANES and HRS Data
SO GERIATRIC ORTHOPAEDIC SURGERY & REHABILITATION
LA English
DT Article
DE osteoporosis; depressive symptoms; NHANES; HRS; subgroup analysis
ID bone-mineral density; fracture risk; epidemiology; system; osteoarthritis; receptors; cytokines; diagnosis; cortisol; insulin
AB Background & Aims: Depression and osteoporosis are common among middle-aged and older adults, both impacting morbidity and quality of life. Their shared risk factors suggest a potential link, but this relationship remains underexplored. This study aimed to assess the association between depressive symptoms and osteoporosis in two large cohorts: the National Health and Nutrition Examination Survey (NHANES, 2005-2010) and Health and Retirement Study (HRS, 2012). Methods: We analyzed data from adults aged >= 50 years in NHANES (n = 3612) and HRS (n = 4307). Depressive symptoms were measured using PHQ-9 in NHANES and CES-D 8 in HRS, while osteoporosis was defined by self-reported diagnosis and medication use. Generalized linear models were used to evaluate the association, adjusting for demographic, lifestyle, and comorbidity factors. Subgroup analyses and sensitivity tests were conducted to explore effect modifiers and result robustness. Results: Depressive symptoms were positively associated with osteoporosis in both cohorts (NHANES: adjusted OR = 1.061, 95% CI: 1.034-1.088; HRS: adjusted OR = 1.063, 95% CI: 1.014-1.115). Significant associations were observed across subgroups, with stronger effects in individuals with diabetes and arthritis. Sex differences showed higher odds ratios for men in HRS. The relationship exhibited a linear trend, with increasing risk as depressive severity intensified. Conclusion: Depressive symptoms (PHQ-9/CES-D8) significantly associate with higher osteoporosis risk in older adults, with consistent cross-sectional findings across populations. While causality remains unclear, results

support clinical bone density monitoring in depression care and depression screening in osteoporosis management. Future longitudinal studies should clarify mechanisms, while public health strategies should integrate mental-bone health prevention approaches.

TI The role of the brain-bone axis in skeletal degenerative diseases and psychiatric disorders, A genome-wide pleiotropic analysis
SO PROGRESS IN NEURO-PSYCHOPHARMACOLOGY & BIOLOGICAL PSYCHIATRY
LA English
DT Article
DE Skeletal degenerative diseases; Psychiatric disorders; Immune dysfunction; Inflammation; Genome-wide association study; Mendelian randomization
ID nervous-system; health; set
AB Introduction: Skeletal degenerative diseases and psychiatric disorders often coexist clinically. However, the genetic correlations and underlying biological mechanisms between these two types of diseases remain unclear. Objectives: To investigate the genetic correlations between skeletal degenerative diseases and psychiatric disorders and to identify shared genomic loci, genes, and pathways. Methods: This comprehensive genome-wide pleiotropic association study utilized summary statistics from publicly available genome-wide association data. Various statistical genetic correlation methods were employed, including LDSC, HDL, PLACO, Coloc, Hyprcoloc, and Mendelian randomization (MR) analysis, along with immune cell colocalization analysis. The study aimed to identify potential shared genetic factors among three skeletal degenerative diseases (osteoarthritis, intervertebral disc degeneration, and osteoporosis) and three psychiatric disorders (schizophrenia, anxiety disorder, and major depressive disorder). Results: Analyses using LDSC, HDL, and Bonferroni corrections revealed significant genetic correlations between intervertebral disc degeneration (IVDD) and anxiety disorder (ANX); fractures, IVDD, and arthritis with major depressive disorder (MDD); and arthritis with schizophrenia (SCZ). Significant genetic correlations were also observed between VDD and ANX, fractures, IVDD, hip osteoarthritis (HipOA), knee osteoarthritis (KneeOA) and MDD, and KneeOA and SCZ. Pleiotropy analysis using PLACO, MAGMA, and multitrait colocalization Hyprcoloc identified 65 pleiotropic loci, 27 shared causal loci, and 9 shared risk loci involving immune cells related to both psychiatric and bone-related diseases. Additionally, tissue-specific enrichment analysis showed that genes mapped to these loci were enriched in brain,

cardiovascular, pancreatic, and other tissues. The IVW method demonstrated that MDD increased the risk of IVDD and KneeOA, while IVDD increased the risk of ANX and MDD. Conversely, SCZ was associated with a reduced risk of KneeOA. Multiple sensitivity analyses further supported a positive causal effect of IVDD on MDD. Conclusion: These findings suggest significant genetic correlations between skeletal degenerative diseases and psychiatric disorders, highlighting multiple shared comorbid genes and key immune cell types. Importantly, the study supports the role of the brain-bone axis in the regulation of skeletal degenerative diseases and psychiatric disorders, which could provide valuable insights for potential therapeutic targets and interventions for these conditions.

TI Association between vertebral fractures and brain volume: insights from a community cohort study

SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE Brain volume; Gray matter volume; Magnetic resonance imaging; Vertebral fracture; Voxel-based morphometry
ID mini-mental-state; parahippocampal cortex; osteoarthritis/osteoporosis; hippocampus; memory
AB Investigating vertebral fractures and brain structure, we found significant gray matter volume reductions in the right hippocampus, amygdala, and parahippocampal gyrus, especially in males. These findings emphasize the importance of integrating skeletal and neural health in osteoporosis management. Purpose Vertebral fractures (VF) due to osteoporosis impact morbidity and quality of life in the elderly. The relationship between VF and changes in brain structure remains underexplored. This study aimed to investigate the association between VF and gray matter volume (GMV) reductions in specific brain regions and to explore potential sex differences.MethodsData from 1,751 participants (571 males, 1,180 females; mean age 64.9, range 18-97) in the fourth survey of the population-based Research on Osteoarthritis/Osteoporosis Against Disability study (2015-2016) were used. Participants were classified into those with and without VF (VF + and VF - groups) based on Genant's semiquantitative method, assessed by spine radiographs. Voxel-based morphometry was applied to MRI images to measure GMV, and a general linear model analysis was performed to compare GMV between groups, adjusting for age, sex, total brain volume, and Mini-Mental State Examination scores as covariates. Additionally, a two-way analysis of variance was conducted on the significant GMV cluster, with sex and VF presence as independent variables, to explore interaction effects. Results The VF+ group consisted of 113 participants, while the VF- group included 1,638 participants. The analysis identified a significant cluster with reduced GMV in the VF + group compared to the VF - group. This cluster included the right hippocampus, right amygdala, and right parahippocampal gyrus. Further analysis revealed that males in the VF + group exhibited more pronounced GMV reductions in the significant cluster compared to females. Conclusion These findings suggest that VF is associated with significant reductions in brain regions critical for memory, emotional processing, and visuospatial memory, with more severe effects observed in males.

