TI Immunoexpression of IGF1, IGF2, and osteopontin in craniofacial bone repair associated with autogenous grafting in rat models treated with alendronate sodium
SO CLINICAL ORAL INVESTIGATIONS
LA English
DT Article
DE Bisphosphonates; Rats; Bone healing; IGF1; IGF2; Osteopontin
ID risk-factors; insulin; osteonecrosis; jaw; resorption; implants; estrogen; density; cancer
AB The aim of this study was to verify the likely influence of presurgical administration of low doses of alendronate sodium in craniofacial bone repair and correlate the histological frame found on reparative tissue to the immunohistochemical presence of IGF1, IGF2, and osteopontin (OP). In total, 120 rats were randomly allocated into four groups: group C (control), group OA (autogenous bone), group B (bisphosphonates), and group OA-B (autogenous bone + bisphosphonates). Groups B and OA-B received alendronate sodium (ALN) 0.01 mg/kg subcutaneously on alternate days for 4 weeks. Groups C and OA received saline solution. Critical 5-mm defects were created in rat calvaria, which were filled with blood clot in groups C and B and with autogenous bone in groups OA and OA-B. The animals were euthanized at 15 or 30 days postoperatively. Histological analysis and immunohistochemistry of IGF1, IGF2, and OP proteins was performed. Immunohistochemistry evaluated the expression in cells and extracellular matrix. Groups C and B revealed healing predominantly characterized by connective tissue. In groups OA and OA-B, healing of connective tissue and neoformation of compact bone was observed. Expression of IGF1 an OP was present in all specimens. IGF1 expression in cells was more pronounced in groups OA and OA-B 15 days postoperatively. The expression of IGF2 was only observed in groups OA and OA-B, with greater intensity in group OA-B 30 days postoperatively. OP expression was only observed in cells and not in the extracellular matrix and

was more pronounced in group OA 15 days postoperatively. The application of systemic ALN at a dose of 0.01 mg/kg did not improve cranial bone matrix deposition. Nevertheless, the expression of IGF1 and OP and a slight marking of IGF2 were observed especially in groups OA and OA-B in the wound healing process. Future studies should assess higher doses of ALN to verify its influence on bone repair. The systemic use of ALN 0.01 mg/kg on alternate days 4 weeks prior to surgery did not interfere with bone repair.

TI Five common clinical presentations in the elderly: An anatomical review
SO CLINICAL ANATOMY
LA English
DT Article
DE anatomy; ageing; geriatrics; fractures; spine; congestive heart failure; dementia; airway
ID age-related-changes; alzheimers-disease; computed-tomography; cellular basis; heart-failure; fractures; impact; adults; osteoarthritis; osteoporosis
AB Elderly patients face distinct health challenges and have an increased demand for specific medical procedures. As the aging population continues to increase, age-associated conditions such as congestive heart failure, hip fractures, spine degeneration, dementia, and airway compromise will increase in prevalence and procedures to correct these conditions will be increasingly performed. A clear understanding of the clinical anatomy of these diseases and procedures is imperative for anatomists and clinicians alike in order to best treat patients and continue to advance aging research and better teach future medical practitioners about the specific anatomy often involved in this group. The aging process mirrors in a variety of ways the common pathologies of the elderly, but it is key to draw the distinction between normal aging and pathology, particularly for congestive heart failure and dementia, in the clinical setting. This article aims to review the common presentations or procedures of the elderly and how the normal aging process is associated with the anatomy of these conditions or complications. Clin. Anat. 30:168-174, 2017. (c) 2017 Wiley Periodicals, Inc.

TI Cementless Total Hip Arthroplasty in Octogenarians
SO JOURNAL OF ARTHROPLASTY
LA English
DT Article
DE total hip arthroplasty; cementless; octogenarians; outcome; complications
ID bone-mineral density; early failure rate; periprosthetic fractures; femoral fractures; replacement; older; osteoporosis; femur; joint; stem
AB Background: Although several studies indicate excellent results for cementless implants, controversy persists regarding its use in elderly patients. We determined to evaluate the outcome on patients aged over 80 years who were treated with cementless total hip arthroplasty for primary osteoarthritis of the hip. Methods: We assessed the data of 162 consecutive total hip arthroplasties in octogenarian patients (mean age 83 years, range 80-96 years). A control group was created, consisting of 342 patients aged younger than 80 years (mean age 65 years, range 37-79 years). The median follow-up of the cohort was 128.4 months (range 6-211). Results: Competing risk analyses revealed a cumulative implant survival of 98.1% at 5 and 10 years in the study group compared to 99.1% and 98.4% in the control

group, taking system exchange as the end point. No differences in regard to system exchange could be detected between the groups. A significantly worsened complication-free survival rate was evident in the octogenarian group. Osteoporosis was the most powerful risk factor that proved to have a significant negative impact on development of complications. Conclusion: Uncemented total hip arthroplasty is a viable option for the elderly patient. In this population sector, an excellent rate of implant survival can be expected. However, a significant increase of total complications in the octogenarian group could be detected, and was mainly caused by an elevated number of early postoperative complications. Osteoporosis turned out to be a strong risk factor in regard to complication-free survival. Surgeons should therefore be aware of this. (C) 2017 Elsevier Inc. All rights reserved.

TI Patterns of Care Among Patients Referred to Rheumatologists in Ontario, Canada
SO ARTHRITIS CARE & RESEARCH
LA English
DT Article
ID diagnosed rheumatoid-arthritis; early inflammatory arthritis; quality-of-care; performance-measures; management; physicians; symptoms; delay; onset; time
AB ObjectiveOur aim was to characterize referrals to rheumatologists, the early care management of patients with rheumatic diseases, and timeliness of care and treatment. MethodsWe conducted a retrospective observational study involving patients with first-time rheumatology referrals between 2000 and 2013 in the primary care Electronic Medical Record Administrative data Linked Database (EMRALD) in Ontario, Canada. Referrals were characterized in terms of diagnoses, patient demographics, diagnostic tests, treatment initiated by family physicians and rheumatologists, and other specialists seen prior to rheumatology consultation. Timeliness of referrals, rheumatologist consultations, and treatment were determined overall and for each diagnostic category. ResultsAmong 2,430 patients referred to a rheumatologist, 69% were female, with an average age of 53 years. The principal diagnosis associated with the referral included osteoarthritis (32%), systemic inflammatory rheumatic diseases (31%), regional musculoskeletal conditions (16%), chronic pain conditions (14%), osteoporosis (2%), and other/miscellaneous (5%). Family physicians most frequently prescribed nonsteroidal antiinflammatory drugs/cyclooxygenase 2 inhibitors (38%), and their pre-referral diagnostic testing practice varied considerably. The duration of time from symptom onset to rheumatology consultation varied by diagnoses, with the shortest being for patients with systemic rheumatic diseases; for rheumatoid arthritis (RA), the median time to consultation was 327 days. Most of the delay occurred prior to referral; 36% of RA patients initiated a disease-modifying

antirheumatic drug within 6 months of symptom onset. ConclusionApproximately 1 in 3 referrals to rheumatologists were for a systemic inflammatory rheumatic disease. We observed substantial delays to rheumatology consultations and variations in patterns of care that could be amenable to quality improvement interventions.

TI A review of TiO2 NTs on Ti metal: Electrochemical synthesis, functionalization and potential use as bone implants
SO MATERIALS SCIENCE AND ENGINEERING C-MATERIALS FOR BIOLOGICAL APPLICATIONS
LA English
DT Review
DE Titanium implants; Osteogenesis; TiO2 nanotubes
ID biomedical applications; titania nanotubes; cell-adhesion; surface; growth; anodization; release; biocompatibility; mineralization; therapeutics
AB Degenerative diseases of bone such as osteoarthritis and osteoporosis can lead to bone fractures and immobility, compromising quality of life. Titanium (Ti)-based implants have been intensively investigated for bone repair, with these implants, demonstrating improved outcomes compared to stainless steel and cobalt-chrome alloys, owing to superior mechanical properties and biocompatibility. However, osseointegration between the Ti based implants and the surrounding bone tissue needs to be improved. Surface modification of Ti-based implants provides a solution for addressing this, with electrochemical anodization becoming a realistic approach for the fabrication of hierarchical structured for example nanotubes (NTs), implant surfaces. Using this technique, biocompatibility and osteogenesis of the implant may be improved, by providing an appropriate site for bone cell attachment. In this review, we discuss the anodization of Ti -based implants as an approach for creating titanium dioxide nanotubes (TiO2 NTs) on the implant surface. We further discuss the various ways of functionalizing the NT surface, to reduce post-operative infection and improve implant biocompatibility and osseointegration. (C) 2017 Elsevier B.V. TI Decreased trabecular bone deterioration of proximal tibiae and lumbar vertebrae

in postmenopausal women with osteoarthritis
SO EXPERIMENTAL AND THERAPEUTIC MEDICINE
LA English
DT Article
DE osteoarthritis; postmenopausal osteoporosis; bone morphometry; trabecular bone
ID mineral density; hip osteoarthritis; rheumatoid-arthritis; spine osteoarthritis; knee osteoarthritis; general-population; cancellous bone; femoral-head; osteoporosis; fractures
AB Osteoporosis and osteoarthritis (OA) are two common age-related skeletal disorders, which are associated with substantial morbidity and disability, particularly among elderly women. The present study was performed to investigate the trabecular bone deterioration of proximal tibiae and lumbar vertebrae in postmenopausal women with OA. The results demonstrated that the histomorphometric section of trabecular bone below the growth plate was markedly different between the healthy control and OA group. However, the loss of trabecular bone underneath the growth plate in the healthy control group was significantly worse than that of the OA group. Hematoxylin and eosin staining demonstrated the increased disconnection and separation of the trabecular bone network as well as the reduction of trabecular bone mass of primary and secondary spongiosa throughout the proximal metaphysis of tibia in the healthy control compared to the OA group; similar results were found when the same experiment was repeated on the lumbar vertebrae of healthy control subjects and OA patients from postmenopausal women. The biological properties of trabecular bone in the proximal tibia and lumbar vertebrae were measured in postmenopausal women with OA. Spearman's rank correlation analysis revealed that the bone volume fraction was both positively correlated with radiographic severity and Western Ontario McMaster University Osteoarthritis Index scores in in the proximal tibia and lumbar vertebrae from postmenopausal women with OA. In conclusion, the structural properties of the proximal tibia and lumbar vertebrae supported that an inverse correlation existed between postmenopausal women with OA and healthy controls. Moreover, there is an important protective mechanism of OA on trabecular microstructure in proximal tibiae and lumbar vertebrae from postmenopausal women.

TI Machine Learning Principles Can Improve Hip Fracture Prediction
SO CALCIFIED TISSUE INTERNATIONAL
LA English
DT Article
DE Osteoporosis; Fracture; Machine learning; FRAX; Prediction
ID osteoporotic fractures; risk; men; fit; bmd
AB Apply machine learning principles to predict hip fractures and estimate predictor importance in Dual-energy X-ray absorptiometry (DXA)-scanned men and women. Dual-energy X-ray absorptiometry data from two Danish regions between 1996 and 2006 were combined with national Danish patient data to comprise 4722 women and 717 men with 5 years of follow-up time (original cohort n = 6606 men and women). Twenty-four statistical models were built on 75% of data points through k-5, 5-repeat cross-validation, and then validated on the remaining 25% of data points to calculate area under the curve (AUC) and calibrate probability estimates. The best models were retrained with restricted predictor subsets to estimate the best subsets. For women, bootstrap aggregated flexible discriminant analysis ("bagFDA") performed best with a test AUC of 0.92 [0.89; 0.94] and well-calibrated probabilities following Na < ve Bayes adjustments. A "bagFDA" model limited to 11 predictors (among them bone mineral densities (BMD), biochemical glucose measurements, general practitioner and dentist use) achieved a test AUC of 0.91 [0.88; 0.93]. For men, eXtreme Gradient Boosting ("xgbTree")

performed best with a test AUC of 0.89 [0.82; 0.95], but with poor calibration in higher probabilities. A ten predictor subset (BMD, biochemical cholesterol and liver function tests, penicillin use and osteoarthritis diagnoses) achieved a test AUC of 0.86 [0.78; 0.94] using an "xgbTree" model. Machine learning can improve hip fracture prediction beyond logistic regression using ensemble models. Compiling data from international cohorts of longer follow-up and performing similar machine learning procedures has the potential to further improve discrimination and calibration.

TI Health amongst former rugby union players: A cross-sectional study of morbidity and health-related quality of life
SO SCIENTIFIC REPORTS
LA English
DT Article
ID bone-mineral density; physical-activity; general-population; osteoarthritis; injury; eq-5d; risk; reliability; concussion; benefits
AB In the general population, physical activity is associated with improved health outcomes. However, long-term sports participation may be associated with adverse outcomes, particularly at the elite level. The aims of this study were to assess morbidity and health-related quality of life (HrQoL) amongst former rugby players, compared to an age-standardised general population sample. A cross-sectional study of former elite, male, rugby players (n = 259) was undertaken, and standardised morbidity ratios (SMR) calculated, assessing morbidity prevalence relative to English Longitudinal Study of Aging participants (ELSA, n = 5186). HrQoL, measured using the EQ-5D, was compared to a Health Survey for England (HSE, n = 2981) sample. In SMR analyses of participants aged 50+, diabetes was significantly lower amongst former players, (0.28, 95% CI 0.11-0.66), whereas osteoarthritis (4.00, 95% CI 3.32-4.81), joint replacement (6.02, 95% CI 4.66-7.77), osteoporosis (2.69, 95% CI 1.35-5.38), and anxiety (2.00, 95% CI 1.11-3.61) were significantly higher. More problems in HrQoL were reported amongst former players within the domains of mobility ($p < 0.001$), self-care ($p = 0.041$), usual activities ($p < 0.001$) and pain/discomfort ($p < 0.001$). Morbidity and HrQoL differ between players and the general population, with higher musculoskeletal morbidity and lower diabetes amongst former players. The magnitude of

musculoskeletal morbidity may warrant proactive osteoarthritis management within this population.

TI Associations between systemic bone mineral density and early knee cartilage changes in middle-aged adults without clinical knee disease: a prospective cohort study
SO ARTHRITIS RESEARCH & THERAPY
LA English

DT Article
DE Bone mineral density; Cartilage volume; Cartilage defects; Osteoarthritis; Knee
ID early radiographic osteoarthritis; inverse relationship; subchondral bone; surface-area; volume; osteoporosis; defects; determinants; progression; symptoms
AB Background: Osteoarthritis has a high prevalence in people with high bone mineral density (BMD). Nevertheless, whether high systemic BMD predates early structural features of knee osteoarthritis is unclear. This study examined the association between systemic BMD and knee cartilage defect progression and cartilage volume loss in middle-aged people without clinical knee disease. Methods: Adults (n = 153) aged 25-60 years had total body, lumbar spine, and total hip BMD assessed by dual-energy X-ray absorptiometry at baseline (2005-2008), and tibial cartilage volume and tibiofemoral cartilage defects assessed by magnetic resonance imaging at baseline and follow up (2008-2010). Results: Higher spine BMD was associated with increased risk for progression of medial (OR = 1.45, 95% CI 1.10, 1.91) and lateral (OR = 1.30, 95% CI 1.00, 1.67) tibiofemoral cartilage defects. Total hip BMD was also positively associated with the progression of medial (OR = 1.63, 95% CI 1.10, 2.41) and lateral (OR = 1.53, 95% CI 1.08, 2.18) tibiofemoral cartilage defects. Greater total body, spine, and total hip BMD were associated with increased rate of lateral tibial cartilage volume loss (for every 1 g/10 cm(2) increase in total body BMD: B = 0.44%, 95% CI 0.17%, 0.71%; spine BMD: 0.17%, 95% CI 0.04%, 0.30%; total hip BMD: 0.29%, 95% CI 0.13%, 0.45%), with no significant associations for medial tibial cartilage volume loss. Conclusion: In middle-aged people without clinical knee disease, higher systemic BMD was associated with increased early knee cartilage damage. Further work is needed to clarify the effect of systemic BMD at different stages of the pathway from health through to disease in knee osteoarthritis, as new therapies targeting bone are developed for the management of knee osteoarthritis.

TI Frailty in HIV infected people: a new risk factor for bone mineral density loss
SO AIDS
LA English
DT Article
DE bone mineral density; frailty; HIV
ID antiretroviral therapy; older women; phenotype; osteoporosis; fracture; men
AB Objective:The study aims to assess the association between bone mineral density (BMD) and frailty in a cohort of HIV-infected patients.Design:A cross-sectional study in an HIV outpatient unit where nearly 1000 patients are monitored.Methods:Study participants undergoing bone densitometry were proposed an evaluation of frailty using criteria of the Cardiovascular Health Study (CHS) and the Study of Osteoporotic Fractures (SOF). Frailty markers were weight-loss, self-reported exhaustion, physical activity, grip strength, chair stands, and slow gait. Patients' characteristics were collected from an electronic medical record. Associations of frailty with BMD and osteoporosis were tested using multivariate linear and logit regression models, respectively.Results:In total, 175 HIV-infected patients, 121 (69.14%) men, were analyzed. Prevalence of frailty markers, osteopenia, and osteoporosis were comparable among sexes. Despite a younger age, spinal and femoral neck BMD were lower in women ($P<0.05$). Linear regression model adjusting by age, duration of HIV follow-up, BMI, smoking status, osteoarthritis, osteoporosis treatment, and the age at menopause showed a negative association of spinal and femoral BMD with frailty according to SOF criteria in women ($P<0.05$). In men, SOF-defined frailty was associated with osteoporosis (odds ratio 28.79; 95% confidence interval 2.15-386.4) in a model adjusting for age, duration of HIV follow-up, CD4(+) nadir, CD4(+) T-cell count, tobacco consumption, exposure to tenofovir (TDF) and protease inhibitors. No significant associations were found between BMD and CHS-defined frailty.Conclusion:Our study shows that frailty according to SOF criteria is

associated with low spinal BMD values in female and osteoporosis in male HIV-infected patients. Copyright (C) 2017 Wolters Kluwer Health, Inc. All rights reserved.

TI Results at a minimum follow-up of 5 years of a ligaments-compatible total ankle replacement design
SO FOOT AND ANKLE SURGERY
LA English
DT Article
DE Ankle; Replacement; Arthritis; Trauma
ID long-term; arthroplasty; rates; osteoarthritis; complications; arthrodesis; mobility; motion; range
AB Background: A new design of 3-part ankle replacement was developed to achieve compatibility with the natural ligaments by allowing certain fibers to remain isometric during passive motion. Methods: We evaluate 75 ankle prostheses implanted from July 2003 to December 2008, at a mean follow-up 6.5 +/- 1.1 years (range 5-9 years). The mean age at surgery was 62 +/- 13 years (range 29-82). Results: The mean AOFAS scores achieved at pre-op and at last follow-up were

respectively 37 +/- 5 (23-45) and 78 +/- 8 (64-98). (p < 0.001). Clinical range of motion of the ankle measured by goniometer pre op was 1 degrees +/- 2 of dorsiflexion and 12 degrees +/- 4 degrees of plantarflexion; at last follow- up range of motion increased to 6 degrees +/- 5 degrees in dorsiflexion (p < 0.01) and 18 degrees +/- 7 degrees in plantarflexion (p < 0.05). Radiographs showed no loosening and little signs of radiolucency. Two revisions necessitated component removal, neither for implant loosening. The overall survival rate was 97.3%. Conclusions: Function and Range-of-motion showed significant improvements. These results demonstrate that ligaments-compatible shaped talar and tibial components, with a fully conforming interposed meniscal bearing, can provide satisfactory survival rates and clinical outcomes in the middle term. TI Metabolic Bone Diseases and Total Hip Arthroplasty: Preventing Complications
SO JOURNAL OF THE AMERICAN ACADEMY OF ORTHOPAEDIC SURGEONS
LA English
DT Review
ID pagets-disease; osteogenesis imperfecta; replacement; osteoarthritis; management; fracture; osteonecrosis; osteoporosis; diagnosis; risk
AB Metabolic bone diseases are a diverse group of conditions characterized by abnormalities in calcium metabolism and/or bone cell physiology. These unbalanced processes can eventually lead to bony deformities and altered joint biomechanics, resulting in degenerative joint disease. Not infrequently, patients with metabolic bone diseases have restricting hip joint pain that ultimately necessitates hip arthroplasty. To minimize complications, the surgeon must consider the particular characteristics of these patients. The surgical and medical management of patients with metabolic bone diseases undergoing hip arthroplasty requires appropriate preoperative diagnosis, careful attention to the technical challenges of surgery, and strategies to maximize the long-term results of the surgical intervention, such as the use of bone anabolic and anticatabolic agents.

TI The association between insulin-like growth factor 1 (IGF-1), IGF-binding proteins (IGFBPs), and the carboxyterminal propeptide of type I procollagen (PICP) in pre- and postmenopausal women with rheumatoid arthritis
SO SCANDINAVIAN JOURNAL OF RHEUMATOLOGY
LA English
DT Article

ID bone turnover; cartilage destruction; biochemical markers; disease-activity; female-patients; serum-levels; factor-axis; osteoporosis; osteoarthritis; expression
AB Objectives: To assess the association between plasma levels of the insulin-like growth factor (IGF) system including IGF-1, IGF-binding proteins (IGFBPs) including IGFBP-1, total (t-)IGFBP-3 and functional (f-)IGFBP-3, and the carboxyterminal propeptide of type I procollagen (PICP) in pre- and postmenopausal women with rheumatoid arthritis (RA).Method: Plasma concentrations of IGF-1, IGFBP-1, t-IGFBP-3, f-IGFBP-3, and PICP were measured by immunoassay.Results: No significant difference was observed in plasma IGF-1 levels between pre- and postmenopausal subjects. Plasma levels of IGFBP-1 were elevated in RA. PICP and f-IGFBP-3 were greatly affected by menopausal status. Of the three IGFBPs tested, only f-IGFBP-3 plasma levels in RA women correlated negatively with age and disease duration. A positive correlation was demonstrated between PICP and erythrocyte sedimentation rate (ESR) in RA. Moreover, there was no correlation between PICP and IGF-1 and any of the IGFBPs in RA women.Conclusions: Considerable disruption of the IGF system in RA was found to be related to disease activity and duration. Changes in the IGF-IGFBP axis and PICP levels were different in pre- and postmenopausal women with RA. Elevated plasma PICP concentrations may indicate an increased rate of bone formation in postmenopausal RA women. Additionally, the observed changes in the IGF/IGFBP system did not affect bone formation during RA.

TI Implications of Age-Related Changes in Anatomy for Geriatric-Focused Difficult Airways
SO INTERNATIONAL JOURNAL OF GERONTOLOGY
LA English
DT Review
DE difficult airways; difficult intubation; difficult mask ventilation; geriatric airway
ID impossible mask ventilation; endochondral ossification; chondrocyte apoptosis; predictive factors; older-adults; oral-mucosa; intubation; management; risk; laryngoscopy
AB The structure and function surrounding the airway change by the age, which may ultimately result in having anatomic features of difficult airways in the elderly. Hence, we reviewed the literature focusing on the age-related anatomic changes and accordingly to compare the characteristics of difficult airways. With age, teeth wear and loss, protein and collagen synthesis reduction, and bone loss and muscle atrophy results in aged face (chin protrusion, cheek retraction and drooping), jaw restriction (temporo-madibular joint disc displacement and osteoarthritis), neck and back stiffness, and kyphotic deformities (degeneration of spinal articular cartilage, intervertebral discs, and spinal osteoporosis). These age-related changes in anatomy are compatible with the predictors of a difficult airway. We hope that these age-related anatomic approaches will prospectively allow a detailed understanding of the hallmarks resulting in geriatric-focused difficult airways in the future studies. TI Is osteoporosis a predictor for future sarcopenia or vice versa? Four-year observations between the second and third ROAD study surveys
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE Incidence; Osteoporosis; Osteosarcopenia; Population-based cohort study; Sarcopenia
ID bioelectrical-impedance analysis; dwelling elderly subjects; skeletal-muscle mass; working group; older men; prevalence; community; association; epidemiology; definition
AB In a 4-year follow-up study that enrolled 1099 subjects aged ae60 years, sarcopenia prevalence was estimated at 8.2%. Moreover, the presence of osteoporosis was significantly associated with short-term sarcopenia occurrence, but the reciprocal relationship was not observed, suggesting that osteoporosis would increase the risk of osteoporotic fracture and sarcopenia occurrence. The present 4-year follow-up study was performed to clarify the prevalence, incidence, and relationships between sarcopenia (SP) and osteoporosis (OP) in older Japanese men and women. We enrolled 1099 participants (aged, ae60 years; 377 men) from the second survey of the Research on Osteoarthritis/Osteoporosis against Disability (ROAD) study (2008-2010) and followed them up for 4 years. Handgrip strength, gait speed, skeletal muscle mass, and bone mineral density were assessed. SP was defined according to the Asian Working Group for Sarcopenia. OP was defined based on the World Health Organization criteria. SP prevalence was 8.2% (men, 8.5%; women, 8.0%) in the second survey. In those with SP, 57.8% (21.9%; 77.6%) had OP at the lumbar spine L2-4 and/or femoral neck. SP cumulative incidence was 2.0%/year (2.2%/year; 1.9%/year). Multivariate regression analysis revealed that OP was significantly associated with SP occurrence within 4 years (odds ratio, 2.99; 95% confidence interval, 1.46-6.12; $p < 0.01$), but the reciprocal relationship was not significantly observed (2.11; 0.59-7.59; $p = 0.25$). OP might raise the short-term risk

of SP incidence. Therefore, OP would not only increase the risk for osteoporotic fracture but may also increase the risk for SP occurrence.

TI Reported balance confidence and movement reinvestment of younger knee replacement patients are more like younger healthy individuals, than older patients
SO GAIT & POSTURE
LA English
DT Article
DE Total knee replacement; Age-related differences; Balance confidence; Movement reinvestment; Functional mobility
ID joint replacement; community; pain; efficacy; surgery; falls
AB This study focused on differences between the rapidly growing younger (< 65 years old) and older (> 65 years old) total knee replacement (TKR) patients for measures of balance confidence, movement reinvestment, and functional mobility. Fifty-nine participants, including twenty-nine primary unilateral TKR patients (six months post-TKR) formed the four experimental groups: 1) Younger TKR Patient (YP), 2) Younger Control (YC), 3) Older TKR Patient (OP), and 4) Older Control (OC). The Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC), the Oxford Knee Score (OKS), Activities-specific Balance Confidence scale (ABC), the Movement-Specific Reinvestment Scale (MSRS), and the Timed Up and Go (TUG) test were measured. The YP group reported a significantly lower WOMAC score ($p < 0.001$), and higher perceived knee joint function ($p = 0.001$), compared to the OP group. The YP group also reported significantly higher balance confidence ($p < 0.001$) and less movement reinvestment ($p = 0.001$) than the OP group. TUG durations revealed that the YP group had significantly higher functional mobility compared to the OP group ($p = 0.001$). The YP group did not differ from the YC group across any of these measures ($p > 0.05$). These results identify a clear distinction between younger and older TKR patients for fall risk and TKR outcome, which argues that age should be a factor clinicians take into account when addressing the management and care of individuals recovering from TKR.

TI Association between bone mineral density and knee osteoarthritis in Koreans: the Fourth and Fifth Korea National Health and Nutrition Examination Surveys
SO OSTEOARTHRITIS AND CARTILAGE

LA English
DT Article
DE Osteoarthritis; Bone density; Osteoporosis; Epidemiology; Aged
ID elderly-men; radiographic osteoarthritis; vitamin-d; women; osteoporosis; turnover; population; rotterdam; hip; incident
AB Objective: The objective of the study was to investigate the association of hip and lumbar spine (LS) bone mineral density (BMD) with the presence and severity of radiographic knee osteoarthritis (OA), including both men and women over 50 years of age, while adjusting for potential confounders. Design: Cross-sectional data from 5793 community-dwelling subjects (2491 men and 3302 women) aged >= 50 years in the Korea National Health and Nutrition Examination Surveys (KNHANES) were analyzed. BMDs for femoral neck (FN), total hip (TH), and LS were measured using dual-energy X-ray absorptiometry. Radiographic changes relating to OA were assessed using the Kellgren-Lawrence (KL) grading scale. The mean BMD, according to the presence of knee OA (KL grade >= 2) and the KL grades, were analyzed using the general linear models (GLM) adjusted for anthropometric and biochemical confounders. Results: Adjusted FN and LS BMD were significantly higher in subjects with knee OA (P = 0.036 and P = 0.001, respectively). Within the subjects with knee OA (KL grades 2, 3 and 4), adjusted FN and TH BMD decreased as the KL grades increased, while the adjusted LS BMD was not different. Among the subjects with KL grades of 0, 1 and 2, FN, TH and LS BMD increased as the KL grades increased. These inverted U-shaped associations between adjusted FN and TH BMD and KL grades were presented in both men and women. The proportion of osteoporosis (OP) was as high as 39.5% among subjects with KL grade 4. Conclusion: There is an inverse relationship between OP and the presence of knee OA, but there is a nonlinear and site-specific association between OP and the severity of knee OA. The relationship between the two diseases has to take into account potential covariates. (C) 2018 Osteoarthritis Research Society International. Published by Elsevier Ltd. All rights reserved.

ID nf-kappa-b; stress-induced apoptosis; articular-cartilage; oxidative stress; inhibition; metabolism; mediators; disease; metalloproteinase; osteoporosis
AB Therapeutics for osteoarthritis (OA) are intended to restore chondrocyte function and inhibit cell apoptosis. Previous studies have shown that gastrodin had anti-apoptotic and anti-inflammatory effects. However, little is known about whether gastrodin has protective effects against the processes of OA. We studied the potential effects of gastrodin on chondrocytes and the underlying mechanisms. Our results showed that gastrodin could prevent chondrocyte apoptosis induced by IL-1 beta. Additionally, gastrodin suppressed the nuclear factor kappa B (NF-kappa B) pathway, decreased the release of inflammatory mediators (IL-6, TNF-alpha), and reduced matrix catabolism in IL-1 beta-treated chondrocytes. Furthermore, gastrodin ameliorated rat cartilage degeneration in an OA model of knee joints in vivo, suggesting its potential as a candidate therapeutic for OA.

TI Visfatin alters the cytokine and matrix-degrading enzyme profile during osteogenic and adipogenic MSC differentiation
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE Osteoporosis; Osteoarthritis; Fragility fracture; Adipokines; Adipogenesis; Osteogenesis; Mesenchymal stem cell
ID mesenchymal stem-cells; rheumatoid-arthritis; bone-marrow; stromal cells; leptin; resistin; disease; osteoclastogenesis; adiponectin; resorption

AB Objectives: Age-related bone loss is associated with bone marrow adiposity. Adipokines (e.g., visfatin, resistin, leptin) are adipocyte-derived factors with immunomodulatory properties and might influence differentiation of bone marrow-derived mesenchymal stem cells (MSC) in osteoarthritis (OA) and osteoporosis (OP). Thus, the presence of adipokines and MMPs in bone marrow and their effects on MSC differentiation were analyzed. Methods: MSC and ribonucleic acid (RNA) were isolated from femoral heads after hip replacement surgery of OA or osteoporotic femoral neck fracture (FF) patients. Bone structural parameters were evaluated by microcomputed tomography (mCT). MSC were differentiated towards adipocytes or osteoblasts with/without adipokines. Gene expression (adipokines, bone marker genes, MMPs, TIMPs) and cytokine production was evaluated by realtime-polymerase chain reaction (realtime-PCR) and enzymelinked immunosorbent assay (ELISA). Matrix mineralization was quantified using Alizarin red S staining. Results: mCT showed an osteoporotic phenotype of FF compared to OA bone (reduced trabecular thickness and increased ratio of bone surface vs volume of solid bone). Visfatin and leptin were increased in FF vs OA. Visfatin induced the secretion of IL-6, IL-8, and MCP-1 during osteogenic and adipogenic differentiation. In contrast to resistin and leptin, visfatin increased MMP2 and MMP13 during adipogenesis. In osteogenically differentiated cells, MMPs and TIMPs were reduced by visfatin. Visfatin significantly increased matrix mineralization during osteogenesis, whereas collagen type I expression was reduced. Conclusion: Visfatin-mediated increase of matrix mineralization and reduced collagen type I expression could contribute to bone fragility. Visfatin is involved in impaired bone remodeling at the adipose tissue/bone interface through induction of proinflammatory factors and dysregulated MMP/TIMP balance during MSC differentiation. TI Development of quality indicators for hip and knee arthroplasty rehabilitation
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE Osteoarthritis; Knee arthroplasty; Hip arthroplasty; Quality; Indicators; Rehabilitation
ID post-acute rehabilitation; of-care; health-care; replacement surgery; united-states; exercise; osteoarthritis; physiotherapy; interventions; metaanalysis
AB Objective: To develop quality indicators (QIs) reflecting the minimum acceptable standard of rehabilitation care before and after elective total hip arthroplasty (THA) and total knee arthroplasty (TKA) for osteoarthritis (OA). Methods: Informed by high quality evidence and using a modified RAND-UCLA Delphi approach, an 18-member Canadian panel of clinicians, researchers and patients considered 81 proposed QIs (40 for THA, 42 for TKA) addressing rehabilitation before and after elective THA and TKA. Panelists rated QIs for their importance and validity on a 9-point Likert scale through two rounds of online rating interspersed with a moderated and anonymous online discussion forum. Those QIs with median ratings of similar to 7 for importance and validity with no disagreement based on the inter-percentile range adjusted for symmetry were included in the final sets. Results: Fifteen panelists from seven provinces and varied practice settings completed the Delphi process. Of the 81 plus one additional QIs (total of 82), 67 (82%) were rated as both important and valid (31 for THA, 36 for TKA). For THA, 14 pre-op, six acute and eight post-acute QIs were accepted. For TKA, 16 pre-op, 10 acute and eight post-acute indicators were accepted. Two of three 'across-continuum' QIs were rated appropriate for both procedures. Conclusion: This work represents the first QIs with which to measure, report and benchmark quality of care in patients receiving rehabilitation before and after THA/TKA surgery. The QIs will be further tested for reliability and feasibility before being widely disseminated in clinical settings and used to assess care gaps. (c) 2018

TI Medical Comorbidity in Alzheimer's Disease: A Nested Case-Control Study
SO JOURNAL OF ALZHEIMERS DISEASE
LA English
DT Article
DE Alzheimer's disease; cholinesterase inhibitors; comorbidity; dementia; nested case-control studies
ID diabetes-mellitus; glucose-levels; risk-factors; dementia; epidemiology; pathology; prevalence; insulin; impact; care
AB Background: Little is known about the distribution of medical comorbidities in Alzheimer's disease (AD). Objective: We aimed to describe the comorbidity pattern of AD in a nested case-control study. Methods: Incident AD cases were identified by International Classification of Diseases codes in a random sample of 2 million individuals in Taiwan National Health Insurance program during 2001-2011. We further restricted cases to those treated with AD drugs of approved reimbursement. We sampled a set of age-and sex-matched control subjects (2: 1 ratio) and employed conditional logistic regression to estimate the associations between pre-specified 14 comorbidities and AD. The clusters of multiple chronic diseases

were then identified by exploratory factor analysis. Results: A total of 2,618 AD cases were identified during 2001-2011 with a mean age of 76.1 years and female preponderance (59%). The most common 5 comorbidities in AD were hypertension (55.1%), osteoarthritis (38.2%), depression (32.3%), diabetes mellitus (DM) (25.7%), and cerebrovascular disease (CVD) (22.7%). After adjusting for age and sex, DM, osteoporosis, depression, and CVD were significantly associated with AD. The number of comorbidity was 3-fold greater in the AD group. The cluster of hypertension, DM, and hyperlipidemia was the most common combination in old age, whereas the cluster osteoarthritis and osteoporosis was the only multimorbidity pattern significantly associated with AD. Conclusion: Multimorbidity is common in AD. Depression, CVD, osteoporosis, and DM are associated with incident AD, supporting that their co-existence is a typical feature of AD at old age. Comorbidity care should be integrated into current management for patients with AD.

TI Evaluation of laser ablation microtomy for correlative microscopy of hard tissues
SO JOURNAL OF MICROSCOPY
LA English
DT Article
DE Bone; enthesis; ligament; osteoarthritis; osteoporosis; tendon
ID articular calcified cartilage; backscattered electron; undecalcified bone; subchondral bone; soft-tissue; osteoarthritis; immunohistochemistry; protrusions; imperfecta; density
AB Laser ablation machining or microtomy (LAM) is a relatively new approach to producing slide mounted sections of translucent materials. We evaluated the method with a variety of problems from the bone, joint and dental tissues fields where we require thin undecalcified and undistorted sections for correlative light microscopy (LM) and backscattered electron scanning electron microscopy (BSE SEM). All samples were embedded in poly-methylmethacrlate (PMMA) and flat block surfaces had been previously studied by BSE-SEM and confocal scanning light microscopy (CSLM). Most were also studied by X-yay microtomography (XMT). The block surface is stuck to a glass slide with cyanoacrylate adhesive. Setting the section thickness and levelling uses inbuilt optical coherence tomographic imaging. Tight focusing of near-infrared laser radiation in the sectioning plane gives extreme intensities causing photodisruption of material at the focal point. The laser beam is moved by a fast scanner to write a cutting line, which is simultaneously moved by an XY positioning unit to create a sectioning

plane. The block is thereby released from the slide, leaving the section stuck to the slide. Light, wet polishing on the finest grade (4000 grit) silicon carbide polishing paper is used to remove a 1-2 m thick damaged layer at the surface of the section. Sections produced by laser cutting are fine in quality and superior to those produced by mechanical cutting and can be thinner than the voxel' in most laboratory X-ray microtomography systems. The present extensive pilot studies have shown that it works to produce samples which we can study by both light and electron microscopy.

TI Orthosiphon stamineus (Misai Kucing) ameliorated postmenopausal osteoporosis in rat model
SO MENOPAUSE-THE JOURNAL OF THE NORTH AMERICAN MENOPAUSE SOCIETY
LA English
DT Article
DE Bone histomorphometry; Orthosiphon stamineus; Osteoporosis; Ovariectomy; Postmenopausal; Rat
ID osteoarthritis; turnover; estrogen; collagen; extract
AB Objective:Orthosiphon stamineus (OS) or Misai Kucing (Java tea) is a popular herbal supplement from Southeast Asia for various metabolic, age-related diseases. This study investigated the potential use of OS leaf extracts to ameliorate osteoporosis in ovariectomized rats.Methods:Fifty-six female Sprague-Dawley rats were randomly allocated into eight groups (n=7): SHAM (healthy sham control); OVX (ovarietomized) nontreated rats (negative control); OVX+Remifemin (100mg/kg body weight), and 2% green tea extract (positive controls); OVX+OS 50% ethanolic and aqueous extracts, both at either 150 or 300mg/kg. After 16 weeks, the rats' bones and blood were evaluated for osteoporosis indicators (protein and mRNA expressions), micro-computed tomography for bone histomorphometry, and three-point bending test for tibia mechanical strength.Results:The extracts dose-dependently and significantly (P<0.05) improved bone strength and flexibility, bone mineral density, bone formation protein markers (P1NP), and bone histomorphometry. All extracts reduced the inflammation biomarker (interleukin-6). The extracts up-regulated osteoblastogenesis (bone morphogenetic protein-2) and collagen-1 synthesis (collagen type 1 alpha-1) mRNA expressions, and down-regulated bone resorption (TNFSF11 and nuclear factor-kappa B) mRNA expressions. Both the water and 50% ethanolic extract were effective. The effective dose is equivalent to 25 to 50mg/kg extract for humans.Conclusions:The extract showed bone-protective and antiosteoporotic effects (improving bone strength, flexibility, bone density, and bone morphometry) by reducing inflammation and the bone resorption biomarkers, while enhancing bone formation biomarkers and collagen synthesis.

TI Postpartum sacral stress fracture associated with mechanical sacroiliac joint disease: A case report
SO MEDICINE
LA English
DT Article
DE osteoarthritis; postpartum; sacroiliac joint; sacrum; stress fracture
ID insufficiency fractures; low-back; pregnancy; osteoporosis; pain
AB Rationale:Stress fractures of the sacrum and mechanical sacroiliac joint disease can occur not only during pregnancy but also postpartum. Mechanical sacroiliac joint disease is common in patients with low back pain but often misdiagnosed by practitioners. The association of the 2 conditions has not been studied yet.Patient

concerns:A 37-year-old woman physiatrist presented with 8-week history of persistent low back and left buttock pain that started in the third trimester of her pregnancy.Diagnoses:Laboratory investigation, dual-energy x-ray absorptiometry, magnetic resonance imaging, and CT of the pelvic region were performed. The patient was diagnosed with postpartum sacral stress fracture associated with mechanical sacroiliac joint disease.Interventions:Treatment consisted in pain killers and tailored to a nonweight-bearing period of 3 months.Outcomes:Painful symptoms disappeared and the patient was able to walk and perform other daily activities normally.Lessons:Clinician should be aware of the clinical context and the possible association of these 2 conditions in order to undertake an early and appropriate treatment.