ID mesenchymal stem-cells; human articular chondrocytes; necrosis-factor-alpha; platelet-rich plasma; growth-factor; rheumatoid-arthritis; gene-expression; rat model; osteoblast differentiation; osteogenic differentiation
AB Musculoskeletal disorders are age-related illnesses that substantially impact the locomotor system. These problems can lead to serious complications, such as fractures, which can severely compromise the quality of life of patients. With the aging of the global population, the incidence and prevalence of musculoskeletal disorders are gradually increasing. Proliferation, differentiation, and cellular fate are extensively regulated by the BMP signaling pathway, which is expressed in approximately all organ systems. Musculoskeletal diseases are generally influenced by BMP signaling, which impedes the degeneration of musculoskeletal diseases. In this review, the pathophysiological functions of BMP signaling in four main musculoskeletal disorders (osteoporosis, osteoarthritis, rheumatoid arthritis, and sarcopenia) are summarized, and the role of cross talk between BMP signaling and other signaling pathways in the development of musculoskeletal disorders is reviewed. Finally, a conclusion regarding research on the role of BMP signaling in musculoskeletal disorders is formulated. Targeting the BMP signaling pathway is a promising therapeutic approach, and related studies have offered insights into the

pathophysiological mechanism of musculoskeletal disorders. The Translational Potential of This Article: The identification of the BMP signaling pathway involved in the development of musculoskeletal disorders and the investigation of their signaling cross talk can pave the way for effective treatments and management strategies for patients with musculoskeletal disorders

TI Helicobacter pylori-Related Chronic Gastritis as a Risk Factor for Lower Bone Mineral Density
SO CALCIFIED TISSUE INTERNATIONAL
LA English
DT Article
DE Population-based study; Pepsinogen; Atrophic gastritis; <italic>Helicobacter pylori</italic>; Bone mineral density
ID postmenopausal osteoporosis; combination; gastrectomy; pepsinogen; infection; diagnosis; arthritis; estrogen; cohort
AB We evaluated the role of Helicobacter pylori (H. pylori)-related chronic gastritis in the development of osteoporosis in a population-based study. A total of 1690 subjects in the cohort of the Research on Osteoarthritis/ osteoporosis Against Disability (ROAD) were investigated, and the association between gastritis and osteoporosis was evaluated by the presence of serologically assessed H. pylori-related chronic gastritis and its stage, based on H. pylori antibody titer and pepsinogen. The presence of the gastritis was associated with significantly lower bone mineral density (BMD) assessed by dual-energy x-ray absorptiometry and a significant risk of lower BMD was observed in femoral neck (adjusted odds ratio [OR]: 0.78, 95% confidence interval [CI]: 061-0.99). The progression of the gastritis appeared to further increase the risk. In the stage of non-atrophic gastritis, the risk of lower BMD was significantly high, especially in a subgroup with higher gastritis activity in the femoral neck (adjusted OR: 0.61, 95% CI: 0.42-0.89). Meanwhile, in the stage of atrophic gastritis, the highest and significant risk of lower BMD was observed in a subgroup with the most extensive and severe atrophy in femoral neck (adjusted OR: 0.62, 95% CI: 0.42-0.91). These results suggest that H. pylori-related chronic gastritis is involved in the risk of osteoporosis, with higher activity of gastritis and more extensive atrophy leading to further increased risk. The serologically assessed stage of the gastritis could be used to identify a high-risk group for osteoporosis in H. pylori-infected subjects from general population.

TI Research Progress of Senolytic Drugs in the Treatment of Orthopedic Diseases
SO GERONTOLOGY
LA English
DT Review
DE Senolytic drugs; Orthopedic diseases
ID oxidative stress; senescent cells; heat-shock; osteoarthritis; apoptosis; activation; mechanisms; cartilage; agent
AB Background: Orthopedic diseases, including osteoarthritis, osteoporosis, and age-related musculoskeletal disorders, significantly impact quality of life and are becoming increasingly prevalent with aging populations. A growing body of evidence highlights the role of cellular senescence in the pathogenesis of these conditions. Senescent cells(SCs), characterized by irreversible cell cycle arrest, accumulate in tissues over time, contributing to inflammation, tissue degeneration, and impaired regeneration. The emerging field of senolytics, which aims to selectively eliminate these SCs, has garnered attention as a novel therapeutic strategy in orthopedics. Summary: Senolyticdrugs, including small molecules, peptides, and natural compounds, have shown promise in preclinical models and

early clinical trials for the treatment of various age-related diseases. In orthopedics, senolytics have been investigated for their potential to ameliorate cartilage degradation, bone fragility, and other degenerative changes associated with aging. Recent studies have demonstrated that targeting SCsin musculoskeletal tissues can improve tissue function, re-duce inflammation, and promote regeneration. Although the majority of research is still in the preclinical phase, the positive outcomes from animal studies and early clinical trials suggest that senolytic drugs may offer new therapeutic avenues for orthopedic diseases.
 Key Messages: Senolytic therapies hold significant potential for treating orthopedic diseases by targeting the underlying cellular senescence that contributes to tissue degeneration and inflammation. Preclinical and clinical studies indicate that senolytic drugs may enhance tissue repair, alleviate symptoms, and slow disease progression in musculoskeletal disorders. Further research is needed to optimize drug efficacy, ensure safety, and identify patient populations that may benefit the most from these treatments. The development of senolytic drugs could revolutionize the management of aging-related orthopedic diseases, providing a more targeted and effectiveapproach than current treatments