TI Epigenetics, Bone Remodeling and Osteoporosis
SO CURRENT STEM CELL RESEARCH & THERAPY
LA English
DT Review
DE Epigenetic; DNA methylation; histone modification; bone remodeling; osteoblastogenesis; osteoclastogenesis; osteoporosis
ID histone deacetylase inhibitors; mesenchymal stem-cells; de-novo methylation; dna methylation; osteogenic differentiation; osteoclast differentiation; in-vivo; receptor activator; osteocalcin gene; osteoblast
AB Background: Osteoporosis is a common degenerative bone disease which is

characterized with decreased bone strength and increased risk of fracture. The abnormal bone metabolism homeostasis, especially in osteoclastic function, takes a fundamental role in osteoporosis pathogenesis. In the past decade, epigenetic regulation of bone homeostasis are widely investigated and considered as a vital factor in the regulation of the differentiation and functions of osteoblasts, osteoclasts and osteocytes. The relationship between osteoporosis and epigenetic regulations has gradually become as an important issue in the mechanism study of osteoporosis. Objective: In this review, we summarize the recent progresses of epigenetic regulation mechanism in bone development and remodeling, and emphasize the epigenetic features of osteoporosis and the potent therapy application of epigenetic drugs for osteoporosis. Conclusion: DNA methylation and histone modification regulated bone development and remodeling via affecting both osteoblastogenesis and osteoclastogenesis. And the abnormal epigenetic status is relevant to bone disease such as osteoporosis and osteoarthritis. Several inhibitors of DNMTs or HDACs exhibit a potential application for osteoporosis, and the side effects of these drugs should also be considered in the future applications.

TI Physical activity participation and the risk of chronic diseases among South Asian adults: protocol for a systematic review and meta-analysis
SO SYSTEMATIC REVIEWS
LA English
DT Review
DE Physical activity; Chronic diseases; Systematic review; South Asia; Adults
ID coronary-heart-disease; noncommunicable diseases; all-cause; interventions; prevention; mortality; time
AB Background: Chronic diseases contribute to about half of the adult disease burden in the South Asian region. Meanwhile, physical activity levels are declining despite the global evidence of its role in the prevention of chronic diseases. While there are a plethora of systematic reviews on the effects of physical activity on chronic diseases, there has not yet been a synthesis of the evidence concerning the nature of this relationship among people living in South Asian countries incorporating multiple chronic diseases and a focus on physical activity domains. The aim of this protocol is to describe the rationale and methods for a systematic review of published research to identify the association between physical activity

and selected chronic diseases and their markers and analysis of the strength of association with a focus on physical activity domains among South Asian adults 40 years and older. Methods: Nine electronic databases including Medline, PsycINFO, Embase, CENTRAL, CINAHL Plus, AgeLine, SPORTDiscus, Scopus and Web of Science will be systematically searched for papers reporting the association between physical activity and selected chronic diseases (type 2 diabetes mellitus, breast cancer, colorectal cancer, coronary heart disease, stroke, vascular diseases and musculoskeletal diseases (osteoarthritis, osteoporosis, back and neck pain)) and their markers using predefined search terms. Searches will be limited to peer-reviewed, English language papers with a quantitative design. In addition, a manual search of references of relevant systematic reviews as well as citations and references of eligible studies will also be carried out. The methodological appraisal will be performed using the National Institutes of Health quality assessment checklist for observational studies and the Effective Public Health Practice Project quality assessment tool for intervention studies. The overall quality of evidence for the study outcomes across the study designs will be assessed using the Grading of Recommendations Assessment, Development and Evaluation (GRADE) framework. The review results will be presented in the form of narrative synthesis, and a random effects meta-analysis is planned depending on the nature of included studies and available data. Discussion: This review will summarise the strength of the association between physical activity and selected chronic diseases and their markers among South Asian adults 40 years or older. The findings will provide an evidence base to guide public health policy and interventions in the South Asian region and to inform future research to address the rising burden of chronic diseases.

TI Role of advanced glycation end products in mobility and considerations in possible dietary and nutritional intervention strategies
SO NUTRITION & METABOLISM
LA English
DT Review
DE Advanced glycation end products (AGEs); Mobility; AGEs inhibitors; Dietary intervention strategies
ID maillard reaction-products; renal-failure patients; experimental diabetic-retinopathy; n-epsilon-carboxymethyllysine; leukemia inhibitory factor; low-density-lipoprotein; protein cross-linking; oxidative stress; skin autofluorescence; in-vitro
AB Advanced glycation end products (AGEs), a group of compounds that are formed by non-enzymatic reactions between carbonyl groups of reducing sugars

and free amino groups of proteins, lipids or nucleic acids, can be obtained exogenously from diet or formed endogenously within the body. AGEs accumulate intracellularly and extracellularly in all tissues and body fluids and can cross-link with other proteins and thus affect their normal functions. Furthermore, AGEs can interact with specific cell surface receptors and hence alter cell intracellular signaling, gene expression, the production of reactive oxygen species and the activation of several inflammatory pathways. High levels of AGEs in diet as well as in tissues and the circulation are pathogenic to a wide range of diseases. With respect to mobility, AGEs accumulate in bones, joints and skeletal muscles, playing important roles in the development of osteoporosis, osteoarthritis, and sarcopenia with aging. This report covered the related pathological mechanisms and the potential pharmaceutical and dietary intervention strategies in reducing systemic AGEs. More prospective studies are needed to determine whether elevated serum AGEs and/or skin autofluorescence predict a decline in measures of mobility. In addition, human intervention studies are required to investigate the beneficial effects of exogenous AGEs inhibitors on mobility outcomes.

TI Local delivery of tetramethylpyrazine eliminates the senescent phenotype of

bone marrow mesenchymal stromal cells and creates an anti-inflammatory and angiogenic environment in aging mice
SO AGING CELL
LA English
DT Article
DE bone marrow niche; bone marrow stem; progenitor cells; cellular senescence; EZH2-H3K27me3; H-type vessel; tetramethylpyrazine
ID analog cxc195 protects; cellular senescence; stem-cells; osteogenic differentiation; induced apoptosis; osteoarthritis; osteoporosis; methylation; dysfunction; homeostasis
AB Aging drives the accumulation of senescent cells (SnCs) including stem/progenitor cells in bone marrow, which contributes to aging-related bone degenerative pathologies. Local elimination of SnCs has been shown as potential treatment for degenerative diseases. As LepR(+) mesenchymal stem/progenitor cells (MSPCs) in bone marrow are the major population for forming bone/cartilage and maintaining HSCs niche, whether local elimination of senescent LepR(+) MSPCs delays aging-related pathologies and improves local microenvironment need to be well defined. In this study, we performed local delivery of tetramethylpyrazine (TMP) in bone marrow of aging mice, which previously showed to be used for the prevention and treatment of glucocorticoid-induced osteoporosis (GIOP). We found the increased accumulation of senescent LepR(+) MSPCs in bone marrow of aging mice, and TMP significantly inhibited the cell senescent phenotype via modulating Ezh2-H3k27me3. Most importantly, local delivery of TMP improved bone marrow microenvironment and maintained bone homeostasis in aging mice by increasing metabolic and anti-inflammatory responses, inducing H-type vessel formation, and maintaining HSCs niche. These findings provide evidence on the mechanisms, characteristics and functions of local elimination of SnCs in bone marrow, as well as the use of TMP as a potential treatment to ameliorate human age-related skeletal diseases and to promote healthy lifespan.

TI Assessing long-term return to play after hip arthroscopy in football players evaluating risk factors for good prognosis
SO KNEE SURGERY SPORTS TRAUMATOLOGY ARTHROSCOPY
LA English
DT Article
DE Groin pain; Hip arthroscopy; Soccer; Return to play
ID professional hockey players; femoroacetabular impingement; follow-up; sport; outcm; athlete; league; osteoarthritis; microfracture; management
AB Groin pain is the third most common disease in football players and has often been associated with hip pathology such as femoroacetabular impingement and labral lesions. Hip arthroscopy offers possibilities of function restoration via minimally invasive procedures. The aim of this study is to evaluate professional football player's injuries and their return to play after hip arthroscopy for FAI and labral injuries. Patients that underwent hip arthroscopy between 2009 and 2014 were selected retrospectively. From this population, only professional soccer players competing at national level were included (Tegner 10). Arthroscopic surgery was proposed in patients with persistent pain. All patients were assessed for VAS score preoperatively and at 3, 6, 12 and 24 months post-op. HOS (sport and DLA) and mHHS tests were performed at the same time periods. All patients were men with a mean age of 26.5 +/- 7.1 years old. Preoperative VAS (7.4 +/- 1.3), HOS ADL (67.7 +/- 5.5), HOS sport (37.6 +/- 18.7) and mHHS (72.5 +/- 8.8) showed improved scores during long-term follow-up. Time to return to play was 10.8 months (SD +/- 4.3), with range between 4 and 20 months. Mean follow-up was 45.4 +/- 15.6 months (range from 26 to 72 months). No differences were observed between non-active and active patients at final follow-up with respect to chondral lesions, but significant differences were observed with reference to management of the labrum ($p = 0.031$), where a higher rate of labrectomies existed among inactive patients and a higher rate of suture among active patients. Hip arthroscopy is a safe procedure with very good return to play results, but for optimized return to football one should consider patient age at the time of surgery, the condition of the labrum and low scores on the Harris Hip Score (mHHS) and HOS (sport version)

as predictive factors for poor prognosis. Level of evidence IV.

TI Mesenchymal Stem Cell Migration during Bone Formation and Bone Diseases Therapy
SO INTERNATIONAL JOURNAL OF MOLECULAR SCIENCES
LA English
DT Review
DE mesenchymal stem cells; migration; bone formation; bone diseases; therapy
ID hypoxia-inducible factor-1-alpha; endothelial growth-factor; in-vitro; osteogenic differentiation; fracture repair; synovial-fluid; nod/scid mice; stromal cells; marrow; cxcr4
AB During bone modeling, remodeling, and bone fracture repair, mesenchymal stem cells (MSCs) differentiate into chondrocyte or osteoblast to comply bone formation and regeneration. As multipotent stem cells, MSCs were used to treat bone diseases during the past several decades. However, most of these implications just focused on promoting MSC differentiation. Furthermore, cell migration is also a key issue for bone formation and bone diseases treatment. Abnormal MSC migration could cause different kinds of bone diseases, including osteoporosis. Additionally, for bone disease treatment, the migration of endogenous or exogenous MSCs to bone injury sites is required. Recently, researchers have paid more and more attention to two critical points. One is how to apply MSC migration to bone disease therapy. The other is how to enhance MSC migration to improve the therapeutic efficacy of bone diseases. Some considerable outcomes showed that enhancing MSC migration might be a novel trick for reversing bone loss and other bone diseases, such as osteoporosis, fracture, and osteoarthritis (OA). Although plenty of challenges need to be conquered, application of endogenous and exogenous MSC migration and developing different strategies to improve therapeutic efficacy through enhancing MSC migration to target tissue might be the trend in the future for bone disease treatment.

TI Gypenoside inhibits RANKL-induced osteoclastogenesis by regulating NF-B, AKT, and MAPK signaling pathways
SO JOURNAL OF CELLULAR BIOCHEMISTRY
LA English
DT Article
DE gypenoside(GP); osteoporosis; osteoclast differentiation; receptor activator of nuclear factor-B ligand (RANKL)
ID c-fos; differentiation; activation; cells; nfatc1; matrix-metalloproteinase-9; osteoporosis; induction; mechanism; erk
AB Gypenoside (GP) is one of the most pharmacologically active components in

Gynostemma pentaphyllum and possesses neuroprotective, anticancer, anti-oxidant, anti-inflammatory, anti-diabetic, and anti-osteoarthritis effects. However, the involvement of GP the osteoclast differentiation has not yet been investigated. In the present study, we examined the effect of GP on receptor activator of nuclear factor-B ligand (RANKL)-induced osteoclast formation. Our results demonstrated that GP significantly inhibited the formation of osteoclast, as well as suppressed the expression of osteoclastogenesis-related marker proteins in RANKL-stimulated bone marrow macrophages (BMMs). For molecular mechanisms, GP inhibited RANKL-induced NF-B and MAPK activation and AKT phosphorylation in BMMs. Collectively, these findings suggest that GP inhibits RANKL-induced osteoclastogenesis via regulating NF-B, AKT, and MAPK signaling pathways. Therefore, GP may be a potential agent in the treatment of osteoclast-related diseases such as osteoporosis.

TI Calcium, magnesium, zinc and lead concentrations in the structures forming knee joint in patients with osteoarthritis
SO JOURNAL OF TRACE ELEMENTS IN MEDICINE AND BIOLOGY
LA English
DT Article
DE Trace elements; Cartilage; Anterior cruciate ligament; Meniscus; Osteoarthritis
ID bone-mineral density; age-related-changes; hip-replacement surgery; element contents; trace-elements; serum magnesium; hypertension; meniscus; cadmium; osteoporosis
AB The aim of the study was to investigate the relationships between the concentrations of calcium (Ca), magnesium (Mg), zinc (Zn), and lead (Pb) in cartilage, anterior cruciate ligament, and meniscus samples obtained following knee joint surgery in patients with osteoarthritis in northwestern Poland. Furthermore, we examined the relationships between the concentrations of these metals in the studied parts of the knee joint and the influences of gender, age, BMI and hypertension. We found significantly higher concentrations of Ca, Mg, and Zn in the cartilage of men than in women and a significantly higher Pb concentration in the meniscus of the men. We also found a higher concentration of Pb in the cartilage of patients over 65 years of age. There were no differences in the concentrations of the studied metals between patients with and without hypertension. There was no relationship between Ca, Mg, Zn, and Pb levels in analyzed materials and BMI. Furthermore, we noted some new interactions between metals in the studied structures of the knee joint. The results reported in the study shows the influence of age, gender and BMI on the Ca, Mg, Zn and Pb in the studied structures of the knee joint.

TI Oleanolic Acid Exerts Osteoprotective Effects and Modulates Vitamin D Metabolism
SO NUTRIENTS
LA English
DT Article
DE oleanolic acid; ovariectomised; aging; osteoporosis; calcium; vitamin D
ID ligustri-lucidi extract; intestinal calcium-absorption; bone-mineral density; parathyroid-hormone; 1,25-dihydroxyvitamin d-3; 25-hydroxyvitamin d-3; ethanol extract; gene-expression; 1-alpha-hydroxylase gene; d supplementation
AB Oleanolic acid (OA) is a triterpenoid with reported bone anti-resorption activities. The present study aimed to characterize its bone protective effects in vivo and to study its effects on vitamin D metabolism, both in vivo and in vitro. OA significantly increased bone mineral density, improved micro-architectural properties, reduced urinary Ca excretion, increased 1,25(OH)(2)D-3 and renal CYP27B1 mRNA expression in mature C57BL/6 ovariectomised (OVX) mice. OA also improved bone properties, Ca balance, and exerted modulatory effects on renal CYP27B1 and CYP24A1 expressions in aged normal female Sprague-Dawley rats. In addition, OA significantly increased renal CYP27B1 mRNA and promoter activity, and suppressed CYP24A1 mRNA and protein expressions in human proximal tubule HKC-8 cells. OA exerted bone protective effects in mature OVX mice and aged female rats. This action on bone might be, at least in part, associated with its effects on Ca and vitamin D metabolism. The present findings suggest that OA is a potential drug candidate for the management of postmenopausal osteoporosis.

TI Validation of the German version of the Kujala score in patients with patellofemoral instability: a prospective multi-centre study
SO ARCHIVES OF ORTHOPAEDIC AND TRAUMA SURGERY
LA English
DT Article
DE Kujala score; Patellofemoral instability; Validation; Kujala patellofemoral score; Patellofemoral pain syndrome (PFPS); Questionnaire
ID sulcus-deepening trochleoplasty; anterior knee pain; recurrent patellar dislocations; osteoarthritis outcome score; cultural-adaptation; trochlear dysplasia; follow-up; ligament reconstruction; translation; scale
AB The Kujala score is the most frequently used questionnaire for patellofemoral disorders like pain, instability or osteoarthritis. Unfortunately, we are not aware of a validated German version of the Kujala score. The aim of our study was the translation and linguistic validation of the Kujala score in German-speaking patients with patella instability and the assessment of its measurement characteristics. The German Kujala score was developed in several steps of translation. In addition to healthy controls, the Kujala German was assessed in consecutive patients undergoing reconstruction of the medial patellofemoral ligament for recurrent patellar dislocations. Pre-op, 6 and 12 months postop the patients completed the Kujala German score, the KOOS, the Lysholm score, a VAS Pain, and the SF-12v2 scores. In addition, there was a Kujala German Score retest preop after a 1-week interval. We found high reliability in terms of internal consistency for the Kujala score (Cronbach's alpha = 0.87). Convergent validity with the KOOS (symptom r = 0.65, pain r = 0.78, ADL r = 0.74, sports/recreation r = 0.84, quality of life r = 0.70), the Lysholm score (r = 0.88) and the SF-12 physical component summary score (r = 0.79) and VAS pain (r = - 0.71) was also very high. Discriminant validity in terms of correlation with the SF-12 mental component summary Score was satisfactory (r = 0.14). In conclusion, the German version of the Kujala score proved to be a reliable and valid instrument in the setting of a typical patellofemoral disease treated with a standard patellofemoral procedure.

TI Impact of Osteoarthritis on Household Catastrophic Health Expenditures in Korea
SO JOURNAL OF KOREAN MEDICAL SCIENCE
LA English
DT Article
DE Osteoarthritis; Health Expenditure; Households
ID of-pocket costs; policy; care; prescription; coverage
AB Background: Osteoarthritis (OA) is a disease of old age whose prevalence is increasing. This study explored the impact of OA on household catastrophic health expenditure (CHE) in Korea. Methods: We used data on 5,200 households from the Korea Health Panel Survey in 2013 and estimated annual living expenses and out-of-pocket (OOP) payments. Household CHE was defined when a household's total OOP health payments exceeded 10%, 20%, 30%, or 40% of the household's capacity to pay. To compare the OOP payments of households with OA individuals and those without OA, OA households were matched 1:1 with households containing a member with other chronic disease such as neoplasm, hypertension, heart disease, cerebrovascular disease, diabetes, or osteoporosis. The impact of OA on CHE was determined by multivariable logistic analysis. Results: A total of 1,289 households were included, and households with and without OA patients paid mean annual OOP payments of $2,789 and $2,607, respectively. The prevalence of household CHE at thresholds of 10%, 20%, 30%, and 40% were higher in households with OA patients than in those without OA patients (P<0.001). The presence of OA patients in each household contributed significantly to CHE at thresholds of10% (odds ratio [OR], 1.48; 95% confidence interval [CIL 1.16-1.87), 20% (OR, 1.29; 95% Cl, 1.014.66), and 30% (OR, 1.37; 95% CI, 1.05-1.78), but not of 40% (OR, 1.17; 95% CI, 0.87-1.57). Conclusion: The presence of OA patients in Korean households is significantly related to CHE. Policy makers should try to reduce OOP payments in households with OA patients.

TI Influence of scanner, powder application, and adjustments on CAD-CAM crown misfit
SO JOURNAL OF PROSTHETIC DENTISTRY
LA English
DT Article
ID marginal fit; ceramic crowns; internal fit; system; restorations; experience; thickness; future; 3d
AB Statement of problem. The manufacturers of computer-aided design and computer-aided manufacturing (CAD-CAM) systems emphasize that new technologies can improve the marginal fit of dental crowns. However, data supporting this claim are limited. Purpose. The purpose of this in vitro study was to investigate the differences among the following fabrication methods on the marginal discrepancy of dental crowns: intraoral optical scanners, powder application, and adjustments of intaglio surface. Material and methods. A single human premolar was fixed on a typodont and prepared to receive crowns prepared by the CEREC CAD-CAM system. Three fabrication techniques were used: digital scans using the CEREC Bluecam scanner with titanium dioxide powder (TDP), digital scans using the CEREC Omnicam scanner without TDP, and digital scans using the Omnicam scanner with TDP. Five experimental groups (n=10) were designated: Bluecam (group B), Bluecam with adjustments (group BA), Omnicam (group 0), Omnicam with adjustments (group OA), and Omnicam with TDP (group OP). The specimens were scanned using microcomputed tomography to measure the vertical, horizontal, and internal fit and volumetric 3-dimensional (3D) internal fit values of each luting space. The paired t test was used to evaluate mean marginal fit change after adjustments within the same group. One-way analysis of variance and post hoc tests were used to compare groups B, 0, and OP (alpha=.05). Results. Mean vertical fit values standard deviations of group B=29.5 +/- 13.2 mu m; BA=26.9 +/- 7.7 mu m; 0=149.4 64.4 mu m; 0A=49.4 +/- 12.7 mu m; and OP=33.0 +/- 8.3 mu m. Adjustments in the intaglio surface and TDP application statistically influenced the vertical fit of group 0 (P<.001). The percentage of vertical fit values <75 mu m in group B=89.3%, BA=92.7%, O=31.0%, OA=73.5%, and OP=92.0%. Mean horizontal fit values for group B=56.2 +/- 21.5 mu m; 85.8 +/- 44.4 mu m for group BA; 77.5 +/- 11.8 mu m for group 0; 102.5 +/- 16.2 mu m for group OA; and 91.4 +/- 19.4 mu m for group OP. Results from group B were significantly different from those of the other test groups (P<.05). The percentages of horizontal misfit were 61.2% in group B; 73.5% in group BA; 88.1% in group O; 92.4% in group OA; and 85.0% in group OP. Volumetric 3D internal fit values in group B were 9.4 +/- 1.3 mm(3); 10.7 +/- 1.0 mm(3) in group BA; 11.8 +/- 2.1 mm(3) in group O; 11.0 +/- 1.3 mm(3) in group OA; and 9.6 +/- 0.9 mm(3) in group OP. The overall results from groups B and OP were better than those of group O, with regard to vertical misfit and volumetric 3D internal fit. Conclusions. Different intraoral optical scanners, powder application, and internal adjustments influenced the marginal discrepancy of crowns. Crowns fabricated using the Omnicam system had significantly higher vertical discrepancy and volumetric 3D internal fit than those fabricated using the

Bluecam scanner with TDP. Adjustments of the intaglio surface improved the vertical fit of crowns made using the Omnicam scanner; however, TDP application before Omnicam scanning improved the vertical fit as well as the volumetric 3D internal fit value of the luting space of crowns.

TI Immunoporosis: Immunology of Osteoporosis-Role of T Cells
SO FRONTIERS IN IMMUNOLOGY
LA English
DT Review
DE immunoporosis; osteoimmunology; bone loss; T lymphocytes; osteoporosis
ID osteoclastic bone-resorption; in-vivo; immune-system; rheumatoid-arthritis; parathyroid-hormone; helper-cells; tnf-alpha; inflammatory diseases; peripheral-blood; synovial-fluids

AB The role of immune system in various bone pathologies, such as osteoporosis, osteoarthritis, and rheumatoid arthritis is now well established. This had led to the emergence of a modern field of systems biology called as osteoimmunology, an integrated research between fields of immunology and bone biology under one umbrella. Osteoporosis is one of the most common inflammatory bone loss condition with more than 200 million individuals affected worldwide. T helper (Th) cells along with various other immune cells are major players involved in bone homeostasis. In the present review, we specifically discuss the role of various defined T lymphocyte subsets (Th cells comprising Th1, Th2, Th9, Th17, Th22, regulatory T cells, follicular helper T cells, natural killer T cells, gamma delta T cells, and CD8(+) T cells) in the pathophysiology of osteoporosis. The study of the specific role of immune system in osteoporosis has now been proposed by our group as "immunoporosis: the immunology of osteoporosis" with special emphasis on the role of various subsets of T lymphocytes. The establishment of this new field had been need of the hour due to the emergence of novel roles of various T cell lymphocytes in accelerated bone loss observed during osteoporosis. Activated T cells either directly or indirectly through the secretion of various cytokines and factors modulate bone health and thereby regulate bone remodeling. Several studies have summarized the role of inflammation in pathogenesis of osteoporosis but very few reports had delineated the precise role of various T cell subsets in the pathobiology of osteoporosis. The present review thus for the first time clearly highlights and summarizes the role of various T lymphocytes in the development and pathophysiology of osteoporosis, giving birth to a new field of biology termed as "immunoporosis". This novel field will thus provide an overview of the nexus between the cellular components of both bone and immune systems, responsible for the observed bone loss in osteoporosis. A molecular insight into the upcoming and novel field of immunoporosis would thus leads to development of innovative approaches for the prevention and treatment of osteoporosis.

TI Low risk for hip fracture and high risk for hip arthroplasty due to osteoarthritis among Swedish farmers
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE Arthroplasty; Epidemiology; Hip fracture; Occupation; Osteoarthritis; Osteoporosis; Physical activity; Sweden
ID body-mass index; physical-activity; knee osteoarthritis; men; population; women; work; occupation; metaanalysis; association
AB We aimed to study the risk of hip fracture and risk of hip arthroplasty among farmers in Sweden. Our results indicate that farming, representing an occupation with high physical activity, in men is associated with a lower risk of hip fracture but an increased risk of hip arthroplasty. Introduction The risks of hip fracture and hip arthroplasty are influenced by factors including socioeconomic status, education, urbanization, latitude of residence, and physical activity. Farming is an occupation encompassing rural living and high level of physical activity. Therefore, we aimed to study the risk of hip fracture and risk of hip arthroplasty among farmers in Sweden. Methods We studied the risk of hip fracture, and hip arthroplasty due to primary osteoarthritis, in all men and women aged 35 years or more in Sweden between 1987 and 2002. Documented occupations were available in 3.5 million individuals, of whom 97,136 were farmers. The effects of age, sex, income, education, location of residence, and occupation on risk of hip fracture or hip arthroplasty were examined using a modification of Poisson regression. Results A total of 4027 farmers and 93,109 individuals with other occupations sustained a hip fracture,

while 5349 farmers and 63,473 others underwent a hip arthroplasty. Risk of hip fracture was higher with greater age, lower income, lower education, higher latitude, and urban area for all men and women. Compared to all other occupations, male farmers had a 20% lower age-adjusted risk of hip fracture (hazard ratio (HR) 0.80, 95% CI 0.77-0.84), an effect that was not seen in female farmers (HR 0.96, 95% CI 0.91-1.01). Both male and female farmers had a higher age-adjusted risk for hip arthroplasty. Conclusions Our results indicate that farming, representing an occupation with high physical activity, in men is associated with a lower risk of hip fracture but an increased risk of hip arthroplasty.

TI Articular cartilage protection in Ctsk-/- mice is associated with cellular and molecular changes in subchondral bone and cartilage matrix
SO JOURNAL OF CELLULAR PHYSIOLOGY
LA English
DT Article
ID adult rhesus-monkeys; cathepsin-k; gene-expression; ovariectomized monkeys; odanacatib treatment; knee osteoarthritis; mouse model; hip; mineralization; degeneration
AB Osteoarthritis (OA) is a degenerative disease and a major cause of chronic disability in aging individuals. Cathepsin K (CatK), encoded by the Ctsk gene, has been implicated in the pathogenesis of pycnodysostosis and osteoporosis. The use of a selective inhibitor of CatK was recently shown to delay OA progression in rabbits. However, the cellular mechanisms underlying these protective effects remain unexplored. We examined articular cartilage maintenance and joint bone remodeling using Ctsk null mice (Ctsk(-/-)) which underwent destabilization of the

medial meniscus (DMM). We found that Ctsk(-/-) mice displayed delayed remodeling of subchondral and calcified cartilage by osteoclasts and chodroclasts respectively in DMM-induced osteoarthritis. While WT mice displayed a more severe OA phenotype than Ctsk(-/-) mice at 16 weeks, higher subchondral bone volume and lower trabecular spacing were also observed in surgically-induced OA joints of Ctsk(-/-) mice. However, no differences were seen in non-surgical controls. During OA progression, TRAP(+) osteoclast numbers were increased in both WT and Ctsk(-/-) mice. However, Ctsk(-/-) mice had fewer physis-derived chondroclasts than WT when OA was present. These data suggest that CatK may differentially regulate chondroclastogenesis in the growth plate. Targeted PCR arrays of RNA harvested from laser captured osteoclasts in the subchondral bone and chondroclasts in the growth plate demonstrated differential expression of Atp6v0d2, Tnfrsf11a, Ca2, Calcr, Ccr1, Gpr68, Itgb3, Nfatc1, and Syk genes between WT and Ctsk(-/-) mice at 8- and 16-weeks post-DMM. Our data provide insight into the cellular mechanisms by which cathepsin K deletion delays OA progression in mice.

TI Subchondral bone fragility with meniscal tear accelerates and parathyroid hormone decelerates articular cartilage degeneration in rat osteoarthritis model
SO JOURNAL OF ORTHOPAEDIC RESEARCH
LA English
DT Article

DE osteoarthritis; subchondral bone; articular cartilage; parathyroid hormone; cartilage degeneration
ID cruciate ligament transection; experimental mouse models; knee-joint instability; synovial mast-cells; endochondral ossification; transcription factor-2; strontium ranelate; controlled-trial; teriparatide; osteoporosis
AB The aims of this study were to investigate the influence of subchondral bone fragility (SBF) on the progression of the knee osteoarthritis by using a novel rat model, and to examine the preventive effect of parathyroid hormone (PTH) on cartilage degeneration. First, 40 rats were assigned to the following four groups: Sham, SBF, Medial meniscal tear (MMT), and MMT+SBF groups. In SBF and MMT+SBF groups, we induced SBF by microdrilling the subchondral bone. Second, 10 additional rats were randomly assigned to the following two groups: MMT+SBF+saline and MMT+SBF+PTH groups. Osteoarthritic changes in the articular cartilage and subchondral bone were evaluated using safranin-O/fast green staining, matrix metalloproteinase-13 (MMP-13), and type X collagen immunohistochemistry, toluidine blue staining, and micro-CT scanning. The combination of SBF and meniscal tear increased the number of mast cells in the subchondral bone, and led to the abnormal subchondral bone microarchitecture, such as abnormally decreased trabecular number and increased trabecular thickness, compared with meniscal tear alone. Moreover, SBF with meniscal tear enhanced articular cartilage degeneration and increased the expression of MMP-13 and type X collagen, compared with meniscal tear alone. The administration of PTH decreased the number of mast cells in the subchondral bone and improved the microstructural parameters of the subchondral bone, and delayed the progression of articular cartilage degeneration. These results suggest that SBF is one of the factors underlying the osteoarthritis development, especially in knees with traumatic osteoarthritis, and that the administration of PTH is a potential therapeutic treatment for preventing OA progression. DT Review
DE Acid-base homeostasis; Bone mineral density; Bone turnover; Dairy products; Fracture; Osteoporosis
ID postmenopausal chinese women; randomized controlled-trial; hip fracture risk; potassium citrate supplementation; net acid excretion; growth-factor-i; mineral density; older men; milk supplementation; vitamin-d
AB A summary of systematic reviews and meta-analyses addressing the benefits and risks of dietary protein intakes for bone health in adults suggests that dietary protein levels even above the current RDA may be beneficial in reducing bone loss and hip fracture risk, provided calcium intakes are adequate. Several systematic reviews and meta-analyses have addressed the benefits and risks of dietary protein intakes for bone health in adults. This narrative review of the literature summarizes and synthesizes recent systematic reviews and meta-analyses and highlights key messages. Adequate supplies of dietary protein are required for optimal bone growth and maintenance of healthy bone. Variation in protein intakes within the "normal" range accounts for 2-4% of BMD variance in adults. In older people with osteoporosis, higher protein intake (ae<yen> 0.8-g/kg body weight/day, i.e., above the current RDA) is associated with higher BMD, a slower rate of bone loss, and reduced risk of hip fracture, provided that dietary calcium intakes are adequate. Intervention with dietary protein supplements attenuate age-related BMD decrease and reduce bone turnover marker levels, together with an increase in IGF-I and a decrease in PTH. There is no evidence that diet-derived acid load is deleterious for bone health. Thus, insufficient dietary protein intakes may be a more severe problem than protein excess in the elderly. Long-term, well-controlled randomized trials are required to further assess the influence of dietary protein intakes on fracture risk.

AB Objectives: To gather expert opinion on the conduct of clinical trials that will facilitate regulatory review and approval of appropriate efficacious pharmacological treatments for hand osteoarthritis (OA), an area of high unmet clinical need. Methods: The European Society on Clinical and Economic Aspects of Osteoporosis, Osteoarthritis and Musculoskeletal diseases (ESCEO) organized a working group under the auspices of the International Osteoporosis Foundation (IOF) and the World Health Organization (WHO). Results: This consensus guideline is intended to provide a reference tool for practice, and should allow for better standardization of the conduct of clinical trials in hand OA. Hand OA is a heterogeneous disease affecting different, and often multiple, joints of the thumb and fingers. It was recognized that the various phenotypes and limitations of diagnostic criteria may make the results of hand OA trials difficult to interpret. Nonetheless, practical recommendations for the conduct of clinical trials of both symptom and structure modifying drugs are outlined in this consensus statement, including guidance on study design, execution, and analysis. Conclusions: While the working group acknowledges that the methodology for performing clinical trials in hand OA will evolve as knowledge of the disease increases, it is hoped that this guidance will support the development of new pharmacological treatments targeting hand OA. TI Serum levels of matrix metalloproteinase-3 and autoantibodies related to rheumatoid arthritis in the general Japanese population and their association with osteoporosis and osteoarthritis: the ROAD study
SO JOURNAL OF BONE AND MINERAL METABOLISM
LA English
DT Article
DE Biomarkers; Matrix metalloproteinase-3; Osteoporosis; Rheumatoid arthritis; Osteoarthritis
ID citrullinated peptide antibody; hand osteoarthritis; american-college; human skin; prevalence; mmp-3; biomarkers; criteria; disease; damage
AB To purpose of this study was to reveal the mean levels and positive proportion of serological markers related to rheumatoid arthritis, and clarify their relationship

with osteoporosis and hand osteoarthritis (OA). A total of 1546 participants from the third survey of the research on osteoarthritis/osteoporosis against disability study were enrolled in the current study. Using participant blood samples, the levels of anti-cyclic citrullinated protein (CCP) antibody, rheumatoid factor (RF), matrix metalloproteinase-3 (MMP-3), C-reactive protein (CRP), and high-sensitivity CRP (hsCRP) were measured. Subjects with higher than normal levels were defined as being positive. Osteoporosis was defined according to the recommendations set by World Health Organization criteria in 1994. Radiographic hand OA was evaluated using the modified Kellgren-Lawrence (KL) scale. The positive proportion of anti-CCP antibody, RF, MMP-3, CRP, and hsCRP was 1.8, 7.1, 15.0, 6.7, and 6.4%, respectively. MMP-3 was associated with age, and was significantly higher in men than in women. Positive MMP-3 was not significantly related to osteoporosis or severe hand OA (KL grade >= 3) after adjustment for other factors including age, sex, and body mass index. The results from this study clarified the values and positive proportion of RA-related markers and revealed their relationship with osteoporosis and hand OA.

TI Interleukin-35 Inhibits TNF-α-Induced Osteoclastogenesis and Promotes Apoptosis via Shifting the Activation From TNF Receptor-Associated Death Domain (TRADD)-TRAF2 to TRADD-Fas-Associated Death Domain by JAK1/STAT1
SO FRONTIERS IN IMMUNOLOGY
LA English
DT Article
DE TNF-alpha; osteoclast; apoptosis; FADD; interleukin-35
ID nf-kappa-b; bone-marrow-cells; rankl-induced osteoclastogenesis; rheumatoid-arthritis; signaling complex; mediated osteoclastogenesis; up-regulation; in-vitro; t-cells; il-35
AB Over-activated osteoclasts derived from myeloid or peripheral blood monocytes by inflammatory cytokines results in osteoporosis, osteoarthritis, and other bone erosion-related diseases. Interleukin 35 (IL-35) is a novel anti-inflammatory and immunosuppressive factor. This study investigated the effect of IL-35 on TNF-alpha-induced osteoclastogenesis. In the presence of IL-35, this process was detected by Tartrate-Resistant Acid Phosphatase (TRAP) staining, F-actin staining, and bone resorption assays. The effects of IL-35 on TNF-alpha-induced apoptosis were demonstrated by TUNEL staining, cell viability assays, and flow cytometry. Moreover, a microarray was performed to detect the effect of IL-35 on TNF-alpha-activated phosphatase kinase. The effect of IL-35 on the TNF-alpha-mediated activation of NF-kappa B, MAPK, TRAF2, RIP1, Fas-associated death domain (FADD), and caspase3 was further investigated. In addition, a murine calvarial osteolysis model was established via the subcutaneous injection of TNF-alpha onto the calvaria, and histological analysis was subsequently performed. As a result, IL-35 inhibited TNF-ainduced osteoclast formation and bone resorption in vitro and osteolysis calvaria in vivo. NFATc1, c-fos, and TRAP were downregulated by IL-35 through the inhibition of NF-kappa B and MAPK, during which JAK1/STAT1 was activated. Moreover, based on TUNEL staining and flow cytometry, IL-35 was shown to enhance TNF-alpha-induced osteoclast apoptosis. Meanwhile, FADD and cleaved-caspase 3 were increased in cells treated with TNF-alpha and IL-35, whereas the DNA-binding activity of NF-kappa B was

increased in TNF-alpha-treated cells, but was decreased in cells treated with both TNF-alpha and IL-35. In conclusion, IL-35 inhibits TNF-alpha-induced osteoclastogenesis and promotes apoptosis by activating JAK1/STAT1 and shifting activation from TNF receptor-associated death domain (TRADD)-TRAF2/RIP1-NF-kappa B to TRADD-FADD-caspase 3 signaling.

TI Changes in Local Bone Density in Early Thumb Carpometacarpal Joint Osteoarthritis
SO JOURNAL OF HAND SURGERY-AMERICAN VOLUME
LA English
DT Article
DE Hounsfield units; osteoarthritis; thumb
ID x-ray absorptiometry; hounsfield units; mineral density; pinch strength; osteoporosis; scans; women; grip
AB Purpose Thumb carpometacarpal (CMC) osteoarthritis (OA) represents a major source of functional morbidity. The effects of early CMC OA on loading and use patterns potentially lead to changes in local bone density and microarchitecture. Hounsfield units (HU), a quantitative attenuation coefficient obtained from computed tomography (CT) scans, have been shown to be a reliable marker of bone density. We hypothesized that early CMC OA is associated with lower local bone density about the CMC joint as assessed by HU. Methods We examined HU units from CT scans in 23 asymptomatic subjects and 91 patients with early CMC OA. The HU measurements were obtained within cancellous portions of the trapezium, capitate, first and third metacarpal bases, and distal radius. Linear regression models, with age and sex included as covariates, were used to assess the relationship between CMC OA and HU values at each anatomical site. Results Early OA patients had significantly lower HU than asymptomatic subjects within the trapezium (mean, 377 HU vs 436 HU) and first metacarpal bases (265 HU vs 324 HU). No significant group differences were noted at the capitate, third metacarpal, or distal radius. Male sex and younger age were associated with significantly higher HU at all the anatomical sites, except the first metacarpal base, where age had no significant effect. Conclusions Subjects presenting with early CMC OA had significantly lower bone density as assessed with HU at the thumb CMC joint (trapezium and first metacarpal base). Early thumb CMC OA and discomfort may lead to diminished loading across the basal joint, producing focal disuse osteopenia. These findings in symptomatic early arthritis suggest a relationship between symptoms, functional use of the CMC joint, and local bone density.

TI Expressed information needs of patients with osteoporosis and/or fragility fractures: a systematic review
SO ARCHIVES OF OSTEOPOROSIS
LA English
DT Review
DE Information needs; Osteoporosis; Education; Communication
ID health literacy; decision aid; hip fracture; adherence; women; perceptions; medication; management; risk; osteoarthritis
AB This systematic review identified patients have unmet information needs about the nature of osteoporosis, medication, self-management and follow-up. Clinician knowledge and attitudes appear to be of key importance in determining whether these needs are met. Unmet information needs appear to have psychosocial consequences and result in poor treatment adherence. Purpose Patient education

is an integral component of the management of osteoporosis, yet patients are dissatisfied with the information they receive and see this as an area of research priority. This study aimed to describe and summarise the specific expressed information needs of patients in previously published qualitative research. Methods Using terms relating to osteoporosis, fragility fracture and information needs, seven databases were searched. Articles were screened using predefined inclusion and exclusion criteria. Full-text articles selected for inclusion underwent data extraction and quality appraisal. Findings were drawn together using narrative synthesis. Results The search identified 11,024 articles. Sixteen empirical studies were included in the review. Thematic analysis revealed three overarching themes relating to specific information needs, factors influencing whether information needs are met and the impact of unmet information needs. Specific information needs identified included the following: the nature of osteoporosis/fracture risk; medication; self-management and understanding the role of dual energy x-ray absorptiometry and follow-up. Perceived physician knowledge and attitudes, and the attitudes, beliefs and behaviours of patients were important factors in influencing whether information needs were met, in addition to contextual factors and the format of educational resources. Failure to elicit and address information needs appears to be associated with poor treatment adherence, deterioration of the doctor-patient relationship and important psychosocial consequences. Conclusion This is the first study to describe the information needs of patients with osteoporosis and fracture, the impact of this information gap and possible solutions. Further research is needed to co-design and evaluate educational interventions with patients.

TI Engineering in-vitro stem cell-based vascularized bone models for drug screening and predictive toxicology
SO STEM CELL RESEARCH & THERAPY
LA English
DT Review
DE tissue engineering; vascularized bone; three-dimensional microphysiological systems; biomaterial; scaffold; preclinical model; bioreactors
ID endothelial progenitor cells; nitric-oxide synthase; perfusion bioreactor system; microvessel-like structures; beta-tricalcium phosphate; porous ceramic scaffolds; growth-factor delivery; large animal-models; fluid shear-stress; calcium-phosphate
AB The production of veritable in-vitro models of bone tissue is essential to understand the biology of bone and its surrounding environment, to analyze the pathogenesis of bone diseases (e.g., osteoporosis, osteoarthritis, osteomyelitis, etc.), to develop effective therapeutic drug screening, and to test potential therapeutic strategies. Dysregulated interactions between vasculature and bone cells are often related to the aforementioned pathologies, underscoring the need for a bone model that contains engineered vasculature. Due to ethical restraints and limited prediction power of animal models, human stem cell-based tissue engineering has gained increasing relevance as a candidate approach to overcome the limitations of animals and to serve as preclinical models for drug testing. Since bone is a highly vascularized tissue, the concomitant development of vasculature and mineralized matrix requires a synergistic interaction between osteogenic and endothelial precursors. A number of experimental approaches have been used to achieve this goal, such as the combination of angiogenic factors and three-dimensional scaffolds, prevascularization strategies, and coculture systems. In this review, we present an overview of the current models and approaches to generate in-vitro stem cell-based vascularized bone, with emphasis on the main challenges of vasculature engineering. These challenges are related to the choice of

biomaterials, scaffold fabrication techniques, and cells, as well as the type of culturing conditions required, and specifically the application of dynamic culture systems using bioreactors.

TI PROFILE OF PATIENTS WITH OSTEOPOROTIC FRACTURES AT A TERTIARY ORTHOPEDIC TRAUMA CENTER
SO ACTA ORTOPEDICA BRASILEIRA
LA English
DT Article
DE Osteoporotic fractures; Osteoporosis; Epidemiology; Diagnosis; Bone density; Prevalence
ID subsequent fracture; osteoarthritis; prevalence
AB Objective: To evaluate the profile of patients with osteoporotic fractures treated at a tertiary orthopedic hospital. Methods: Using questionnaires, 70 patients with osteoporotic fractures (OF) were compared with 50 outpatients with multiple osteoarthritis (OA) followed through an outpatient clinic. Results: The OF group was older ($p < 0.001$), less heavy ($p=0.003$), had lower BMI ($p=0.006$), was more likely to be white ($p=0.011$), was less likely to be married ($p=0.008$), and had previous falls, previous fractures, old fractures (>1 year), falls in the last 12 months, fractures due to falls, and needed more assistance ($p < 0.05$). They also had lower Lawton & Brody Instrumental Activities of Daily Living scores ($p < 0.05$) and reported less lower limb disability, foot pathology, muscle weakness, hypothyroidism, and vitamin D intake than patients in the OA group. White race, previous falls, and previous fractures increase the risk of osteoporotic fractures by 10.5, 11.4, and 4.1 times, respectively. The chance of fracture dropped 29% for each one-unit increase in Lawton & Brody IADL score. Married participants had fewer fractures than participants with other marital status. Conclusion: Together, race, marital status, previous falls, foot pathologies, previous fractures, and IADL scores define the profile of patients with osteoporotic fractures.

TI Cortical Fractal Analysis and Collagen Crosslinks Content in Femoral Neck After Osteoporotic Fracture in Postmenopausal Women: Comparison with Osteoarthritis
SO CALCIFIED TISSUE INTERNATIONAL
LA English
DT Article
DE Cortical bone; Osteoporosis; Femoral neck; Lacunarity; Fractal dimension
ID trabecular bone-structure; biomechanical property; nonenzymatic glycation;

structural basis; proximal femur; lacunarity; strength; mature
AB The femoral neck (FN) has been previously characterized by thinner cortices in osteoporotic fracture (HF) when compared to hip osteoarthritis (HOA). The purposes of this study were to complete the previous investigations on FNs from HF and HOA by analyzing the complexity of the cortical structure and to approach the intrinsic properties of cortical bone by assessing the collagen crosslink contents. FN samples were obtained during arthroplasty in 35 postmenopausal women (HF; n = 17; mean age 79 +/- 2 years; HOA; n = 18; mean age 66 +/- 2 years). The cortical fractal dimension (Ct.FD) and lacunarity (Ct.Lac) derived from high-resolution peripheral quantitative tomography (isotropic voxel size: 82 mu m) images of FN by using Ctan software and Fraclac running in ImageJ were analyzed. The collagen crosslinks content [pyridinoline, deoxypyridinoline, pentosidine (PEN)] were assessed in cortical bone. Ct.FD was significantly lower ($p < 0.0001$) in HF than HOA reflecting a decreased complexity and was correlated to the age and BMD. In two sub-groups, BMD- and age-matched, respectively, Ct.FD remained significantly lower in HF than HOA ($p < 0.001$). Ct.Lac was not different between HF and HOA. PEN content was two times higher in HF than HOA ($p < 0.0001$) independently of age. In conclusion, FN with HF was characterized by a less complex cortical texture and higher PEN content than HOA. In addition to the decreased bone mass and BMD previously reported, these modifications contribute to the lower bone quality in HF than HOA in postmenopausal women.

TI Fibromodulin: Structure, Physiological Functions, and an Emphasis on its Potential Clinical Applications in Various Diseases
SO JCPSP-JOURNAL OF THE COLLEGE OF PHYSICIANS AND SURGEONS PAKISTAN
LA English
DT Review
DE Fibromodulin; Proteoglycans; Structure; Function; Disease; Human; Scarless healing
ID temporomandibular-joint osteoarthritis; extracellular-matrix; growth-factor; transforming growth-factor-beta-1; proteoglycan fibromodulin; collagen fibrillogenesis; differential expression; intervertebral discs; articular-cartilage; angiogenic factors
AB Fibromodulin (FMOD) is one of the small leucine-rich proteoglycans. A search of the literature did not reveal any paper that specifically reviews the potential clinical applications of FMOD in the management of human diseases. First, the structure and physiological functions of FMOD were reviewed. Then its potential clinical applications in various diseases including diseases of the skin, tendons,

joints, intervertebral discs, blood vessels, teeth, uterus, bone and kidney were reviewed. FMOD is able to switch the adult response to skin wounding to the desired fetal response of scarless healing. Lowered levels of FMOD would be desirable in the management of tendinopathy, uterine fibroids, tumors resistant to radiotherapy, glioblastomas, small-cell lung cancer, and primary liver/lung fibrosis. In contrast, increased levels of FMOD would be desirable in the management of acute tendon injuries, osteoarthritis, rheumatoid arthritis, temporo-mandibular disease, joint laxity, intervertebral disc disease, neo-intimal hyperplasia of vein grafts, teeth caries, periodontal disease, endometrial atrophy, osteoporosis and diabetic nephropathy. Furthermore, FMOD may be used as a prognostic marker of cerebrovascular events in patients undergoing carotid endarterectomy and a marker for prostatic cancer. Finally, the use of FMOD in the treatment of symptomatic endometrial atrophy should be explored in women who are unable to use the standard estrogen management for endometrial atrophy. The review concluded that clinical trials in humans should be initiated to investigate the potential therapeutic effects of FMOD.

TI Genetic variation of SMAD3 is associated with hip osteoarthritis in a Chinese Han population
SO JOURNAL OF INTERNATIONAL MEDICAL RESEARCH
LA English
DT Article
DE Hip osteoarthritis; single nucleotide polymorphism; SMAD3; Chinese Han; case-control study; PCR
ID single nucleotide polymorphisms; knee osteoarthritis; susceptibility; women; epidemiology; osteoporosis
AB Objective This study was performed to investigate the association between genetic variation in SMAD3 and hip osteoarthritis (OA) in a Chinese Han population. Methods The frequency of two single nucleotide polymorphisms of SMAD3, rs1470002 and rs12901499, was examined in 500 patients with hip OA and 1080 healthy controls in a Chinese Han population. Further analysis was performed according to sex and age. Results We detected statistically significant differences in the allele frequency and genotype between the hip OA and healthy control groups. The frequency of the GA+GG and GA genotypes of rs12901499 and the G variant were much higher in patients with hip OA than in healthy controls. This association was also present when the participants were stratified by sex and age. However, there was no significant association between the risk of hip OA and the presence of rs1470002 GA, AA, or GA+AA genotypes, even after sex- and age-stratified analysis. Conclusions The SMAD3 SNP rs12901499 GA genotype and G variant may increase the risk of hip OA in Chinese Han patients.

TI Factors affecting rotation of occiput posterior position during the first stage of labor
SO JOURNAL OF GYNECOLOGY OBSTETRICS AND HUMAN REPRODUCTION
LA English
DT Article
DE First stage of labor; Intrapartum care; Occiput posterior position; Oxytocin; Rotation
ID manual rotation; transverse positions; epidural analgesia; operative delivery; cesarean delivery; fetal position; association; risk; 2nd-stage; impact
AB Introduction. - Fetal occiput posterior (OP) positions account for 15 to 20% of cephalic presentations and are associated with poorer maternal and neonatal

outcomes than occiput anterior (OA) positions. The aim of this study was to identify maternal, neonatal and obstetric factors associated with rotation from OP to OA position during the first stage of labor. Material and methods. - This secondary analysis of a multicenter randomized controlled trial (EVADELA) included 285 laboring women with ruptured membranes and a term fetus in OP position. After excluding women with cesarean deliveries before full dilatation, we compared two groups according to fetal head position at the end of the first stage of labor: those with and without rotation from OP to OA position. Factors associated with rotation were assessed with univariate and multivariate analyses using multilevel logistic regression models. Results. - The rate of anterior rotation during the first stage was 49.1%. Rotation of the fetal head was negatively associated with excessive gestational weight gain (adjusted odds ratio [aOR]: 0.37, 95% confidence interval [CI]: 0.17-0.80), macrosomia (aOR: 0.35, 95% CI: 0.14-0.90), direct OP position (aOR: 0.24, 95% CI: 0.09-0.65), and prelabor rupture of membranes (aOR: 0.40, 95% CI: 0.19-0.86). Oxytocin administration was the only factor positively associated with fetal head rotation (aOR: 2.17, 95% CI: 1.20-3.91). Discussion. - Oxytocin administration may affect rotation of OP positions during the first stage of labor. Further studies should be performed to assess the risks and benefits of its utilization for managing labor with a fetus in OP position. (C) 2018 Elsevier Masson SAS. All rights reserved.

ID mineral density
AB Objectives: This study aims to investigate the role of subchondral trabecular bone thickness in the mechanism of knee osteoarthritis and the correlation of osteoarthritis and osteoporosis pathogenesis. Patients and methods: The study included 62 patients (9 males, 53 females, mean age 66.7 years; range, 50 to 84 years) with osteoarthritk All radiographs were evaluated according to Kellgren and Lawrence classification. The bone mineral density of the patients was measured and bone samples were collected from all patients included in the study during the surgical procedure and investigated pathologically. Results: Osteoarthritis grade and trabecular bone thickness were correlated with each other. Trabecular thickness rate was higher in patients with severe osteoarthritis, whereas trabecular thickness rate was statistically significantly lower than the mean in patients with mild osteoarthritis (p=0.045). Conclusion: Trabecular thickness rate was significantly lower in the mild grade of osteoarthritis compared to the severe grade. As the level of osteoarthritis increased, the number of patients with osteoporosis decreased.

TI Pro-inflammatory dietary pattern is associated with fractures in women: an eight-year longitudinal cohort study
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE Aged; Dietary Inflammatory Index; Fracture; Inflammation; Osteoporosis
ID c-reactive protein; bone-mineral density; independent risk-factor; hip fracture; vertebral fractures; postmenopausal women; mediterranean diet; physical-activity; index; markers
AB In this study, during 8 years of follow-up, we reported that higher dietary inflammatory index values were associated with a higher risk of incident fractures in women, but not in men, after adjusting for potential confounders. Inflammation is a key risk factor for many adverse outcomes in older people. While diet is a potential source of inflammation, little is known about the impact of inflammatory diet on fractures. Thus, we investigated whether higher Dietary Inflammatory Index (DII)(TM) A (R) scores are associated with fractures in a cohort of North American people. This longitudinal study with a follow-up of 8 years included 3648 participants (1577 males and 2071 females; mean age = 60.6 years) with/at risk of knee osteoarthritis participating with in the Osteoarthritis Initiative. DII scores were calculated using the validated Block Brief 2000 Food Frequency Questionnaire, categorized into sex-specific quintiles. Information on fractures was obtained through self-reported history of fractures at hip, spine, and forearm. The relationship between baseline DII score and incident fracture was assessed through a Cox's regression analysis, adjusted for potential baseline confounders, and reported as hazard ratios (HRs). During 8 years of follow-up, 560 individuals developed fractures (15.4%). Adjusting for 10 potential confounders, women in the highest DII score quintile (i.e., most pro-inflammatory diet) had a significantly higher risk for fractures (HR = 1.46; 95% CI = 1.02-2.11) compared to women in the lowest quintile. An increase in one standard deviation of DII scores significantly

predicted fracture onset in women (adjusted HR = 1.14; 95% CI = 1.02-1.27). The association between DII score and fractures was not significant among men or in the sample as whole. Pro-inflammatory diet is associated with a higher incidence of fractures in women but not men.

TI Racial differences in comorbidity profile among patients with chronic obstructive

pulmonary disease
SO BMC MEDICINE
LA English
DT Article
DE COPD; Comorbidity; Race; Ethnicity
ID cardiovascular-disease; united-states; lung-function; copd; mortality; exacerbation; population; obesity; anemia; cohort
AB Background: Chronic obstructive pulmonary disease (COPD) is often accompanied by multiple comorbidities, which are associated with an increased risk of exacerbation, a poor health-related quality of life, and high mortality. However, differences in comorbidity profile by race and ethnicity in COPD patients have not been fully elucidated. Methods: Participants aged 40 to 79 years with spirometry-defined COPD from the U.S. National Health and Nutrition Examination Survey (NHANES) (2007-2012) and from the Korea NHANES (2007-2015) were analyzed to compare the prevalence of comorbidities by race and ethnicity group. Comorbidities were defined using questionnaire data, physical exams, and laboratory tests. Results: Non-Hispanic Whites had the highest prevalence of dyslipidemia (65.5%), myocardial infarction (6.2%), osteoarthritis (40.1%), and osteoporosis (13.6%), while non-Hispanic Blacks had the highest prevalence of asthma (24.0%), hypertension (70.2%), stroke (7.3%), diabetes mellitus (DM) (23.3%), anemia (16.4%), and rheumatoid arthritis (11.9%). Compared to non-Hispanic Whites, non-Hispanic Blacks had a significantly higher prevalence of hypertension, stroke, DM, anemia, and rheumatoid arthritis after adjusting for age, sex, body mass index, and smoking status, while Hispanics had a significantly higher prevalence of DM and anemia, and Koreans had significantly lower prevalences of all comorbidities except stroke, DM, and anemia. Conclusions: COPD-related comorbidities varied significantly by race and ethnicity, and different strategies may be required for the optimal management of COPD and its comorbidities in different race and ethnicity groups.

TI Scoping review of priority setting of research topics for musculoskeletal conditions
SO BMJ OPEN
LA English
DT Review
ID primary-care research; of-the-art; american orthopedic foot; ankle research priority; low-back-pain; research agenda; clinical-research; chiropractic profession; research prioritization; research council
AB Objective Describe research methods used in priority-setting exercises for musculoskeletal conditions and synthesise the priorities identified. Design Scoping review. Setting and population Studies that elicited the research priorities of

patients/consumers, clini cians, researchers, policy-makers and/or funders for any musculoskeletal condition were included. Methods and analysis We searched MEDLINE and EMBASE from inception to November 2017 and the James Lind Alliance top 10 priorities, Cochrane Priority Setting Methods Group, and Cochrane Musculoskeletal and Back Groups review priority lists. The reported methods and research topics/questions identified were extracted, and a descriptive synthesis conducted. Results Forty-nine articles fulfilled our inclusion criteria. Methodologies and stakeholders varied widely (26 included a mix of clinicians, consumers and others, 16 included only clinicians, 6 included only consumers or patients and in 1 participants were unclear). Only two (4%) reported any explicit inclusion criteria for priorities. We identified 294 broad research priorities from 37 articles and 246 specific research questions from 17 articles, although only four (24%) of the latter listed questions in an actionable format. Research priorities for osteoarthritis were identified most often (n=7), followed by rheumatoid arthritis (n=4), osteoporosis (n=4) and back pain (n=4). Nearly half of both broad and specific research priorities were focused on treatment interventions (n=116 and 111, respectively), while few were economic (n=8, 2.7% broad and n=1, 0.4% specific), implementation (n=6, 2% broad and n=4, 1.6% specific) or health services and systems research (n=15, 5.1% broad and n=9, 3.7% specific) priorities. Conclusions While many research priority-setting studies in the musculoskeletal field have been performed, methodological limitations and lack of actionable research questions limit their usefulness. Future studies should ensure they conform to good priority-setting practice to ensure that the generated priorities are of maximum value.

TI Evidence for Ongoing Modeling-Based Bone Formation in Human Femoral Head Trabeculae via Forming Minimodeling Structures: A Study in Patients with Fractures and Arthritis
SO FRONTIERS IN ENDOCRINOLOGY
LA English

DT Article
DE modeling-based bone formation; forming minimodeling structures; femoral head; bone histomorphometry; femoral neck fracture; rheumatoid arthritis; hip osteoarthritis
ID vertebral cancellous bone; microcallus formations; rheumatoid-arthritis; sedimentation-rate; dialysis patients; osteoid seams; cortical bone; osteoporosis; osteocytes; disease
AB Bone modeling is a biological process of bone formation that adapts bone size and shape to mechanical loads, especially during childhood and adolescence. Bone modeling in cortical bone can be easily detected using sequential radiographic images, while its assessment in trabecular bone is challenging. Here, we performed histomorphometric analysis in 21 bone specimens from biopsies collected during hip arthroplasty, and we proposed the criteria for histologically identifying an active modeling-based bone formation, which we call a "forming minimodeling structure" (FMiS). Evidence of FMiSs was found in 9 of 20 specimens (45%). In histomorphometric analysis, bone volume was significant higher in specimens displaying FMiSs compared with the specimens without these structures (BV/TV, 31.7 10.2 vs. 23.1 3.9%; $p < 0.05$). Osteoid parameters were raised in FMiS-containing bone specimens (OV/BV, 2.1 +/- 1.6 vs. 0.6 +/- 0.3%; $p < 0.001$, OS/BS, 23.6 +/- 15.5 vs. 7.6 +/- 4.2%; $p < 0.001$, and O.Th, 7.4 mu m +/- 2.0 vs. 5.2 +/- 1.0; $p < 0.05$). Our results showed that the modeling-based bone formation on trabecular bone surfaces occurs even during adulthood. As FMiSs can represent histological evidence of modeling-based bone formation, understanding of this physiology in relation to bone homeostasis is crucial.

ID n-acetyl cysteine; genome-wide association; ataxia-telangiectasia; knee osteoarthritis; deficient mice; chondrocyte hypertrophy; histone acetylation; clinical-parameters; antioxidant enzymes; articular-cartilage
AB Osteoarthritis is the most common joint disorder with increasing global prevalence due to aging of the population. Current therapy is limited to symptom relief, yet there is no cure. Its multifactorial etiology includes oxidative stress and overproduction of reactive oxygen species, but the regulation of these processes in the joint is insufficiently understood. We report that ANP32A protects the cartilage against oxidative stress, preventing osteoarthritis development and disease progression. ANP32A is down-regulated in human and mouse osteoarthritic cartilage. Micro-array profiling revealed that ANP32A protects the joint by promoting the expression of ATM, a key regulator of the cellular oxidative defense. Antioxidant treatment reduced the severity of osteoarthritis, osteopenia, and cerebellar ataxia features in Anp32a-deficient mice, revealing that the ANP32A/ATM axis discovered in cartilage is also present in brain and bone. Our findings indicate that modulating ANP32A signaling could help manage oxidative stress in cartilage, brain, and bone with therapeutic implications for osteoarthritis, neurological disease, and osteoporosis.

TI Nonclinical and clinical pharmacological characterization of the potent and selective cathepsin K inhibitor MIV-711
SO JOURNAL OF TRANSLATIONAL MEDICINE
LA English
DT Article
DE Cathepsin K; Osteoarthritis; CTX-I; NTX-I; CTX-II; Subchondral bone; Cartilage
ID bone turnover; knee osteoarthritis; postmenopausal osteoporosis; biochemical markers; controlled-trial; double-blind; collagen; expression; biomarkers; cartilage
AB Background: Cathepsin K is an attractive therapeutic target for diseases in which bone resorption is excessive such as osteoporosis and osteoarthritis (OA). The current paper characterized the pharmacological profile of the potent and selective cathepsin K inhibitor, MIV-711, in vitro and in cynomolgus monkeys, and assessed translation to human based on a single dose clinical study in man. Methods: The potency and selectivity of MIV-711 were assessed in vitro using recombinant enzyme assays and differentiated human osteoclasts. MIV-711 was administered to healthy cynomolgus monkeys (3-30 mu mol/kg, p.o.). Plasma levels of MIV-711 and the bone resorption biomarker CTX-I were measured after single dose experiments, and urine levels of CTX-I, NTX-I and CTX-II biomarkers were measured after repeat dose experiments. The safety, pharmacokinetics and pharmacodynamics (serum CTX-I) of MIV-711 were assessed in human healthy subjects after single ascending doses from 20 to 600 mg. Results: MIV-711 was a potent inhibitor of human cathepsin K (K-i: 0.98 nmol/L) with > 1300-fold selectivity towards other human cathepsins. MIV-711 inhibited human osteoclast-mediated bone resorption with an IC50 value of 43 nmol/L. Single oral doses of MIV-711 to monkeys reduced plasma levels of CTX-I in a dose-dependent fashion by up to 57% at trough. The effect on CTX-I was linearly correlated to the plasma exposure of MIV-711, while the efficacy duration outlasted plasma exposure. Repeat oral dosing with MIV-711 also reduced urinary levels of the bone resorption biomarkers CTX-I (by 93%) and NTX-I (by 71%) and the cartilage degradation biomarker CTX-II (by 71%). MIV-711 was safe and well-tolerated when given as single ascending doses to healthy subjects. MIV-711 reduced serum CTX-I levels in a dose-dependent manner by up to 79% at trough. The relationship between MIV-711 exposure and effects on these biomarkers in humans was virtually identical when compared to the corresponding monkey data. Conclusions: MIV-711 is a potent and selective cathepsin K inhibitor with dose-dependent effects on biomarkers of bone and cartilage degradation in monkey and human. Taken together, MIV-711 shows promise for the treatment of bone and cartilage related disorders in humans, such as OA.

TI Emerging role of extracellular vesicles in musculoskeletal diseases
SO MOLECULAR ASPECTS OF MEDICINE
LA English
DT Review
DE Exosomes; Muscular dystrophy; Osteoporosis; Osteoarthritis; microRNA
ID synovial fibroblasts; osteogenic differentiation; matrix-metalloproteinase; muscle; expression; micrornas; myogenesis; mechanism; exosm; osteoarthritis
AB Research into the biology of extracellular vesicles (EVs), including exosomes and microvesicles, has expanded significantly with advances in EV isolation techniques, a better understanding of the surface markers that characterize exosomes and microvesicles, and greater information derived from eomics approaches on the proteins, lipids, mRNAs, and microRNAs (miRNAs) transported by EVs. We have recently discovered a role for exosome-derived miRNAs in age-related bone loss and osteoarthritis, two conditions that impose a significant public health burden on the aging global population. Previous work has also revealed multiple roles for EVs and their miRNAs in muscle regeneration and congenital myopathies. Thus, EVs appear to be involved in a number of degenerative conditions that impact the musculoskeletal system, indicating that the musculoskeletal system is an excellent model for investigating the role of EVs in tissue maintenance and repair. This review highlights the role of EVs in bone, skeletal muscle, and joint health, including both normal tissue metabolism as well as tissue injury repair and regeneration. A consistent theme that emerges from study of musculoskeletal EVs is that various miRNAs appear to mediate a number of key pathological processes. These findings point to a potential therapeutic opportunity to target EV-derived

miRNAs as a strategy for improving musculoskeletal function. (c) 2017 Elsevier Ltd. All rights reserved.

TI Profile of osteoarthritic patients undergoing hip or knee arthroplasty, a step toward a definition of the "need for surgery"
SO AGING CLINICAL AND EXPERIMENTAL RESEARCH
LA English
DT Article
DE Osteoarthritis; Hip; Knee; Arthroplasty; Treatment
ID total joint arthroplasty; quality-of-life; preoperative radiographic severity; european-society; economic-aspects; relevant outcm; physical function; health-status; replacement; osteoporosis

AB Aims The objective of this study is to characterize, based on clinical, radiographic, health-related, quality-of-life-related, and demographic variables, the profile of a large, homogeneous, cohort of patients undergoing knee or hip arthroplasty, in a public hospital. Current regulatory guidelines for structure-modifying agent are not clear regarding hard clinical endpoint. The "need for surgery" has been suggested as a potential relevant outcome, but, until now, it is poorly defined. By characterizing a large number of patients who undergo total hip or total knee replacement, this paper aims at providing a contribution to the better definition of the "need for surgery" in advanced OA of the lower limbs. Methods Consecutive patients who underwent primary knee arthroplasty (KA) or hip arthroplasty (HA) between December 2008 and February 2013, in an academic hospital, and who were diagnosed with hip or knee osteoarthritis (OA) (ACR criteria). Data collected at baseline included demographic and clinical data; Kellgren-Lawrence radiological grading; Western Ontario and Mc Master Universities Arthritis Index (WOMAC); EuroQol five dimensions questionnaire and EuroQol visual analog scale; and 36-item Short Form Health Survey. Results 626 subjects were included, 346 with hip OA and 280 with knee OA. Significant differences between subjects in need of an HA or of a KA were seen in terms of age (66.5 years versus 65 for hip), duration of complaints (2188 days versus 1146.5 for hip), BMI (28.68 kg/mA(2) versus 27.07), radiological status (severe OA were found in 79.85% in knee group and 68.73% in hip group), comorbidities (FCI higher in knee group), traumatic of surgical history (37 versus 6%), and health-related quality of life and function (patients with HA had a poorer clinical status regarding WOMAC and WOMAC subscale). Conclusion Significant differences were observed between patients undergoing KA or HA. These differences might be useful to better understand the "need for surgery" status in these indications. This concept may help to define responders and failures to pharmacological treatment of OA.

ID 316l stainless-steel; mechanical-property; biomedical applications; powder-metallurgy; corrosion behavior; titanium; laser; implants; surface; fatigue
AB Bioimplants are becoming increasingly important in the modern society due to the fact of an aging population and associated issues of osteoporosis and osteoarthritis. The manufacturing of bioimplants involves an understanding of both mechanical engineering and biomedical science to produce biocompatible products with adequate lifespans. A suitable selection of materials is the prerequisite for a long-term and reliable service of the bioimplants, which relies highly on the comprehensive understanding of the material properties. In this paper, most biomaterials used for bioimplants are reviewed. The typical manufacturing processes are discussed in order to provide a perspective on the development of manufacturing fundamentals and latest technologies. The review also contains a discussion on the current measurement and evaluation constraints of the finished bioimplant products. Potential future research areas are presented at the end of this paper.

TI Current methods of preventing aseptic loosening and improving osseointegration of titanium implants in cementless total hip arthroplasty: a review
SO JOURNAL OF INTERNATIONAL MEDICAL RESEARCH
LA English
DT Article
DE Osseointegration; titanium implant; cementless hip arthroplasty; aseptic loosening; osteoarthritis; surgery
ID intensity pulsed ultrasound; bone regeneration; stem; risk; revision; failure; replacement; migration; register; alloys
AB Hip osteoarthritis is the most common joint disorder, and is represented by a

degenerative process, resulting in pain and functional impairment. If conservative treatment for hip osteoarthritis fails, the only remaining option is hip arthroplasty. Despite good survival of implants, loosening of components is the most common complication. This leads to revision surgeries, which are technically demanding, expensive, and result in a low satisfaction rate. Uncemented hip replacements require proper osseointegration for increased survival. Physical characteristics of implants include biocompatibility, Young's modulus of elasticity, strength, and corrosion resistance, and each influence fixation of implants. Moreover, implant surface treatments, pore size, pore density, and femoral stem design should be appropriately selected. Patients' optimization of obesity, osteoporosis, cardiovascular disease, psychotic disorders, and smoking cessation are associated with a higher survival of implants. Surgical factors, such as approach, drilling and rasping, acetabular bone coverage, acetabular cup positioning, and implant size, also affect survival of implants. Avoiding drugs, which may impair osseointegration of implants, and having an appropriate rehabilitation protocol are important. Future directions include anabolic and anti-catabolic bone-acting drugs to enhance osseointegration of implants. Comprehensive knowledge of the factors mentioned above is important for preventing aseptic loosening, with important socioeconomic consequences.

TI A Conceptual Model for the Evaluation of Surgical Missions
SO JOURNAL OF BONE AND JOINT SURGERY-AMERICAN VOLUME
LA English
DT Article
ID total joint replacement; total knee replacement; quality-of-life; functional status; physical-activity; pain management; global burden; total hip; health; dominican
AB Background: Medical missions to low and middle-income countries are increasingly frequent, with an estimated 6,000 trips sponsored by U.S. organizations accounting for approximately 200,000 surgical cases and $250 million in costs annually. However, these missions have received little critical evaluation. This paper describes the research program Operation Walk (Op-Walk) Boston, and proposes an evaluation model for similar surgical missions. Methods: We propose an evaluation model, borrowing from the work of Donabedian and enriched by evidence from our research program. The model calls for evaluation of the salient contextual factors (culture and beliefs), system management (structure, process, and outcomes), and sustainability of the program's interventions. We used these domains to present findings from the quantitative and qualitative research work of Op-Walk Boston. Results: Op-Walk's qualitative research findings demonstrated that cultural factors are important determinants of patients' perceptions of arthritis etiology, physical activity patterns, and treatment preferences. Quantitative assessments documented that Dominican patients had worse lower-extremity functional status (mean Western Ontario and McMaster Universities Osteoarthritis Index [WOMAC] function score of 33.6) and pain preoperatively than patients undergoing total hip or knee replacement in the U.S. (WOMAC function score of 43.3 to 54), yet they achieved excellent outcomes (50-point improvement), comparable to those of their U.S. counterparts. Assessments of the quality and sustainability of the Op-Walk program showed that the quality of care provided by Op-Walk Boston meets Blue Cross Blue Shield Centers of Excellence (Blue Distinction) criteria, and that sustainable changes were transferred to the host hospital. Conclusions: Our proposed model offers a method for formal assessment of medical missions that addresses the call for evidence of their merit. We suggest that surgical missions adopt quantitative and qualitative strategies to document their impact, identify areas of improvement, and justify program continuation, growth, and support.

TI MicroRNAs in orthopaedic research: Disease associations, potential therapeutic applications, and perspectives
SO JOURNAL OF ORTHOPAEDIC RESEARCH
LA English
DT Article
DE MicroRNAs (miRNAs); cartilage; bone; skeletal development; osteoarthritis
ID mesenchymal stem-cells; lumbar disc degeneration; osteogenic differentiation; chondrocyte apoptosis; bone-formation; molecular characterization; intraarticular injection; extracellular vesicles; expression profiles; noncoding rnas
AB MicroRNAs (miRNAs) are small non-coding RNAs that function to control many cellular processes by their ability to suppress expression of specific target genes. Tens to hundreds of target genes may be affected by one miRNA, thereby resulting in modulation of multiple pathways in any given cell type. Therefore, altered expression of miRNAs (i.e., during tissue development or in scenarios of disease or cellular stress) can have a profound impact on processes regulating cell differentiation, metabolism, proliferation, or apoptosis, for example. Over the past 5-10 years, thousands of reports have been published on miRNAs in cartilage and bone biology or disease, thus highlighting the significance of these non-coding RNAs in regulating skeletal development and homeostasis. For the purpose of this review, we will focus on miRNAs or miRNA families that have demonstrated function in vivo within the context of cartilage, bone or other orthopaedic-related

tissues (excluding muscle). Specifically, we will discuss studies that have utilized miRNA transgenic mouse models or in vivo approaches to target a miRNA with the aim of altering conditions such as osteoarthritis, osteoporosis and bone fractures in rodents. We will not discuss miRNAs in the context skeletal cancers since this topic is worthy of a review of its own. Overall, we aim to provide a comprehensive description of where the field currently stands with respect to the therapeutic potential of specific miRNAs to treat orthopaedic conditions and current technologies to target and modify miRNA function in vivo. TI Oral hyaluronan for the treatment of knee osteoarthritis: a systematic review
SO PROGRESS IN NUTRITION

LA English
DT Review
DE Hyaluronic acid; Oral treatments; Dietary supplement; Knee; Osteoarthritis; Objective measures
ID molecular-weight hyaluronan; extract-containing supplement; comb extract; double-blind; clinical-trial; pain; acid; hyalgan(r); absorption; adults
AB Study Objectives: Osteoarthritis (OA) is the most common chronic condition of the joints, affecting approximately 27 million of people in the US and its prevalence is predicted to grow. Recently, symptomatic slowacting drugs for osteoarthritis (SYSADOA) have been vastly studied and have generated considerable interest among clinicians and the public. In particular, the use of oral hyaluronic acid (HA) treatments for knee pain has been the source of much research and it is now widely adopted in the clinic for its safety and relative low cost. The aim of this study is to discuss the efficacy of oral HA in treating knee OA based on the most recent data from the literature as well as to encourage the use of objective measures to determine more effectively the efficacy of current therapies for knee OA. Methods: We searched the PubMed database up to 23/01/2018 based on data from randomized, double-blind, placebo-controlled trials, non-controlled trials and cohort studies conducted in adult subjects. The search words used contained the terms: oral hyaluronan (HA) and knee osteoarthritis (OA). We selected 15 relevant reports. The review was registered on PROSPERO (International prospective register of systematic reviews), registration number CRD42018104127. Results: Companies in Japan, US and Europe produced different oral supplements containing HA in various formulations, which have been tested in clinical trials. The vast majority of the studies analyzed found significant improvements of scores including VAS, WOMAC, JKOM and SF-36v2 in patients with moderate knee OA after short (1 - 4 months) daily treatments with oral HA preparations, compared to placebo-treated controls. Interestingly, few studies proposed the use of objective measures to evaluate the efficacy of HA treatments with ultrasonography and an isokinetic dynamometer, but they obtained modest and controversial results. Conclusions: Current clinical data on oral HA products for the treatment of mild to moderate knee OA are promising and in line with The European Society for Clinical and Economic Aspects of Osteoporosis and Osteoarthritis (ESCEO) recommendation to use SYSADOA. However, more high-quality research with larger sample sizes and longer exposures to the oral treatment is needed to confirm these data. Particularly, more effort is required to standardize the treatments (final dose of HA, molecular weight of HA and presence of other active molecules) and to assess the results on patients with objective measures.

TI Customized post-operative alignment improves clinical outcome following medial open-wedge osteotomy
SO KNEE SURGERY SPORTS TRAUMATOLOGY ARTHROSCOPY
LA English
DT Article
DE High tibial osteotomy; Varus deformity; Osteoarthritis; Cartilage defect; Correction angle
ID high tibial osteotomy; autologous chondrocyte implantation; varus knee; cartilage regeneration; survivorship analysis; limb alignment; osteoarthritis; defects; compartment; evolution
AB Purpose High tibial osteotomy (HTO) has gained more importance in the treatment of cartilage damage or osteoarthritis of the medial compartment with concurrent varus deformity. Concerning the extent of axis correction, various different views exist. The aim of this study was to evaluate the effect of the size of axis correction on functional outcome in patients undergoing a valgus HTO. Methods From 2005 to 2013, 156 patients with an underlying varus deformity and cartilage damages or unicompartimental osteoarthritis of the medial compartment were treated by HTO. Retrospectively patients were allocated into three different groups according to the degree of axis correction. For this purpose, three adjacent areas, respectively, comprising 5% of the tibial plateau were defined. Limits of those areas were set as follows: with the medial border representing the 0% point and the lateral border representing the 100 point, the three areas were separated according to their limiting intersection points (group A 50-55%, group B 55-60%, group C > 60%). For comparison of the functional outcomes, standardized measures and scores were used (pre-OP: VAS, Lysholm; post-OP: VAS, Lysholm, KOOS). Analysis of the pre- and post-operatively recorded X-rays was effected by means of a planning software (mediCAD, Hectec GmbH, Germany), and statistical analysis was carried out using SPSS Statistics 21.0 (IBM Corp., Armonk, USA). A p value of 0.05 was considered statistically significant. Results Thirty-nine patients were allocated to group A, 50 patients to group B and 67 to group C. Pre-operatively, patients in each group were of a homogenous constitution. In the groups A-C, HTO proved to reduce the VAS score and to increase the Lysholm score ($p < 0.001$). Regarding outcome parameters, group A showed significantly better results in terms of increased Lysholm ($p = 0.049$) and KOOS pain score ($p = 0.043$). In patients treated by HTO and ACI implantation for medial compartment lesions, the best results were achieved in group A which was of statistical significance in comparison of the Lysholm ($p = 0.006$) and VAS score ($p = 0.045$) of groups A and C. In this subgroup, the size of the post-operative valgus angle significantly correlated with the final VAS score (PC 0.364; $p = 0.013$), final Lysholm score (PC - 0.390; $p = 0.007$) and KOOS4 (PC - 0.356; $p = 0.014$). Conclusion HTO for varus deformity in patients with concomitant cartilage damage or osteoarthritis

of the medial compartment is a reliable treatment option with satisfying functional outcome. Precise pre-operative planning regarding individual factors in each patient is mandatory; a pathology-based extent of correction leads to a favourable clinical outcome and to a significant reduction in pain.

ID vitamin-d status; dna methylation; osteogenic differentiation; bone mass; histone deacetylases; multiple-myeloma; noncoding rnas; developmental origins; childhood growth; stem-cells
AB Purpose of Review Epigenetic mechanisms modify gene activity in a stable manner without altering DNA sequence. They participate in the adaptation to the environment, as well as in the pathogenesis of common complex disorders. We provide an overview of the role of epigenetic mechanisms in bone biology and pathology. Recent Findings Extensive evidence supports the involvement of epigenetic mechanisms (DNA methylation, post-translational modifications of histone tails, and non-coding RNAs) in the differentiation of bone cells and mechanotransduction. A variety of epigenetic abnormalities have been described in patients with osteoporosis, osteoarthritis, and skeletal cancers, but their actual pathogenetic roles are still unclear. A few drugs targeting epigenetic marks have been approved for neoplastic disorders, and many more are being actively investigated. Summary Advances in the field of epigenetics underscore the

complex interactions between genetic and environmental factors as determinants of osteoporosis and other common disorders. Likewise, they help to explain the mechanisms by which prenatal and post-natal external factors, from nutrition to psychological stress, impact our body and influence the risk of later disease.

TI miRNA-27a regulates arthritis via PPAR in vivo and in vitro
SO MOLECULAR MEDICINE REPORTS
LA English
DT Article
DE microRNA-27a; arthritis; PPAR; IGFBP-5
ID human osteoarthritis chondrocytes; knee osteoarthritis; rat model; signaling pathway; apoptosis; cartilage; gamma; expression; efficacy; matrix
AB The present study investigated the role of microRNA (miR)-27a in the development of arthritis and its mechanism of action. Initially, collagen was used to develop an in vivo rat model of arthritis. Changes in the miRs in the rats were analyzed. It was subsequently observed that miR-27a expression was reduced in patients with arthritis, compared with the control group. In the present study an in vitro miR-27a overexpression model of arthritis was established and it was observed that miR-27a increased the proliferation of osteoblast-like cells in vitro. miR-27a overexpression promoted osteogenic differentiation, increased alkaline phosphatase (ALP) and osteoporosis (OST) content, induced insulin-like growth factor binding protein-5 (IGFBP-5) protein expression, reduced inflammation and suppressed peroxisome proliferator-activated receptor (PPAR) and matrix metalloproteinase-17 (MMP-17) protein expression in arthritis. However, miR-27a downregulation inhibited osteogenic differentiation, increased inflammation and PPAR and MMP-17 protein expression and suppressed ALP and OST content in an in vitro model of arthritis. The PPAR inhibitor reduced the function of miR-27a downregulation on arthritis. Therefore the results of the present study revealed that miR-27a regulates arthritis via PPAR.