TI Autoimmune thyroid disease and human health: a systematic review of Mendelian randomization studies
SO FRONTIERS IN IMMUNOLOGY
LA English
DT Article
DE autoimmune thyroid disease; human health; systematic review; Mendelian randomization; Grave's disease
ID graves-disease; risk; association; depression; prevalence; disorder
AB We systematically summarized current Mendelian randomization (MR) evidence on the causal relationships between autoimmune thyroid disease (AITD) and a wide range of human health outcomes. Original MR studies related to AITD published up to March 1, 2025, were retrieved from PubMed and Embase. For studies investigating the same exposure-outcome associations, meta-analyses were performed to synthesize the evidence after excluding overlapping samples where applicable. The methodological quality of the included studies was assessed using the STROBE-MR checklist. A total of 123 MR publications met the inclusion criteria. MR analyses indicated that AITD significantly increased the risk of coronary atherosclerosis, deep venous thrombosis, chronic obstructive pulmonary disease, major depression, diabetic neuropathy, carpal tunnel syndrome, neuromyelitis

optica spectrum disorder, diabetic retinopathy, childhood absence epilepsy, rheumatoid arthritis, systemic lupus erythematosus, psoriatic arthritis, inflammatory bowel disease, crohn's disease, vitiligo, myasthenia gravis, alopecia areata, type 1 and type 2 diabetes, sarcoidosis, frozen shoulder, drug eruptions, cataract, early age-related macular degeneration, pernicious anemia, Helicobacter pylori infection, temporomandibular disorders, migraine, frailty, primary biliary cholangitis, knee osteoarthritis, gout, and osteoporosis, while decreasing the risk of lung cancer, polyneuropathies, allergic rhinitis, telomere length, and serum vitamin A levels. The included MR studies were of high methodological quality and provided robust evidence supporting the bidirectional relationships between AITD and various health outcomes. These findings emphasize the importance and necessity of preventing and managing AITD while offering new perspectives and directions for future research on its prevention and treatment.Systematic review registration https://www.crd.york.ac.uk/prospero/, identifier CRD42023469038.

DE cuproptosis; osteoporosis; osteoarthritis; osteosarcoma; intervertebral disc degeneration; spinal cord injury; osteomyelitis
ID copper homeostasis; oxidative stress; multidisciplinary approach; extracellular vesicles; rheumatoid-arthritis; cell-death; osteosarcoma; toxicity; tumor; zinc
AB Cuproptosis, a recently identified form of copper-dependent cell death, arises from intracellular copper dyshomeostasis. As an essential trace element, copper plays a critical role in bioenergetic metabolism, redox regulation, and synaptic transmission. However, excessive copper exerts cytotoxic effects through multiple pathways, including increased reactive oxygen species (ROS) production, apoptotic cascade activation, necrotic membrane rupture, inflammatory responses, and mitochondrial dysfunction. Distinct from other cell death mechanisms, cuproptosis is characterized by copper ion binding to acetylated mitochondrial respiratory chain proteins, leading to pathogenic protein aggregation, iron-sulfur cluster depletion, and cellular collapse. Emerging evidence underscores aberrant copper accumulation and resultant proteotoxic stress as pivotal contributors to the pathogenesis of multiple musculoskeletal pathologies, including osteoporosis, osteoarthritis, sarcopenia, osteosarcoma, intervertebral disc degeneration, spinal cord injury, and biofilm-associated orthopedic infections. Understanding the spatiotemporal regulation of cuproptosis may provide novel opportunities for advancing diagnostic and therapeutic approaches in orthopedic medicine. This review synthesizes current insights into the molecular mechanisms of cuproptosis, its pathogenic role in musculoskeletal diseases, and the potential for biomarker-driven therapeutic interventions.

AB Collagen is the most abundant protein in the human body, providing structural stability to connective tissues. It organises and interacts with other proteins to form a complex extracellular matrix (ECM), with loss of collagen in the ECM seen in diseases such as osteoarthritis and osteoporosis. As collagen, and other ECM components, are atypically large proteins, they require specific endoplasmic reticulum (ER) export machinery. A key player in the export of procollagen from the ER is the MIA3 gene product, TANGO1. We introduced mutations to both tango1 isoforms in zebrafish independently to understand the importance of the previously unexplored short isoform in zebrafish development and tissue homeostasis. We show that the long isoform of tango1 (tango1L) is mostly able to compensate for loss of the short isoform (tango1S) in larvae. However, non-collagenous components of the ECM (such as proteoglycans) were disrupted during development, leading to abnormal matrix patterning, visible by electron microscopy. Adult tango1S zebrafish show altered spinal morphology and changes to intervertebral discs, suggesting that tango1S plays a role in skeletal patterning and homeostasis that is independent of the long isoform.

TI Notch signaling pathway in osteogenesis, bone development, metabolism, and diseases
SO FASEB JOURNAL
LA English
DT Review
DE bone formation; <italic>Notch</italic> signal pathway; osteoarthritis; osteoblast differentiation; osteoporosis
ID mesenchymal stem-cells; causes spondylocostal dysostosis; nf-kappa-b; osteoblast differentiation; alagille-syndrome; morphogenetic protein-2; missense mutations; wnt/beta-catenin; sonic hedgehog; beta-catenin
AB The skeletal system provides vital importance to support organ development and functions. The Notch signaling pathway possesses well-established functions in organ development and cellular homeostasis. The Notch signaling pathway comprises five typical ligands (JAG1, JAG2, DLL1, DLL3, and DLL4), four receptors (Notch1-4), and four intracellular domains (NICD1-4). Each component of the Notch signaling pathway has been demonstrated to be fundamental in osteoblast differentiation and bone formation. The dysregulation in the Notch signaling

pathway is highly linked with skeletal disorders or diseases at the developmental and postnatal stages. Recent studies have highlighted the importance of the elements of the Notch signaling pathway in the skeletal system, as well as its interaction with signaling, such as Wnt/beta-catenin, BMP, TGF-beta, FGF, autophagy, and hedgehog (Hh) to construct a potential gene regulatory network to orchestrate osteogenesis and ossification. Our review has provided a comprehensive summary of the Notch signaling pathway in the skeletal system, as well as the insights targeting Notch signaling for innovative potential drug discovery targets or therapeutic interventions to treat bone disorders, such as osteoporosis and osteoarthritis. An in-depth molecular mechanistic strategy to modulate the Notch signaling pathway and its associated signaling pathway will be encouraged for consideration to trigger enhanced therapeutic approaches for bone disorders by defining Notch-regulating drugs for clinical use.