TI Anti-osteoporotic effects of mixed compositions of extracellular polymers isolated from Aureobasidium pullulans and Textoria morbifera in ovariectomized mice
SO BMC COMPLEMENTARY AND ALTERNATIVE MEDICINE
LA English
DT Article
DE Anti-osteoporotic effect; Aureobasidium pullulans; -Glucans; Exopolymer; Textoria morbifera
ID beta-glucan; dendropanax-morbifera; bone loss; induced-osteoarthritis;

antidiabetic activity; alveolar bone; green tea; rats; mouse; polycan
AB BackgroundExtracellular polymeric substances isolated from Aureobasidium pullulans (EAP), containing specifically 13% -1,3/1,6-glucan, have shown various favorable bone-preserving effects. Textoria morbifera Nakai (TM) tree has been used as an ingredient in traditional medicine and tea for various pharmacological purposes. Thus, the present study was aimed to examine the synergistic anti-osteoporotic potential of mixtures containing different proportions of EAP and TM compared with that of the single formulations of each herbal extract using bilateral ovariectomized (OVX) mice, a renowned rodent model for studying human osteoporosis.MethodsThirty five days after bilateral-OVX surgery, 9 combinations of EAP:TM (ratios=1:1, 1:3, 1:5, 1:7, 1:9, 3:1, 5:1, 7:1, 9:1) and single separate formulations of EAP or TM were supplied orally, once a day for 35days at a final concentration of 200mg/kg. Variations in body weight gains during the experimental periods, as well as femur weights, bone mineral density (BMD), bone strength (failure load), and mineral content (calcium [Ca] and inorganic phosphorus [IP]) following sacrifice were measured. Furthermore, histomorphometric and histological profile analyses of serum biochemical parameters (osteocalcin content and bone specific alkaline phosphatase [bALP] activity) were conducted following sacrifice. Femurs histomorphometric analyses were also conducted for bone resorption, structure and mass. The results for the mixed formulations of EAP:TM and separate formulations were compared with those of risedronate sodium (RES).ResultsThe EAP:TM (3:1) formulation synergistically enhanced the anti-osteoporotic potential of individual EAP or TM formulations, possibly due to enhanced variety of the active ingredients. Furthermore, the effects of EAP:TM were comparable to those of RES (2.5mg/kg) treatment.ConclusionThe results of this study suggest that, the EAP:TM (3:1) combination might act as a new pharmaceutical agent and/or health functional food substance for curing osteoporosis in menopausal women.

TI Rapidly Destructive Arthrosis of Bilateral Humeral Heads Caused by Subchondral Insufficiency Fracture
SO ACTA MEDICA OKAYAMA

LA English
DT Article
DE rapidly destructive arthrosis; differential diagnosis; humeral head replacement; osteoporosis; shoulder joint
ID shoulder
AB The bilateral shoulder pain of an 81-year-old Japanese woman due to falls persisted despite celecoxib treatment, and plain X-rays later showed bilateral collapsed humeral heads. After ruling out osteoarthritis, infectious arthritis, crystal-induced arthritis, neuropathic arthropathy, and osteonecrosis, we diagnosed bilateral shoulder joint rapidly destructive arthrosis (RDA). Lumbar bone mineral density showed very low T-score (-4.1). Primary osteoporosis was observed. Histology of biopsied humeral head indicated the features of fracture healing process: callus formation and osteodasts without empty lacunae. Her history thus included an insufficiency fracture due to severe osteoporosis. Bilateral humeral head replacement was performed; her shoulder joint function improved. This case is extremely rare in that RDA was caused by simultaneous bilateral shoulder joint collapse within a very short time, with minimal or low mechanical stress and severe osteoporosis.

TI Mid-term results with a neck-preserving femoral stem for total hip arthroplasty
SO HIP INTERNATIONAL
LA English
DT Article
DE Femoral neck preservation; hip; short stem; stem; THA; total hip arthroplasty
ID survival; implants; design
AB Introduction: This prospective study aims to evaluate the mid-term clinical and radiological performance of a new short, neck-preserving femoral stem in total hip arthroplasty (THA). Patients and methods: 178 consecutive patients (190 hips) underwent THA from November 2008 to July 2016. Mean follow-up is 62.4 months. Women make up 41% of the cohort at a mean age of 50 +/- 4 years, with primary hip osteoarthritis as the main complaint. All patients underwent radiological

evaluation using the modified Gruen method, and clinical assessment via the Harris Hip Score (HHS), preoperatively and at 1, 6, 12, 24, 60, 80 and 106 months post-op. Results: A mean HHS increase (from 50 +/- 12 points preoperatively to 96 +/- 4 at 62 months), together with painless articular improvement, was present at 6 months postoperatively indicating early functional recovery. Effective osteointegration and primary stability were present on radiographic analysis, without evidence of stress shielding or stem mal-positioning: subsidence amounting to <1 mm was present in 40% of implants immediately after surgery, with subsequent stabilisation within 6 months in all cases. Metaphyseal trabecular re-orientation in absence of symptomatic cortical hypertrophy or progressive radiolucency indicates physiological load transfer in the proximal femur. Stem-related revision surgery was necessary for 1.05% of all implants due to fracture and infection. No loosening, dislocations or mechanical failures were reported. Conclusions: All patients show excellent functional recovery and clinical outcomes at 62 months, demonstrating the role optimal primary stability and physiological joint reconstruction play in ensuring stable secondary fixation and long-term survival of a short, neck-preserving stem.

TI Development and Pilot Testing of Multimedia Patient Education Tools for Patients With Knee Osteoarthritis, Osteoporosis, and Rheumatoid Arthritis
SO ARTHRITIS CARE & RESEARCH
LA English
DT Article
ID knowledge questionnaire pkq; quality-of-life; health literacy; entertainment education; randomized-trial; decision aids; responsiveness; validity; association; reliability
AB ObjectiveWe developed and tested multimedia patient education tools (video tools) for patients with knee osteoarthritis (OA), osteoporosis (OP), and rheumatoid arthritis (RA). MethodsWe followed an edutainment model, incorporating educational patient story lines. The goals were designed to make the programs both didactic and entertaining, with navigation and graphic user interfaces as simple as possible. We created both English and Spanish language versions. Once the video tool was finalized, 60 patients, 20 per disease, were shown the tool and interviewed. Disease knowledge was our primary outcome, and decision conflict, disease management, and acceptability were secondary outcomes. ResultsWe observed statistically significant differences in pre- to postintervention knowledge questionnaire scores (before and after viewing the video tool) (OA: P = 0.03, OP: P

= 0.01, and RA: P < 0.0001). Most participants felt they gained clarity on disease duration, symptoms, and the time medication takes to start acting; were encouraged to see their doctor regularly; and were more aware about taking their medications. In terms of acceptability, most patients in all disease groups found the length and amount of information presented in the video tools to be just right, and the presentation to be balanced. In terms of comprehension, all participants provided a favorable evaluation of the video tool; all found the video easy to use, the vocabulary easy to understand, and the materials to be well organized. ConclusionMultimedia tools that incorporate videos may help patients better understand and manage their disease. Patient involvement in the development process is essential to ensure relevant content and usability.

TI Social cognitive or learning theory use to improve self-efficacy in

musculoskeletal rehabilitation: A systematic review and meta-analysis
SO PHYSIOTHERAPY THEORY AND PRACTICE
LA English
DT Article
DE Patient education; therapeutic exercise; movement rehabilitation
ID total knee replacement; functional recovery; health behavior; older women; pain; osteoarthritis; limitations; management; exercise; program
AB Objective: To review the rehabilitation research methodological quality and intervention effectiveness of studies that used social cognitive or learning theory principles to improve self-efficacy in patients with orthopedic or musculoskeletal conditions. Design: A systematic literature review and meta-analysis of peer reviewed studies published in English was performed using the OVID and SPORTDiscus databases. Initial search terms were social cognitive theory or social learning theory combined with rehabilitation. Results: From the 25 total studies that contributed to this review, 23 contributed patient outcome information and 20 contributed to effect size determination. Of 1947 total study participants, most (n=1537, 78.9%) were women. Participants were primarily late middle-age (64.8 +/- 17years). Studies included participants with hip or knee osteoarthritis (OA) or who were post-hip or knee arthroplasty (11/25, 44%), post-femur or tibia fracture (6/25, 24%), adults in assisted living or inpatient rehabilitation facilities (2/25, 8%), independent community dwelling older adults (2/25, 8%), college-age recreational athletes post-sports injury (2/25, 8%), older women with osteoporosis risk (1/25, 4%) or middle-aged adults post-traumatic hand injury (1/25, 4%). For the 20 studies that contributed to effect size determination, a large overall mean effect size (Cohen's d=0.98, 95% CI 0.42-1.86) was observed. Conclusions: Studies that used social cognitive or learning theory principles to improve self-efficacy in patients with orthopedic or musculoskeletal conditions generally displayed moderate to large effect sizes supporting this intervention. Sound research methodological quality and low risk of intervention-related injury or other adverse events were also generally observed. Findings suggest that these interventions may also benefit individuals with conditions that have not progressed to end-stage salvage surgery such as younger, more athletically active individuals for knee OA prevention.

TI Enhancing research publications and advancing scientific writing in health research collaborations: sharing lessons learnt from the trenches
SO JOURNAL OF MULTIDISCIPLINARY HEALTHCARE
LA English
DT Article
DE research publication; scientific writing; health research collaboration
ID randomized controlled-trial; individual patient data; hip osteoarthritis; protocol; biostatistics; osteoporosis; metaanalysis; prevention; adherence; framework
AB Background: Disseminating research protocols, processes, methods or findings via peer-reviewed publications has substantive merits and benefits to various stakeholders. Purpose: In this article, we share strategies to enhance research publication contents (ie, what to write about) and to facilitate scientific writing (ie, how to write) in health research collaborations. Methods: Empirical experience sharing. Results: "lb enhance research publication contents, we encourage identifying appropriate opportunities for publications, publishing protocols ahead of results papers, seeking publications related to methodological issues,

considering justified secondary analyses, and sharing academic process or experience. To advance writing, we suggest setting up scientific writing as a goal, seeking an appropriate mentorship, making full use of scientific meetings and presentations, taking some necessary formal training in areas such as effective communication and time and stress management, and embracing the iterative process of writing. Conclusion: All the strategies we share are dependent upon each other; and they advocate gradual academic accomplishments through study and training in a "success-breeds-success" way. It is expected that the foregoing shared strategies in this paper, together with other previous guidance articles, can assist one with enhancing research publications, and eventually one's academic success in health research collaborations.

AB Matrix-assisted laser desorption/ionisation mass spectrometric imaging (MALDI MSI) is a technique that provides localized information on intact molecules in a sample. Micro X-ray fluorescence (mu XRF) imaging allows the examination of the spatial distribution of elements in a sample without any morphological changes. These methods have already been applied separately to different tissues, organs, plants and bacterial films, but, to the best of our knowledge, they have yet to be coupled in a multimodal analysis. In this proof-of-principle study, we established and tested sample preparation strategies, allowing the multimodal analysis of lipids (sphingomyelin and phosphatidylcholines) and elements relevant to bone structures as calcium, phosphorous and sulphur in the very same sample section of a chicken phalanx without tissue decalcification. The results of the investigation of such parameters as adhesive tapes supporting tissue sections, and the sequence of the imaging experiments are presented. We show specific lipid distributions in skin, cartilage, muscle, nail, and the intact morphology of bone by calcium and phosphorus imaging. A combination of molecular and elemental imaging was achieved, thus, providing now for the first time the possibility of gathering MALDI MSI and mu XRF information from the very same sample without any washing steps omitting therefore the analytical artifacts that inevitably occur in approaches using consecutive tissue sections. The proposed combination can benefit in research studies regarding bone diseases, osteoporosis, osteoarthritis, cartilage failure, bone/tendon distinguishing, where elemental and lipid interaction play an essential role.

TI Higher Rates of Operative Delivery and Maternal and Neonatal Complications in Persistent Occiput Posterior Position with a Large Head Circumference: A Retrospective Cohort Study
SO FETAL DIAGNOSIS AND THERAPY
LA English
DT Article
DE Head circumference; Instrumental delivery; Occiput posterior position; Operative delivery; Prolonged second stage of labor
ID anal-sphincter injury; fetal position; labor; risk; association; 2nd-stage
AB Introduction: We investigated whether large head circumference (HC) combined with persistent occiput posterior (OP) position is associated with higher rates of operative delivery and obstetric and neonatal complications than OP deliveries without large HC or in occiput anterior (OA) position. Materials and Methods: Term singleton deliveries in our centers from January 2010 to December 2014, delivered in cephalic OA (n = 41,038) or OP position (n = 1,740), were assessed. We compared delivery modes, maternal and neonatal complications in OA versus OP deliveries, and HC >= 90th centile versus HC <90th centile in persistent OP position. Results: Persistent OP position combined with HC >= 90th centile was associated with higher rates of vacuum extraction and unplanned cesarean delivery than HC <90th centile in OP position (20.1 vs. 17.2%, OR 1.53 [95% CI 0.99-2.36], and 23.4 vs. 9.2%, OR 3.326 [95% CI 2.17-5.11], respectively). Rates of prolonged second stage of labor and neonatal intensive care unit admission were also increased compared to those in either OA position with HC >= 90th centile or OP

position with HC <90th centile. Discussion: Large HC combined with OP position is associated with higher rates of operative delivery and prolonged second stage of labor compared to OP delivery with HC <90th centile. HC might be included with other measures to assess women in labor, as it is associated with fetal outcomes in OP deliveries. (C) 2017 S. Karger AG, Basel

TI Usefulness of bone microarchitectural and geometric DXA-derived parameters in haemophilic patients
SO HAEMOPHILIA
LA English
DT Article
DE bone mineral density; bone strain; dual energy X-ray absorptiometry; haemophilia; haemophilia joint health score; hip structural analysis; trabecular bone score
ID mineral density; hip fracture; knee osteoarthritis; lumbar spine; score; strength; risk; osteoporosis; strategy; children
AB Introduction Haemophilia is a recessive X-linked inherited bleeding disorder, whose typical symptom is spontaneous intra-articular haemorrhage leading to joint damage, which can be quantified by the Haemophilia Joint Health Score (HJHS). Arthropathy and other characteristics of haemophilic patients may reduce bone mineral density (BMD), increasing the risk for fragility fractures, which also may occur due to bone quality impairment. Aim Methods To evaluate bone quantity by BMD and bone quality by Trabecular Bone Score (TBS), bone strain (BS) and hip structural analysis (HSA) in a haemophilic population, and to relate these parameters to general and specific risk factors for osteoporosis and to HJHS. Seventy haemophilic patients >= 18 years were enrolled. Densitometric derived lumbar spine and femoral BMD with TBS, BS and HSA were performed. Data regarding risk factors for osteoporosis, presence of arthroprosthesis or arthrodesis were collected, and HJHS was calculated. A Z-score <=-2.0 defined a low bone mass. Results Conclusions Overall, a reduced bone mass was present in 52 patients at the femur and in 38 at the lumbar spine. Lumbar spine BMD, TBS and BS did not correlate with HJHS. HSA bone geometric parameters correlated negatively with HJHS. BMD and HSA correlated with some risk factors for osteoporosis, namely HIV and its therapy, hepatitis C and smoking. Haemophilic patients showed a reduced

BMD at lumbar spine and/or femur. Femoral bone density and geometry correlated with HJHS. The microarchitecture of the trabecular vertebral bone seemed to be not influenced by the haemophilic joint damage.

ID stimulates osteoblast differentiation; ovariectomy-induced osteoporosis; nf-kappa-b; postmenopausal osteoporosis; osteogenic differentiation; signaling pathway; ugonin k; in-vivo; osteoarthritis; cells
AB Bone metabolism involves a complex balance between matrix deposition, mineralization, and resorption. Numerous evidences have revealed that dietary components and phytoconstituents can influence these processes, through inhibition of bone resorption, thus exhibiting beneficial effects on the skeleton. Various traditional herbal formulae in ayurvedic and Chinese medicine have shown demonstrable benefits in pharmacological models of osteoporosis. The present review discusses normal bone metabolism and disorders caused by bone disruption, with particular reference to osteoporosis and current therapeutic treatment. Furthermore the effects of constituents from natural products on bone tissue are explained, with relevant evidences of efficacy in various experimental

models.

TI Obesity, Metabolic Syndrome, and Musculoskeletal Disease: Common Inflammatory Pathways Suggest a Central Role for Loss of Muscle Integrity
SO FRONTIERS IN PHYSIOLOGY
LA English
DT Review
DE joint diseases; muscle; bone; tendon; NFkB; MAPK
ID diet-induced obesity; glycation end-products; high-fat diet; necrosis-factor-alpha; skeletal-muscle; gut microbiota; adipose-tissue; knee osteoarthritis; sarcopenic obesity; oxidative stress
AB Inflammation can arise in response to a variety of stimuli, including infectious agents, tissue injury, autoimmune diseases, and obesity. Some of these responses are acute and resolve, while others become chronic and exert a sustained impact on the host, systemically, or locally. Obesity is now recognized as a chronic low-grade, systemic inflammatory state that predisposes to other chronic conditions including metabolic syndrome (MetS). Although obesity has received considerable attention regarding its pathophysiological link to chronic cardiovascular conditions and type 2 diabetes, the musculoskeletal (MSK) complications (i.e., muscle, bone, tendon, and joints) that result from obesity-associated metabolic disturbances are less frequently interrogated. As musculoskeletal diseases can lead to the worsening of MetS, this underscores the imminent need to understand the cause and effect relations between the two, and the convergence between inflammatory pathways that contribute to MSK damage. Muscle mass is a key predictor of longevity in older adults, and obesity-induced sarcopenia is a significant risk factor for adverse health outcomes. Muscle is highly plastic, undergoes regular remodeling, and is responsible for the majority of total body glucose utilization, which when impaired leads to insulin resistance. Furthermore, impaired muscle integrity, defined as persistent muscle loss, intramuscular lipid accumulation, or connective tissue deposition, is a hallmark of metabolic dysfunction. In fact, many common inflammatory pathways have been implicated in the pathogenesis of the interrelated tissues of the musculoskeletal system (e.g., tendinopathy, osteoporosis, and osteoarthritis). Despite these similarities, these diseases are rarely evaluated in a comprehensive manner. The aim of this review is to summarize the common pathways that lead to musculoskeletal damage and disease that result from and contribute to MetS. We propose the overarching hypothesis that there is a central role for muscle damage with chronic exposure to an obesity-inducing diet. The inflammatory consequence

of diet and muscle dysregulation can result in dysregulated tissue repair and an imbalance toward negative adaptation, resulting in regulatory failure and other musculoskeletal tissue damage. The commonalities support the conclusion that musculoskeletal pathology with MetS should be evaluated in a comprehensive and integrated manner to understand risk for other MSK-related conditions. Implications for conservative management strategies to regulate MetS are discussed, as are future research opportunities.

TI The contribution of thoracic vertebral deformity and arthropathy to trunk pain in patients with chronic obstructive pulmonary disease (COPD)
SO RESPIRATORY MEDICINE
LA English
DT Article
DE Pain; Chronic obstructive pulmonary disease; Vertebral deformity; Arthropathy; Thoracic vertebrae; Osteoporosis
ID back-pain; physical-activity; ct; osteoarthritis; epidemiology; osteoporosis; mortality; fracture; people; cancer
AB Background: Pain, commonly localized to the trunk in individuals with COPD, may be due to osteoporosis-related vertebral deformity and chest wall hyper-expansion causing misalignment of joints between the ribs and vertebrae. The purpose of this study was to determine if thoracic vertebral deformity and arthropathy were independent contributors to trunk pain in COPD patients compared to people with a significant smoking history. Method: Participants completed the Brief Pain Inventory (BPI) on the same day as chest CT scans and spirometry. Current and ex-smokers were separated into COPD (n=91) or non-COPD (n=80) groups based on spirometry. Subsequently, CT images were assessed for thoracic vertebral deformity, bone attenuation values, and arthropathy

of thoracic vertebral joints. Results: The trunk area was the most common pain location in both COPD and non-COPD groups. Thoracic vertebral deformity and costotransverse joint arthropathy were independent contributors to trunk pain in COPD patients (adjusted OR=3.55 and 1.30, respectively) whereas alcohol consumption contributed to trunk pain in the non-COPD group (adjusted OR=0.35 in occasional alcohol drinkers; 0.08 in non-alcohol drinkers). The spinal deformity index and the number of narrowed disc spaces were significantly positively related to the BPI intensity, interference, and total scores significantly in COPD patients. Conclusion: Trunk pain, at least in part, is caused by thoracic vertebral deformity, and costotransverse and intervertebral arthropathy in patients living with COPD. The results of this study provided the foundation for the management of pain, which requires further exploration.

TI Mesenchymal Stem Cells in the Musculoskeletal System: From Animal Models to Human Tissue Regeneration?
SO STEM CELL REVIEWS AND REPORTS

LA English
DT Review
DE Musculoskeletal system; Mesenchymal stem cells; Bone; Muscles; Synovium; Regenerative medicine; Osteoarthritis; Osteoporosis
ID skeletal-muscle regeneration; side population cells; bone-marrow; satellite cells; stromal cells; intraarticular injection; progenitor cells; clinical-trial; joint disease; in-vivo
AB The musculoskeletal system includes tissues that have remarkable regenerative capabilities. Bone and muscle sustain micro-damage throughout the lifetime, yet they continue to provide the body with the support that is needed for everyday activities. Our current understanding is that the regenerative capacity of the musculoskeletal system can be attributed to the mesenchymal stem/ stromal cells (MSCs) that reside within its different anatomical compartments. These MSCs can replenish various tissues with progenitor cells to form functional cells, such as osteoblasts, chondrocytes, myocytes, and others. However, with aging and in certain disorders of the musculoskeletal system such as osteoarthritis or osteoporosis, this regenerative capacity of MSCs appears to be lost or diverted for the production of other non-functional cell types, such as adipocytes and fibroblasts. In this review, we shed light on the tissue sources and subpopulations of MSCs in the musculoskeletal system that have been identified in animal models, discuss the mechanisms of their anti-inflammatory action as a prerequisite for their tissue regeneration and their current applications in regenerative medicine. While providing up-to-date evidence of the role of MSCs in different musculoskeletal pathologies, in particular in osteoporosis and osteoarthritis, we share some thoughts on their potential as diagnostic markers in musculoskeletal health and disease.

TI Cost Effectiveness of Intra-Articular Hyaluronic Acid and Disease-Modifying Drugs in Knee Osteoarthritis
SO PHARMACOECONOMICS
LA English
DT Review

ID alongside clinical-trials; european-society; economic-aspects; glucosamine sulfate; hip osteoarthritis; african-americans; symptomatic knee; prevalence; osteoporosis; classification
AB Background The place of disease-modifying osteoarthritis drugs (DMOADs) and intra-articular hyaluronic acid (IAHA) in the therapeutic arsenal for knee osteoarthritis (OA) remains uncertain. Indeed, these treatments have demonstrated symptomatic efficacy but no efficacy for disease modification. Objective This report reviews the cost effectiveness of IAHA and DMOADs used in the treatment of knee OA. Methods A systematic literature search of the MEDLINE, Scopus, EMBASE and Cochrane databases was performed independently by two rheumatologists who used the same predefined eligibility criteria to identify relevant articles. Papers without abstracts and in languages other than English or French were excluded. Extracted costs were annualised and converted to 2015 euros (sic) using the Consumer Price Index of the relevant countries and the 2013 Purchasing Power Parities between these countries and the European Union average. Results A total of 95 abstracts were selected, and 13 articles were considered for the review: nine articles on IAHA and four on DMOADs. Only one article directly compared different IAHA compounds. Articles showed substantial heterogeneity in methodological approaches. The incremental cost-effectiveness ratios (ICERs) ranged from (sic)4000 to (sic)57,550 and from (sic)240 to (sic)53,225 per quality-adjusted life-year (QALY) gained for DMOADs and IAHA, respectively. Conclusions This review highlights substantial heterogeneity between studies, ranging from a cost saving (or dominating) position to very high ICERs, far above the acceptability threshold of (sic)50,000/QALY. Additional research is needed to determine reliable and robust ICER estimates for knee OA therapies.

TI Age-Related Changes in Femoral Head Trabecular Microarchitecture
SO AGING AND DISEASE
LA English
DT Article
DE micro computed tomography (mu-CT); osteoporosis; aging; microarchitecture; trabecular bone; femoral head
ID bone-mineral density; postmenopausal women; cancellous bone; structural basis; iliac crest; x-ray; mechanical-property; hip osteoarthritis; osteoporosis; fracture
AB Osteoporosis is a prevalent bone condition, characterised by low bone mineral density and increased fracture risk. Currently, the gold standard for identifying osteoporosis and increased fracture risk is through quantification of bone mineral density using dual energy X-ray absorption. However, many studies have shown that bone strength, and consequently the probability of fracture, is a combination of both bone mass and bone 'quality' (architecture and material chemistry). Although the microarchitecture of both non-fracture and osteoporotic bone has been previously investigated, many of the osteoporotic studies are constrained by factors such as limited sample number, use of ovariectomised animal models, and lack of male and female discrimination. This study reports significant differences in bone quality with respect to the microarchitecture between fractured and non-fractured human femur specimens. Micro-computed tomography was utilised to investigate the microarchitecture of femoral head trabecular bone from a relatively large cohort of non-fracture and fracture human donors. Various microarchitectural parameters have been determined for both groups, providing an understanding of the differences between fracture and non -fracture material. The microarchitecture of non-fracture and fracture bone tissue is shown to be significantly different for many parameters. Differences between sexes also exist, suggesting differences in remodelling between males and females in the fracture group. The results from this study will, in the future, be applied to develop a fracture model which encompasses bone density, architecture and material chemical properties for both female and male tissues.

TI Oleanolic acid exerts bone protective effects in ovariectomized mice by inhibiting osteoclastogenesis
SO JOURNAL OF PHARMACOLOGICAL SCIENCES
LA English
DT Article
DE Postmenopausal osteoporosis (POP); Oleanolic acid (OA); Ovariectomy (OVX); Osteoclastogenesis; Bone resorption
ID differentiation; activation; therapy
AB Postmenopausal osteoporosis (POP) is quite prevalent and many new drugs are under development to obtain better therapeutic outcomes. Oleanolic acid (OA) has been reported to prevent bone loss in ovariectomized (OVX) rats by stimulating osteoblastogenesis. One previous study has demonstrated that acetate of OA suppressed lipopolysaccharides (LPS)-induced bone loss in mice. However, the role of OA in the receptor activator of nuclear factor kappa-B ligand (RANKL)-mediated osteoclastogenesis is still not elucidated. Here we show that OA dose-dependently inhibits RANKL-mediated osteoclastogenesis and the formation of functional osteoclasts without impairing the viability and osteoclastic potential in bone marrow macrophages (BMMs). Moreover, OA administration attenuates bone loss in OVX mice by inhibiting osteoclast's densities. Mechanistically, OA does not affect RANKL-induced activation of the NF-kappa B, JNK, p38, ERK and Alt pathways, but inhibits the expression of the nuclear factor of activated T-cells c1(NFATc1) and c-Fos. Moreover, OA significantly suppresses the expression of RANKL-activated

osteoclast genes encoding matrix metalloproteinase 9 (MMP9), Cathepsin K(Ctsk), tartrate-resistant acid phosphatase (TRAP) and carbonic anhydrase ll (Car2). This work has elucidated the molecular mechanism of OA in RANKL-mediated osteoclastogenesis and revealed the promising potential of OA to be further developed as a new drug to prevent and treat POP. (C) 2018 The Authors. Production and hosting by Elsevier B.V. on behalf of Japanese Pharmacological Society.

TI Surface damage of bovine articular cartilage-off-bone: the effect of variations in underlying substrate and frequency
SO BMC MUSCULOSKELETAL DISORDERS
LA English
DT Article
DE Articular cartilage; Bone mineral density; Damage; Frequency; Mechanical loading; Osteoarthritis
ID radiographic knee osteoarthritis; mineral density; subchondral bone; unconfined compression; osteoporosis; women; joint; hand; indentation; association
AB BackgroundChanges in bone mineral density have been implicated with the onset of osteoarthritis, but its role in inducing failure of articular cartilage mechanically is unclear. This study aimed to determine the effect of substrate density, as the underlying bone, on the surface damage of cartilage-off-bone, at frequencies associated with gait, and above.MethodsBovine articular cartilage samples were tested off-bone to assess induced damage with an indenter under a

compressive sinusoidal load range of 5-50N at frequencies of 1, 10 and 50Hz, corresponding to normal and above normal gait respectively, for up to 10,000cycles. Cartilage samples were tested on four underlying substrates with densities of 0.1556, 0.3222, 0.5667 and 0.6000g/cm(3). India ink was applied to identify damage as cracks, measured across their length using ImageJ software. Linear regression was performed to identify if statistical significance existed between substrate density, and surface damage of articular cartilage-off-bone, at all three frequencies investigated (p<0.05).ResultsSurface damage significantly increased (p<0.05) with substrate density at 10Hz of applied frequency. Crack length at this frequency reached the maximum of 10.959.12mm (mean +/- standard deviation), across all four substrates tested. Frequencies applied at 1 and 50Hz failed to show a significant increase (p>0.05) in surface damage with an increase in substrate density, at which the maximum mean crack length were 3.01 +/- 3.41mm and 5.65 +/- 6.54mm, respectively. Crack formation at all frequencies tended to form at the periphery of the cartilage specimen, with multiple straight-line cracking observed at 10Hz, in comparison to single straight-line configurations produced at 1 and 50Hz.Conclusions p id= Par4 The effect of substrate density on the surface damage of articular cartilage-off-bone is multi-factorial, with an above-normal gait frequency. At 1Hz cartilage damage is not associated with substrate density, however at 10Hz, it is. This study has implications on the effects of the factors that contribute to the onset of osteoarthritis.

TI Model for improved correlation of BMD values between abdominal routine Dual energy CT data and DXA scans
SO EUROPEAN JOURNAL OF RADIOLOGY
LA English
DT Article
DE Osteoporosis; Bone mass density; Dual-energy CT; DXA; Osteoarthritis of the spine; Aortic calcium score
ID computed-tomography; screening tool; osteoporosis; density; osteoarthritis; colonography; fragility; system
AB Background: Osteoporosis is a common but underdiagnosed and undertreated disease causing severe morbidity and economic burden. The gold standard for detection of osteoporosis is DXA (dual energy x-ray absorptiometry), which is a dedicated examination for osteoporosis. Dual energy CT (DECT) examinations are increasingly used in daily routine for a wide variety of diagnoses. In the present study, we wanted to examine whether vBMD (volume bone mass density) could be evaluated as a side product in non-contrast as well as contrast phases as well as to evaluate a correction model taking known shortcomings for DXA into account. Methods: A total of 20 patients, i.e. 79 vertebrae (one excluded due to vertebral fracture), mean age 71 years (range 43-85) with a mean BMI (body mass index) of 26 (range 17-33) were examined with both abdominal/pelvic DECT as well as DXA. Furthermore, aortic calcium was measured as well as the presence of osteoarthritis of the spine (OAS) and osteoarthritis in facet joints (OAF) with a 5-grade scaling system. Results: A significant correlation was found between DXA BMD and vBMD from DECT with no contrast (WNC) ($r=0.424$, $p=0.001$), and with venous contrast (WVC) ($r=0.402$, $p < 0.001$), but no significant correlation was found with arterial contrast (WAC). Using multivariate linear regression with DXA BMD as dependent, two models were created combining DECT WNC, aortic calciumscore (ACS), OAS and BMI yielding an R-2 = 0.616 (model 1) and replacement of WNC to WVC a R-2 = 0.612 (model 2). The Pearson correlation between DXA and predictive DXA BMD value of model 1 was $r=0.785$ ($p < 0.001$) and model 2 $r=0.782$ ($p < 0.001$). Conclusion: There is a correlation between DXA BMD and DECT in non-contrast and venous contrast scans but not in arterial scans. The correlation is further improved by quantifying the degree of different confounding factors (osteoarthritis

of the spine, body mass index and aortic calcium score) and taking these into account in an explanatory model. Future software solutions with DECT data as input data might be able to automatically measure the BMD in the trabecular bone as well as measuring the confounding factors automatically in order to obtain spinal DXA comparable BMD values.

TI Osteogenesis potential of different titania nanotubes in oxidative stress microenvironment
SO BIOMATERIALS
LA English
DT Article
DE TiO2 nanotubes; Oxidative stress; ITG alpha 5 beta 1; Wnt signals; Osteogenesis
ID osteoblast differentiation; tio2 nanotubes; bone-formation; stem-cells; growth; alpha(5)beta(1); proliferation; improvement; topography; mechanisms
AB Oxidative stress is commonly existed in bone degenerative disease (osteoarthritis, osteoporosis etc.) and some antioxidants had great potential to enhance osteogenesis. In this study, we aim to investigate the anti-oxidative properties of various TiO2 nanotubes (TNTs) so to screen the desirable size for improved osteogenesis and reveal the underlying molecular mechanism in vitro. Comparing cellular behaviors under normal and oxidative stress conditions, an interesting conclusion was obtained. In normal microenvironment, small TNTs were beneficial for adhesion and proliferation of osteoblasts, but large TNTs greatly increased osteogenic differentiation. However, after H2O2 (300 mu M) treatment (mimicking oxidative stress), only large TNTs samples demonstrated superior cellular behaviors of increased osteoblasts' adhesion, survival and differentiation when comparing with those of native titanium (control). Molecular results revealed that oxidative stress resistance of large nanotubes was closely related to the high expression of integrin alpha 5 beta 1 (ITG alpha 5 beta 1), which further up-regulated the production of anti-apoptotic proteins (p-FAK, p-Akt, p-FoxO3a and Bcl2) and down-regulated the expression of pro-apoptotic protein (Bax). Moreover, we found that Wnt signals (Wnt3a, Wnt5a, Lrp5, Lrp6 and beta-catenin) played an important role in promoting osteogenic differentiation of osteoblasts under oxidative condition. TI Inappropriate claims from non-equivalent medications in osteoarthritis: a position paper endorsed by the European Society for Clinical and Economic

Aspects of Osteoporosis, Osteoarthritis and Musculoskeletal Diseases (ESCEO)
SO AGING CLINICAL AND EXPERIMENTAL RESEARCH
LA English
DT Review
DE Chondroitin sulfate; Glucosamine; Symptomatic slow-acting drugs for osteoarthritis; Knee; Osteoarthritis
ID crystalline glucosamine sulfate; knee osteoarthritis; double-blind; avocado/soybean unsaponifiables; chondroitin sulfate; symptomatic efficacy; hip osteoarthritis; global burden; task-force; placebo
AB Osteoarthritis (OA) is a progressive joint disease, that occurs frequently in the aging population and is a major cause of disability worldwide. Both glucosamine and chondroitin are biologically active molecules that are substrates for proteoglycan, an essential component of the cartilage matrix. Evidence supports the use of glucosamine and chondroitin as symptomatic slow-acting drugs for osteoarthritis (SYSADOAs) with impact on OA symptoms and disease-modifying effects in the long term. Glucosamine and chondroitin are administered in exogenous form as a sulfate salt and multiple formulations of these agents are available, both as prescription-grade products and nutritional supplements. However, while all preparations may claim to deliver a therapeutic level of glucosamine or chondroitin not all are supported by clinical evidence. Only patented crystalline glucosamine sulfate (pCGS) is shown to deliver consistently high glucosamine bioavailability and plasma concentration in humans, which corresponds to demonstrated clinical efficacy. Similarly, clinical evidence supports only the pharmaceutical-grade chondroitin sulfate. The European Society for Clinical and Economic Aspects of Osteoporosis, Osteoarthritis and Musculoskeletal Diseases (ESCEO) advocates, through careful consideration of the evidence base, that judicious choice of glucosamine and chondroitin formulation is essential to maximize clinical benefit, patient adherence and satisfaction with treatment. In future, the ESCEO recommends that complex molecules with biological activity such as pCGS may be treated as "biosimilars" akin to the European Medicines Agency guidance on biological medicinal products. It seems likely that for all other complex molecules classed as SYSADOAs, the recommendation to use only formulations clearly supported by the evidence-base should apply.

TI Unassisted quiet standing and walking after crutch usage in patients with total hip replacements: Does crutch length matter?
SO GAIT & POSTURE

DT Article
DE Unaided gait; Static stability; Hip arthroplasty; Crutch length setup; Rehabilitation
ID ground reaction forces; spatiotemporal gait parameters; exercise program; older; people; speed; aids; osteoarthritis; arthroplasty; variability
AB Background: Crutch use is prescribed early in the rehabilitation process following total hip replacement (THR) surgery to improve safety and promote return to active living. Research question: Purpose of this study was to understand mid-term effects of crutch length setup on quiet standing and walking two months post-op when crutch use was no longer required. Methods: Thirty patients were evaluated 2 months post-surgery when they had been walking without crutch for a month. The patients had previously been assigned randomly to elbow flexed (EF) or elbow extended (EE) crutch set-ups and evaluated 3 days post-surgery. Quiet standing stability was assessed with participants standing in a comfortable position with each foot on separated force platforms, facing forward for 10 s. In addition, participants walked on the laboratory path, instrumented with motion tracking system and force platforms. For the quiet standing trial, centre of pressure measure, acromial height and lower limbs load bearing symmetry were evaluated. For the walking trial, spatiotemporal and ground reaction force (GRF) parameters were evaluated together with side symmetry indices. Results: Results showed no significant differences in any standing trial variables between groups. For walking, GRF parameters and symmetry indices were similar for both groups. However, increased base of support width, reduced self-selected walking speed and stride length were found for the EF group. Significance: This study showed that crutch set-up influenced gait after patients started to walk unassisted. Patients that previously used crutch adjusted according to the EE setup, demonstrated a more efficient gait with higher self-selected speed and longer and narrower stride. Clinicians may use these results for a proper crutch height adjustment, which improves walking and, in turn, functional recovery in post THR patients.

TI Fetal rotation during vacuum extractions for prolonged labor: a prospective cohort study
SO ACTA OBSTETRICIA ET GYNECOLOGICA SCANDINAVICA
LA English
DT Article
DE delivery; fetal rotation; prolonged labor; ultrasound; vacuum extraction
ID persistent occiput posterior; assisted vaginal delivery; head position; intrapartum sonography; instrumental delivery; cesarean delivery; 2nd-stage; ultrasound; outcm; forceps
AB IntroductionThe aim of the study was to investigate fetal head rotation during vacuum extraction. Material and methodsWe conducted a prospective cohort study from November 2013 to July 2016 in seven European hospitals. Fetal head position was determined with transabdominal or transperineal ultrasound and categorized

as occiput anterior (OA), occiput transverse (OT) or occiput posterior (OP) position. Main outcome was the proportion of fetuses rotating during vacuum extraction. Secondary outcomes were conversion of delivery method, duration of vacuum extraction, umbilical artery pH <7.10 and agreement between clinical and ultrasound assessments. ResultsThe study population comprised 165 women. During vacuum extraction 117/119 (98%) remained in OA and two fetuses rotated to OP position. Rotation from OT to OA position occurred in 14/19 (74%) and to OP position in 5/19 (26%). Rotation from OP to OA position occurred in 15/25 (60%), and 10/25 (40%) fetuses remained in OP position. Delivery information was missing in two cases. The conversion rate from vacuum extraction to cesarean section or forceps was 10% in the OA group vs. 23% in the non-OA group; p<0.05. The estimated duration of vacuum extraction was significantly shorter in OA fetuses, 7min vs. 10min (log rank test p<0.01). There was no significant difference in umbilical artery pH <7.10 between OA and non-OA position. Cohens Kappa of agreement between clinical and ultrasound assessments was 0.42 (95% CI 0.26-0.57). ConclusionMost fetuses in OP or OT positions rotated to OA position during vacuum extraction, but the proportion of failed vacuum extractions remained high.

TI Nonstandard Lumbar Region in Predicting Fracture Risk
SO JOURNAL OF CLINICAL DENSITOMETRY
LA English
DT Article
DE Bone mineral density; femoral neck; fracture risk prediction; lumbar spine; osteoporosis
ID bone-mineral density; osteoporotic fractures; multiple sites; femoral-neck; spine bmd; women; men; frax; hip; osteoarthritis
AB Femoral neck (FN) bone mineral density (BMD) is the most commonly used skeletal site to estimate fracture risk. The role of lumbar spine (LS) BMD in fracture risk prediction is less clear due to osteophytes that spuriously increase LS BMD, particularly at lower levels. The aim of this study was to compare fracture predictive ability of upper L1-L2 BMD with standard L2-L4 BMD and assess whether the addition of either LS site could improve fracture prediction over FN BMD. This study comprised a prospective cohort of 3016 women and men over 60 yr from the Dubbo Osteoporosis Epidemiology Study followed up for occurrence of minimal trauma fractures from 1989 to 2014. Dual-energy X-ray absorptiometry was used to measure BMD at L1-L2, L2-L4, and FN at baseline. Fracture risks were estimated using Cox proportional hazards models separately for each site. Predictive performances were compared using receiver operating characteristic curve analyses. There were 565 women and 179 men with a minimal trauma fracture during a mean of 11 +/- 7 yr. L1-L2 BMD T-score was significantly lower than L2-L4 T-score in both genders ($p < 0.0001$). L1-L2 and L2-L4 BMD models had a similar fracture predictive ability. LS BMD was better than FN BMD in predicting vertebral fracture risk in women [area under the curve 0.73 (95% confidence interval, 0.68-0.79) vs 0.68 (95% confidence interval, 0.62-0.74), but FN was superior for hip fractures prediction in both women and men. The addition of L1-L2 or L2-L4 to FN BMD in women increased overall and vertebral predictive power compared with FN BMD alone by 1% and 4%, respectively ($p < 0.05$). In an elderly population, L1-L2 is as good as but not better than L2-L4 site in predicting fracture risk. The addition of LS BMD to FN BMD provided a modest additional benefit in overall fracture risk. Further studies in individuals with spinal degenerative disease are needed.