TI The YAP1/GPX4 axis alleviates osteoporosis by affecting ferroptosis in osteoblasts
SO MOLECULAR MEDICINE
LA English
DT Article
DE GPX4; YAP1; Ferroptosis; Osteoblasts; Osteoporosis
AB BackgroundOsteoporosis (OP) is a disease in which weak bones increase the risk of fracture. It has been reported that the occurrence of ferroptosis accelerated the progression of OP. However, the underlying mechanism of ferroptosis in OP remains unclear.MethodsClinical samples from OP patients were collected and ovariectomized (OVX)-induced mouse models with GPX4 knockout was established. The expression of genes and proteins was determined by RT-qPCR, western blot, IHC and IF. Bone mineral density (BMD) of the lumbar vertebrae was evaluated using DXA. Pearson correlation analysis was used to analyze the relationship between GPX4 expression and BMD. The femoral morphology was detected by HE staining. Images and relevant parameters of the femur were acquired using micro-CT. Ultrastructural changes in mitochondria were observed using TEM. MDA and GSH levels in mice and cells were examined using commercial kits. Lipid peroxidation was detected using Bodipy-C11 fluorescent probe. ALP activity was measured using ALP staining and calcified nodules were examined using ARS staining. The interaction between YAP1 and GPX4 promoter was validated using ChIP and dual-luciferase reporter gene assay.ResultsGPX4 expression was downregulated in clinical samples of OP and positively correlated with BMD. GPX4 knockout exacerbated bone loss and promoted ferroptosis in OVX-induced mice. Besides, GPX4 overexpression inhibited ferroptosis and enhanced osteogenic potential of osteoblasts. Moreover, YAP1 positively regulated GPX4 expression in

osteoblasts through activating transcriptional activity of GPX4 promoter and YAP1 overexpression suppressed ferroptosis and enhanced osteogenic potential of osteoblasts via enhancing GPX4 expression.ConclusionGPX4 was positively regulated by YAP1, which in turn inhibited ferroptosis and enhanced osteogenic potential of osteoblasts, thereby alleviating OA progression.

TI The interplay between the immune microenvironment and bone aging: From molecular mechanisms to therapeutic interventions
SO EXPERIMENTAL GERONTOLOGY
LA English
DT Review
DE Bone aging; Bone cells; Immune cells; Immune microenvironment; Therapy
ID stem-cells; osteoblastic differentiation; cellular senescence; dendritic cells; t-cells; macrophages; ferroptosis; diseases; osteoclastogenesis; osteoarthritis
AB The core mechanism of skeletal aging lies in the comprehensive disruption of microenvironmental homeostasis, involving a multidimensional interactive network comprising immune cells, mesenchymal stem cells, and their differentiated lineages. Although osteoporosis (OP) and osteoarthritis (OA) have traditionally

been viewed as distinct degenerative disorders, recent breakthroughs in osteoimmunology reveal their shared immune-aging mechanism: immune cell dysfunction within the bone marrow microenvironment triggers inflammaging, subsequently driving a vicious cycle of bone formation and resorption through the senescence-associated secretory phenotype (SASP). This review not only integrates the molecular landscape of osteoclast-osteoblast-immune triangular crosstalk but also highlights emerging mechanisms such as mitochondrial dysfunction, exosomal communication, and cell death mechanisms, systematically establishing the pivotal role of the immune microenvironment in bone aging and providing a theoretical framework for developing next-generation targeted therapies against skeletal aging.

DT Review
DE alpha-ketoglutarate; bone metabolism; osteoporosis; osteoarthritis; rheumatoid arthritis; periodontitis
ID 2-oxoglutaric acid; growth-plate; amino-acids; sodium-salt; differentiation; absorption; cartilage; glutamine; supplementation; dehydrogenase
AB Bone metabolism in bone tissue is constantly maintained in a state of dynamic equilibrium. The mass of bone and joint tissues is determined by both bone formation and bone resorption. It is hypothesized that disrupted metabolic balance leads to osteoporosis, osteoarthritis, rheumatoid arthritis, and bone tumors. Such disruptions often manifest as either a reduction or abnormality in bone mass and are frequently accompanied by pathological changes such as inflammation, fractures, and pain. alpha-Ketoglutarate (alpha-KG) serves as a pivotal intermediate in various metabolic pathways in mammals, significantly contributing to cellular energy metabolism, amino acid metabolism, and other physiological processes. alpha-KG may be a therapeutic target for a variety of bone-related diseases, such as osteoporosis, osteoarthritis, and rheumatoid arthritis, because of its role in maintaining the metabolic balance of bone. After the application of alpha-KG, bone loss and inflammation in bone tissue are alleviated. This review focuses on the regulatory effects of alpha-KG on various cells in bone and joint tissues. Owing to the regulatory effect of alpha-KG on the balance of bone metabolism, the application of alpha-KG in the treatment of osteoporosis, osteoarthritis, rheumatoid arthritis, bone tumors, and other bone tissue diseases has been clarified.

TI Research Progress of Bone Grafting A Comprehensive Review

SO INTERNATIONAL JOURNAL OF NANOMEDICINE
LA English
DT Review
DE bone graft; true bone ceramics; decalcified bone matrix; freeze-dried bone; bone regeneration
ID ridge preservation; tooth extraction; morphogenetic protein-2; extracellular-matrix; progenitor cells; calcium-sulfate; bioactive glass; fiber membrane; bovine bone; scaffold
AB Bone tissue, the second most transplanted tissue after blood, is utilized in over 2.2 million bone grafts annually to address various bone-related conditions including fractures, tumors, bone infections, scoliosis, congenital defects, osteoporosis, osteoarthritis, and osteogenesis imperfecta. According to incomplete statistics, $4.3 billion was spent on bone graft materials in 2015 alone, with projections suggesting this figure may reach $66 billion by 2026. The limited availability of autogenous bone graft considered the gold standard due to their three critical biological properties: osteoconduction, osteoinduction, and osteogenesis-alongside the increasing global aging population, may be contributing to this rising expenditure. Furthermore, advancements in biomaterials and engineering technologies have created opportunities for the exploration of new bone graft substitutes. In this review, we will examine the fundamental structure of natural bone and the characteristics of ideal bone graft, highlighting common bone graft materials currently available, such as true bone ceramics, decalcified bone matrix, freeze-dried bone and demineralized freeze-dried bone, bioactive glasses, bone marrow aspirate concentrate, polymer nanocomposites, which have different characteristics in osteogenic, osteoconductivity, osteoinductivity, biocompatibility, mechanical properties, and resorption. How to utilize its advantages to maximize the osteogenic effect will be the focus of this review, and some of the current challenges in the field of bone grafting will be identified, outlining potential directions for future development. In conclusion, the choice of bone graft is critical to bone repair and regeneration, and a comprehensive understanding of the advantages and disadvantages of bone graft materials can improve the effectiveness of related surgical interventions.

TI A Comparison Between Two Bearing Surfaces for Total Hip Arthroplasty-Ceramic-on-Ceramic and Metal-Polycarbonate-Urethane-A Pseudo-Randomized Study
SO JOURNAL OF FUNCTIONAL BIOMATERIALS
LA English
DT Article
DE polycarbonate-urethane; ceramic-on-ceramic; total hip arthroplasty; bearing surface; Harris Hip Score; WOMAC; implant survival; patient satisfaction; complications; squeaking

ID polyethylene; uhmwpe; motion; range
AB Background: Polycarbonate-urethane (PCU) is a recently developed bearing surface used in prosthetic hip surgery. It offers several theoretical advantages, including an elasticity modulus similar to that of natural cartilage, good lubrication properties, low wear, and the possibility of using large heads. However, comparative clinical experience is limited. The purpose of this study was to analyze the results of the PCU bearing surface and compare them with those of ceramic-on-ceramic (CoC) bearings using the same femoral stem model. (2) Methods: Following a propensity score matching analysis of a prospectively collected database, patients with a primary total hip arthroplasty aged between 18 and 60 years were included. Subjects were divided into two groups (PCU and CoC). Demographic, patient satisfaction, and implant survival data were recorded. Clinical results were evaluated using the Harris Hip Score (HHS) and the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC). (3) Results: A total of 105 patients were included in each group. All patients exhibited a positive evolution on both the HHS and the WOMAC subscales between pre-op and one year post-op, no statistically significant differences being found between the groups with respect to improvement on the HHS ($p = 0.172$) or the pain ($p = 0.523$), stiffness ($p = 0.448$), and physical function ($p = 0.255$) subscales of the WOMAC. Head sizes in the PCU group were found to be larger, but this was not seen to have any effect on the patients' clinical status or the prostheses' dislocation rate. Although the complication rate was similar across the groups ($p = 0.828$), the incidence of squeaking was higher in the PCU group ($p = 0.010$). No differences were observed when comparing the implant survival rate ($p = 0.427$). nor in mean patient satisfaction ($p = 0.138$). (4) Conclusions: No differences were found in terms of clinical results, complications, implant survival, or patient satisfaction between the bearing surfaces under analysis, indicating that all of them are valid alternatives in total hip replacement, although the higher proportion of squeaking observed makes it advisable to exercise some caution.

TI Reduction of subchondral bone marrow lesions concurrent with early recovery of trabecular bone mineral density in knee osteoarthritis following RANKL inhibitor administration for the treatment of osteoporosis: Implying human osteoporotic osteoarthritis?
SO SEMINARS IN ARTHRITIS AND RHEUMATISM
LA English
DT Article
DE Knee osteoarthritis; Osteoporosis; Subchondral bone marrow lesions; Hounsfield unit; Bone mineral density
ID postmenopausal women; cartilage damage; pain; progression; replacement; spine
AB Objective: To illustrate the correlation between the reduction of subchondral bone marrow lesions (BMLs) and the early recovery of trabecular bone mineral density (TBMD) in symptomatic knee osteoarthritis (KOA) patients. Methods: A RANKL inhibitor was applied to osteoporosis (OP) patients who also had symptomatic KOA and BMLs and whose knee symptoms were refractory to NSAID therapy. Clinical symptoms, HRQoL, BMLs, knee TBMD, systemic BMD, and bone turnover markers were evaluated within a 6-month follow-up. The correlation between early TBMD recovery and BML reduction was explored. Results: Following a RANKL inhibitor application: (1) At the first-week follow-up, clinical symptoms were relieved and persisted until the final follow-up; HRQoL showed improvement. (2) BMLs and TBMD progressively improved at 4-week and 3-month follow-ups; the bone turnover markers significantly decreased. (3) Systemic BMD improved at the 6-month follow-up. (4) At the 3-month follow-up, the reduction in subchondral BML areas positively correlated with the increase in CT-HU values (r = 0.329; BML areas reduction: 173.09 +/- 45.23 mm2; CT-HU values increase: 23.72 +/- 3.77). Conclusion: In this clinical study, after the application of a RANKL inhibitor for OP treatment, BMLs and knee pain were effectively reduced in OP patients with symptomatic KOA and BMLs. In addition, the correlation between early recovery of TBMD and reduction in BML area was also demonstrated. This study supports the concept of osteoporotic osteoarthritis (OPOA) and highlights the potential of subchondral bone as a target for KOA treatment.

TI Changes of spino-pelvic characteristics post-THA are independent of surgical approach: a prospective study
SO ARCHIVES OF ORTHOPAEDIC AND TRAUMA SURGERY
LA English
DT Article
DE Pelvic tilt; Outcomes; Approach; Change; Spinopelvic
ID total hip-arthroplasty; acetabular component; orientation; risk
AB Aims Spinopelvic characteristics change after THA. Whether this change varies between approaches, is of interest for pre-op cup orientation planning. The aims of this study were to (1) Characterize changes in standing PT amongst patients with hip osteoarthritis treated with THA; (2) Test whether certain patient-related factors may predict PT change; and (3) Assess the association between surgical approach and PT change. Methods This was a prospective, two-center, radiographic outcome study including 424 hips, consisting of anterior approach for 171 (40.3%) hips, lateral approach for 181 hips (42.7%) and posterior approach for 72 hips (17.0%). Spinopelvic characteristics were determined from lateral radiographs (before and one year after THA). Parameters of interest included: Pelvic tilt (PT), lumbar lordosis, sacral slope, pelvic incidence. PT change of more than 7 degrees was considered clinically relevant. Results Pelvic tilt increased by 2 degrees from 15.1 degrees (+/- 8.9) to 17.1 degrees (+/- 9.7) after THA ($p < 0.001$). 19 hips (4.5%) experienced a relevant PT decrease, 337 (79.5%) had no clinically significant change in pelvic tilt, and 68 (16.0%) showed a moderate increase. Age, female sex and preoperative spinopelvic parameters including PT, SS and PI were predictive of PT change more than 7 degrees. PT increased most with lateral approach (2.9 +/- 6.2) and least with anterior approach (1.1 +/- 6.2, $p = 0.024$). Conclusion Preoperative PT is the best predictor for PT change. PT is generally normalizing after THA and patients with

low PT due to hip flexion contractures tend to increase PT after THA, few patients with high PT will decrease after THA. Anterior approach with capsulectomy was associated with the least change in PT post-THA. However, the approach-specific changes, although statistically significant, were too small to be considered during clinical practice, therefore no approach-specific prediction of PT change needs to be considered during preoperative planning for primary THA.