TI Vitamin D Receptor in Muscle Atrophy of Elderly Patients: A Key Element of Osteoporosis-Sarcopenia Connection
SO AGING AND DISEASE
LA English
DT Article
DE Vitamin d receptor; polymorphisms; sarcopenia; osteoporosis; osteoarthritis; aging
ID bone-mineral density; cdx-2 polymorphism; satellite cells; gene; osteoarthritis; association; mechanisms; expression; genotype; fracture
AB In this study, we investigated the relationship between sarcopenia (evaluated in term of fibers atrophy), vitamin d receptor protein expression and TaqI/Cdx2/FokI VDR genotypes in an Italian cohort of osteoporosis(n=44) and osteoarthritis (n=55) patients. Muscle biopsies were fixed and investigated by both immunohistochemistry (vitamin d receptor expression) and transmission electron microscopy (satellite stem cells niches). Vitamin d receptor polymorphisms were studied on DNA extracted from muscle paraffin sections. For the first time, we reported that aging differently affects the VDR activation in OA and OP patients. In particular, while in OP patients we observed a significant reduction of VDR positive myonuclei with age, no "age effect" was observed in OA patients. The frequent activation of VDR could explain the lower number of atrophic fiber that we observed in OA patients respect to OP. From genetic point of view, we showed a putative association among polymorphisms FokI and Cdx2 of VDR gene, vitamin d receptor activation and the occurrence of sarcopenia. Altogether these data open new prospective for the prevention and cure of age-related muscle disorders.

TI Bone changes after short-term whole body vibration are confined to cancellous bone
SO JOURNAL OF MUSCULOSKELETAL & NEURONAL INTERACTIONS
LA English
DT Article
DE Vibration; Osteoporosis; Osteoarthritis; Biomechanics; Rats
ID postmenopausal women; mechanical signals; muscle strength; mineral density; frequency; osteoarthritis; quality; rat; identification; degeneration
AB Objective: This study assessed femur properties in 80 adult female rats exposed to a range of whole body vibration amplitudes at 45 Hz over five weeks. Our hypothesis was that an optimal amplitude for whole body vibration would be apparent and would result in increased bone strength. Methods: Animals were treated in five amplitude groups (0 g. 0.15 g, 0.3 g, 0.6 g, and 1.2 g peak), for 15 minutes per day, five days per week, for five weeks. Femur strength was assessed via: (1) three-point bending of the shaft, (2) cantilever bending of the neck, and (3) indentation of distal cancellous bone. Femoral bone mineral density, plasma prostaglandin E2 (PGE(2)) concentrations, cartilage thickness, and histopathologic properties were measured. Results: Vibration doubled (P=0.039) cancellous bone stiffness in the 0.6 g and 1.2 g groups and induced a 74% increase in PGE(2) concentrations (P=0.007). However, femoral densitometry and strength of the neck and shaft were unchanged and the cancellous bone indentation strength did not differ statistically (P=0.084). Cartilage thickness of vibrated groups at the medial condyle did not increase significantly (P=0.142) and the histopathologic grade did not change. There was no definitive optimal vibration amplitude. Conclusion: The benefits of vibration therapy over five weeks were confined to cancellous bone.

TI Flavopiridol Protects Bone Tissue by Attenuating RANKL Induced Osteoclast Formation
SO FRONTIERS IN PHARMACOLOGY
LA English
DT Article
DE flavopiridol; CDK9; osteoclast; bone resorption; NF-kappa B
ID nf-kappa-b; inducible gene-expression; transcriptional elongation; signaling pathway; p-tefb; inhibition; resorption; cartilage; osteoarthritis; osteoporosis
AB Bone resorption and homeostasis is carried out by osteoclasts, whose differentiation and activity are regulated by the RANK/RANKL axis. Our previous studies using a mouse model of joint injury show that joint trauma induces local inflammation followed by bone remodeling. The transcription factor cyclin-dependent kinase 9 (CDK9) is the major regulator of inflammation, as CDK9 inhibitor flavopiridol effectively suppress injury-induced inflammatory response. The objective of this study was to investigate the underlying mechanism through which flavopiridol regulates bone resorption. The effects of CDK9 inhibition, by the specific-inhibitor flavopiridol, on bone resorption were determined in vivo using two distinct and clinically relevant bone remodeling models. The first model

involved titanium particle-induced acute osteolysis, and the second model was ovariectomy-induced chronic osteoporosis. The effects and mechanism of CDK9 inhibition on osteoclastogenesis were examined using in vitro culture of bone marrow macrophages (BMMs). Our results indicated that flavopiridol potently suppressed bone resorption in both in vivo bone-remodeling models. In addition, CDK9 inhibition suppressed in vitro osteoclastogenesis of BMM and reduced their expression of osteoclast-specific genes. Finally, we determined that flavopiridol suppressed RANKL signaling pathway via inhibition of p65 phosphorylation and nuclear translocation of NF-kappa B. Summary, CDK9 is a potential therapeutic target to prevent osteolysis and osteoporosis by flavopiridol treatment.

TI Kiwi omnicup handheld versus Mityvac M-style conventional vacuum system: a retrospective observational study
SO JOURNAL OF MATERNAL-FETAL & NEONATAL MEDICINE
LA English
DT Article
DE Conventional vacuum system; hand-held vacuum system; Kiwi omnicup; M-style Mityvac cup; vacuum assisted delivery
ID randomized controlled-trial; postpartum hemorrhage; extraction; delivery; cup
AB Introduction: To improve the choice of vacuum-assisted delivery (VAD) system, we compared the outcomes of Kiwi handheld system and Mityvac M-style conventional system (both use disposable plastic cups).Materials and methods: Retrospective observational study with data collection from electronic medical records. The study was conducted at a tertiary medical center, with approximately 7000 deliveries annually. Categorical and continuous variables were analyzed using chi-square test and t-test, respectively. p value<.05 was considered significant. The main outcomes assessed were the overall failure rate of each system, failure rates for occipito-anterior (OA) versus occipito-transverse/occipito-anterior (OT/OP) positions, +1 versus +2 fetal stations, and early maternal/neonatal outcomes.Results: During a 10-month period, there were 507 (8.4%) attempted VADs, 36 failed (7.1%), and eight (1.5%) converted to cesarean section. Of these, 364 were Kiwi-assisted and 143 Mityvac-assisted. Background characteristics were similar. The handheld system had more failures overall (9.6 versus 0.7%), at OA (7.6 versus 0.9%), and non-OA positions (17.3% versus none), at +1 (13.25 versus 0.96%) and at +2/3 stations (6.1% versus none), than the conventional system did, respectively. There was a higher rate of early post-partum hemorrhage (15.3 versus

7.4%) in the conventional group. Both systems had similar rates of third/fourth degree perineal tears, shoulder dystocia and adverse neonatal outcomes.Conclusions: Our results suggest more failures with Kiwi compared to Mityvac, overall and at any fetal position/station, without a significant difference in adverse outcome profile.

TI Sintered dicalcium pyrophosphate treatment attenuates estrogen deficiency-associated disc degeneration in ovariectomized rats
SO DRUG DESIGN DEVELOPMENT AND THERAPY
LA English
DT Article
DE sintered dicalcium pyrophosphate; ovariectomy; disc degeneration; matrix metalloprotease; inflammation
ID knee osteoarthritis; subchondral bone; articular-cartilage; osteoporosis; alendronate; osteoclast; expression; cells; model; osteopenia
AB Background: Estrogen deficiency is associated with musculoskeletal disorders. Sintered dicalcium pyrophosphate (SDCP) is a novel antiosteoporotic agent. In this

study, we examined its use for restoration of bone quality and attenuation of disc degeneration in ovariectomy rats. Methods: Sixty female Sprague Dawley rats were randomly divided into 3 groups, namely sham group undergoing sham surgery, ovariectomy (OVX) group receiving an equivalent volume of isotonic sodium chloride solution, and OVX/SDCP group orally administered with 0.25 mg/mL SDCP. Animals were sacrificed at 3 and 6 months post ovariectomy and lumbar vertebrae and intervertebral discs were harvested. Bone mineral density, micro-computed tomography analysis, and biomechanical testing were performed to assess bone quality. Histological analysis with hematoxylin and eosin, Alcian blue, and Masson's trichrome stain were conducted to determine disc degeneration. Immunohistochemistry and real-time PCR were carried out to measure the expressions of aggrecan, type I collagen, type II collagen, and MMP-1, MMP-3, and MMP-13. Results: SDCP improved bone quality as observed by the results of increased bone mineral density and stiffness in OVX rats. The improvement in disc degeneration induced by estrogen withdrawal was associated with reduced gene expressions of MMPs and increased production of collagen type II. Conclusion: SDCP prevents osteoporosis and meliorates disc degeneration in OVX rats. It represents a favorable therapeutic agent for osteoporotic and osteoarthritic conditions in clinical practice.

TI Noncommunicable disease and multimorbidity in young adults with cerebral palsy
SO CLINICAL EPIDEMIOLOGY
LA English
DT Article
DE cerebral palsy; noncommunicable disease; multimorbidity; osteoporosis; osteoarthritis; cardiovascular disease; diabetes; pulmonary disease
ID spinal-cord-injury; physical-activity; sedentary behavior; older-adults; children; muscle; health; risk; individuals; population
AB Purpose: Individuals with cerebral palsy (CP) are at increased risk for frailty and chronic disease due to factors experienced throughout the lifespan, such as excessive sedentary behaviors and malnutrition. However, little is known about noncommunicable diseases (NCDs) and multimorbidity profiles in young adults with CP. The study objective was to compare NCD and multimorbidity profiles between young adults with and without CP. Methods: A clinic-based sample of adults (18-30 years) with (n=452) and without (n=448) CP was examined at the University of Michigan Medical Center. The prevalence and predictors of 13 NCDs were evaluated, including existing diagnoses or historical record of musculoskeletal, cardiometabolic, and pulmonary morbidities. The level of motor impairment was determined by the Gross Motor Function Classification System (GMFCS) and stratified by less vs more severe motor impairment (GMFCS I-III vs IV-V). Logistic regression was used to determine the odds of NCD morbidity and multimorbidity in adults with CP compared to adults without CP, and for GMFCS IV-V compared to GMFCS I-III in those with CP, after adjusting for age, sex, body mass index, and smoking. Results: Adults with CP had a higher prevalence of osteopenia, osteoporosis, hypertension, myocardial infarction, hyperlipidemia, asthma, and multimorbidity compared to adults without CP, and higher odds of musculoskeletal (odds ratio [OR]: 6.97) and cardiometabolic morbidity (OR: 1.98), and multimorbidity (OR: 2.67). Adults with CP with GMFCS levels IV-V had a higher prevalence of osteopenia/osteoporosis, osteoarthritis, hypertension, other cardiovascular conditions, pulmonary embolism, and multimorbidity, and higher odds of musculoskeletal (OR: 3.41), cardiometabolic (OR: 2.05), pulmonary morbidity (OR: 1.42), and multimorbidity (OR: 3.45) compared to GMFCS I-III. Conclusion: Young adults with CP have a higher prevalence of chronic NCDs and multimorbidity compared to young adults without CP, which is pronounced in those with more severe motor impairment. These findings reiterate the importance of early screening for prevention of NCDs in CP.

TI Changes in bone mineral density and bone metabolic indexes in ankylosing spondylitis mouse model complicated with osteoporosis
SO EXPERIMENTAL AND THERAPEUTIC MEDICINE
LA English
DT Article
DE ankylosing spondylitis; osteoporosis; bone mineral density; bone metabolism
ID vertebral fractures; induced arthritis
AB Changes in bone mineral density and bone metabolic indexes in a model of ankylosing spondylitis (AS) mice complicated with osteoporosis (OP) were investigated. BLAB/c mice were used as the subjects. AS was induced using proteoglycan, and OP was induced using tail suspension method. The mice were randomly divided into four groups: AS group, OP group, AS + OP group and negative control group. Changes in bone mineral density, bone strength, serum calcium (Ca), phosphorus, alkaline phosphatase (ALP) and tartrate-resistant acid phosphatase (TRACP), in mice of each group were detected and compared. There were statistically significant differences in bone mineral density and bone strength

among groups. Compared with the negative control group, bone mineral density and bone strength in the AS, the OP and the AS + OP groups were significantly decreased, and the lowest bone mineral density and bone strength were found in the AS + OP group ($P<0.05$). There were no significant differences in bone mineral density and bone strength between the AS group and the OP group. Significant differences in serum Ca, ALP and TRACP but not in serum phosphorus were found among groups. Compared with the control group, serum levels of Ca and TRACP in the AS, the OP and the AS + OP groups were significantly increased, while levels of ALP were obviously decreased ($P<0.05$). Bone destruction in AS mice complicated with osteoarthritis was more serious than that in mice with simple AS.

TI Locomotive syndrome: clinical perspectives
SO CLINICAL INTERVENTIONS IN AGING
LA English
DT Review
DE locomotive syndrome; long-term care; frailty; sarcopenia; functional disability;

osteoarthritis; spondylosis; osteoporosis
ID bone-mineral density; quality-of-life; physical performance-measures; syndrome risk test; elderly-people; cognitive impairment; musculoskeletal pain; body-composition; muscle strength; older adults
AB The deterioration of locomotive components, which comprise bones, joints, and intervertebral discs, and muscles and nerves, can lead to symptoms such as pain, limitations in the range of joint mobility, malalignment, impaired balance, and difficulty walking. Locomotive syndrome (LoS) was proposed by the Japanese Orthopedic Association in 2007 as a concept for people who are at a high risk of developing a musculoskeletal ambulation disability attributed to locomotor organs. Although many international articles related to LoS have been published, an international consensus of this concept seems to be lacking. This review article on LoS introduces the concept, the related assessment methods, and the condition's prevalence based on the most up-to-date literature, and discusses discrimination from frailty and sarcopenia, relevance to musculoskeletal problems, management plan, and future directions. Familiarity with recent evidence would be useful for the health care providers in an aging society to educate individuals with LoS or pre-LoS and to maintain their well-being and prevent them from requiring long-term care.

TI Ficus deltoidea Prevented Bone Loss in Preclinical Osteoporosis/Osteoarthritis Model by Suppressing Inflammation
SO CALCIFIED TISSUE INTERNATIONAL
LA English
DT Article
DE Ficus deltoidea; Osteoporosis; Osteoarthritis; Microstructure; NF-kappa beta; TNF-alpha
ID nf-kappa-b; nonsteroidal antiinflammatory drugs; articular-cartilage; subchondral bone; rat models; fracture; osteoarthritis; risk; microarchitecture; osteoporosis
AB Osteoporosis (OP) and osteoarthritis (OA) are debilitating musculoskeletal diseases of the elderly. Ficus deltoidea (FD) or mistletoe fig, a medicinal plant, was pre-clinically evaluated against OP- and OA-related bone alterations, in postmenopausal OA rat model. Thirty twelfth-week-old female rats were divided into groups (n=6). Four groups were bilateral ovariectomized (OVX) and OA-induced by intra-articular monosodium iodoacetate (MIA) injection into the right knee joints. The Sham control and OVX-OA non-treated groups were given deionized water. The three other OVX-OA groups were orally administered daily with FD extract (200, 400mg/kg) or diclofenac (5mg/kg) for 4weeks. The rats' bones and blood were evaluated for protein and mRNA expressions of osteoporosis and inflammatory indicators, and micro-CT computed tomography for bone microstructure. The non-treated OVX-OA rats developed severe OP bone loss and bone microstructural damage in the subchondral and metaphyseal regions, supported by reduced serum bone formation markers (osteocalcin, osteoprotegerin) and increased bone resorption markers (RANKL and CTX-I). The

FD extract significantly ($p<0.05$) mitigated these bone microstructural and biomarker changes by dose-dependently down-regulating pro-inflammatory NF-, TNF-, and IL-6 mRNA expressions. The FD extract demonstrated good anti-osteoporotic properties in this OP/OA preclinical model by stimulating bone formation and suppressing bone resorption via anti-inflammatory pathways. This is among the few reports relating the subchondral bone plate and trabecular thickening with the metaphyseal trabecular osteopenic bone loss under osteoporotic-osteoarthritis conditions, providing some insights on the debated inverse relationship between osteoporosis and osteoarthritis.

TI High-throughput metabolomics investigates anti-osteoporosis activity of oleanolic acid via regulating metabolic networks using ultra-performance liquid chromatography coupled with mass spectrometry
SO PHYTOMEDICINE
LA English
DT Article
DE Oleanolic acid; Osteoporosis; Metabolomics; Metabolites; Pathway
ID bone-mineral density; disease; women; men
AB Background: Osteoporosis has brought about heavy socio-economic burden in

the morbidity and medical expenses associated with osteoporosis treatment and various restrictions on behavior of their social roles. Oleanolic acid (OA) is an anti-osteoporosis natural product, but molecular mechanisms of therapeutic effect are not still well known. Purpose: In this study, we explore anti-osteoporosis activity of oleanolic acid and predict the underlying mechanisms by metabolomics strategy. Methods: SD rats were intraperitoneal injection with prednison for once to establish osteoporosis model. Using metabolomics strategy based on ultra-performance liquid chromatography coupled with quadrupole time-offlight/ mass spectrometry (UPLC-TOF/MS), serum samples of 24 rats were analyzed to seek differential metabolites and pathway associated with OA treatment of osteoporosis. In addition, the effect of OA on osteoporosis rats was also evaluated by clinical biochemistry indicators and bone density analysis. Results: Clinical biochemistry indicators and bone density of lumbar and femur were reversed by OA treatment. A total of 25 potential biomarkers were identified in the rats model of glucocorticoid-induced osteoporosis, and oleanolic acid have a regulatory effect on 17 of them that related to some vital metabolic pathway such as linoleic acid metabolism, valine, leucine and isoleucine biosynthesis, phenylalanine, tyrosine and tryptophan biosynthesis as well as cysteine and methionine metabolism. The ingenuity pathway analysis (IPA) platform is applied to further understanding the relationship between metabolic changes and therapeutic effect of OA, which the disordered state carbohydrate metabolism, molecular transport and lipid metabolism in glucocorticoid-induced osteoporosis rats are mainly ameliorated by oleanolic acid. Conclusion: Metabolomics provides a novel method to investigate the anti-osteoporosis effects of OA and probe into the potential mechanisms, and will contributes to the development of new drugs.

TI The effect of Chinese martial arts Tai Chi Chuan on prevention of osteoporosis: A systematic review
SO JOURNAL OF ORTHOPAEDIC TRANSLATION
LA English
DT Review
DE Bone mineral density; Osteoporosis; Prevention; Tai Chi Chuan
ID bone-mineral density; randomized controlled-trial; postmenopausal women; older-adults; muscle strength; exercise; balance; falls; risk; osteoarthritis
AB Background/Objective: Tai Chi Chuan (TCC) is suggested to have beneficial effects on the musculoskeletal system. The aim of this systematic review is to evaluate the evidence of the effect of TCC on bone mineral density (BMD) and its potential for prevention of osteoporosis. Methods: A literature search was conducted using PubMed, Embase, and Cochrane databases from inception to January 2017. Randomized controlled studies, case-control trials, prospective cohort studies, and cross-sectional studies which evaluated the effect of TCC on BMD were selected without any subject or language restriction. Results: Nine articles met the inclusion criteria, including seven randomized controlled trials (RCTs), one case-control trial (CCT), and one cross-sectional study, encompassing a

total of 1222 participants. Five studies showed statistically significant improvements in BMD after TCC, three studies showed nonsignificant intergroup differences, and one study provided no statistical evaluation of results. The studies with nonsignificant results tended to have a shorter total duration of TCC practice. Apart from dual-energy X-ray absorptiometry (DXA), two studies additionally used peripheral quantitative computed tomography (pQCT) which showed statistically significant positive effects of TCC on preventing osteoporosis. Conclusion: TCC is beneficial to BMD and may be a cost-effective and preventive measure of osteoporosis. This beneficial effect is better observed in long-term TCC practice. (C) 2018 The Authors. Published by Elsevier (Singapore) Pte Ltd on behalf of Chinese Speaking Orthopaedic Society.

TI Pitfalls in the measurement of muscle mass: a need for a reference standard
SO JOURNAL OF CACHEXIA SARCOPENIA AND MUSCLE
LA English
DT Article
DE Lean mass; Muscle mass; Lean body mass; Reference standard
ID x-ray absorptiometry; electrical-impedance myography; in-vivo precision; cell lung-cancer; body-composition; skeletal-muscle; bioelectrical-impedance; serological biomarkers; bioimpedance analysis; adipose-tissue
AB BackgroundAll proposed definitions of sarcopenia include the measurement of muscle mass, but the techniques and threshold values used vary. Indeed, the literature does not establish consensus on the best technique for measuring lean body mass. Thus, the objective measurement of sarcopenia is hampered by limitations intrinsic to assessment tools. The aim of this study was to review the methods to assess muscle mass and to reach consensus on the development of a reference standard. MethodsLiterature reviews were performed by members of the

European Society for Clinical and Economic Aspects of Osteoporosis and Osteoarthritis working group on frailty and sarcopenia. Face-to-face meetings were organized for the whole group to make amendments and discuss further recommendations. ResultsA wide range of techniques can be used to assess muscle mass. Cost, availability, and ease of use can determine whether the techniques are better suited to clinical practice or are more useful for research. No one technique subserves all requirements but dual energy X-ray absorptiometry could be considered as a reference standard (but not a gold standard) for measuring muscle lean body mass. ConclusionsBased on the feasibility, accuracy, safety, and low cost, dual energy X-ray absorptiometry can be considered as the reference standard for measuring muscle mass.

TI Primary Osteoporosis Is Not Reflected by Disease-Specific DNA Methylation or Accelerated Epigenetic Age in Blood
SO JOURNAL OF BONE AND MINERAL RESEARCH
LA English
DT Article
DE OSTEOPOROSIS; DNA METHYLATION; EPIGENETIC; AGING; BIOMARKER

ID epigenome-wide association; mesenchymal stem-cells; bone-mineral density; dvo-guideline; osteoarthritis; mutations; fracture; therapy; risk; life
AB Osteoporosis is an age-related metabolic bone disease. Hence, osteoporotic patients might suffer from molecular features of accelerated aging, which is generally reflected by specific age-associated DNA methylation (DNAm) changes. In this study, we analyzed genomewide DNAm profiles of peripheral blood from patients with manifest primary osteoporosis and non-osteoporotic controls. Statistical analysis did not reveal any individual CG dinucleotides (CpG sites) with significant aberrant DNAm in osteoporosis. Subsequently, we analyzed if age-associated DNAm patterns are increased in primary osteoporosis (OP). Using three independent age-predictors we did not find any evidence for accelerated epigenetic age in blood of osteoporotic patients. Taken together, osteoporosis is not reflected by characteristic DNAm patterns of peripheral blood that might be used as biomarker for the disease. The prevalence of osteoporosis is age-associatedbut it is not associated with premature epigenetic aging in peripheral blood. (c) 2017 American Society for Bone and Mineral Research.

TI Glucosamine promotes osteoblast proliferation by modulating autophagy via the mammalian target of rapamycin pathway
SO BIOMEDICINE & PHARMACOTHERAPY
LA English
DT Article
DE Autophagy; Glucosamine; Osteoblast; mTOR; Proliferation
ID bone mass; osteoporosis; cells; protects; cancer
AB Glucosamine is effective in the treatment of osteoarthritis; however, its effect on osteoporosis remains unclear. Decreased activity of osteoblasts is the main cause of osteoporosis. Here, we examined the effects of glucosamine on osteoblasts. The potential underlying mechanisms were explored. The results showed that

glucosamine had a biphasic effect on the viability of hFOB1.19 osteoblasts. At low concentrations (<0.6 mM), glucosamine induced hFOB1.19 cell proliferation, whereas at high concentrations (>0.8 mM) it induced apoptosis. The autophagy inhibitor 3-methyladenine (3-MA) was used to verify that glucosamine modulated hFOB1.19 cell viability via autophagy. The induction of apoptosis by high concentrations of glucosamine was significantly exacerbated by 3-MA, whereas the promotion of cell proliferation by low concentrations of glucosamine was significantly suppressed by 3-MA. Autophagy was examined by western blot detection of autophagy-related proteins including LC3, Beclin-1, and SQSTM1/p62 and by immunofluorescence analysis of autophagosomes. Glucosamine activated autophagy in a time-and concentration-dependent manner. Investigation of the underlying mechanism showed that glucosamine inhibited the phosphorylation of m-TOR in a concentration-dependent manner within 48 h, and rapamycin significantly inhibited the phosphorylation of m-TOR. These results demonstrated that glucosamine promoted hFOB1.19 cell proliferation and increased autophagy by inhibiting the m-TOR pathway, suggesting its potential as a therapeutic agent for osteoporosis.

TI Strontium ranelate as a possible disease-modifying osteoarthritis drug: a systematic review
SO BRAZILIAN JOURNAL OF MEDICAL AND BIOLOGICAL RESEARCH
LA English
DT Review
DE Osteoarthritis; Strontium ranelate; Treatment; Pain; Symptoms
ID knee osteoarthritis; subchondral bone; osteoporosis; hip; risk; progression; management; arthritis; cartilage; outcm
AB Considering that osteoarthritis (OA) is the most prevalent joint disease worldwide, multiple pharmacological treatments have been proposed to alter the articular structure with potential benefit in the progression of the disease. The so-called disease-modifying OA drugs have been frequently investigated but conclusive findings are rare. Strontium ranelate (SrRan) is a drug usually prescribed to treat osteoporosis, with proven effects in decreasing the risk of fractures and possible effect in reducing the progression of OA. The objective of this review was to demonstrate the current panorama of knowledge on the use of SrRan in clinical and experimental models, clarifying its mechanisms of action and describing possible anti-nociceptive and anti-inflammatory effects. The systematic review was based on the PRISMA statement and included articles that are indexed in scientific databases. Fifteen studies were included: seven pre-clinical and eight clinical studies. Despite the limited number of studies, the results suggest a positive effect of SrRan in patients with OA, through changes in functional capacity and reduction of progression of morphological parameters and joint degradation, with moderate quality of evidence for those clinical outcomes. Novel studies are necessary to elucidate the molecular targets of SrRan, focusing on anti-inflammatory effects and histological changes promoted by SrRan, which seemed to reduce the progression of OA in the experimental and clinical studies.

TI Medial Tibial Periprosthetic Bone Resorption and Its Effect on Clinical Outcomes After Total Knee Arthroplasty: Cobalt-Chromium vs Titanium Implants

SO JOURNAL OF ARTHROPLASTY
LA English
DT Article
DE total knee arthroplasty; implant material; implant design; periprosthetic bone resorption; radiolucent line; bone mineral density
ID mineral density changes; high-viscosity cement; follow-up; standard radiographs; proximal tibia; replacement; component; design; tray; fixation
AB Background: Recently, concerns arose over the medial tibial bone resorption of a novel cobalt-chromium implant. This study aimed at investigating the effects of tibial component material, design, and patient factors on periprosthetic bone resorption and at determining its association with clinical outcomes after total knee arthroplasty (TKA). Methods: A total of 462 primary TKAs using 5 types of implants were included. To evaluate tibial periprosthetic bone resorption, we assessed radiolucent lines and change in bone mineral density at the medial tibial condyle (BMDMT). Factors related to bone resorption were assessed using regression analysis. Clinical outcomes were also evaluated with respect to periprosthetic bone resorption. Results: Compared to titanium implants, cobalt-chromium implants showed a higher incidence of complete radiolucent lines (23.1% vs 7.9% at 2 years post-TKA) and a greater degree of BMDMT reduction. However, there was no significant difference between the implants made of the same material. Increased medial tibial bone resorption was associated with male sex, osteoporosis, larger preoperative varus deformity, longer follow-up period, and lower body mass index. The periprosthetic bone resorption was not associated with clinical outcomes including changes in range of motion and Western Ontario and McMaster Universities Osteoarthritis Index score. Furthermore, no cases warranted additional surgery. Conclusion: Periprosthetic bone resorption was associated with implant material but not with implant design. Moreover, patient factors were related to the medial tibial bone resorption post-TKA. However, the periprosthetic bone resorption was not associated with short-term clinical outcomes. We contend that researchers should incorporate integrative considerations when developing and assessing novel implants. (C) 2018 Elsevier Inc. All rights reserved.

TI Epidemiology of arthritis, chronic back pain, gout, osteoporosis, spondyloarthropathies and rheumatoid arthritis among 1.5 million patients in Australian general practice: NPS MedicineWise MedicineInsight dataset
SO BMC MUSCULOSKELETAL DISORDERS
LA English
DT Article
DE Pain; chronic; Back pain; Musculoskeletal; Arthritis; Epidemiology; Population health
ID global burden; chronic diseases; prevalence; osteoarthritis; impact; management; perception; health
AB Background: Previous estimates for the prevalence of musculoskeletal conditions (MSK) and chronic pain in Australia have been based on self-report. We aimed to determine the prevalence and distribution of arthritis, chronic back pain, gout, osteoporosis, spondyloarthropathies and rheumatoid arthritis and current consultations for chronic pain among adults attending Australian general practice, and describe their distribution according to sociodemographic characteristics and presence of co-morbidities. Methods: We investigated 1,501,267 active adult patients (57.6% females; 22.5% >= 65y) evaluated between 2013 and 2016 and

included in the MedicineInsight database (a National Prescribing Service MedicineWise program), a large general practice data program that extracts longitudinal de-identified electronic medical record data from 'active' patients in over 550 practices. Three main groups of outcomes were investigated: 1) "prevalence" of arthritis, chronic back pain, gout, osteoporosis, spondyloarthropathies, and/or rheumatoid arthritis between 2000 and 2016; 2) "current" diagnosis/encounter for the same conditions occurring between 2013 and 2016, and; 3) "current" consultations for chronic pain of any type occurring between 2013 and 2016. Results: The combined "prevalence" of the investigated MSK (diagnosis between 2000 and 2016) among adults attending Australian general practice was 16.8% (95% CI 15.9; 17.7) with 21.3% (95% CI 20.2; 22.4) of the sample consulting for chronic pain between 2013 and 2016. The investigated MSK with the highest "prevalence" were arthritis (9.5%) and chronic back pain (6.7%). Patients with some of these MSK attended general practices more frequently than those without these conditions (median 2.0 and 1.0 contacts/year, respectively). The "prevalence" of the investigated MSK and "current" consultations for chronic pain increased with age, especially in women, but chronic pain remained stable at 22% for males aged > 40 years. The investigated MSK and chronic pain were more frequent among those in lower socioeconomic groups, veterans, Aboriginal and Torrent Strait Islanders, current and ex-smokers, and patients with chronic obstructive pulmonary disease or heart failure. Conclusions: The investigated MSK are more frequent among lower socioeconomic groups and the elderly. Based on information collected from adults attending Australian general practices, MedicineInsight provided similar estimates to those obtained from population-based studies, with the advantage of being based on medical diagnosis and including a national sample.

TI Dexamethasone Down-regulates Osteocalcin in Bone Cells through Leptin Pathway
SO INTERNATIONAL JOURNAL OF MEDICAL SCIENCES
LA English
DT Article
DE osteocalcin downregulation; dexamethasone; osteoblast
ID glucocorticoid-induced osteoporosis; body-weight; receptor; osteoarthritis; osteogenesis; obesity; marrow; tissue; mice; mass
AB Glucocorticoid therapy, especially at higher doses, is associated with significant adverse side effects including osteoporosis. Leptin, secreted from adipose tissue, has diverse effects on bone tissue regulation. As glucocorticoids stimulate leptin synthesis and secretion directly in adipose tissue we hypothesised that dexamethasone (DEX) induced osteoporosis may, in part, be mediated by an osteoblast dependent leptin-leptin receptor pathway. Human bone cells expressed leptin and leptin receptors (Ob-Ra and Ob-Rb). DEX increased leptin, Ob-Ra and Ob-Rb expression in a dose-dependent manner while decreasing expression of osteocalcin. In the presence of leptin, Cbfa1 and osteonectin expression showed no significant change, whereas osteocalcin expression was decreased. Recombinant human quadruple antagonist leptin suppressed DEX-induced osteocalcin downregulation. The signaling pathway involved up-regulation of JAK2. In conclusion, upregulation of leptin and Ob-Rb in human bone cells by DEX is associated with down-regulation of osteocalcin expression. The down regulation of osteocalcin by DEX was partially through a leptin autocrine/paracrine loop. Adverse effects of DEX on the skeleton may be modified by targeting leptin signaling pathways.

DT Review
DE High resolution peripheral quantitative; computerized tomography; Bone microarchitecture; Osteoporosis; Fragility fracture; Therapy; Erosion; Porosity
ID distal radius; rheumatoid-arthritis; hr-pqct; postmenopausal women; cortical porosity; computed-tomography; trabecular bone; geometric-property; cancellous bone; skeletal sites
AB Many imaging modalities have been described to diagnose and monitor osteoporosis (OP), osteoarthritis and inflammatory rheumatic diseases. Over the last ten years, High Resolution peripheral Quantitative Computerized Tomography (HR-pQCT) was shown to be a precise and non invasive technique to study bone and joint diseases in clinical research. It allows the study of both cortical and trabecular bone microarchitecture at the distal tibia and radius, and further applications have been developed such as the study of mechanical properties by the finite element analysis. Thus, in case-control and cross-sectional studies, microarchitecture parameters discriminated fractured individuals independently of areal BMD. Also, microstructure parameters can predict incident fracture in postmenopausal women. In metabolic diseases associated with bone fragility, HR-pQCT may also be used to explore bone changes. In joint disease studies, HR-pQCT was a remarkable tool to assess bone erosion and joint space narrowing at the hand. This article gives an overview of this imaging technique. TI Bisphosphonates intake and its association with changes of periarticular bone area and three-dimensional shape: data from the Osteoarthritis Initiative (OAI)
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE Bisphosphonates; Periarticular bone; Osteoarthritis; 3T MRI; Knee
ID subchondral bone; knee osteoarthritis; progression
AB Objective: To determine the association between bisphosphonate treatment with the change of periarticular bone area and three-dimensional (3D) shape in participants of the Osteoarthritis Initiative (OAI) study. Design: Using propensity score (PS) matching method in females, 48 bisphosphonate users and 105 non-users, who were matched for osteoarthritis (OA) and osteoporosis (OP) related factors were included. Baseline and 24-month magnetic resonance imaging (MRI)-based periarticular bone area and 3D shape measurements were used. The association between bisphosphonate intake and 24-month interval changes of the periarticular bone area and 3D shape were evaluated using paired Wilcoxon signed rank test. We used conditional logistic regression models for determining the association between bisphosphonate intake and periarticular bone change, defined using the standard deviation of difference (SDD) and reliable change index (RCI) methods. P-values have been adjusted for multiple comparisons using Benjamini & Hochberg procedure and false discovery rate (FDR)-adjusted P-values were reported. Results: The 24-month interval increases in the periarticular bone area in medial side of tibia were significantly greater in non-users than users

(FDR-adjusted P-value: 0.002). There was an approaching significance trend for lower medial tibial periarticular bone area expansion in bisphosphonate users in comparison with non-users (For 1SDD change, odds ratio 95% confidence interval (OR (95% CI)): 0.514 (0.271-0.975), FDR-adjusted P-value: 0.085) (For 1.96RCI change, OR (95% CI): 0.552 (0.309-0.986), FDR-adjusted P-value: 0.085). Conclusions: Bisphosphonate intake was associated with a reduction in the odds (approaching but not achieving significance) of expansion periarticular bone area, specifically in the medial tibial sub-region. TI Preiser disease after repeated local glucocorticoid injections A case report
SO MEDICINE
LA English
DT Article
DE aseptic avascular necrosis; glucocorticoid; Preiser disease; scaphoid; steroid; wrist
ID idiopathic avascular necrosis; radial wedge osteotomy; femoral-head; induced osteonecrosis; induced osteoporosis; steroid treatment; rabbits; vascularity; bone; wrist
AB Rationale: Preiser disease or avascular necrosis (AVN) of the scaphoid causes intolerable wrist pain and malalignment of the carpal bones. In previously reported cases, patients have had a history of steroid use for systemic illness such as autoimmune hemolytic anemia, systemic lupus erythematosus, or renal transplantation, or have had other risk factors, such as smoking, alcoholism, or infection. In particular, systemic glucocorticoid therapy has been most commonly associated with the disease. Although there are reports of AVN of the scaphoid induced by systemic glucocorticoids, no prior report has associated AVN of the carpal bones with repeated local injections of glucocorticoids. Patient concerns: We present a case in which it was strongly suspected that AVN of the scaphoid was induced by repeated local glucocorticoid injections. The patient had no history of excessive alcohol use, smoking, or trauma, except for local repeated steroid injections. Diagnoses: Initially, she had diagnosed with de Quervain's disease and was treated by repeated local glucocorticoid injections followed by surgery for de Quervain's disease. Five years after surgery for de Quervain's disease, the patient presented at our hospital with sudden onset of intolerable pain in her right wrist without a history of trauma. In spite of nonsurgical treatment with rest, immobilization, analgesia, and surgery, her wrist pain was not improved. After further repeated local steroid injections in her wrist, radiographs, and magnetic resonance imaging of her wrist showed the AVN of the scaphoid. Interventions: Surgery was performed and the fragmented proximal scaphoid and the entire lunate were resected. Outcomes: The diagnosis was confirmed according to the histopathological examination of the proximal scaphoid bone, which showed the characteristic of AVN of the scaphoid. At follow-up evaluation, radiographs of the right wrist showed no progression of osteoarthritis. The patient had no tenderness or residual pain at the wrist and had no desire to pursue additional surgery. Lessons: We have presented a case with AVN of the scaphoid, which was strongly suspected to be associated with the repeated local steroid injections. Further studies are required to more fully elucidate the association between AVN of the scaphoid and repeated local steroid injections.

TI Pharmaceutical-grade chondroitin sulfate in the management of knee osteoarthritis
SO EXPERT OPINION ON PHARMACOTHERAPY
LA English
DT Review
DE Knee osteoarthritis; treatment; pain; function; chondroitin sulfate
ID glucosamine sulfate; consensus statement; european-society; economic-aspects; double-blind; placebo; trial; recommendations; osteoporosis; esceo
AB Introduction: Chondroitin Sulfate (CS) is a drug which is available as pharmaceutical-grade and nutriceutical-grade products, with important variations in preparation, composition, purity and therapeutic effects. Previous studies using pharmaceutical-grade CS suggested that the compound improves pain and function and delays structural progression in knee osteoarthritis (OA), whereas discrepant results were observed when lower grade preparations were investigated.Areas covered: The recently published chondroitin versus celecoxib versus Placebo Trial (CONCEPT) assessed the symptomatic effect of pharmaceutical-grade CS 800 mg/day in symptomatic knee OA.Expert opinion:This prospective, randomized, 6-month, 3-arm, double-blind, double-dummy, placebo and celecoxib (200 mg/day) - controlled trial involved 604 patients aged above 50years with primary knee OA. This study showed that CS is superior to placebo and similar to celecoxib in reducing pain and improving function in Kellgren-Lawrence grade 1-3 patients supporting the role of pharmaceutical-grade CS as a potential first-line treatment for the management of patients with mild to moderate knee OA.

TI mTOR signaling in skeletal development and disease
SO BONE RESEARCH
LA English
DT Review
ID bone mass; immunosuppressant rapamycin; mammalian protein; binding partner; growth; activation; osteoblast; autophagy; complex; rictor
AB The mammalian/mechanistic target of rapamycin (mTOR) is a serine/threonine protein kinase that integrates inputs from nutrients and growth factors to control many fundamental cellular processes through two distinct protein complexes mTORC1 and mTORC2. Recent mouse genetic studies have established that mTOR pathways play important roles in regulating multiple aspects of skeletal development and homeostasis. In addition, mTORC1 has emerged as a common effector mediating the bone anabolic effect of Igf1, Wnt and Bmp. Dysregulation of mTORC1 could contribute to various skeletal diseases including osteoarthritis and osteoporosis. Here we review the current understanding of mTOR signaling in skeletal development and bone homeostasis, as well as in the maintenance of articular cartilage. We speculate that targeting mTOR signaling may be a valuable approach for treating skeletal diseases.

TI Chronic Medical Conditions and CA125 Levels among Women without Ovarian Cancer
SO CANCER EPIDEMIOLOGY BIOMARKERS & PREVENTION
LA English
DT Article
ID antigen 125 levels; serum ca-125; heart-failure; tumor-markers; carbohydrate antigen-125; inflammatory activation; high-risk; prostate; lung; epidemiology
AB Background: Randomized trials using the biomarker cancer antigen (CA) 125, with or without pelvic ultrasound, have failed to show a clear benefit of general population screening for ovarian cancer. In part, this may be due to a lack of information about conditions, besides ovarian cancer, that can alter CA125 levels and affect specificity or sensitivity. We evaluated the association between common medical conditions and CA125 levels among women without ovarian cancer. Methods: We used data and specimens from 2,004 women without ovarian cancer who participated in the New England Case Control study between 1992 and 2008. Participants completed in-person interviews and donated blood samples at enrollment. We measured CA125 using the CA12511 assay and calculated the association between medical conditions and log-transformed CA125 using linear regression. Results: The median age of participants was 53 years and 1,119 (56%) were postmenopausal. The average CA125 level was 14.5 units/nil, for premenopausal and 11.7 for postmenopausal women. Among premenopausal women, CA125 was significantly lower for women with colon polyps (P = 0.06) and hysterectomy (P = 0.01) and significantly higher with endometriosis (P 0.05). CA125 was also significantly higher in premenopausal women with coronary artery disease (CVD) (P < 0.01, n 2 cases) but not among postmenopausal with CM (n 79). Furthermore, among postmenopausal women, CA1.25 was significantly lower for women with osteoporosis, hypercholesterolemia, and osteoarthritis (P = 0.03, 0.02, and 0.01 respectively) and higher for women with a history of inflammatory bowel disease (P = 0.04). Conclusions: Several chronic diseases are associated with CA125, which could influence the interpretation of CA125 in the context of ovarian cancer screening. Impact: Consideration of chronic medical conditions may he necessary to interpret CA125 values. (C) 2018 AACR.