TI Angelica gigas Nakai (Korean Dang-gui) Root Alcoholic Extracts in Health Promotion and Disease Therapy - active Phytochemicals and In Vivo Molecular Targets
SO PHARMACEUTICAL RESEARCH
LA English
DT Article
DE decursin; decursinol; decursinol angelate; nodakenin; ROCK1/2
ID decursinol angelate; compound; pharmacokinetics; identification; mice; pyranocoumarins; decarboxylase; antiandrogen; inhibition; metabolism
AB Angelica gigas Nakai (AGN) root is a medicinal herbal widely used in traditional medicine in Korea. AGN root ethanolic extracts have been marketed as dietary supplements in the United States for memory health and pain management. We have recently reviewed the pharmacokinetics (PK) and first-pass hepatic metabolism of ingested AGN supplements in humans for the signature pyranocoumarins decursin (D, C-max 1x), decursinol angelate (DA, C-max similar to 10x) and their common botanical precursor and hepatic metabolite decursinol (DOH, C-max similar to 1000x). Here we update in vivo medicinal activities of AGN and/or its pyranocoumarins and furanocoumarin nodakenin in cancer, pain, memory loss, cerebral ischemia reperfusion stroke, metabolic syndrome and vascular endothelial dysfunctions, anxiety, sleep disorder, epilepsy, inflammatory bowel disease, osteoporosis and osteoarthritis. Given their polypharmacology nature, the pertinent mechanisms of action are likely misrepresented by many cell culture studies that did not consider the drug metabolism knowledge. We report here Rho-associated protein kinases (ROCK1/2) as novel targets for DA and DOH. Combining with published inhibitory activity of DOH on acetylcholinesterase,

agonist activity of DOH and antagonist/degrader activity of DA/D on androgen and estrogen receptors, D/DA promoting activity for glutamic acid decarboxylase (GAD)- gamma-aminobutyric acid (GABA) inhibitory axis and inhibition of glutamate dehydrogenase (GDH), monoamine oxidase-A (MAO-A) and transient receptor potential vanilloid 1 (TRPV1), we postulate their contributions to neuro-cognitive, metabolic, oncologic, vascular and other beneficial bioactivities of AGN extracts. A clinical trial is being planned for an AGN extract to manage side effects of androgen deprivation therapy in prostate cancer patients.

TI Thiram-induced ER stress promotes mitochondrial calcium signaling and NLRP3 inflammasome activation in a tissue specific manner
SO ECOTOXICOLOGY AND ENVIRONMENTAL SAFETY
LA English
DT Article
DE Thiram; Endoplasmic reticulum; Calcium signaling; NLRP3; Inflammasome; Liver-bone axis
ID bone
AB Thiram, a broadly used dithiocarbamate fungicide, exaggerates endoplasmic reticulum (ER) stress and interferes with mitochondrial function, thus disrupting cellular homeostasis. Here, we intend to identify the molecular actions of thiram at the mitochondrial-associated ER membranes (MAMs) that lead to the induction of ER stress and mitochondrial calcium overload in both liver and bone tissues. Taken together, we show that thiram-induced remodelling of MAMs leads to huge ER stress and calcium dysregulation. Histological and immunohistochemical examinations revealed that thiram-induced hyperactivation of IP3R1 mediated the release of endoplasmic reticulum calcium, but mitochondrial calcium uptake was

mediated by voltage-dependent anion channels VDAC1. This stress response was characterized by increased glucose regulated protein 78 (GRP78) expression in the liver and tibial growth plates (GP). In this respect, a new liver-bone axis was delineated for thiram-induced ER stress. More interestingly, the activation of NLRP3 inflammasome was very striking in tibial growth plates but not in liver tissues. Hence, the results highlight the systemic effects of thiram by identifying a critical metabolic junction that might play a role in metabolic disorders such as tibial dyschondroplasia and related bone disorders, e.g., osteoarthritis and osteoporosis.

TI Eucommia ulmoides Oliv. and its bioactive compounds: therapeutic potential in bone diseases
SO FRONTIERS IN PHARMACOLOGY
LA English
DT Review
DE <italic>Eucommia ulmoides</italic> Oliv.; bioactive compounds; aging-related bone diseases; bone formation; bone resorption; pharmacological mechanisms
ID induced osteoporosis; inhibits osteoarthritis; water extract; in-vitro; cortex; differentiation; phytochemistry; proliferation; inflammation; apoptosis
AB Background Aging-related bone diseases encompass a range of conditions that emerge or worsen with advancing age, including osteoporosis and osteoarthritis, and they are placing an increasing burden on society. Although these diseases differ in clinical manifestations and pathological features, they often share common

age-associated mechanisms such as impaired bone remodeling, chronic low-grade inflammation, cellular senescence, oxidative stress, and hormonal changes. Current therapies often face limitations in efficacy or long-term safety, highlighting the need for alternative strategies. Phytochemicals derived from Chinese medicine herb have emerged as promising candidates due to their multi-target effects on bone homeostasis. Eucommia ulmoides Oliv. (EU) and its bioactive compounds (e.g., quercetin, aucubin, geniposide, geniposidic acid). may regulate key pathways to restore bone balance, offering potential for treating osteoporosis and other aging-related bone diseasesObjectives This study aims to assess the therapeutic potential of EU in the treatment of aging-related bone diseases.Methods A literature search was conducted on the PubMed database up to November 2024 using the search term: "Eucommia AND (bone OR cartilage OR joint)."Results The review indicates that EU formulas, extracts, and bioactive components promote osteogenesis, suppress bone resorption, and exert anti-inflammatory and antioxidant properties. These effects contribute positively to the treatment of aging-related bone diseases.Conclusion The therapeutic benefits of EU support its development as a promising tool for preventing and treating aging-related bone diseases. These findings provide new research directions to address related health challenges associated with population aging.

TI Ultra-Processed Food and Its Impact on Bone Health and Joint Diseases: A Scoping Review

SO NUTRIENTS
LA English
DT Review
DE ultra-processed; food; osteoporosis; bone; osteoarthritis; rheumatoid arthritis; gout
ID mineral density; dietary pattern; consumption; risk; guidance; milk
AB Background/Objectives: This scoping review explores the relationship between ultra-processed food (UPF), bone health, and joint diseases, focusing on its potential impact on bone mineral density (BMD), osteoporosis, osteoarthritis, and inflammatory arthritis, including rheumatoid arthritis (RA), gout, and spondyloarthritis. Methods: A search strategy was developed using key terms such as "ultra-processed food" and related terms like "fast food," alongside various definitions of bone health impairment, chronic degenerative joint diseases, and inflammatory arthritis. Results: A total of 19 studies were included: 12 on bone health, 3 on osteoarthritis, and 4 on inflammatory arthritis. Preclinical studies showed that UPF consumption negatively affects bone structure and strength. In studies on children and adults, four investigations (2013-2017) found no association between fast food intake and BMD. However, more recent large-scale cross-sectional studies linked higher UPF consumption to lower BMD, increased osteoporosis risk, and greater prevalence of osteopenia, particularly in postmenopausal women. UPF intake was associated with knee osteoarthritis risk, with evidence suggesting an interaction with cartilage thickness, though no association was found for hip osteoarthritis. In inflammatory arthritis, UK Biobank data indicated a higher risk of RA and gout in UPF consumers, while a Brazilian study reported worse metabolic profiles in RA patients. No significant differences in UPF intake were found in spondyloarthritis. Conclusions: This review highlights relevant considerations about the deleterious role of UPF on bone health and joint diseases, providing additional evidence to suggest healthier dietary patterns to patients and to the general population.

TI Genomic structural equation modeling uncovers novel risk loci for bone metabolic disorders: cross-tissue genetic mechanisms and bone-brain axis regulation
SO BMC MUSCULOSKELETAL DISORDERS
LA English
DT Article
DE Bone metabolic disorders; Genomic structural equation modeling; Risk loci; Bone-brain axis; Transcriptome-wide association study
ID markers; cells
AB Objective The genetic architecture underlying bone metabolic disorders

(BMetDs) remains poorly characterized. Utilizing genomic structural equation modeling (Genomic-SEM) and multiple post-GWAS approaches, we estimated causal single nucleotide polymorphisms (SNPs) associated with BMetDs-independent metabolic variations, identifying 26 novel risk loci (including 14 genome-wide significant loci). Multi-omics analyses-including tissue-specific, cellular-level, and genomic element annotations-were applied to prioritize susceptibility loci and regulatory elements. Additionally, polygenic risk scores (PRS) derived from summary statistics were used to evaluate chromosomal contributions to BMetDs risk. For the first time, we present a comprehensive genetic landscape of BMetDs through a GWAS targeting an unmeasured latent phenotype. Methods We conducted a multivariate GWAS of BMetDs using genomic structural equation modeling (Genomic-SEM) on six BMetDs-related traits: osteoporosis, type 2 diabetes (T2D), body mass index (BMI), osteoarthritis (OA), ankylosing spondylitis (AS), and rheumatoid arthritis (RA) (total sample size: N = 462,933-461,194 Europeans). Genetic covariance matrices were constructed via LD score regression, followed by latent factor modeling to dissect shared genetic architecture. Novel loci were prioritized using FUMA-based functional annotation, fine-mapping (SuSIE/FINEMAP), transcriptome-wide association studies (TWAS/FUSION), and cell-type enrichment analyses. Results Genomic-SEM identified 37 novel risk loci ($P < 5 \times 10(-)(8)$), including 14 genome-wide significant loci ($P < 5 \times 10(-)(1)(6)$). Fine-mapping revealed causal variants (posterior probability > 0.95) on chromosome 1 (rs1415145), chromosome 2 (rs35802221), and chromosome 7 (rs2367906). TWAS implicated FERMT3 (beta = +1.85, $P = 2.3 \times 10(-)(6)$), CCDC88B (beta = +2.01, $P = 1.7 \times 10(-)(5)$), and USP53 (beta = -1.72, $P = 4.1 \times 10(-)(4)$) in BMetDs through cerebellar-hypothalamic gene expression. Cell-type enrichment highlighted pancreatic B cells (FDR = 0.03) and brain non-myeloid neurons (FDR = 0.04) as key mediators. Partitioned heritability analysis demonstrated significant enrichment in enhancer (H3K27ac, $P = 1.1 \times 10(-)(7)$) and chromatin boundary (CTCF, $P = 3.4 \times 10(-)(5)$) regions, supporting epigenetic dysregulation in BMetDs pathogenesis. Conclusion This study uncovers novel genetic loci and cross-tissue regulatory mechanisms driving BMetDs, emphasizing the pivotal roles of the bone-brain axis and non-coding regulatory elements. Our findings bridge genomic insights with translational applications, offering actionable targets for precision interventions in metabolic bone diseases.

ID progression; severity; luteolin; access; il-17
AB BackgroundOsteoarthritis (OA), a leading cause of disability worldwide, is characterized by complex interactions between cartilage degradation and synovial inflammation. While NSAIDs are the primary treatment, their prolonged use exacerbates gastrointestinal risks and does not alter disease progression. Xianlinggubao (XLGB), an approved Chinese herbal remedy for osteoporosis, has demonstrated promising anti-osteoarthritic effects in preliminary studies. However, its multi-component mechanisms targeting OA-related inflammation require further clarification. This study integrates network pharmacology with experimental validation to investigate XLGB's anti-inflammatory mechanisms in OA.MethodsBioactive compounds of XLGB and their respective targets were sourced from the TCMSP, ETCM, SymMap, and ChEMBL databases. Targets linked to OA-related inflammation were identified through differential expression analysis and by querying OMIM, GeneCards, and PubMed Gene databases. Network pharmacology and bioinformatics approaches were employed to construct compound-target and protein-protein interaction (PPI) networks, enabling the identification of pivotal therapeutic targets. Functional enrichment of these targets was performed using the ClusterProfiler package in R. The binding affinity of compounds to anti-inflammatory OA targets was assessed through molecular docking, dynamics simulations, RT-PCR, and immunofluorescence assays.ResultsFifty-five bioactive compounds corresponding to 475 XLGB targets and 125 genes involved in OA-related inflammation were identified. PPI network analysis revealed that XLGB may alleviate OA inflammation by modulating key genes, including COX-2, IL-1 beta, TNF, IL-6, and MMP-9. Molecular simulations indicated strong binding affinities between bioactive compounds in XLGB and these critical targets. Functional enrichment analysis suggested that XLGB's anti-inflammatory action in OA may involve regulation of pathways such as IL-17, TNF, and NF-kappa B. In vitro experiments further confirmed that XLGB mitigates OA inflammation by modulating these genes, proteins, and signaling pathways.ConclusionsThrough network pharmacology, this study elucidated the mechanisms of XLGB in OA inflammation, highlighting its modulation of IL-6, IL-1

beta, TNF-alpha, PTGS2, MMP-9, and the NF-kappa B pathway. These findings provide strong support for the clinical application of XLGB in managing OA-related inflammation.