TI Real-world retrospective cohort study ARCTIC shows burden of comorbidities in Swedish COPD versus non-COPD patients
SO NPJ PRIMARY CARE RESPIRATORY MEDICINE
LA English
DT Article
ID obstructive pulmonary-disease; economic burden; prevalence; outcm; risk
AB This study aimed to generate real-world evidence to assess the burden of comorbidities in COPD patients, to effectively manage these patients and optimize the associated healthcare resource allocation. ARCTIC is a large, real-world, retrospective cohort study conducted in Swedish COPD patients using electronic medical record data collected between 2000 and 2014. These patients were studied for prevalence of various comorbidities and for association of these comorbidities with exacerbations, mortality, and healthcare costs compared with an age-, sex-, and comorbidities-matched non-COPD reference population. A total of 17,479 patients with COPD were compared with 84,514 non-COPD reference population. A significantly higher prevalence of various comorbidities was observed in COPD patients 2 years post-diagnosis vs. reference population, with the highest percentage increase observed for cardiovascular diseases (81.8% vs. 30.7%). Among the selected comorbidities, lung cancer was relatively more prevalent in COPD patients vs. reference population (relative risk, RR = 5.97, $p < 0.0001$). Ischemic heart disease, hypertension, depression, anxiety, sleep disorders, osteoporosis, osteoarthritis, and asthma caused increased mortality rates in COPD patients. Comorbidities that were observed to be significantly associated with increased number of severe exacerbations in COPD patients included heart failure, ischemic heart disease, depression/anxiety, sleep disorders, osteoporosis, lung cancer, and stroke. The cumulative healthcare costs associated with comorbidities over 2 years after the index date were observed to be significantly higher in COPD patients ((sic) 27,692) vs. reference population ((sic) 5141) ($p < 0.0001$). The data support the need for patient-centered treatment strategies and targeted healthcare resource allocation to reduce the humanistic and economic burden associated with COPD comorbidities.

TI Clodronate in the management of different musculoskeletal conditions
SO MINERVA MEDICA
LA English
DT Review

DE Clodronic acid; Osteoporosis; Osteoarthritis; Arthroplasty
ID bone-mineral density; regional-pain-syndrome; breast-cancer patients; cyclical intravenous clodronate; randomized controlled-trials; induced ovarian failure; total hip-arthroplasty; total knee patients; syndrome type-i; double-blind
AB INTRODUCTION: Clodronic acid is a non-nitrogen-containing bisphosphonate largely used from some decades in the prevention and treatment of postmenopausal and secondary osteoporosis. In addition to antiresorptive activity, clodronate has shown anti-inflammatory and analgesic properties, and modulatory effects on bone and cartilage metabolism. EVIDENCE ACQUISITION: A literature review has been conducted to characterize the mechanism of action of clodronate and to retrieve available evidence about the use of clodronate in primary and secondary osteoporosis, and its potential role in other musculoskeletal conditions and orthopedic surgery. EVIDENCE SYNTHESIS: The efficacy and safety of the available clodronate formulations (oral, intravenous and intramuscular) in the prevention and treatment of postmenopausal and secondary osteoporosis, including corticosteroid-induced osteoporosis and bone mass loss secondary to endocrine, gastrointestinal and neoplastic diseases, have been demonstrated in a variety of clinical trials. The analgesic, anti-inflammatory, bone-and chondro-modulating properties of clodronate have allowed to expand its use in other musculoskeletal conditions to those currently approved. Clodronate has proven to be beneficial in the treatment of osteoarthritis of the knee and of the hand, in the management of complex regional pain syndrome, and in the peri-and postoperative phase in subjects undergoing arthroplasty. CONCLUSIONS: The analysis of the available literature has shown that clodronate has relevant musculoskeletal effects beyond the antiresorptive activity. Further research is needed to better position clodronate therapy in the management of these conditions and to define the optimal formulation and dose regimen in any of the tested new indications.

TI Effect of Total Flavonoids of Rhizoma drynariae on Tibial Dyschondroplasia by Regulating BMP-2 and Runx2 Expression in Chickens
SO FRONTIERS IN PHARMACOLOGY
LA English
DT Article
DE Rhizoma drynariae; tibial dyschondroplasia; BMP-2; Runx2; gene expression
ID bone morphogenetic protein-2; liver oxidative stress; osteoblast differentiation; growth-plate; in-vitro; cells; toxicity; apigenin
AB Tibial dyschondroplasia (TD) is an abnormality of the growth cartilage that occurs in chickens and other rapidly growing avian species. This disease not only cause huge economic losses, but also greatly affects animal welfare. The total flavonoids of Rhizoma drynariae (TFRD) has been used to cure wide variety of diseases including bone fractures and osteoarthritis and osteoporosis. However, less information is available about the using of TFRD against the TD. The aim of this study was to determine the effect of TFRD on TD by regulating BMP-2 and Runx2 in chickens. A total of 200 birds were randomly divided into control, TD, TD recovery (TDR), and TFRD groups. All the groups were given standard diet with an addition of thiram (50 mg/kg) from days 3 to 7 in TD, TDR, and TFRD groups in order to induce TD in chickens. After the induction of TD, the birds of TFRD group were fed standard diet with the addition of TFRD at 20 mg/kg. Clinical results conveyed that TFRD can improve the growth performance of the TD chickens and recover normal activity, and it is more obvious than TDR. Gene expressions of BMP-2 and Runx2 were down-regulated during the development of the disease and were up-regulated obviously after TFRD treatment. In conclusion, TFRD not only decreased the mortality rate but also increased the growth performance of TD in chickens. In conclusion, TFRD plays important role in improving the growth performance, adjusting the relevant physiological indicators, and regulating BMP-2 and Runx2 in chickens.

TI Both Oleanolic Acid and a Mixture of Oleanolic and Ursolic Acids Mimic the Effects of Fructus ligustri lucidi on Bone Properties and Circulating 1,25-Dihydroxycholecalciferol in Ovariectomized Rats
SO JOURNAL OF NUTRITION
LA English
DT Article
DE bone; calcium; Fructus ligustri lucidi; oleanolic acid; ursolic acid
ID ethanol extract; calcium balance; mineral density; gene-expression; improvement; differentiation; kinetics; cells
AB Background: Oleanolic acid (OA) and ursolic acid (UA) are major chemical constituents found in Fructus ligustri lucidi (FLL), a Chinese herb previously shown to increase bone properties and modulate calcium-vitamin D metabolism in rats. OA and UA have been reported to exert osteoprotective effects in vitro. Objective: The present study was designed to determine whether OA or OA + UA mimicked the effects of FLL on bone and calcium homeostasis using ovariectomized rats. Methods: Three-month-old ovariectomized Sprague-Dawley rats were stabilized for 2 mo and randomly assigned to 4 groups offered the same amount (15-17 g/d) of a control diet or experimental diets containing FLL (18.8 g/kg), OA (0.67 g/kg), or OA (0.67 g/kg) + UA (0.22 g/kg) for 6 wk. Serum was obtained formeasurement of 1,25-dihydroxycholecalciferol [1,25(OH)(2)D-3] and bones were collected for micro-CT analysis. Calcium balance was measured at weeks 1 and 6. A calcium kinetic study using Ca-45 was conducted at week 6 and modeled using WinSAAM software. Results: Compared with the control group, rats fed the FLL-, OA-, and OA

+ UA-enriched diets had better bone properties and 51%, 31%, and 27% higher serum 1,25(OH)(2)D-3 concentrations at week 6, respectively. These variables did not differ between the treatments. Calcium balance was not affected by diet at either week 1 or week 6. Kinetic modeling predicted that FLL and OA + UA diet-fed rats had 9% and 15% less endogenous excretion of calcium, respectively, compared with the control group. All 3 treatments resulted in a higher calcium mass of compartment 3 because of changes in transfer rate between compartments 2 and 3, and were positively associated with the serum 1,25(OH)(2)D-3 concentration (R-2 = 0.28; P < 0.01). Conclusion: Similar to FLL, OA and OA + UA increase bone properties, serum 1,25(OH)(2)D-3 concentration, and calcium use in ovariectomized rats, suggesting their potential role in management of osteoporosis.

TI Cross-Validation of Arthroplasty Records Between Arthroplasty and Hospital Discharge Registers, Self-Reports, and Medical Records Among a Cohort of 14,220 Women
SO JOURNAL OF ARTHROPLASTY
LA English
DT Article
DE arthroplasty; osteoarthritis; validation studies; cohort studies; registers; self-report
ID hip
AB Background: There are no actual validation studies of the Finnish Arthroplasty Register (FAR), and only a few studies about the accuracy of self-reported hip and knee arthroplasty exist. Therefore, we examine how reliably total hip (THA) and knee (TKA) arthroplasties can be identified from multiple data sources, including self-reports, the hospital discharge register, the arthroplasty register, and medical records. Methods: Data from the FAR and from the Finnish Hospital Discharge Register (FHDR) during the years 1980-2010 were cross-checked to identify all THA and TKA events for the Kuopio Osteoporosis Risk Factor and Prevention Study cohort (n = 14,220). Unclear events were further checked from the medical records. After establishing a gold standard, by referring to confirmed THAs and TKAs, we examined the validity of self-reports in identifying the prevalent population with THA/TKA and in identifying incident THA/TKA. Results: Completeness of 2820 total arthroplasty events was 96.1% in FAR and 98.3% in FHDR. The self-reports had 95.1% sensitivity and 92.9% positive predictive value (PPV) to identify population with THA and for TKA sensitivity was 94.6% and PPV 95.2%. Self-reports' sensitivity of finding the actual surgery events was 65.3% and PPV 85.4% for THA and for TKA sensitivity was 62.9% and PPV 83.4%. Conclusion: The best way to identify THAs and TKAs in Finland is to combine data from the FAR and the FHDR. Self-reports can be considered as suitable to identify the prevalent population with THA/TKA, and they do not work as well to identify the actual surgery events. (C) 2018 Elsevier Inc. ID air displacement plethysmography; south indian children; x-ray absorptiometry; mass index cutoffs; fat-free mass; waist circumference; asian indians; 4-compartment model; adipose-tissue; cellular-level
AB Body composition is known to be associated with several diseases, such as cardiovascular disease, diabetes, cancers, osteoporosis and osteoarthritis. Body composition measurements are useful in assessing the effectiveness of nutritional interventions and monitoring the changes associated with growth and disease conditions. Changes in body composition occur when there is a mismatch between nutrient intake and requirement. Altered body composition is observed in conditions such as wasting and stunting when the nutritional intake may be inadequate. Overnutrition on the other hand leads to obesity. Many techniques are available for body composition assessment, which range from simple indirect measures to more sophisticated direct volumetric measurements. Some of the methods that are used today include anthropometry, tracer dilution, densitometry,

dual-energy X-ray absorptiometry, air displacement plethysmography and bioelectrical impedance analysis. The methods vary in their precision and accuracy. Imaging techniques such as nuclear magnetic resonance imaging and computed tomography have become powerful tools due to their ability of visualizing and quantifying tissues, organs, or constituents such as muscle and adipose tissue. However, these methods are still considered to be research tools due to their cost and complexity of use. This review was aimed to describe the commonly used methods for body composition analysis and provide a brief introduction on the latest techniques available.

TI Preoperative dual-energy X-ray absorptiometry and FRAX in patients with lumbar spinal stenosis
SO JOURNAL OF ORTHOPAEDIC SURGERY AND RESEARCH
LA English
DT Article
DE Lumbar spinal stenosis; DXA; FRAX; Osteoporosis; Bone mineral density
ID bone-mineral density; walking capacity; osteoporosis; diagnosis; osteoarthritis; performance; prevalence; fixation; surgery; quality
AB BackgroundOsteoporosis implies an increased risk of complications after orthopedic surgery. For the mostly elderly group of patients undergoing lumbar spinal stenosis surgery (LSS), it is important to include skeletal health evaluation in the preoperative planning. The aim of this study was to assess spine and femoral neck (FN) bone mineral density (BMD) in LSS patients and to evaluate whether the

World Health Organization (WHO) fracture risk assessment tool (FRAX) can identify patients with reduced BMD levels in the spine.MethodsThe study involved 65 LSS patients and 53 patients with hip osteoarthritis (HOA) for comparison. BMD was measured with dual-energy X-ray absorptiometry (DXA) in the lumbar spine in three projections: anterior-posterior (AP), lateral and lateral-mid (the mid-portion of the vertebrae), and FN. The LSS patients filled out the FRAX questionnaire.ResultsIn the LSS group, 43% of the women and 8% of the men were classified as being osteoporotic/osteopenic by AP spine measurement. The corresponding proportions using the lateral spine T-score -2.5 were 87% and 57%, respectively, and 82% and 53%, respectively, for the FN. The FN BMD T-score was significantly lower in the LSS group compared with the HOA group. The FRAX questionnaire identified 40% of the LSS patients with a moderate/high risk of sustaining an osteoporotic fracture within 10years, with or without simultaneous FN BMD, while 71% of these patients were classified as being osteoporotic with DXA lateral spine measurement.ConclusionIt is common with osteoporosis/osteopenia in patients undergoing spine surgery, and the identification may influence the surgical treatment why the evaluation of BMD is important preoperatively. FRAX evaluation could not replace DXA measurement of the spine regarding the identification of osteoporosis patients in the preoperative planning phase.

TI Ajuga decumbens stimulates mesenchymal stem cell differentiation and regenerates cartilage in a rabbit osteoarthritis model
SO EXPERIMENTAL AND THERAPEUTIC MEDICINE
LA English
DT Article
DE Ajuga decumbens; anti-inflammation; cartilage regeneration; mesenchymal stem cell; osteoarthritis; osteogenesis
ID glucosamine hydrochloride; chondrocytes; injury; tissue; osteoporosis; expression; arthritis; sulfate; repair; bone
AB In a previous study by our group, Ajuga decumbens extract (ADE) was demonstrated to decrease the number of osteoclasts in subchondral bone and to have a synergistic effect with glucosamine in improving cartilaginous injuries in a rabbit model of osteoarthritis. In the present study, a concentrate of the useful fraction of ADE, termed extra ADE (EADE), which includes higher concentrations of the active component 20-hvdroxyecdysone, was evaluated for its efficacy to accelerate the healing of experimental cartilage injury. Cartilage injuries were surgically induced in rabbits by creating three holes; one in the articular cartilage of the medial trochlea and two in the trochlear sulcus of the distal femur. The rabbits were divided into the following four groups (n=3 in each): Control, ADR (0.5 g/kg), low dosage EADE (0.05 g/kg; low EADE) and high dosage EADE (0.5 g/kg; high EADE). ADE and EADE were dissolved in tap water and each dosage was orally administered every day for 3 weeks. At the end of the experimental period, histological analysis indicated that the cartilage matrix was regenerated in the low and high EADE groups. On counting of cells in the histological specimens, it was determined that the mean number of osteoclasts per 100 osteoblasts in subchondral bone was lower in the high EADE group compared with the control group. Furthermore, the results indicated that treatment with EADE (1-100 mu g/ml) stimulated chondrogenic differentiation of mesenchymal stem cells and induced proteoglycan production to a greater extent than the control in vitro. EADE treatment (10 and 100 mu g/ml) was also observed to significantly attenuate

interleukin-l beta-induced prostaglandin R2 production in chondrocytes (P<0.05). In summary, the results of the present study suggest that EADE may have greater curative sffects on bone injiury compared with the currently used therapeutic ADE.

TI Epigenetic enzymes influenced by oxidative stress and hypoxia mimetic in osteoblasts are differentially expressed in patients with osteoporosis and

osteoarthritis
SO SCIENTIFIC REPORTS
LA English
DT Article
ID bone; disease; angiogenesis; receptors; tissue; genes; model; mice
AB Epigenetic mechanisms including posttranslational histone modifications and DNA methylation are emerging as important determinants of bone homeostasis. With our case-control study we aimed to identify which chromatin-modifying enzymes could be involved in the pathology of postmenopausal osteoporosis and osteoarthritis while co-regulated by estrogens, oxidative stress and hypoxia. Gene expression of HAT1, KAT5, HDAC6, MBD1 and DNMT3A affected by oxidative stress and hypoxia in an in vitro qPCR screening step performed on an osteoblast cell line was analysed in trabecular bone tissue samples from 96 patients. Their expression was significantly reduced in patients with postmenopausal osteoporosis and osteoarthritis as compared to autopsy controls and significantly correlated with bone mineral density and several bone histomorphometry-derived parameters of bone quality and quantity as well as indicators of oxidative stress, RANK/RANKL/OPG system and angiogenesis. Furthermore, oxidative stress increased DNA methylation levels at the RANKL and OPG promoters while decreasing histone acetylation levels at these two genes. Our study is the first to show that higher expression of HAT1, HDAC6 and MBD1 is associated with superior quantity as well as quality of the bone tissue having a more favourable trabecular structure.

DT Review
ID positron-emission-tomography; early-stage osteoarthritis; f-18-sodium fluoride pet; fdg-pet; diagnosing infection; f-18-fdg pet/ct; bone; f-18-fluoride; inflammation; metabolism
AB Medical imaging plays a particularly important role in the care of elderly patients, in whom complex symptomatology and a high prevalence of musculoskeletal diseases necessitate sensitive imaging modalities. MRI is the most commonly used imaging modality in the evaluation of various musculoskeletal disorders. The integration of positron emission technique and computed tomography as well as magnetic resonance imaging allows for generating complimentary data for accurate and quantitative diagnosis. This article highlights the implementations of molecular imaging probes in the assessment of prevalent musculoskeletal disorders among geriatric population with emphasis on osteoarthritis, osteoporosis, diabetic foot, and prosthetic joint infections. We also discuss the sensitivity of FDG-PET imaging in differentiating polymyalgia

rheumatica from other diseases that have similar clinical presentation. (C) 2018 Published by Elsevier Inc.

TI Do sarcopenia and/or osteoporosis increase the risk of frailty? A 4-year observation of the second and third ROAD study surveys
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE Frailty; Incidence; Osteoporosis; Population-based cohort study; Sarcopenia
ID bioelectrical-impedance analysis; dwelling elderly subjects; muscle; mass; association; consensus; adults
AB In this 4-year follow-up study including 1083 subjects (60years), the prevalence of frailty was estimated to be 5.6%; osteoporosis was found to be significantly associated with frailty. Moreover, the presence of both osteoporosis and sarcopenia increased the risk of frailty compared to the presence of osteoporosis or sarcopenia alone.IntroductionThis study aims to examine the contribution of sarcopenia and osteoporosis to the occurrence of frailty using 4-year follow-up information of a population-based cohort study.MethodsThe second survey of the Research on Osteoarthritis/Osteoporosis Against Disability (ROAD) study was conducted between 2008 and 2010; 1083 subjects (aged 60years, 372 men, 711 women) completed all examinations on frailty, sarcopenia, and osteoporosis, which were defined using Fried's definition, Asian Working Group for Sarcopenia criteria, and WHO criteria, respectively. The third survey was conducted between 2012 and 2013; 749 of 1083 individuals enrolled from the second survey (69.2%, 248 men, 501 women) completed assessments identical to those in the second survey.ResultsThe prevalence of frailty in the second survey was 5.6% (men, 3.8%; women, 6.6%). The cumulative incidence of frailty was 1.2%/year (men, 0.8%/year;

women, 1.3%/year). After adjustment for confounding factors, logistic regression analysis indicated that osteoporosis was significantly associated with the occurrence of frailty (odds ratio, 3.07; 95% confidence interval, 1.26-7.36; p=0.012). Moreover, the occurrence of frailty significantly increased according to the presence of osteoporosis and sarcopenia (odds ratio vs. neither osteoporosis nor sarcopenia: osteoporosis alone, 2.50; osteoporosis and sarcopenia, 5.80).ConclusionsPreventing osteoporosis and coexistence of osteoporosis and sarcopenia may help reduce the risk of frailty.

AB Osteoclasts are absorptive cells that play a critical role in homeostatic bone remodeling and pathological bone resorption. Emerging evidence suggests an important role of epigenetic regulation in osteoclastogenesis. In this study, we investigated the role of DOT1L, which regulates gene expression epigenetically by histone H3K79 methylation (H3K79me), during osteoclast formation. Using RANKL-induced RAW264.7 macrophage cells as an osteoclast differentiation model, we found that DOT1L and H3K79me2 levels were upregulated during osteoclast differentiation. Small molecule inhibitor-(EPZ5676 or EPZ004777) or short hairpin RNA-mediated reduction in DOT1L expression promoted osteoclast differentiation and resorption. In addition, DOT1L inhibition increased osteoclast surface area and accelerated bone-mass reduction in a mouse ovariectomy (OVX) model of osteoporosis without alter osteoblast differentiation. DOT1L inhibition increase reactive oxygen species (ROS) generation and autophagy activity, and cell migration in pre-osteoclasts. Moreover, it strengthened expression of osteoclast fusion and resorption-related protein CD9 and MMP9 in osteoclasts derived from RAW264.7. Our findings support a new mechanism of DOT1L-regulated, H3K79me2-mediated, epigenetic regulation of osteoclast differentiation, implicating DOT1L as a new therapeutic target for osteoclast dysregulation-induced disease.

TI Effect of advanced age and/or systemic medical conditions on dental implant survival: A systematic review and meta-analysis
SO CLINICAL ORAL IMPLANTS RESEARCH
LA English
DT Review

ID bisphosphonate-related osteonecrosis; type-2 diabetes-mellitus; oral bisphosphonates; loading protocols; follow-up; osseointegrated implants; edentulous patients; irradiated patients; parkinsons-disease; neck-cancer
AB Objectives: This review evaluated implant survival in geriatric patients (>= 75 years) and/or the impact of systemic medical conditions. Materials and Methods: Systematic literature searches were performed to identify studies reporting on geriatric subjects with dental implants and on implant patients who had any of the seven most common systematic conditions among geriatric patients. Meta-analyses were performed on the postloading implant survival rates. The impact of systemic medical conditions and their respective treatment was qualitatively analyzed. Results: A total of 6,893 studies were identified; of those, 60

studies were included. The fixed-effects model revealed an overall implant survival of 97.3% (95% CI: 94.3, 98.7; studies = 7) and 96.1% (95% CI: 87.3, 98.9; studies = 3), for 1 and 5 years, respectively. In patients with cardiovascular disease, implant survival may be similar or higher compared to healthy patients. High implant survival rates were reported for patients with Parkinson's disease or diabetes mellitus type II. In patients with cancer, implant survival is negatively affected, namely by radiotherapy. Patients with bone metastases receiving high-dose antiresorptive therapy (ART) carry a high risk for complications after implant surgery. Implant survival was reported to be high in patients receiving low-dose ART for treatment of osteoporosis. No evidence was found on implant survival in patients with dementia, respiratory diseases, liver cirrhosis, or osteoarthritis. Conclusions: Implant prostheses in geriatric subjects are a predictable treatment option with a very high rate of implant survival. The functional and psychosocial benefits of such intervention should outweigh the associated risks to common medical conditions.

TI Acetabular Reconstruction Using a Cage in Complex Primary Total Hip Replacement in a Developing Country: An Assessment of Early Functional Outcome
SO NIGERIAN JOURNAL OF CLINICAL PRACTICE
LA English
DT Article
DE Acetabular defect; clinical outcome; complex primary total hip replacement; DePuy antiprotrusio cage
ID traumatic posterior dislocation; follow-up; revision arthroplasty; pelvic discontinuity; surgical technique; minimum 5-year; allograft bone; deficiency; components; classification
AB Background: Acetabular reconstruction following bone loss is a major challenge facing the arthroplasty surgeon. Traditionally, the armamentarium for the treatment of large bone defects (Paprosky Type 2C or 3) included antiprotrusio cages (APC). The aim of this study is to determine the pattern of presentation and assess the early functional outcome of patients who had undergone acetabular reconstruction using APC in complex primary total hip replacement (THR). Patients

and Method: Between November 2008 and November 2015, 38 THR were carried out in 35 patients who required acetabular reconstruction, at Davidson and Judith Consultants Clinics Enugu, Nigeria. Results: There were 25 males and 10 females, with a ratio of 2.5:1. The average age of the patients was 61.33 +/- 6.92 with a range of 56 to 72. The mean pre-op Harris score was 49.02 +/- 2.3. The mean post-op Harris hip score (HSS) was 88.75 +/- 10 ($P < 0.001$) at one year and 92.25 +/- 13 ($P < 0.001$) at 5 years. The etiology showed that most (52.63%) of our patients had primary osteoarthritis with Type 3 acetabular defect. Two (5.26%) patients had the following complications: dislocation (2.63%) and screw breakage (2.63%). The minimum follow-up period was 5 years. Discussion: After follow-up at 1 year and 5 years, the hips showed significant improvement concerning pain, gait, and mobility based on HHS and were able to return to their various professions. Conclusion: APC provides a satisfactory solution for patients who present with acetabular deficiency in complex primary THR.

TI A study of the relationship between meniscal injury and bone microarchitecture in ACL reconstructed knees
SO KNEE
LA English
DT Article
DE HR-pQCT; Bone microarchitecture; Knee; Meniscus repair; Meniscectomy; Anterior cruciate ligament reconstruction
ID anterior cruciate ligament; subchondral bone; articular-cartilage; mineral density; partial meniscectomy; cancellous bone; high prevalence; soccer players; osteoarthritis; model
AB Background: Anterior cruciate ligament (ACL) tears increase the risk of developing knee osteoarthritis. This risk increases further with concurrent meniscus injury. The role of bone changes during knee osteoarthritis development are not well-understood, but may be important to its etiology. Purpose: To explore the effects of ACL tears on bone mineral density (BMD) and bone microarchitecture at five years post-op and their relationship to meniscal pathology, using high-resolution peripheral quantitative computed tomography (HR-pQCT). Methods: Twenty-eight participants with unilateral ACL reconstructions five years prior and no evidence of clinical or radiographic osteoarthritis were recruited. All participants represented one of three meniscus statuses: meniscus intact, meniscus repair, or meniscectomy. BMD and bone microarchitecture of the subchondral bone plate and adjacent trabecular bone were assessed using HR-pQCT, and percent-differences between the injured and contralateral knee were determined. Results: Subchondral bone plate thickness in the lateral femoral condyle was higher in the reconstructed knee (9.0%, $p = 0.002$), driven by the meniscus repair and meniscectomy groups (15.2% to 15.4%, $p < 0.05$). Trabecular BMD was lower in the reconstructed knee in the medial femoral condyle (-4.8% to 7.6%, $p < 0.05$), driven by all meniscus statuses. In the lateral compartments, few differences in trabecular bone were found. However, accounting for meniscus status, the meniscus intact

group had lower trabecular BMD throughout both femur and tibia. Conclusions: Five years post-op, reconstructed knees demonstrated detectable differences in BMD and bone microarchitecture, despite having normal radiographs. Meniscus damage affected primarily the lateral compartment, warranting further investigation to determine if these changes relate to osteoarthritis development (C) 2018 Elsevier B.V. TI Progressive pseudorheumatoid dysplasia with new-found gene mutation of Wntl

inducible signaling pathway protein 3
SO PEDIATRIC RHEUMATOLOGY
LA English
DT Article
DE Progressive pseudorheumatoid dysplasia; Wntl inducible signaling pathway protein 3
ID wisp3 mutations; arthropathy
AB Background: As one kind of osteochondrodysplasia, progressive pseudorheumatoid dysplasia (PPD) is also known as spondyloepiphyseal dysplasia tarda with progressive arthropathy or arthropathy progressive pseudorheumatoid of childhood. PPD is a very rare disease, especially in China, and has an estimated prevalence of 1/1000000 due to lacking definite prevalence survey. It is an autosomal recessive disorder caused by gene mutation of Wntl inducible signaling pathway protein 3 (WISP3). Its basic pathological change is persistent degeneration and loss of articular cartilage in multiple joints. Its clinical appearances include bone enlargement, platyspondyly, irregular endplate, secondary osteoarthritis, extensive osteoporosis, joint rigidity and function loss. Clinical diagnosis of PPD is made based on clinical appearance and imaging examinations, whereas its definite diagnosis depends on gene sequencing. PPD has no severe effect on life span, but causes high disability rate and very poor prognosis. There are only case reports with limited information in China. Case presentation: One female patient was diagnosed as PPD and secondary osteoarthritis. She had typical clinical appearance and imaging examinations, and received individualized therapeutic regimens. She had a gene mutation (c.72delT, p.T24TfsX4) of WISP3. This gene mutation has not been reported by previous literatures and included in Single Nucleotide Polymorphism Database. Conclusions: As the first time, this paper reported a patient with PPD caused by new-found gene mutation (c.72delT, p.T24TfsX4) of WISP3.

TI Relationship between endothelial function and skeletal muscle strength in community dwelling elderly women
SO JOURNAL OF CACHEXIA SARCOPENIA AND MUSCLE
LA English
DT Article
DE Sarcopenia; Endothelial function; EndoPAT
ID sarcopenic obesity; disease; risk; prevalence; consensus
AB Background The aim of this study is to determine whether there is correlation between endothelial function and skeletal muscle function measured by hand grip strength in elderly women. Methods Results This cross-sectional study used data of NAMGARAM-2 cohort. The NAMGARAM-2 cohort consisted of a group of people living in three rural communities. They were enrolled for studies on activity limitation due to age-related musculoskeletal disorders including knee osteoarthritis, osteoporosis, and sarcopenia. They were residents aged 40 years or older. They agreed to participate in this cohort from March 2016 to May 2017. Peripheral endothelial function was assessed by reactive hyperaemia-peripheral arterial tonometry using EndoPAT2000 system. Hand grip strength was measured using a digital hand dynamometer. Endothelial function index assessed by EndoPAT was worse in the low grip strength group than that in the normal group of elderly women (1.54 +/- 0.51 in the low grip strength group vs. 1.77 +/- 0.67 in the normal group, P = 0.003). There was a positive correlation between hand grip strength and endothelial function (r = 0.176, P = 0.007). On stepwise multivariate analysis, endothelial dysfunction (reactive hyperaemia-peripheral arterial tonometry index < 1.67) significantly increased the risk of low hand grip strength (odds ratio = 2.019; 95% confidence interval = 1.107-3.682; P = 0.022). Conclusions Endothelial function and skeletal muscle strength had a significant correlation in elderly women, providing additional support for the relevant role of vascular system in sarcopenia.

TI Effects of anti-osteoporosis medications on total hip arthroplasty risks in osteoporotic patients with hip osteoarthritis in Taiwan: a nationwide cohort study
SO ARCHIVES OF OSTEOPOROSIS
LA English
DT Article
DE Osteoporosis; Hip osteoarthritis; Total hip arthroplasty; Anti-osteoporosis medications
ID health insurance research; bone-marrow lesions; knee osteoarthritis; cartilage degradation; oarsi recommendations; biochemical markers; consensus; bisphosphonates; replacement; progression
AB A Summary This nationwide cohort study examined the potential disease-modifying effect of anti-osteoporosis medication on hip osteoarthritis. The results revealed that the usage of anti-osteoporosis medication is not associated with decreased risk in undergoing total hip arthroplasty in patient with hip osteoarthritis. Purpose This study aimed to assess the association between use of anti-osteoporosis medications (AOMs) and the risk of undergoing total hip arthroplasty (THA) in patients with hip osteoarthritis (OA). Methods Using the 2008-2013 National Health Insurance Research Database, we identified patients who were first diagnosed as having hip OA. All identified patients were followed until THA, death of any cause, or December 31, 2013, whichever occurred first. All AOM exposures were divided into three categories: bisphosphonates use, non-bisphosphonates use, and no use of AOMs and assessed in a time-varying manners. The primary outcome was THA. The secondary outcome was the differences in the longitudinal utilization of NSAIDs between AOM users and non-users. Time-dependent Cox proportional hazards models were used to investigate the effect of AOM use on the risk of THA. Results We identified 35,870 patients who were first diagnosed as having hip OA and had no history of AOM use between 2009 and 2012. Among them, 3162 and 1667 patients had their first

prescription of bisphosphonates and other non-bisphosphonates AOMs during the follow-up period. Mean age of bisphosphonates users, non-bisphosphonates users, and non-users was 75.62, 76.84, and 67.39 years, respectively. Bisphosphonates or non-bisphosphonates users did not show significant change when compared to non-users in terms of risk of undergoing THA [adjusted hazard ratio (aHR) 0.972, 95% confidence interval (CI) 0.743-1.273; aHR 0.926, 95% CI 0.672-1.277]. Conclusion Our results showed that the use of AOMs is not associated with decreased risk of THA in patients with hip OA.

TI Fractal dimension: A complementary diagnostic indicator of osteoporosis to bone mineral density
SO MEDICAL HYPOTHESES

LA English
DT Article
DE Osteoporosis; Diagnostic indicator; Fractal dimension; Bone mineral density
ID trabecular bone; postmenopausal women; risk; microarchitecture; osteoarthritis; radiographs; outcm; disease
AB Morbidity of osteoporosis is increasing as the world population grows and ages, but bone mineral density (BMD) as a common-used diagnostic indicator is not omnipotent in predicting the bone fragility. According to the definition of osteoporosis by World Health Organization (WHO), the present hypothesis proposes an additional fractal-dimension indicator less than 3 to measure the structural change of bones, and further to diagnose osteoporotic patients with complications, to which BMD is insensitive. Literature reports support that the fractal dimension is more sensitive than BMD in specific cases. The hypothesis shows a promise not only in improving the accuracy of screening osteoporotic patients as a complementary indicator to BMD, but also in evaluating mechanical properties of osteoporotic bone and bone-repair effect of bone tissue engineering.

TI Clinical manifestations of osteoarthritis in osteoporotic and osteopenic postmenopausal women
SO JOURNAL OF MUSCULOSKELETAL & NEURONAL INTERACTIONS
LA English
DT Article
DE Osteoarthritis; Osteoporosis; Osteopenia; Postmenopausal Woman; Bone Mineral Density
ID neck-pain-questionnaire; bone-mineral density; fracture risk; epidemiology; prevalence; impact
AB Objective: We investigated the frequency of clinical manifestations of osteoarthritis in women with low BMD. Methods: This prospective epidemiological study investigated the degree of osteoarthritic pain and functional disability in symptomatic joints of a randomly selected population of postmenopausal Greek women aged >45 years with osteoporosis or osteopenia. Degree of osteoarthritic impairment (none, mild, moderate or severe) was classified at the knee, hip, neck or hand using a site-specific internationally validated osteoarthritis questionnaire. Results: 3000 women were included with mean age of 66.7 years. Osteoporosis was more common than osteopenia. Mild osteoarthritic impairment was most prevalent. An inverse relationship between severity of osteoarthritic impairment and mean femoral neck T-score was observed, regardless of site. There was a significant difference in mean femoral neck T-score between patients with severe osteoarthritic impairment and those with no, mild, or moderate impairment. This was also observed when lumbar spine BMD results were pooled. Conclusions: Most postmenopausal women with low BMD suffer from osteoarthritic impairment, with an inverse association between severity of osteoarthritic impairment and mean

femoral neck T-score. Mean lumbar spine or femoral neck T-scores of patients with severe osteoarthritic impairment were significantly lower than those of patients with less impairment.

TI Advanced Therapy Medicinal Products: A Guide for Bone Marrow-derived MSC Application in Bone and Cartilage Tissue Engineering
SO TISSUE ENGINEERING PART B-REVIEWS
LA English
DT Review
DE ATMPs; GMP; mesenchymal stromal cells; bone tissue engineering; cartilage tissue engineering
ID mesenchymal stem-cells; autologous chondrocyte implantation; sinus floor augmentation; collagen-based scaffold; cyclic tensile strain; platelet-rich plasma;

chondrogenic differentiation; osteogenic differentiation; articular-cartilage; stromal cells
AB Millions of people worldwide suffer from trauma- or age-related orthopedic diseases such as osteoarthritis, osteoporosis, or cancer. Tissue Engineering (TE) and Regenerative Medicine are multidisciplinary fields focusing on the development of artificial organs, biomimetic engineered tissues, and cells to restore or maintain tissue and organ function. While allogenic and future autologous transplantations are nowadays the gold standards for both cartilage and bone defect repair, they are both subject to important limitations such as availability of healthy tissue, donor site morbidity, and graft rejection. Tissue engineered bone and cartilage products represent a promising and alternative approach with the potential to overcome these limitations. Since the development of Advanced Therapy Medicinal Products (ATMPs) such as TE products requires the knowledge of diverse regulation and an extensive communication with the national/international authorities, the aim of this review is therefore to summarize the state of the art on the clinical applications of human bone marrow-derived stromal cells for cartilage and bone TE. In addition, this review provides an overview of the European legislation to facilitate the development and commercialization of new ATMPs.

TI In vivo identification of Bmp2-correlation networks during fracture healing by means of a limb-specific conditional inactivation of Bmp2
SO BONE
LA English
DT Article

DE Bmp2; Fracture healing; Co-expression; Differential gene expression; Conditional knockout; Networks
ID bone morphogenetic proteins; factor-beta superfamily; candidate genes; knee osteoarthritis; messenger-rna; expression; association; defects; osteoporosis; polymorphism
AB Bmp2 is known to play an essential role in the initiation of fracture healing via periosteal activation. Specifically, activation and subsequent differentiation of periosteal progenitor cells requires Bmp2 signaling for activation of the osteo-chondrogenic pathway. Here, we explored the interactive transcriptional gene-gene interplays between Bmp2 and 150 known candidate genes during fracture repair. We constructed the interactive Bmp2 signaling pathways in vivo, by comparing gene expression levels prior and 24 h post femur fracture, in presence (wild type) and in absence of Bmp2 (Bmp2c/c;Prx1::cre limb-specific conditional knockout). Twenty-six differentially expressed genes (pre- vs. post-fracture), which demonstrated high correlations within each experimental condition, were used to construct the co-expression networks. Topological dynamic shifts across different co-expression networks characterized the 26 differentially expressed genes as non-redundant focal linking hubs, redundant connecting hubs, periphery genes, or non-existent. Top-ranked up- or down-regulated genes were identified and discussed. Protein-protein interactions in public databases support our findings. Thus, the co-expression networks from this study can be used for future experimental hypotheses.

AB The vibrational characteristics of ligand-capped lead sulfide (PbS) quantum dots (QDs) were clarified via electrochemical surface-enhanced Raman spectroscopy (EC-SERS) using a hybridized system of gold (Au) nanodimers and PbS Qps under electrochemical potential control. Enhanced electromagnetic field caused by the coupling of QDs with plasmonic Au nanodimers allowed the characteristic behavior of the ligand oleic acid (OA) on the PbS Op surface to be detected under electrochemical potential control. Binding modes between the QDs and OA

molecules were characterized using synchronous two-dimensional correlation spectra at distinct electrochemical potentials, confirming that the bidentate bridging mode was probably the most stable mode even under relatively negative potential polarization. Changes in binding modes and molecular orientations resulted in fluctuations in EC-SERS spectra. The present observations strongly recommend the validity of the QD-plasmonic nanostructure coupled system for sensitive molecular detection via EC-SERS. (C) 2018 Elsevier B.V. All rights reserved.

TI Comparison of a Patient-Centered Weight Loss Program starting before versus after knee replacement: A pilot study
SO OBESITY RESEARCH & CLINICAL PRACTICE
LA English
DT Article
DE Weight loss; Surgery; Intervention
ID total hip; physical-activity; arthroplasty; osteoarthritis; obesity; outcm; health; disease; surgery
AB Background: Most patients risk gaining weight in the years after knee replacement, adding further concern to a population that is mostly overweight/obese prior to surgery. Objective: Via a randomised pilot study, we assessed changes in weight during a Patient Centered Weight Loss Program (PACE) initiated either before or after knee replacement, while simultaneously examining

the feasibility of recruiting and retaining participants over 26 weeks. Methods: Recruitment outreach was made to 133 patients scheduled for knee replacement. Sixteen participants were randomised to a 14-session weight loss program that started either <6 weeks before surgery (PACE) or at 12 weeks post-op (Delayed PACE). Repeated measures ANOVAs were used to examine preliminary changes in weight, function, patient-reported outcomes, and physical activity across time (baseline/pre-op, 12 and 26 weeks after surgery) and group. Results: Retention was 75% and 69% at 12 and 26 weeks after surgery, respectively. Weight significantly decreased across the 26 weeks (P< 0.001). A group by time interaction (A= 0.03) demonstrated Delayed PACE [-7.6 +/- 5.9 kg (-7.9 +/- 5.9%)] lost significantly more weight than PACE [-2.5 +/- 2.7 kg (-2.6 +/- 2.6%)] participants at 26 weeks. Significant improvements across time were seen for all function and patient reported outcomes, however activity did not change. Conclusion: Conducting a behavioural intervention was challenging but feasible in a knee replacement population, with preliminary evidence suggesting that initiating a program 12 weeks after surgery produces greater weight losses at 26 weeks compared to a program starting before knee replacement. TI Trends and Determinants of Osteoporosis Treatment and Screening in Patients With Rheumatoid Arthritis Compared to Osteoarthritis
SO ARTHRITIS CARE & RESEARCH
LA English
DT Article
ID united-states; prevention; fracture; women; management; care; therapy; risk; men; disparity
AB Objective. To profile osteoporosis (OP) care in patients with rheumatoid arthritis (RA) over the past decade. Methods. Patients with RA or osteoarthritis (OA) were followed from 2003 through 2014. OP care was defined as receipt of OP treatment (with the exception of calcium/vitamin D) or screening (OPTS). Adjusted trends over followup, and the factors associated with OP care, were examined using multivariable Cox proportional hazards. Results. OPTS was reported in 67.4% of 11,669 RA patients and in 64.6% of 2,829 OA patients during a median (interquartile range) 5.5 (2-9) years of followup. In patients for whom treatment was recommended by the 2010 American College of Rheumatology (ACR) glucocorticoid-induced OP (GIOP) guidelines (48.4% of RA patients and 17.6% of OA patients), approximately 55% overall reported OP medication use. RA patients were not more likely to undergo OPTS compared to OA patients (hazard ratio 1.04 [95% confidence interval 0.94-1.15]). Adjusted models showed a stable trend for OPTS between 2004 and 2008 compared to 2003, with a significant downward trend after 2008 in both RA and OA patients. Factors associated with receipt of OP care in RA patients were older age, postmenopausal state, prior fragility fracture or diagnosis of OP, any duration of glucocorticoid treatment, and use of biologic agents. Conclusion. Approximately half of RA patients for whom treatment was indicated never received an OP medication. OP care in RA patients was not better than in OA patients, and the relative risk of the application of this care has been decreasing in RA and OA patients since 2008 without improvement after the release of the 2010 ACR GIOP guideline.