TI Side-to-side differences in hip bone mineral density in patients with unilateral hip osteoarthritis
SO BONE
LA English
DT Article
DE Artificial intelligence; Discordance; Divergence; Deep learning; DXA; Quantitative computed tomography
ID diagnosis; osteoporosis; association; prevalence; validation; dysplasia; femur; women; knee
AB Background: Accurately evaluating bone mineral density (BMD) in patients with unilateral hip osteoarthritis (OA) is crucial for diagnosing osteoporosis and selecting implants for hip arthroplasty. Our goal was to measure the BMD differences between sides, examine contributing factors, and identify the optimal side for BMD assessment in these patients. Methods: We analyzed 108 women with unilateral hip OA. Bilateral hip BMD was assessed automatically through quantitative CT (QCT) utilizing a validated, deep-learning-based approach. We evaluated BMD variations between the OA and healthy hips across total, neck, and distal regions. To determine their contributions, we analyzed factors, including patient demographics, Crowe classification, Bombelli classification, knee OA status, hip functional score, and gluteal muscle volume and density. Furthermore, we examined how side-to-side BMD differences influenced osteoporosis diagnosis using T-scores based on QCT. Results: The average BMD on the OA side was 6.9 % lower in the total region, 14.5 % higher in the neck region, and 9.4 % lower in the distal region than on the healthy side. Contributing factors to the reduced BMD in the OA hip included younger age, Bombelli classification (atrophic type), and significant gluteal muscle atrophy. Diagnoses from the OA side revealed lower sensitivity (61 %) than those from the healthy side (88 %). Conclusions: Analysis on one side alone yields a more precise osteoporosis diagnosis from the healthy side. Nonetheless, bilateral BMD assessment remains crucial, particularly in younger individuals and those with atrophic OA types. Although based on QCT, our findings support bilateral analysis by dual-energy X-ray absorptiometry for these patients.

TI Molecular mechanisms and therapeutic implications of the sympathetic nervous system in bone-related disorders: a brain-bone axis perspective
SO BONE RESEARCH
LA English
DT Review
ID vasoactive-intestinal-peptide; neuropeptide-y; leptin receptor; rheumatoid-arthritis; synovial tissue; innervation; expression; osteoporosis; antagonist; inhibition
AB The global aging crisis has increased the prevalence of skeletal disorders, necessitating innovative therapeutic strategies. This review employs the brain-bone axis (BBA) framework to examine the role of the sympathetic nervous system (SNS) in bone metabolism. The research systematically elucidates the molecular mechanisms by which the SNS mediates signaling pathways through neurofibers and neurotransmitters, such as norepinephrine, dopamine, neuropeptide Y, and leptin, regulating interactions between bone-related cells to maintain skeletal homeostasis. It also identifies the pathological associations between the dysregulation of these pathways and the progression of bone-related conditions, such as osteoporosis, osteoarthritis, and intervertebral disc degeneration. By integrating current evidence, we identify novel therapeutic targets within the BBA and propose neuro-centric intervention strategies to mitigate skeletal diseases. This review deepens the understanding of neuro-skeletal interactions and lays a foundation for innovative treatments for bone-related pathologies.

TI Treatment of Osteoporosis and Osteoarthritis in the Oldest Old
SO DRUGS
LA English
DT Review
ID nonsteroidal antiinflammatory drugs; bone-mineral density; dietary-protein intake; proton-pump inhibitors; women aged 80; postmenopausal women; fracture risk; hip fracture; knee osteoarthritis; zoledronic acid
AB Osteoporosis and osteoarthritis are key diseases of musculoskeletal ageing and are increasing in prevalence and burden with the progressively ageing population worldwide. These conditions are thus particularly common in 'the oldest old', and there are complexities of managing them within the context of extensive multimorbidity, physical and mental disability, and polypharmacy, the rates for all of which are high in this population. In this narrative review, we explore the epidemiology of osteoporosis and osteoarthritis in the oldest old before examining trials and real-world data relating to the pharmacological treatment of these diseases in older adults, including anti-resorptives and bone-forming agents in osteoporosis and symptomatic slow-acting drugs for osteoarthritis, paracetamol, and non-steroidal anti-inflammatory drugs in osteoarthritis, recognising that the oldest old are usually excluded from clinical trials. We then review the potential benefits of nutritional interventions and exercise therapy before highlighting the health economic benefits of interventions for osteoporosis and osteoarthritis. The high prevalence of risk factors for both disease and adverse events associated with treatment in the oldest old mean that careful attention must be paid to the potential benefits of intervention (including fracture risk reduction and improvements in osteoarthritis pain and function) versus the potential harms and adverse effects. Further direct evidence relating to such interventions is urgently needed from future research.

TI Bone mineral density assessment using radiofrequency echographic multispectrometry (REMS) in patients before and after total hip replacement
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE Bone mineral density; Osteoporosis; Radiofrequency echographic multispectrometry
ID calcaneus in-vivo; methodology
AB REMS-BMD by radiofrequency echographic multispectrometry is primarily determined by a patient's BMI, age, and sex. Only about 2.8% of the changes in

femoral neck REMS-BMD can be attributed to replacement of the total hip with metal implants. Purpose This study aimed to evaluate how total hip replacement affects femoral neck REMS-BMD and to examine the contributions of a patient's sex, age, and BMI to the REMS-BMD assessment. Methods REMS-BMD was measured at the proximal femur using EchoStation (Echolight Spa, Lecce, Italy) in 27 women and 23 men with advanced hip osteoarthritis before surgery and again on the third day following total hip joint arthroplasty. For seven men, REMS-BMD was measured at both the proximal femur and lumbar spine, taking into account their actual as well as varying age, height, and weight. Results The patients' ages ranged from 49 to 84 years, with the REMS-BMD T-score values for the femoral neck varying from + 1.8 to - 3.2. There was a significant correlation between the femoral neck REMS-BMD values measured before and after total hip arthroplasty. Post-surgery, the femoral neck REMS-BMD values showed a consistent decrease of - 0.021 g/cm(2) (approximately 2.8%, $p < 0.05$) compared to pre-operative measurements. A model incorporating age, sex, and BMI accurately predicted femoral neck REMS-BMD in both pre- and postoperative settings, with no evidence of systematic bias. Variations in REMS-BMD were observed in both the femoral neck and lumbar spine when measurements were taken in the same patients under different conditions of age, height, and weight. Conclusion Approximately 90% of the variability in REMS-BMD of the femoral neck can be attributed to the patient's age, sex, and BMI. Further research is needed to determine the extent to which REMS-BMD reflects areal or volumetric BMD, and how backscattered radiofrequency ultrasound signals influence the REMS-BMD.