TI Sesamin Protects the Femoral Head From Osteonecrosis by Inhibiting ROS-Induced Osteoblast Apoptosis in Rat Model
SO FRONTIERS IN PHYSIOLOGY
LA English
DT Article
DE sesamin; ONFH; dexamethasone; ROS; apoptosis
ID endothelial dysfunction; hypertensive-rats; cell-line; stress; activation; osteocytes; signal
AB Glucocorticoids intake has become the most common pathogenic factor for osteonecrosis of the femoral head (ONFH). Annually, tens of millions of patients suffer from pain related to ONFH. Researchers have proposed several underlying mechanisms of ONFH, including osteocyte apoptosis, cell differentiation disorder, and angiogenesis hindrance. Sesamin, isolated from Sesamum indicum seeds, was reported could affect osteocyte inflammation and differentiation in osteoarthritis and osteoporosis. We investigated the underlying influence of sesamin on ONFH rat model. Fifteen male Sprague-Dawley rats were randomly divided into three groups. The ONFH model group only received the methylprednisolone (MPS) and lipopolysaccharide (LPS) injection to promote the development of ONFH. The sesamin treatment group was injected with sesamin, MPS, and LPS. The control group was untreated. Rats from above groups were sacrificed 4 weeks later. The effect of sesamin on ONFH rats was validated by H&E staining. TUNEL staining

showed that femoral head necrosis was attenuated by sesamin. Furthermore, the phosphorylation of Akt was increased and the downstream cellular apoptosis signal pathway was inhibited. Intracellular ROS level was decreased after sesamin treatment. In conclusion, our findings suggest that sesamin protects the femoral head from osteonecrosis by inhibiting ROS-induced osteoblast apoptosis.

TI Accounting for frailty when treating chronic diseases
SO EUROPEAN JOURNAL OF INTERNAL MEDICINE
LA English
DT Review
DE Frailty; Chronic diseases; Multimorbidity; Personalized medicine
ID older-adults; predict frailty; blood-pressure; health; pain; prevalence; impact; women; risk; osteoporosis
AB Chronic diseases are considered to be major determinants of frailty and it could be hypothesized that their treatment may counteract the development of frailty. However, the hypothesis that intensive treatment of chronic diseases might reduce the progression of frailty is poorly supported by existing studies. In contrast, some evidence suggests that intensive treatment of chronic diseases may increase negative health outcomes in frail older adults. In particular, if treatment of symptoms related to chronic diseases (i.e. pain in osteoarthritis, dyspnoea in respiratory disease, motor symptoms in Parkinson disease) might potentially reverse frailty, the benefits related to preventive pharmacological treatment of chronic diseases (i.e. antihypertensive treatment) in patients with prevalent frailty is not certain. In particular, several factors might alter the risk/benefit ratio of a given treatment in persons with frailty. These include: exclusion of frail persons from clinical studies, reduced life expectancy in frail persons, increased susceptibility to iatrogenic events, and functional deficits associated with frailty. Therefore, frailty acts as an effect modifier, by modifying the risks and benefits of chronic disease treatments. This hypothesis must be considered and tested in future clinical intervention studies and clinical guidelines should provide specific recommendations for the treatment of frail people, underlining the pros and the cons of pharmacological treatment and possible targets for therapy in this

population. Meanwhile, in older patients, the prescribing process should be individualized and flexible.

TI Sex disparities in health and health care utilization after Parkinson diagnosis: Rethinking PD associated disability
SO PARKINSONISM & RELATED DISORDERS
LA English
DT Article
DE Parkinson disease; Comorbidity; Gender; Epidemiology; Health services; Disparities
ID brain-stimulation surgery; medicare claims data; gender-differences; nonmotor symptoms; disease; women; accuracy; outcm; men
AB Objective: To examine sex differences and trends in comorbid disease and

health care utilization in individuals with newly diagnosed Parkinson disease (PD). Design: Retrospective cohort study. Participants: Over 133,000 Medicare beneficiaries with a new PD diagnosis in 2002 followed through 2008. Methods: We compared the prevalence and cumulative incidence of common medical conditions, trends in survival and health care utilization between men and women with PD. Results: Female PD patients had higher adjusted incidence rate ratio (IRR) of depression (IRR: 1.28, 1.25-1.31), hip fracture (IRR: 1.51, 1.45-1.56), osteoporosis (3.01, 2.92-3.1), and rheumatoid/osteoarthritis (IRR: 1.47,1.43-1.51) than men. In spite of greater survival, women with PD used home health and skilled nursing facility care more often, and had less outpatient physician contact than men throughout the study period. Conclusions: Women experience a unique health trajectory after PD diagnosis as suggested by differing comorbid disease burden and health care utilization compared to men. Future studies of sex differences in care needs, care quality, comorbidity related disability, PD progression, and non-clinical factors associated with disability are needed to inform research agendas and clinical guidelines that may improve quality survival for women with PD. TI Factors related with osteoporosis treatment in postmenopausal women
SO MEDICINE
LA English
DT Article
DE bone densitometry; information; osteoporosis; post-menopause; treatment
ID bisphosphonate therapy; health plan; bone mass; persistence; adherence; fracture; determinants; medication; brazil; drugs
AB Although fractures had high mortality and morbidity, many studies proved that fracture risk might be decreased by pharmacological therapy, although a low treatment adherence rate is observed. The aim of this study was to identify factors associated with osteoporosis treatment in postmenopausal women. A

cross-sectional study was carried out from March to August 2013 at the primary care setting. Postmenopausal women were recruited. A standardized questionnaire was applied. Women who were using at least one of the following drugs at the moment of the survey were considered as current treatment: bisphosphonates, raloxifene, estrogen, calcitonin, teriparatide, or strontium ranelate. Women who had used any of the mentioned medications before the study were considered as past treatment. Of the 1025 women included in the study, 8% were on current treatment, 5.7% had past treatment, and 86.3% had not received treatment. Treated women (either current or past) had a higher rate of osteoarthritis, had more falls, had higher education level, presented a higher rate of private health insurance, and received more information about osteoporosis. They also had more dual-energy x-ray absorptiometry (DXA) scans and were more frequently diagnosed with osteoporosis by these DXA scans. The factors independently associated with treatment in the regression analysis were the DXA scan itself, the diagnosis of osteoporosis by DXA, and information about osteoporosis. Current and past treatments of osteoporosis were associated with DXA and information. These results suggest that some measures to inform women about osteoporosis and or even the popularization of DXA scans could improve the treatment.

TI Age trajectoreis of musculoskeletal morbidities in adults with cerebral palsy
SO BONE
LA English
DT Article
DE Cerebral palsy; Osteoporosis; Arthritis
ID disabilities monitoring network; hip fracture; young-adults; ambulatory ability; muscle pathology; united-states; bone mass; children; prevalence; disease
AB Background: Individuals with cerebral palsy (CP) are at an increased risk for age-related morbidities due to functional impairments, maladapted growth, and altered body composition. While musculoskeletal (MSK) def lcits are present in children, little is understood about MSK morbidity throughout the lifespan in those with CP. The purpose of this study was to examine the age-related trajectories of

MSK morbidity and multimorbidity throughout adulthood in those with CP. Methods: A clinic-based sample of adults with CP (n = 1395; <= 18 years) was examined to determine prevalence of MSK morbidities at the University of Michigan Medical Center. Logistic regression was used to determine the effects of age on individual MSK morbidities and multimorbidity (i.e., <= 2 morbidities) after adjusting for sex, race, weight, and smoking. Results: With the 18-30 year age group as Lhe reference, the adjusted odds of osteopenia was lower in the 41-50 and > 50 year age groups, the odds of osteoporosis and rheumatoid arthritis was higher in 41-50 and > 50 year age groups, and the odds of osteoarthritis was higher in 31-40, 41-50, and > 50 year age groups. The adjusted odds of MSK multimorbidity increased substantially with increasing age for 31-40 year olds (OR 1 919; 95% CI 1.05-3.52), 41-50 year olds (OR 4.30; 95% CI 2.40-7.69), and > 50 year olds (OR 6.05; 95% CI 3.56-10.27). Conclusions: Adults with CP are at high risk for MSK morbidities across all ages. Future studies are needed to examine the global aging trajectories of MSK health among adults with CP. Study findings highlight the importance of maximizing MSK accretion, and developing programs to assist individuals with CP and their care givers to maintain MSK mass and function throughout the lifespan.

TI Prevention of articular cartilage degeneration in a rat model of monosodium iodoacetate induced osteoarthritis by oral treatment with Withaferin A
SO BIOMEDICINE & PHARMACOTHERAPY
LA English
DT Article
DE Chondrocytes; Cartilage; Osteoarthritis; Interleukin-1 beta; Monosodium iodoacetate
ID il-1-beta-induced inflammatory response; chondrocytes; mice; bone; disease; injury; mineralization; ossification; osteoporosis; hypertrophy

AB Withaferin A (WFA), a highly oxygenated withanolide is used for anti-osteoporotic, fracture healing, obesity control as medicine and dietary supplement in Ayurveda and Unani medicine but its potential remains to be investigate for the osteoarthritis studies. In the present study, chondro-protective effects of WFA, under in vitro and in vivo conditions were evaluated. In-vitro pharmacological activity of WFA was tested on rat articular chondrocytes through MTT, DPPH, different staining, FACS and translation studies. In-vivo studies of WFA were evaluated through monosodium iodoacetate (MIA) induced osteoarthritis studies. DPPH assay, alcian blue and toluidine blue staining indicated the chondrogenic potential of WFA. Similarly, WFA enhance chondrogenesis through up-regulation of SOX9 protein. In addition, WFA reduced the ROS generation, mitochondrial depolarization and apoptosis induced by inflammatory cytokines IL-1 beta and TNF-alpha. Furthermore, WFA treatment in MIA treated rats alleviated cartilage erosion and improvement in sub-chondral bone micro-architecture by decrease in Tissue volume (similar to 32%), and trabecular bone pattern factor (similar to 28%). Taken together, our study provides convincing evidence for the candidature of WFA (10 mg kg(-1) day(-1)) as a potential agent for the treatment of cartilage degenerative diseases like osteoarthritis.

TI Relationship Between Subchondral Bone Microstructure and Articular Cartilage in the Osteoarthritic Knee Using 3T MRI
SO JOURNAL OF MAGNETIC RESONANCE IMAGING
LA English
DT Article
ID magnetic-resonance images; in-vivo mri; trabecular bone; topological analysis; resolution regime; tesla; microarchitecture; osteoporosis; arthritis; fracture
AB Background: The importance of subchondral bone in the pathogenesis of osteoarthritis (OA) has drawn interest. Purpose: To investigate subregional trabecular bone microstructural features and to determine the relationship between cartilage and trabecular bone in the osteoarthritic human knee. Study Type: Prospective study. Subjects: In all, 92 knees were enrolled and divided into three groups: without OA, mild OA, and severe OA. Sequence: A sagittal 3D balanced fast field echo (3D B- FFE) sequence and FatSat 3D fast field echo (3D-FFE) sequence at 3T MRI. Assessment: The trabecular bone in 12 sites of the knee joint was evaluated using digital topological analysis, and the cartilage thickness in four sites was calculated. Statistical Test: Trabecular bone and cartilage parameters between groups were compared using analysis of variance (ANOVA) with

Bonferroni adjustment, and their correlations were analyzed using Pearson's correlation coefficient. Results: Within both femoral condyles, the trabecular bone structure deteriorated in mild OA, showing a lower bone volume fraction (BVF) (0.15 to 0.12, P< 0.05), higher erosion index (EI) (2.25 to 2.28, P< 0.01), and a lower plate- to- rod ratio (SCR) (6.22 to 5.96, P< 0.05). Within medial and lateral tibia, deterioration in the trabecular bone was also observed, demonstrating a lower BVF (0.15 to 0.12 P< 0.05) and a higher EI (2.25 to 2.61, P< 0.05). Cartilage attrition mainly occurred in the medial joint. Extensive correlations were found between the medial cartilage thickness and subregional trabecular parameters. There was mainly a positive correlation with both femoral BVFs (r> 0.3, P< 0.05), and a negative correlation with the tibia SCR (r<- 0.2, P< 0.05). Data Conclusion: In the early stage of OA, trabecular bone osteoporotic changes were observed in both femoral condyles and the tibia. Based on a strong correlation with the medial cartilage thickness, the trabecular structural topological analysis may be useful for elucidating OA onset and progression. Level of Evidence: 2 Technical Efficacy: Stage 2

TI Integrative Bone Metabolomics-Lipidomics Strategy for Pathological Mechanism of Postmenopausal Osteoporosis Mouse Model
SO SCIENTIFIC REPORTS
LA English
DT Article

ID osteoblast proliferation; mass-spectrometry; mineral density; differentiation; metabonomics; insulin; acid; osteoarthritis; intervention; metabolism
AB Osteoporosis, characterized by bone mass reduction and increased fractures, has become a global health problem that seriously affects the health of people, especially postmenopausal women; however, the current pathogenesis of postmenopausal osteoporosis (PMOP) has not been thoroughly elucidated to date. In this study, bilateral ovariectomy was performed to establish an OVX mouse model of osteoporosis. UPLC-Q-TOF-MS-based lipidomics in combination with metabolomics were used to analyze the femur tissue of osteoporosis mice. We found that 11 polar metabolites and 93 lipid metabolites were significantly changed and were involved in amino acid metabolism, nucleotide metabolism and lipid metabolism. Among the lipids, fatty acyls, glycerolipids, glycerophospholipids, sphingolipids and sterols showed robust changes. These results revealed that several metabolic disorders caused by changes in the hormone levels in OVX, especially disordered lipid metabolism, are closely related to the imbalance between bone resorption and formation and may underlie the development of PMOP. The data generated via lipidomics and metabolomics presented in this study shows good applicability and wide coverage in the construction of the metabolic profile of bone tissue. Therefore, this approach may provide the pathway focusing and data support at the metabolite level for the in-depth mechanism of PMOP.

TI Sarcopenic osteoarthritis: a new entity in geriatric medicine?
SO EUROPEAN GERIATRIC MEDICINE
LA English
DT Review
DE Sarcopenia; Osteoarthritis; Physical performance; Therapy
ID serum 25-hydroxyvitamin d; vitamin-d supplementation; quality-of-life; knee osteoarthritis; physical frailty; orthostatic hypotension; mediterranean diet; hypovitaminosis d; european project; economic-aspects
AB Purpose Osteoarthritis, a disease characterized by cartilage degradation, abnormal subchondral bone remodeling and some grade of inflammation, and sarcopenia, a condition of low muscle mass associated with reduced strength and function, are prevalent disorders in older adults. In this review, we examine what is known about the relationship between osteoarthritis and sarcopenia, with particular focus on the older population. We also discuss how osteoarthritis and sarcopenia may interact and affect each other in clinical progression and the potential benefits from developing treatments that address such muscular-skeletal interaction. Methods We searched in Pubmed and Scopus through a combination of search and MESH terms, for osteoarthritis and sarcopenia. Results Even if more literature is needed, there is increasing evidence that decline in lower limb muscle strength is associated with knee or hip osteoarthritis in a pathological network of pain, altered joint stability, maladapted postures and defective neuromuscular communication. At the cellular levels, chondrocytes and myoblasts share common pathways, and the close anatomical location of both cell types also suggest the possibility of paracrine communication. Conclusions Sarcopenia and osteoarthritis

are significantly intercorrelated and in the near future should be considered as an only entity, as we have recently proposed for sarcopenia and osteoporosis. The treatment of both sarcopenia and osteoarthritis is based on physical exercise and nutritional interventions with the aim of improving cartilage, bone and muscle health. Future studies are needed, particularly to know the exact prevalence of sarcopenia in people with osteoarthritis, its peculiar consequences and the most appropriate treatments.

TI Abatacept might increase bone mineral density at femoral neck for patients with

rheumatoid arthritis in clinical practice: AIRTIGHT study
SO RHEUMATOLOGY INTERNATIONAL
LA English
DT Article
DE Rheumatoid arthritis; Bone mineral density; Bone mineral markers; Osteoporosis; Abatacept
ID antitumor necrosis factor; double-blind; risk; methotrexate; efficacy; safety; classification; osteoporosis; multicenter; metabolism
AB We investigated the influence of abatacept (ABT) on bone mineral density (BMD) and bone metabolic markers (BMMs) in patients with rheumatoid arthritis (RA) compared to other biologic disease-modifying anti-rheumatic drugs (bDMARDs). This prospective, comparative, non-randomized study (the AIRTIGHT study; UMIN000005570) investigated the effects of ABT and other bDMARDs on bone metabolism. A total of 165 RA patients were divided into ABT (n = 50) and non-ABT (n = 115). We evaluated percentage changes in BMD (%Delta BMD) at the lumbar spine and femoral neck using dual-energy X-ray absorptiometry. Urinary levels of cross-linked N-telopeptide of type I collagen (uNTx) and bone-specific alkaline phosphatase (BAP) were used as markers of bone resorption and formation, respectively. No significant differences in 1-year completion rates were seen between ABT (64%) and non-ABT (72%; p = 0.387). The %Delta BMD at the femoral neck was significantly higher in the ABT group (0.97%) than in the non-ABT group (- 2.19%; p = 0.026). Whereas, no significant difference in %Delta BMD at the lumbar spine was observed between groups (ABT, - 0.40%; Non-ABT, - 1.67%; p = 0.524). No significant differences were observed in changes to uNTx or BAP. ABT treatment was significantly associated with increased BMD at the femoral neck (odds ratio (OR) 8.84; 95% CI 1.08-72.4; p = 0.04), and baseline lumbar osteoarthritis was significantly associated with BMD at the lumbar spine (OR 2.97; 95% CI 1.23-7.13; p = 0.02). The efficacy of ABT for increasing BMD at the femoral neck was superior to that of other bDMARDs. ABT may offer good efficacy for improving BMD at the femoral neck in patients with RA.

TI Quantification of bone microstructure in the wrist using cone-beam computed tomography
SO BONE
LA English
DT Article
DE Cone-beam computed tomography; Bone parameters; Micro-computed tomography; Medical imaging processing; Quantification
ID resolution; ct; accuracy; microarchitecture
AB Due to the rising life expectancy, bone diseases (e g osteoporosis, osteoarthritis) and trauma (e.g. fracture) have become an important socio-economic burden Accurate visualization and quantification of the bone micro structure in vivo is seen as an important step to enhance diagnosis and treatment. Micro-computed tomography (microCT) has become the gold standard in three-dimensional (3D) imaging of trabecular bone structure. Yet, usage is limited

to ex vivo analyses, hence, it cannot be used to evaluate bone and bone adaptive responses in a patient High-resolution peripheral computed tomography (HR-pQCT) is considered the best technique to measure the bone microarchitecture in vivo By design HR pQCT is limited to scanning extremities, such as the distal radius and distal tibia with a limited field of view and long scanning time (similar to 2a 3 mm for a stack of 0.9 cm). Cone-beam computed tomography (CBCT) is a promising alternative with a much larger field of view. Yet, CBCT is challenged by artefacts that reduce image contrast, such that it is currently being used for qualitative evaluation only. Therefore, the aims of this work were first to enhance image contrast and second to determine the accuracy of high-resolution CBCT for bone microarchitectural assessment. Trapezia of nineteen female arthritic patients were scanned twice ex vivo, once using CBCT (NewTom 5G, Cefla, Verona, Italy) at a nominal voxel size of 75 mu m and once using microCT (SkyScan 1172, Bruker, Kontich, Belgium) at a voxel size of 19 84 mu m. The CBCT-scans were reconstructed following 2 protocols: (1) using the commercial software delivered with the scanner and (2) using in-house developed software After reconstruction and image processing, the images were segmented using adaptive thresholding Bone morphometry parameters including bone volume (BV), total tissue volume (TV), bone volume fraction (BV/TV), bone surface density (BS/ TV), trabecular thickness (Tb.Th), trabecular separation (Tb Sp) and trabecular number (Tb N) were calculated Statistical evaluations were made at a significance level of 5%. Significant correlations were found between the CBCT based bone parameters and the microCT based parameters with R-2 > 0.68 The in house reconstructed software outperformed the commercial software. Smaller bias (overestimation of TbTh decreased from 114.24% to 59.96%) as well as higher correlations were observed for the in-house processed images. Still, a significant overestimation was observed for BV/TV and Tb. Th and an underestimation for Tb.N. We conclude that our CBCT image reconstruction improved image contrast which allowed for an accurate quantification of trabecular bone microarchitecture.

TI Prevalence of Vitamin D Deficiency in Patients With Talar Osteochondral Lesions
SO FOOT & ANKLE INTERNATIONAL
LA English
DT Article
DE talus; osteochondral lesion; vitamin D; deficiency; hypovitaminosis D
ID united-states; talus; fractures; season; ankle; osteoarthritis; skin; osteoporosis; population; dissecans
AB Background: Vitamin D deficiency affects over 1 billion people worldwide and is common in foot and ankle patients. The prevalence in those with osteochondral lesions of the talus (OLTs) is unknown. This study identified the prevalence and risk factors for hypovitaminosis D in patients with an OLT. Methods: Serum 25(OH)D levels were obtained from patients presenting with an OLT from May to November during 2007 to 2016. Hypovitaminosis D was defined as 25(OH)D less than 30 ng/mL (75 nmol/L). Patients presenting with an acute ankle sprain (AS) during the same months served as a control group. Specific medical risk factors for hypovitaminosis D were recorded. The final OLT population included 46 patients (31 women [67.4%]; mean [SD] age 43.6 [14.8] years). The comparison AS group had 40 patients (32 women [80.0%]; mean [SD] age 56.2 [13.0] years). Results: The mean (SD) 25(OH)D in the OLT and AS cohorts were 31.2 (12.6) ng/mL and 37.1 (13.5) ng/mL, respectively (P = .039). Hypovitaminosis D was identified in 54% of the OLT population and 28% of the AS population (P = .012). Conclusion: Hypovitaminosis D is intimately related to decreased bone mineral density. This study identified a significantly higher rate of hypovitaminosis D in patients with an OLT compared to a cohort of AS patients. These findings suggest that when patients present with an OLT, health care providers should consider evaluating for and treating hypovitaminosis D. Level of Evidence: Level III, comparative study.

ID nf-kappa-b; controlled-release strategy; natural-products; rat model; osteoporosis; mechanisms; differentiation; angiogenesis; cartilage; expression
AB The use of natural compounds for treating chronic bone diseases holds remarkable potential. Among these therapeutics, naringin, a flavanone glycoside, represents one of the most promising candidates owing to its multifaceted effect on bone tissues. This review provides an up-to-date overview on naringin applications in the treatment of bone disorders, such as osteoporosis and osteoarthritis, and further highlights its potential for stem cell pro-osteogenic differentiation therapies. A critical perspective on naringin clinical translation is also provided. The topic is discussed in light of recently developed biomaterial-based approaches that potentiate its bioavailability and bioactivity. Overall, the reported pro-osteogenic, antiresorptive and antiadipogenic properties establish this flavanone as an exciting candidate for application in bone tissue engineering and regenerative medicine.

TI Multivariate analysis of factors related to radiographic knee osteoarthritis based

on the comparison between football players and matched nonsportsmen
SO INTERNATIONAL ORTHOPAEDICS
LA English
DT Article
DE Knee osteoarthritis; Osteoporosis; Joint wear; Body mass density
ID joint; arthritis; hip
AB Purpose Knee osteoarthritis (KOA) is the most common joint pathology worldwide and a major cause of later disability. It is unknown if the bone mass density (BMD) is correlated with KOA. This study aimed to investigate the prevalence of radiographic KOA among retired professional football players by comparing with matched nonsportsmen, and assess the correlation between BMD and KOA. Methods A cross-sectional, descriptive study was performed on a group of retired professional football players without history of knee injury. A control group of nonsporting volunteers was matched to the football player group in terms of age, height, weight, and body mass index (BMI). Uni- and multivariate analyses were performed to identify risk factors for KOA and predictors for knee function. Results Eighty-six retired male professional football players, with a mean age of 53 (51-58) years and an average period of professional career of 19.8 +/- 6.3 years, were enrolled into the study group. Eighty-six subjects were included in the control group. Radiographic KOA was more common in the control group (45.3%) than in the study group (15.1%;chi(2) = 18.633, P < 0.001). While the HSS, IKS score, and BMD of spine, femoral neck, and trochanter were all higher among sportsmen than the nonsportsmen (z = 10.250, z = 10.450, z = 7.237, z = 8.826, z = 8.776, all P < 0.001). Independent risk factors for ROA were age (55-60 + years, aOR 9.159, P < 0.001) and BMD (decrease, aOR 16.226, P = 0.001; osteoporosis, aOR 8.176, P = 0.005). The mathematical model of multiple linear regression for the HSS and IKS score were Y = 127.217-3.334 age + 8.971 BMD + 4.752 occupation and Y = 57.784-3.022 age + 7.241 BMD + 4.730 occupation, respectively. Conclusions This study reveals that low BMD and advanced age are independent risk factors for KOA. High BMD and regular exercise have a positive impact on knee function as evaluated with the use of HSS and IKS. Our findings guarantee further study to investigate the possibility that KOA may be caused by low BMD.

TI Race, Bundled Payment Policy, and Discharge Destination After TKA: The Experience of an Urban Academic Hospital
SO GERIATRIC ORTHOPAEDIC SURGERY & REHABILITATION
LA English
DT Article
DE payment reform; primary knee arthroplasty; racial disparity; discharge destination; readmission
ID total joint arthroplasty; care; disparity; medicare; outcm; knee
AB Background: Total knee arthroplasty (TKA) provides good clinical outcomes for the treatment of end-stage osteoarthritis; however, discharge destination after TKA has major implications on postoperative adverse outcomes and readmissions. With the initiation of Bundled Payments for Care Improvement (BPCI), it is unclear how racial disparities in discharge destination after TKA will be affected by the new bundled payment for TKA. Methods: Bundled Payments for Care Improvement was implemented in July 01, 2014, at the University of Pennsylvania. We compared differences during early implementation (July 1, 2014, to, March 30, 2016) and during late policy implementation (April 1, 2016, to February 28, 2017) in patient characteristics (including race: African American [AA], white, and other race), discharge destination (skilled nursing facility [SNF], inpatient rehabilitation facility, home, home with home health, or other), and outcomes. Results: We identified 2276 patients who underwent TKA (43.8% AA, 48.2% white, and 8.0% other race). African American patients were more likely to be discharged to SNF as opposed to home than white patients both during the early BPCI (AA: 53.0%, n = 320; white: 32.4%, n = 210, P < .05) and late BPCI implementation (AA: 44.4%, n = 169, white:

26.9%, n = 120, P < .05), though all races showed trends to decreasing SNF use during the late BPCI implementation. Discussion: There were no significant differences in readmissions, length of stay, mortality, or intensive care unit days during early and late implementation of BPCI or when AA patients were compared to white patients. Conclusion: We found no significant changes in racial variations in discharge destination and outcomes after elective TKA. Bundled Payments for Care Improvement has encouraged better preoperative preparation of patients and discharge planning; however, payment reforms alone might not be sufficient to address variation in post-op management following elective surgery.

TI Treadmill Running Ameliorates Destruction of Articular Cartilage and Subchondral Bone, Not Only Synovitis, in a Rheumatoid Arthritis Rat Model
SO INTERNATIONAL JOURNAL OF MOLECULAR SCIENCES
LA English
DT Article
DE treadmill running; exercise; articular cartilage; rheumatoid arthritis; collagen-induced arthritis; pro-inflammatory cytokine; cnnexin43; osteoporosis
ID induced osteoarthritis; monoclonal-antibody; expression; alpha; methotrexate; connexin-43; recommendations; interleukin-6; infliximab; exercise
AB We analyzed the influence of treadmill running on rheumatoid arthritis (RA) joints using a collagen-induced arthritis (CIA) rat model. Eight-week-old male Dark Agouti rats were randomly divided into four groups: The control group, treadmill group (30 min/day for 4 weeks from 10-weeks-old), CIA group (induced CIA at 8-weeks-old), and CIA + treadmill group. Destruction of the ankle joint was evaluated by histological analyses. Morphological changes of subchondral bone were analyzed by -CT. CIA treatment-induced synovial membrane invasion, articular cartilage destruction, and bone erosion. Treadmill running improved these changes. The synovial membrane in CIA rats produced a large amount of tumor necrosis factor- and Connexin 43; production was significantly suppressed by treadmill running. On -CT of the talus, bone volume fraction (BV/TV) was significantly decreased in the CIA group. Marrow star volume (MSV), an index of bone loss, was significantly increased. These changes were significantly improved by treadmill running. Bone destruction in the talus was significantly increased with CIA and was suppressed by treadmill running. On tartrate-resistant acid phosphate and alkaline phosphatase (TRAP/ALP) staining, the number of osteoclasts around the pannus was decreased by treadmill running. These findings indicate that treadmill running in CIA rats inhibited synovial hyperplasia and joint destruction.

TI Bone quality, and the combination and penetration of cement-bone interface A comparative micro-CT study of osteoarthritis and rheumatoid arthritis
SO MEDICINE
LA English
DT Article
DE bone-cement interface; bone quality; micro-CT; osteoarthritis; rheumatoid arthritis
ID mineral density; cancellous bone; bristol oa500; femoral-head; osteoporosis; disease; model; micromechanics; progression; frequency
AB To compare the microstructure, bone quality, and the combination and penetration of cement-bone interface in tissue specimens from patients with osteoarthritis (OA) and rheumatoid arthritis (RA). A total of 80 femoral condyle tissue specimens from 20 OA patients (40 condyles) and 20 RA patients (40 condyles) who underwent total knee arthroplasty at the Department of Orthopaedics in Tengzhou Central People's Hospital were collected between January 2017 and September 2017. According to the random number table method, 20 specimens from the OA group were defined as group A, and 20 specimens in the RA group were defined as group B The bone quality parameters were measured by micro-CT. The remaining 20 specimens in the OA group and the remaining 20 specimens in the RA group were defined as group C and group D, the cement-bone interfaces were established by the self-made bone cement compression device, and were analyzed by micro-CT. Micro-CT measurement revealed that the bone volume fraction (BV/TV), trabecular thickness (Tb.Th), and trabecular number (Tb.N) in group A were significantly higher than those in group B (all $P < .05$). The bone surface/bone volume (BS/BV), structure model index (SMI), trabecular separation (Tb.Sp), and degree of anisotropy (DA) in group A were significantly lower than those in group B (all $P < .05$). The penetration depth of bone cement in group D was significantly greater than those in group C via x-ray detection. The bone quality of OA patients is better than that of RA patients, but the combination and penetration of cement-bone interface of RA patients are better than that of OA patients. The findings advance our understanding of knee prosthesis and have important clinical implications, but they require validations in future studies with larger sample sizes.

TI Extracorporeal shock wave treatment can normalize painful bone marrow edema in knee osteoarthritis A comparative historical cohort study
SO MEDICINE
LA English
DT Article
DE alendronate; bone marrow edema; MRI; osteoarthritis; pain; shock wave
ID necrotic femoral heads; intravenous ibandronate; transient osteoporosis; pressure measurements; core decompression; subchondral bone; hip; therapy; rabbits; expression
AB Bone marrow edema (BME) represents a reversible but highly painful finding in magnetic resonance imaging (MRI) of patients with knee osteoarthritis. The aim of this retrospective study was to evaluate the efficacy of extracorporeal shock wave treatment (ESWT) on painful BME in osteoarthritis of the knee. This study focuses on people who had early-to-mid stage osteoarthritis with knee pain and MRI findings of BME. Patients who underwent ESWT treatment or prescribed alendronate treatment in our department were analyzed. Knee pain and function were measured using the visual analog scale (VAS) for pain and the Western Ontario and McMaster University Osteoarthritis Index (WOMAC), respectively. The degree of BME was measured with MRI scans. A total of 126 patients who received ESWT treatment (Group A, n=82) or alendronate treatment (Group B, n=44) were included. All patients were followed up clinically and radiographically for a minimum of 12 months. The mean follow-up was 23.5 months (range, 12-38 months). The VAS and WOMAC score decreased more significantly after treatment in Group A than that in Group B (P<.01) within 3 months. In 6-month MRI follow-ups, there was higher incidence of distinct reduction and complete regression of BME of the affected knee in Group A than that in Group B (P<.01). ESWT is an effective, reliable, and noninvasive treatment in patients with painful BME in osteoarthritis of the knee followed by a rapid normalization of the MRI appearance. It has the potential to shorten the natural course of this disease.

TI Ultrastructural change of the subchondral bone increases the severity of cartilage damage in osteoporotic osteoarthritis of the knee in rabbits
SO PATHOLOGY RESEARCH AND PRACTICE
LA English
DT Article
DE Osteoarthritis; Osteoporosis; Subchondral bone; Cartilage; Scanning electron microscopy
ID tougu xiaotong capsule; articular-cartilage; experimental-model; pathogenesis;

prevalence; morphology; hip
AB Osteoporotic osteoarthritis is a phenotype of osteoarthritis (OA) manifested as fragile and osteoporotic subchondral bone. However, the ultrastructural features of subchondral bone in osteoporosis OA have not been determined. The study was aimed to investigate the ultrastructural dynamic changes of subchondral bone in osteoporotic OA model and how the ultrastructural damage in the subchondral bone caused by osteoporosis deteriorated the cartilage damage in OA. Eighteen rabbits were equally randomized to three groups, including the control, the OA and the osteoporotic OA groups. The structural changes of cartilage were evaluated by HE and safranin-O fast green staining, the Mankin's grading system was used to assess the stage of OA progression. And microstructural or ultrastructural changes in subchondral bone were assessed by micro-computed tomography or by scanning electron microscopy. According to the changes of cartilage histopathology, the OA group was in the early pathological stage of OA while the osteoporotic OA group was in the middle stage of OA based on Mankin's grading system. In addition, the damage of cartilage surface, reduction in the number of chondrocytes and the matrix staining were more increased in the osteoporotic OA group compared to the OA group. Compared to the OA group, the subchondral bone in the microstructure and ultrastructure in the osteoporotic OA group showed more microfracture changes in trabecular bone with more destructions of the tree-like mesh. Moreover, the collagen fibers were random rough with a fewer amount of bone lacunae in subchondral cortical plate in the osteoporotic OA group compared to the OA group. These findings indicated that the subchondral bone ultrastructure in the osteoporotic OA model was characterized by the destruction of the network structure and collagen fibers. The subchondral bone ultrastructural damage caused by osteoporosis may change mechanical properties of the upper cartilage and aggravate OA cartilage. Therefore, early diagnosis and treatment of osteoporosis is of great significance to prevent early OA from further developing osteoporotic OA.

TI Is trabecular bone score less affected by degenerative-changes at the spine than lumbar spine BMD?
SO ARCHIVES OF OSTEOPOROSIS
LA English
DT Article
DE Trabecular bone score; Men; Lumbar spine degenerative-changes; Bone mineral density
ID predicts osteoporotic fractures; mineral density; geelong osteoporosis; tbs; men; women; microarchitecture; osteoarthritis; osteopenia; diagnosis
AB It has been established that degenerative-changes at the spine elevate bone mineral density at the lumbar spine. This study in men reports that trabecular bone score may be less affected by spinal degenerative-changes.PurposeA recent tool for assessing trabecular microarchitecture at the lumbar spine, trabecular bone score (TBS), provides information about bone health complementary to lumbar spine areal BMD (here referred to as BMD). In men, mean BMD increases with increasing age due to degenerative-changes at the spine including osteophytes and aortic calcification. The aim of this study was to investigate whether TBS is similarly affected by the presence of degenerative-changes in men.MethodsThis study included 728 men aged 40-90years enrolled in the Geelong Osteoporosis Study. Lumbar spine DXA scans (Lunar Prodigy) were used to determine TBS retrospectively (TBS iNsight software, Version 2.2), and for identification of degenerative-changes. Using multivariable regression techniques, the relationships between TBS or BMD and degenerative-changes were assessed, further adjusting for age and weight. The difference between each of the two methods was examined through testing interactions between method, degenerative-changes and age.ResultsOf 728 men, 439 (60.3%) were identified as having one or more degenerative-changes at the lumbar spine. Adjusted mean TBS was 1.219 (1.203-1.232) and 1.196 (1.179-1.212) for those with and without degenerative-changes, respectively. Adjusted mean BMD was 1.317g/cm(2)

(1.297-1.336) and 1.198g/cm(2) (1.173-1.223) for those with and without degenerative-changes, respectively. Partial r(2) for degenerative-changes in the model for TBS was 0.076 and for BMD, 0.257 (both p<0.05). The three-way interaction between method, degenerative-changes and age was significant (p=0.05) indicating significant effect of artefacts on the standardised values, affected by age and method.ConclusionThis study suggests that TBS is less affected by degenerative-changes at the spine than is BMD. Thus, TBS may prove useful in the assessment of fracture risk in men with degenerative-changes at the spine.

TI Primary total knee arthroplasty for acute fracture around the knee
SO ORTHOPAEDICS & TRAUMATOLOGY-SURGERY & RESEARCH
LA English
DT Review

DE Distal femur fracture; Proximal tibia fracture; Total knee arthroplasty; Elderly; Osteoporosis; Adult
ID distal femoral fractures; elderly-patients; supracondylar fractures; osteoporotic fractures; hip fracture; revision; replacement; management; femur; mortality
AB Relatively poor results have been reported with open reduction and internal fixation of complex fractures around the knee in elderly osteoporotic patients, and primary total knee arthroplasty (TKA) has been proposed as an alternative solution. While limiting the number of procedures, it meets two prerequisites: (1) to save the patient's life, thanks to early weight-bearing, to limit decubitus complications; and (2) to save knee function and patient autonomy, thanks to early knee mobilization. There are 3 main indications: complex articular fractures in elderly patients with symptomatic osteoarthritis prior to fracture; complex articular fractures of the tibial plateau in elderly patients whose bone quality makes internal fixation hazardous; and major destruction of the distal femur in younger patients. Although admitted in emergency, these patients require adequate preoperative management, including a multidisciplinary approach to manage comorbidities, control of anemia and pain, and assessment and management of vascular and cutaneous conditions. Preoperative planning is crucial, to order appropriate implants and materials that may be needed intraoperatively. Surgical technique is based on the basic principles of revision surgery as regards choice of implant, steps of reconstruction, bone defect management and implant fixation. For complex fractures of the distal femur, primary temporary reduction is a useful "trick", to determine the level of the joint line and femoral rotation. Complementary internal fixation may be required incase of diaphyseal extension of the fracture and to prevent inter-prosthetic fractures. In the literature, the results of primary TKA for fracture are encouraging and better than for secondary TKA after failure of non-operative treatment or internal fixation, with lower rates of revision and complications, earlier full weight-bearing and better functional results. Loss of autonomy is, however, frequent, and 1-year mortality is high, especially following complex femoral fractures in the elderly. (c) 2017 Elsevier Masson SAS. All rights reserved.

TI Osteoactivin inhibits dexamethasone-induced osteoporosis through up-regulating integrin β1 and activate ERK pathway
SO BIOMEDICINE & PHARMACOTHERAPY
LA English

DT Article
DE BMSC; ERK; Intergrin beta 1; Osteoactivin; Osteoporosis
ID mesenchymal stem-cells; osteoclast differentiation; regeneration; expression; plays
AB Backgrounds: Dexamethasone (Dex) is widely used in autoimmune diseases and inflammation treatment. A sever side effect of prolonged exposure to Dex is increased risk of osteoporosis (OP) or even femoral head necrosis, which would cause much suffer to patients. To reveal the mechanism behind this phenomenon, provide therapeutic guidance and potential target, we analyzed the inhibitory mechanism of Dex on osteogenesis of rat-BMSC. Methods: Rat BMSC were obtained and characterized with FACS analysis. Osteogenesis and adipogenesis abilities were detected with Oil-O-Red staining, Alizarin Red staining and ALP activity analysis. These BMSC were then treated with Dex in combination with recombinant OA or not and detected for osteogenesis related gene expression with qRT PCR. Protein interaction and expression were detected by Co-Immunoprecipitation and western blot. Results: Osteoactivin (OA) could promote integrin beta 1 expression and interact with this protein physically, leading to ERK activation and promoting osteogenesis related genes' expression including Runx2, Coll a and OCN in BMSC. Dex, however, could block expression of several upstream genes of OA and decrease OA mRNA and protein level, and eventually suppress integrin beta 1 ERK activation and lead to decreased osteogenesis, which could finally develop into OP. Conclusion: Recombinant OA treated BMSC exerted better osteogenesis potency even with Dex administration. This is because additional OA in medium counter-acts with Dex's influence and rescued osteoblast differentiation via up-regulating integrin beta 1 and activate ERK/MAPK pathway which promotes osteogenesis. Hence, OA/integrin beta 1 could serve as potential therapeutic target for OP.

TI Application of 2012 EULAR/ACR criteria for polymyalgia rheumatica to Korean patients previously classified by Chuang and Hunder criteria or Healey criteria
SO INTERNATIONAL JOURNAL OF RHEUMATIC DISEASES
LA English
DT Article
DE classification criteria; polymyalgia rheumatica; reclassification
AB Aim: To apply 2012 European League Against Rheumatism/American College of Rheumatology (EULAR/ACR) criteria to Korean patients previously classified as polymyalgia rheumatica (PMR) by Chuang and Hunder criteria or Healey criteria and investigated whether they might be still reclassified as PMR or not. Methods: We retrospectively reviewed the medical records of 113 previously classified PMR patients. We applied 2012 EULAR/ACR criteria without ultrasonography to PMR patients, and fulfilment required at least 4 points. We evaluated odds ratios (OR) using logistic regression analyses. Results: The mean age was 61.7 years. Seventy-one patients (62.8%) fulfilled Chuang and Hunder criteria, and 113 patients (100%) met Healey criteria. When we applied 2012 EULAR/ACR criteria, 98 patients fulfilled essential items (>= 50 years, bilateral shoulder aching and abnormal C-reactive protein or erythrocyte sedimentation rate), and only 80 patients

achieved points >= 4. Eight patients fulfilling the criteria exhibited higher frequencies of all the detailed items than those who did not. In multivariate logistic regression analysis, absence of rheumatoid factor or anti-citrullinated peptide antibodies was the only independent contributing item to the fulfilment of 2012 EULAR/ACR criteria (OR 23.571, 95% CI 6.357-87.407, P < .001). When we reclassified 33 excluded patients, the most common newly classified disease was generalized osteoarthritis (24.2%), followed by osteoporosis with compression fracture (15.2%). Conclusion: Eighty of 113 patients (81.6%) previously classified by Chuang and Hunder criteria or Healey criteria fulfilled 2012 EULAR/ACR criteria for PMR.

TI The renin-angiotensin system in the synovium promotes periarticular osteopenia in a rat model of collagen-induced arthritis
SO INTERNATIONAL IMMUNOPHARMACOLOGY
LA English
DT Article
DE Periarticular osteopenia; Rheumatoid arthritis; Renin-angiotensin system; Synovial tissue; Bone metabolism; Perindopri
ID rheumatoid-arthritis; converting enzyme; therapeutic target; type-1 receptor; bone; differentiation; inhibitor; rankl; osteoporosis; mechanisms
AB Periarticular osteopenia is the most specific hallmark of rheumatoid arthritis

(RA). The renin-angiotensin system (RAS) in the synovium has been found to participate in the pathogenic process of RA. This study examined whether and how RAS regulates periarticular osteopenia in RA. The synovial tissues from patients with RA and osteoarthritis (OA) were prepared. Female Sprague-Dawley rats were treated with either saline, bovine type II collagen (CII) to induce arthritis (CIA), or CII combined with perindopril, an inhibitor of angiotensin-converting enzyme (ACE). Expressions of RAS components, including AT1R, AT2R and ACE, in human and rat synovial tissues were detected. Bone mass of rat joints was examined. Levels of RANKL, OPG and DKK-1 in rat synovium and expressions of TRAF6 and beta-catenin in rat bone were examined. The results showed that AT1R, AT2R and ACE in human and rat synovium were up-regulated, but the increased ACE in rat synovial tissues was abrogated by perindopril. While CIA rats displayed increased bone resorption and decreased bone formation, perindopril treatment almost completely abrogated the RAS-mediated osteopenia, indicating that inhibition of ACE reduced the joint damages in rats. The expressions of RANKL and DKK-1 increased in CIA rats as compared with those in the control; TRAF6 was up-regulated and beta-catenin was down-regulated in the bone tissues of CIA rats. The changes were then reversed by the use of perindopril. Our findings demonstrate that RAS in the synovium promotes periarticular osteopenia by increasing bone resorption and decreasing bone formation through modulating the RANKL/RANK/TRAF6 and Wnt/beta-catenin pathways.

TI The effects of POSS particles on the flame retardancy of intumescent polypropylene composites and the structure-property relationship
SO POLYMER DEGRADATION AND STABILITY
LA English
DT Article
DE Polypropylene; Flame retardant; POSS; Intumescence
ID polyhedral oligomeric silsesquioxane; mechanical-property; thermal-degradation; fire retardancy; polymer nanocomposites; ammonium polyphosphate; physical-property; epoxy-resin; behavior; flammability
AB In the current study, the effects of four different POSS nanoparticles on the flame retardant properties of intumescent PP were investigated through mass-loss calorimetry (MLC), limiting oxygen index (LOI) test and UL-94 ratings. In addition,

the structure-property relationship was enlightened via thermal, morphological and mechanical tests. The four different POSS types, namely aminopropyl isobutyl-POSS (A-POSS), octaphenyl-POSS (OP-POSS), octaammonium-POSS (OA-POSS) and trissulfonic acid propyl-POSS (TS-POSS), were used. The ratio of ammonium polyphosphate (APP) to pentaerythritol (PER) was kept constant and the POSS content was varied as 0.5%, 1% and 3%. The MLC, LOI and UL-94 tests revealed that the addition of POSS particles had adjuvant on the flame retardant properties of PP/IFR system. All POSS nanoparticles showed their highest adjuvant effect at the lowest concentration of 0.5 wt%. The highest UL-94 rating and the highest LOI values were achieved in the presence of OA-POSS and TS-POSS. The ceramic layer formation was monitored using scanning electron microscopy (SEM) and FTIR on the char residues. The thermal properties of PP/IFR/POSS composites were obtained via differential scanning calorimeter and thermo-gravimetric analysis. The inline melt flow properties were observed via vertical force measurements. The fracture morphology was investigated using SEM. Mechanical tests showed that the yield strengths of the composites were lower than that of pristine PP; in contrast, the elongation at break and the impact strength of composites enhanced in A-POSS and TS-POSS based composites.

DE Sinusoidal electromagnetic fields; Exposure duration; Osteoblasts; Peak bone mass; Bone mineral density
ID mesenchymal stem-cells; magnetic-field; double-blind; osteogenic differentiation; knee osteoarthritis; clinical-trial; in-vitro; mineralization; osteoporosis; stimulation
AB We proposed a three-step strategy to obtain the optimal therapeutic parameters, which is composed of large-scale screening at cellular level, verification in animal experiments, and confirmation by a clinical trial. The objective of the current study was to test the feasibility of our strategy. Newborn rat calvarial osteoblasts were treated by 50 Hz 1.8 mT sinusoidal electromagnetic fields (SEMFs) with 0.5, 1.0, 1.5, 2.0, 2.5, and 3.0 h/days, respectively. The osteogenic differentiation and maturation of the osteoblast were assayed and compared to obtain the optimal duration. One-month-old growing rats were then treated by the same SEMFs with 0.5, 1.5, and 2.5 h/days, respectively, and the peak bone mass was analyzed after 2 months. It was found that the optimal exposure duration to promote the osteogenic differentiation and maturation of osteoblasts was 1.5 h/days, judging by the increasing degrees of ALP activity, calcified nodules formed, the gene and protein expression levels of Runx-2, BMP-2, and Col-I, as well as the expression levels of signaling proteins of the BMP-2/Smad1/5/8 pathway. The highest increase of peak bone mass after 2 months was also obtained by 1.5 h/days, judging by the results of X-ray dual-energy absorptiometry, mechanical property analysis, micro-CT scanning, and serum bone turnover marker examinations. The above results indicated that exposure duration is a determinant for the therapeutic effect of EMFs, and the optimal therapeutic effects only can be obtained by the optimal exposure duration.

AB Musculoskeletal disorders affect morbidity, quality of life and mortality, and represent an increasing economic and societal burden in the context of population aging and increased life expectancy. Improvement of quality of life should be one of the priorities of any interventions to prevent and treat musculoskeletal disorders in the ageing population. Two main approaches, namely generic and disease-specific instruments, can be applied to measure health-related quality of life. Among the generic tools available in scientific literature, the short form 36 questionnaire (SF-36) and the Euroqol five item questionnaire (EQ-5D) are two of the most popular questionnaires used to quantify the health related quality of life in people with musculoskeletal disorders. However, because generic tools may not always be able to detect subtle effects of a specific condition on quality of life, a specific tool is highly valuable. Specific tools improve the ability to clinically characterize quality of life in subjects with a specific musculoskeletal disorder, as well as the capacity to assess changes over time in the QoL of these subjects. The recent development of specific tools should help to validate preventive and therapeutic interventions in this field.

TI Reverse shoulder arthroplasty vs BIO-RSA: clinical and radiographic outcomes at short term follow-up
SO JOURNAL OF ORTHOPAEDIC SURGERY AND RESEARCH

LA English
DT Article
DE Reverse shoulder arthroplasty; BIO-RSA; Scapular insufficiency fractures; Scapular notching; Functional outcomes
ID glenohumeral osteoarthritis; prosthesis; fractures; cuff; classification; complications; reliability; arthritis; revision; design
AB BackgroundBony increased-offset reverse shoulder arthroplasty (BIO-RSA) may address issues such as inferior scapular notching, prosthetic instability and limited postoperative shoulder rotation; all of which have been reported with the standard RSA and attributed to the medialized design. We hypothesised that this lateralization may increase the rate of scapular stress fractures.MethodsA retrospective review of prospectively collected data was performed on patients who had undergone a RSA between January 2013 and October 2016. A comparative cohort study was designed to compare patients with a standard Grammont-style RSA to those with a BIO-RSA using the same implant. Functional outcome was measured by the American Shoulder and Elbow Surgeons (ASES) Shoulder Score, the Subjective Shoulder Value (SSV), the Western Ontario Osteoarthritis of the Shoulder (WOOS) index and pain scores. Radiographs were obtained for all patients and examined for the presence of scapular fracture as well as scapular notching and graft incorporation.ResultsA total of forty patients (22 patients in the standard RSA cohort and 18 with BIO-RSA) were included in the study. Patient characteristics (including age, gender, length of follow-up, dominant side and osteoporosis) were similar in both groups ($p>0.05$). The average postoperative follow-up was 20months (range 12-48months). There was bone graft incorporation in all BIO-RSA patients at the final radiological follow-up, with no evidence of graft resorption. The overall scapular stress fracture rate was 12.5% (9.1% in the standard RSA and 16.7% in the BIO-RSA). The rates were similar in both cohorts ($p=0.64$). All fractures were managed conservatively. To determine whether the presence of a scapular stress fracture had an influence on outcomes, the cohort was divided into cases with and without fracture. Patients with a stress fracture had worse ASES ($p=0.028$) and WOOS ($p=0.048$) scores. Additionally, osteoporosis was present more commonly in the fracture group (80% vs 17%; $p=0.01$). A statistically significant difference was identified when comparing the rates of scapular notching between standard RSA and BIO-RSA cohorts (68% vs 33%; $p=0.028$). Furthermore, when notching was present, significantly worse outcome scores were present in all outcome measures ($p<0.001$).ConclusionThe BIO-RSA technique was associated with an increase in scapular stress fracture rate when compared to the standard RSA; however, this was not found to be significant. Furthermore, both techniques resulted in similar improvements in the measured functional outcomes. BIO-RSA, however, was associated with a lower scapular notching rate, justifying further evaluation of this technique.Level of evidenceRetrospective cohort study, level III

TI Osteoimmunology: The Nexus between bone and immune system
SO FRONTIERS IN BIOSCIENCE-LANDMARK
LA English
DT Article
DE Osteoimmunology; Osteoblasts; Osteoclasts; Bone loss; Treg cell; Th17 cell; Ovariectomy; Osteoporosis; RA; Osteoarthritis; Review
ID growth-factor-beta; kappa-b ligand; tumor-necrosis-factor; regulatory t-cells; phosphoinositide 3-kinase p110-delta; natural-killer-cells; rheumatoid-arthritis; receptor activator; dendritic cells; estrogen deficiency
AB Osteoimmunology is an interdisciplinary research field which combines the existing fields of osteology (bone biology) and immunology under one umbrella. The observation that contributed enormously to the emergence of osteoimmunology as an independent field of investigation was the enhanced bone loss in various inflammatory bone diseases such as rheumatoid arthritis, osteoporosis and periodontitis. T helper cells (Th1, Th2, Treg and Th17) along with various other immune cells (B cells, DC, macrophages etc.) are actively involved in bone homeostasis. The present review thus provides an overview of the nexus between these two prominent systems (Bone and Immune system) of an organism, which reside in a common niche (bone marrow) and thus cross-commumcate to modulate their respective development. Investigations in the field of osteoimmunology thus promise the advent of new era in the field with novel therapeutics for bone loss in various inflammatory conditions. A molecular insight into the field of osteoimmunology can lead to novel approaches for the prevention and treatment of diverse inflammatory conditions such as osteoporosis, rheumatoid arthritis and osteoarthritis.

TI Nrf2 as a therapeutic target for rheumatic diseases
SO BIOCHEMICAL PHARMACOLOGY
LA English
DT Article
DE Nrf2; Rheumatic conditions; Rheumatoid arthritis; Systemic lupus erythematosus; Osteoarthritis; Osteoporosis
ID nf-kappa-b; erythroid 2-related factor-2; systemic-lupus-erythematosus; human osteoarthritis chondrocytes; t-cell-activation; heme oxygenase-1; nlrp3 inflammasome; antioxidant response; signaling pathway; oxidative stress
AB Nuclear factor (erythroid-derived 2)-like 2 (Nrf2) is a master regulator of cellular protective processes. Rheumatic diseases are chronic conditions characterized by inflammation, pain, tissue damage and limitations in function. Main examples are rheumatoid arthritis, systemic lupus erythematosus, osteoarthritis and osteoporosis. Their high prevalence constitutes a major health problem with an important social and economic impact. A wide range of evidence indicates that Nrf2 may control different mechanisms involved in the physiopathology of rheumatic conditions. Therefore, the appropriate expression and balance of Nrf2 is necessary for regulation of oxidative stress, inflammation, immune responses, and cartilage and bone metabolism. Numerous studies have demonstrated that Nrf2 deficiency aggravates the disease in experimental models while Nrf2 activation results in immunoregulatory and anti-inflammatory effects. These reports reinforce the increasing interest in the pharmacologic regulation of Nrf2 and its potential

applications. Nevertheless, a majority of Nrf2 inducers are electrophilic molecules which may present off-target effects. In recent years, novel strategies have been sought to modulate the Nrf2 pathway which has emerged as a therapeutic target in rheumatic conditions.

TI The role of illness burden in theory of mind performance among older adults
SO EXPERIMENTAL AGING RESEARCH
LA English
DT Article
ID cognitive function; executive function; age-differences; hypertension; guidelines; management
AB Background/Study Context: Theory of Mind (ToM) reflects the ability to reason about mental states in order to understand and predict behavior. Research has identified links between increased pulse pressure, a measure of vascular health, and reduced cognitive ToM in older adults. However, the relationships between other vascular and nonvascular conditions and reduced ToM are unknown. We examined (1) illnesses as predictors of cognitive and affective ToM and (2) neurocognitive mediators of illness burden and ToM. Methods: We used hierarchical regression and mediation to investigate the effects of vascular illness burden (hypertension, Type 2 diabetes, high cholesterol, and high pulse pressure) and nonvascular illness burden (osteoporosis, osteoarthritis, rheumatoid arthritis, and thyroid dysfunction) on cognitive and affective ToM in N = 86 community-dwelling older adults (59 females; 27 males, M age = 71.74 years). Results: Vascular illness burden emerged as a significant predictor of older adults' cognitive ToM (R-2 = .43, p < .001), and this relationship was mediated by executive functioning. Nonvascular illness burden did not predict cognitive nor affective ToM in this sample. Conclusion: Our findings highlight the specific importance of considering vascular health as a risk factor for declines in ToM in later life. Further elucidation of the associations between health, neurocognition, and ToM will be valuable in developing effective interventions for older adults given the high prevalence of vascular illness in later life.

TI A long-lasting bisphosphonate partially protects periprosthetic bone, but does not enhance initial stability of uncemented femoral stems: A randomized placebo-controlled trial of women undergoing total hip arthroplasty
SO JOURNAL OF BIOMECHANICS
LA English
DT Article
DE Total hip arthroplasty; Radiostereometric analysis; Bone mineral density; Bisphosphonates; Postmenopausal osteoporosis
ID early implant migration; yearly zoledronic acid; double-blind; follow-up; mineral density; radiostereometric analysis; postmenopausal women; 2-year rsa; fixation; osteoarthritis
AB Low bone quality may compromise the success of cementless total hip arthroplasty in high-risk patients such as elderly women. Zoledronic acid is a long-lasting antiresorptive agent, which is known to reduce short-term periprosthetic bone loss. However, its effect on femoral stem stability is not well known. Forty-nine female patients with a mean age of 68 years (range, 51-85 years) scheduled to undergo cementless total hip arthroplasty due to osteoarthritis were randomized in this double-blind, placebo controlled trial to receive a single postoperative infusion of zoledronic acid or placebo. Patients were evaluated for up to four years postoperatively for femoral stem migration measured by radiostereometric analysis, bone mineral density (BMD) measured by dual X-ray absorptiometry, functional recovery, and patient-reported outcome scores. Implant survival was determined at nine years postoperatively. Zoledronic acid did not reduce the femoral stem migration that occurred predominantly during the settling period of the first 3-6 months. Subsequently, all femoral stems were radiographically osseointegrated. Zoledronic acid maintained periprosthetic BMD, while the expected loss of periprosthetic bone during the first 12 months was

found in controls. Thereafter, periprosthetic BMD of Gruen zone 7 decreased even in the zoledronic acid group but remained 14.6% higher than that in the placebo group at four years postoperatively. Functional recovery was comparable across the groups. At nine years postoperatively, no revision arthroplasty had been performed. In conclusion, in women at high-risk for low BMD, zoledronic acid had a long-lasting, partially protective effect on periprosthetic bone loss, but the treatment did not enhance the initial femoral stem stability. TI Integrating genome-wide DNA methylation and mRNA expression profiles identified different molecular features between Kashin-Beck disease and primary osteoarthritis
SO ARTHRITIS RESEARCH & THERAPY
LA English
DT Article
DE Kashin-Beck disease; Osteoarthritis; Methylation; Gene expression
ID susceptibility gene; articular-cartilage; abnormal expression; skeletal growth; chondrocytes; association; china; glycosaminoglycans; osteoporosis; metabolism
AB Background: Kashin-Beck disease (KBD) is an endemic osteochondropathy of unknown etiology. Osteoarthritis (OA) is a form of degenerative joint disease sharing similar clinical manifestations and pathological changes to articular cartilage with KBD. Methods: A genome-wide DNA methylation profile of articular cartilage from five KBD patients and five OA patients was first performed using the Illumina Infinium HumanMethylation450 BeadChip. Together with a previous gene expression profiling dataset comparing KBD cartilage with OA cartilage, an integrative pathway enrichment analysis of the genome-wide DNA methylation and the mRNA expression profiles conducted in articular cartilage was performed by InCroMAP software. Results: We identified 241 common genes altered in both the DNA methylation profile and the mRNA expression profile of articular cartilage of KBD versus OA, including CHST13 (NM_152889, fold-change = 0.5979, P-methy = 0.0430), TGFBR1 (NM_004612, fold-change = 2.077, P-methy = 0.0430), TGFBR2 (NM_001024847, fold-change = 1.543, P-methy = 0.037), TGFBR3 (NM_001276, fold-change = 0.4515, P-methy = 6.04 x 10(-4)), and ADAM12 (NM_021641, fold-change = 1.9768, P-methy = 0.0178). Integrative pathway enrichment analysis identified 19 significant KEGG pathways, including mTOR signaling (P = 0.0301), glycosaminoglycan biosynthesis-chondroitin sulfate/dermatan sulfate (P = 0.0391), glycosaminoglycan biosynthesis-keratan sulfate (P = 0.0278), and PI3K-Akt signaling (P = 0.0243). Conclusion: This study identified different molecular features between Kashin-Beck disease and primary osteoarthritis and provided novel clues for clarifying the pathogenetic differences between KBD and OA.

TI Oleanolic Acid and Ursolic Acid Improve Bone Properties and Calcium Balance and Modulate Vitamin D Metabolism in Aged Female Rats
SO FRONTIERS IN PHARMACOLOGY
LA English
DT Article
DE oleanolic acid; ursolic acid; bone protection; calcium balance; vitamin D metabolism; aged rats
ID fructus-ligustri-lucidi; parathyroid-hormone; ethanol extract; 25-hydroxyvitamin d-3; 1,25-dihydroxyvitamin d-3; mineral density; gene-expression; in-vitro; osteoblast differentiation; 1-alpha-hydroxylase gene
AB Oleanolic acid (OA) and ursolic acid (UA) are the major chemical constituents in Fructus Ligustri Lucidi (FLL), a kidney-tonifying Chinese herb that is previously shown to improve bone properties and enhance calcium balance in aged female rats. The present study was designed to study if OA and UA act as the active ingredients in FLL to exert the positive effects on bone and mineral metabolism in aged rats. Aged (13-month-old) Sprague-Dawley female rats were randomly assigned to four groups with oral administration of drug or vehicle treatment for 12 weeks: medium calcium diet (MCD, 0.6% calcium), high calcium diet (HCD, 1.2% calcium), MCD + FLL (700 mg/kg/day), MCD + OA (23.6 mg/kg/day) + UA (8.6 mg/kg/day). A group of mature (3-month-old) female rats fed with MCD was

included as positive control. The results demonstrated that FLL and OA+UA increased bone mineral density and improved microarchitectural properties of aged female rats. The osteoprotective effects of FLL and OA+UA might be, at least in part, associated with their actions on enhancing calcium balance and suppressing age-induced secondary hyperparathyroidism in aged female rats. FLL and OA+UA also significantly induced renal CYP27B1 protein expression and OA+UA treatment decreased CYP24A1 mRNA and protein expressions in aged female rats. In addition, FLL and OA+UA significantly increased the promoter activity, mRNA and protein expressions of renal CYP27B1 in vitro in human proximal tubule HKC-8 cells. The present findings suggest that OA+UA can be regarded as the active ingredients of FLL and might be a potential drug candidate for prevention and treatment of osteoporosis.

TI MRI-detected osteophytes of the knee: natural history and structural correlates of change
SO ARTHRITIS RESEARCH & THERAPY
LA English
DT Article
DE Osteoarthritis; Magnetic resonance imaging; Osteophyte; Natural history
ID radiographically diagnosed osteophytes; population-based cohort; cartilage volume loss; older-adults; imaging findings; surface-area; joint space; osteoarthritis; association; pain
AB BackgroudThe natural history of semi-quantitative magnetic resonance imaging (MRI)-detected osteophytes (MRI-detected OPs) has not been described and it is unknown whether knee structural abnormalities can predict MRI-detected OP change over time. Thus, the aim of current study is to describe the natural history of knee MRI-detected OP, and to determine if knee structural abnormalities are associated with change of MRI-detected OP in a longitudinal study of older adults.MethodsRandomly selected older adults (n = 837, mean age 63years) had MRI at baseline and 413 of them had MRI 2.6years later to measure MRI-detected OP, cartilage defects, cartilage volume, bone marrow lesions (BMLs), meniscal extrusion, infrapatellar fat pad (IPFP) quality score/maximum area and effusion-synovitis.ResultsOver 2.6years, average MRI-detected OP score increased significantly in all compartments. The total MRI-detected OP score remained stable in 53% of participants, worsened (1-point increase) in 46% and decreased in 1%. Baseline cartilage defects (RR, 1.25-1.35), BMLs (RR, 1.16-1.17), meniscal extrusion (RR, 1.22-1.33) and IPFP quality score (RR, 1.08-1.20) site-specifically and independently predicted an increase in MRI-detected OP (p values all 0.05), after adjustment for covariates. Presence of IPFP abnormality was significantly associated with increased MRI-detected OPs but became non-significant after adjustment for other structural abnormalities. Total (RR, 1.27) and suprapatellar pouch effusion-synovitis (RR, 1.22) were both associated with increased MRI-detected OPs in the lateral compartment only (both p<0.04).ConclusionKnee MRI-detected OPs are common in older adults and are likely to progress. The association between

baseline structural abnormalities and worsening MRI-detected OPs suggest MRI-detected OP could be a consequence of multiple knee structural abnormalities.

TI Risk factors for nonunion of bone fracture in pediatric patients An inception cohort study of 237,033 fractures
SO MEDICINE
LA English
DT Article
DE cardiovascular disease; fracture nonunion; opioid use; risk factors; scaphoid fractures; tobacco smoking; vitamin D deficiency
ID atypical femoral fractures; shaft fractures; limb fractures; children; bisphosphonates; pain; osteoporosis; metaanalysis; management; initiation
AB Adult fracture nonunion risk is related to injury severity and surgical technique, yet nonunion is not fully explained by these risk factors alone; biological risk factors are also important. We test a hypothesis that risk factors associated with pediatric fracture nonunion are similar to adult nonunion risk factors. Inception cohort study in a large payer database of pediatric fracture patients (0-17 years) in the United States in calendar year 2011. Continuous enrollment in the database was required for 12 months, to allow time to capture a nonunion diagnosis. The final database collated demographic descriptors, treatment procedures as per Current Procedural Terminology (CPT) codes, comorbidities as per International Statistical Classification of Diseases and Related Health Problems (ICD-9) codes, and drug prescriptions as per National Drug Code Directory (Red Book) codes. Logistic regression was used to calculate odds ratios (ORs) for variables associated with nonunion. Among 237,033 pediatric fractures in 18 bones, the nonunion rate was 0.85%. Increased nonunion risk was associated with increasing age, male gender, high body-mass index, severe fracture (e.g., open fracture, multiple fractures), and tobacco smoking (all, P < .0001). Nonunion rate varied with fracture location; scaphoid, neck of femur, and tibia/fibula were most likely to go to nonunion. Nonunion ORs were significantly increased for risk factors including; surgical procedure, cardiovascular disease, Vitamin D deficiency, osteoarthritis, osteoporosis, and opioid prescription (all, multivariable P < .001). Nonunion is rare in pediatric patients, but nonunion risk increases with increasing age. We confirm a hypothesis that risk factors for pediatric nonunion are similar to adult nonunion risk factors. Scaphoid fractures in adolescents have nearly the same risk of nonunion as in adults. Opioids should be used cautiously in pediatric patients, as they are associated with a significant and substantial elevation of nonunion risk.

TI Prevalence and co-existence of locomotive syndrome, sarcopenia, and frailty: the third survey of Research on Osteoarthritis/Osteoporosis Against Disability (ROAD) study
SO JOURNAL OF BONE AND MINERAL METABOLISM
LA English
DT Article
DE Disability; Locomotive syndrome; Sarcopenia; Frailty; Co-existence
ID bioelectrical-impedance analysis; dwelling elderly subjects; older-adults; association; mass; consensus; decline
AB This study aimed to estimate the prevalence of locomotive syndrome, sarcopenia, and frailty and clarify their co-existence in a population-based cohort. The third survey of Research on Osteoarthritis/Osteoporosis Against Disability (ROAD) study was conducted between 2012 and 2013, examining 963 subjects (aged >= 60 years; 321 men, 642 women). Locomotive syndrome, sarcopenia, and frailty were defined using three tests proposed by Japanese Orthopaedic Association, Asian Working Group for Sarcopenia criteria, and Fried's definition, respectively. Prevalence of locomotive syndrome stages 1 and 2 were 81.0% (men, 80.4%; women, 81.3%) and 34.1% (men, 30.5%; women, 35.8%), respectively, and those of sarcopenia and frailty were 8.7% (men, 9.7%; women, 8.3%) and 4.5% (men, 2.8%; women, 5.3%), respectively. Locomotive syndrome stage 1, sarcopenia, and frailty co-existed in 2.1%; 6.5% had locomotive syndrome stage 1 and sarcopenia, 2.4% had locomotive syndrome stage 1 and frailty, while none had sarcopenia and frailty. Locomotive syndrome stage 1 presented alone in 70.0%, sarcopenia in 0.1%, and no frailty. The remaining 18.9% had none of these conditions. Co-existence of locomotive syndrome stage 2, sarcopenia, and frailty

was observed in 2.0%; 5.0% had locomotive syndrome stage 2 and sarcopenia, 2.2% had locomotive syndrome stage 2 and frailty, and 0.1% had sarcopenia and frailty. Locomotive syndrome stage 2, sarcopenia, and frailty alone, presented in 24.9%, 1.7%, and 0.2%, respectively. The remaining 64.0% had none of these conditions. Most subjects with sarcopenia and/or frailty also had locomotive syndrome. Preventing locomotive syndrome may help prevent frailty and sarcopenia and subsequent disability.

TI Effect of glucosamine sulfate on intraocular pressure in patients with knee osteoarthritis: A prospective randomized controlled trial
SO JOURNAL FRANCAIS D OPHTALMOLOGIE
LA English
DT Article
DE Knee osteoarthritis; Crystalline glucosamine sulfate; Intraocular pressure; Osteoarthritis
ID european-society; economic-aspects; osteoporosis; management
AB Purpose. Glucosamine sulfate is one of the treatment options for patients with osteoarthritis of the knee. It has been postulated that glucosamine sulfate affects intraocular pressure (10P), This study aimed to evaluate the effect of crystalline glucosamine sulfate on 10P in patients with osteoarthritis of the knee. Methods. Forty-two patients with osteoarthritis of the knee were randomized into two groups. The first group of patients received 1500 mg of crystalline glucosamine sulfate once daily for 6 months and the conventional treatment protocol. The second group of patients received only the conventional treatment protocol. 10P was recorded at the start of the study and at 6 weeks, 3 months, 6 months, and 9 months. Results. The patient demographic data were not different between the two groups. There were no differences in the 10Ps between the groups ($P > 0.05$) nor differences in baseline 10Ps within each group compared with each follow-up visit ($P > 0.05$). Conclusions. Glucosamine sulfate is still an option without significant concern over elevated 10P in patients with osteoarthritis of the knee and normal ocular pressure. (C) 2019 Elsevier Masson SAS. TI East meets West: current practices and policies in the management of musculoskeletal aging
SO AGING CLINICAL AND EXPERIMENTAL RESEARCH
LA English
DT Review

DE Osteoarthritis; Osteoporosis; Sarcopenia; FRAX; Prevention; Treatment
ID bone turnover markers; nonsteroidal antiinflammatory drugs; chinese postmenopausal women; hydroxy-beta-methylbutyrate; vitamin-d supplementation; serum 25-hydroxyvitamin d; knee osteoarthritis; muscle strength; hyaluronic-acid; global burden
AB Healthy aging is defined as the process of developing and maintaining the functional ability that enables wellbeing in older age. Healthy aging is dependent upon intrinsic capacity, a composite of physical and mental capacities, and the environment an individual inhabits and their interactions with it. Maintenance of musculoskeletal health during aging is a key determinant of functional ability. Sarcopenia, osteoporosis and osteoarthritis, are a triad of musculoskeletal diseases of aging that are major contributors to the global burden of disease and disability worldwide. The prevention and management of these disorders is of increasing importance with pressure mounting from the aging population. In a new initiative, the Chinese Medical Association, Chinese Society of Osteoporosis and Bone Mineral Research, and the European Society for Clinical and Economic Aspects of Osteoporosis, Osteoarthritis and Musculoskeletal Diseases jointly organized a symposium to discuss current practices and policies in the management of musculoskeletal aging. The meeting allowed experts from Europe and China to share their experience and recommendations for the management of these three major diseases. Discussing and analyzing similarities and differences in their practice should lead, through a mutual enrichment of knowledge, to better management of these diseases, in order to preserve intrinsic capacity and retard the age-related degradation of physical ability. In future, it is hoped that sharing of knowledge and best practice will advance global strategies to reduce the burden of musculoskeletal disease and promote healthy aging tailored to meet the individual patient's needs.

TI Biodegradable polymers: an update on drug delivery in bone and cartilage diseases
SO EXPERT OPINION ON DRUG DELIVERY
LA English
DT Review
DE Bone diseases; cartilage diseases; biodegradable polymers; drug delivery systems; controlled drug release; targeted drug delivery; tissue engineering
ID mesenchymal stem-cells; autologous chondrocyte implantation; sustained-release formulation; thickness chondral defects; collagen-induced arthritis; in-vitro characterization; growth-factor receptor; rheumatoid-arthritis; plga nanoparticles; targeted delivery
AB Introduction: The unique structure of bone and cartilage makes the systemic delivery of free drugs to those connective tissues very challenging. Consequently, effective and targeted delivery for bone and cartilage is of utmost importance. Engineered biodegradable polymers enable designing carriers for a targeted and temporal controlled release of one or more drugs in concentrations within the therapeutic range. Also, tissue engineering strategies can allow drug delivery to advantageously promote the in situ tissue repair. Areas covered: This review article highlights various drug delivery systems (DDS) based on biodegradable biomaterials to treat bone and/or cartilage diseases. We will review their applications in osteoporosis, inflammatory arthritis (namely osteoarthritis and rheumatoid arthritis), cancer and bone and cartilage tissue engineering. Expert opinion: The increased knowledge about biomaterials science and of the pathophysiology of diseases, biomarkers, and targets as well as the development of innovative tools has led to the design of high value-added DDS. However, some challenges persist and are mainly related to an appropriate residence time and a controlled and sustained release over a prolonged period of time of the therapeutic agents. Additionally, the poor prediction value of some preclinical animal models hinders the translation of many formulations into the clinical practice.

TI PROFILE OF PATIENTS WITH OSTEOPOROTIC FRACTURES AND FACTORS THAT DECREASE PREVENTION
SO ACTA ORTOPEDICA BRASILEIRA
LA English
DT Article
DE Osteoporotic Fractures; Osteoporosis; Epidemiology; Prevalence; Secondary Prevention
ID implementation; people; models; care
AB Objective: To evaluate the epidemiological profile of patients with osteoporotic fractures compared to patients with osteoarthritis (OA) and identify factors that diminish adherence to secondary prevention. Methods: A total of 108 patients with osteoporotic fractures (OF) were compared to 86 patients with OA. Results: Patients in the OF group were older ($p < 0.001$); had a lower body mass index ($p < 0.001$); were less literate ($p = 0.012$); were more frequently Caucasian ($p = 0.003$); were less frequently married ($p < 0.001$); experienced more falls, cognitive deficiency, previous fractures, old fracture, falls in the last year, and fall fractures; needed more help and took more medicine for osteoporosis ($p < 0.05$); and showed less pathology in the feet, muscle weakness, less vitamin D intake, and lower Katz & Lawton scores ($p < 0.001$). Factors that increased the chance of nonadherence included older age ($p = 0.020$), falls ($p = 0.035$), cognitive deficiency ($p = 0.044$), and presence of depression/apathy/confusion ($p < 0.001$). Conclusion: Patient age, ethnicity, marital status, previous falls, foot pathologies, muscle weakness, previous fractures, use of vitamin D, use of osteoporosis drugs, and lower Katz & Lawton scale score defined the OF group. Factors that increased the chance of nonadherence included older age, sedative use, cognitive disorders, and symptoms of depression/apathy/confusion.

TI Predatory journals: a major threat in orthopaedic research
SO INTERNATIONAL ORTHOPAEDICS
LA English
DT Review
DE Predatory journals; Legitimate publishing; Open access
AB Predatory publishing is a major threat to contemporary publishing, as it offers 'to unaware scientist's',a quick open-access publication against fees without peer-review procedures.. Lack of peer-review leads to unethical practices, as plagiarism, publication of unscientific falsified data, and even unsafe clinical practices. As these journals threaten the credibility of academic publishing,

significant work has been done from many scientific teams, in the last years, in establishing discriminating criteria between predatory and legitimate publishing. In the present review, we include mechanisms used by predatory editors to convince eager researchers to submit to their journals. We also provide useful links giving information about potential predatory journals and publishers, as well as scholarly writing. Joining the efforts of different scientific disciplines which compiled green lists with journals in their field, we conducted a green list with genuine orthopaedic research journals based on the directory of open-access journals (DOAJ) and Thomson Reuters journal citation reports. Ninety-six legitimate orthopaedic journals were identified based on the Thomson Reuters journal citation reports. One hundred thirty hits were found on the DOAJ site using the keywords orthopaedics, orthopedics, sports medicine, musculoskeletal, trauma, traumatology, osteoarthritis, osteoporosis, cartilage, bone, hand, shoulder, knee, hip, foot, wound. Twenty-one journals on the DOAJ site occurred overlapping with keywords. Researchers and clinicians in the field of orthopaedics are advised to use all available tools in order to recognize predatory practices and avoid publishing in predatory journals.

TI Musculoskeletal Pain in Individuals With Inflammatory Bowel Disease Reflects Three Distinct Profiles
SO CLINICAL JOURNAL OF PAIN
LA English
DT Article
DE musculoskeletal pain; central sensitization; inflammatory bowel disease
ID latent class analysis; quality-of-life; central sensitization; extraintestinal manifestations; questionnaire; comorbidity; classification; osteoarthritis; subgroups; diagnosis
AB Objectives: Pain affects over 70% of individuals with inflammatory bowel disease (IBD), with abdominal and musculoskeletal pain representing the most common symptoms. Musculoskeletal pain in IBD is reported to be associated with multiple clinical features, however the scope and nature of pain is not well understood. Primary aims were to identify subgroups of musculoskeletal pain in individuals with IBD based on clinical features of pain and assess how these subgroups differ in aspects of demographics, comorbidity, and IBD characteristics. Methods: Cross-sectional online survey was performed on adults with IBD. Domains included: demographics, comorbidity, and clinical IBD and pain features. Latent class analysis was used to identify subgroups with similar attributes of: pain (severity, location, interference, and quality), IBD (activity, quality of life, and abdominal pain), and symptoms related to central sensitization. Correlation and regression analyses were used to profile identified subgroups. Results: Of 305 included participants, 208 indicated the presence of musculoskeletal pain. Three identified subgroups were characterized as "mixed mechanism," "central mechanism," and "regional and remission." Between subgroup differences included: total comorbidity score (P=0.005), osteoarthritis (P=0.027), osteoporosis (P=0.045), depression (P=0.001), anxiety (P=0.025), and chronic fatigue syndrome (P=0.020). Sex and age were identified as confounders for depression and anxiety. Conclusions: Study results suggest multiple mechanisms contributing to pain experiences in IBD, to include central mechanisms. Features related to demographics, extraintestinal manifestations, IBD subtype, and clinical IBD features were not predictors of subgroup membership. However, total comorbidity

demonstrated association with pain subgroups in this population.

TI Natural joints: Boundary lubrication and antiphospholipid syndrome (APS)
SO BIOSYSTEMS

LA English
DT Article
DE Articular cartilage degradation; Phospholipids deactivation; Antiphospholipid syndrome (APS); beta(2)-Glycoprotein I, beta(2)-GPI as deactivator; Friction coefficient
ID domain-i
AB The paper shows that osteoporosis (OA) changes the SF content and the lipid profile substantially. To estimate the implication of the lipid environment in case the articular cartilage (AC) changes, we measured friction coefficient normal samples, with early and late stages of (OA). During joint inflammation and osteoarthritis, enzymatically activated beta(2)-Glycoprotein I is transformed into antibody conformation. Our hypothesis about cartilage degradation of PL bilayers by antibodies (beta(2)-Glycoprotein I) is considering antiphospholipid syndrome (APS), which was not discussed in the literature before. Deactivated PL molecule has no ability to form bilayers, lamellar phases, and liposomes. The phospholipid content in synovial fluid (SF) during joint inflammation, osteoarthritis, and rheumatoid arthritis is significantly higher (2-3 times) above the normal concentration of PL, and has a poor boundary-lubricating ability is deactivated.

AB Skeletal regenerative medicine aims to repair or regenerate skeletal tissues using pharmacotherapies, cell-based treatments, and/or surgical interventions. The field is guided by biological principles active during development, wound healing, aging, and carcinogenesis. Skeletal development and tissue maintenance in adults represent highly intricate biological processes that require continuous adjustments in the expression of cell type-specific genes that generate, remodel, and repair the skeletal extracellular matrix. Errors in these processes can facilitate musculoskeletal disease including cancers or injury. The fundamental molecular mechanisms by which cell type-specific patterns in gene expression are established and retained during successive mitotic divisions require epigenetic control, which we review here. We focus on epigenetic regulatory proteins that control the mammalian epigenome at the level of chromatin with emphasis on proteins that are amenable to drug intervention to mitigate skeletal tissue degeneration (e.g., osteoarthritis and osteoporosis). We highlight recent findings on a number of druggable epigenetic regulators, including DNA methyltransferases (e.g., DNMT1, DNMT3A, and DNMT3B) and hydroxylases (e.g., TET1, TET2, and TET3), histone methyltransferases (e.g., EZH1, EZH2, and DOT1L) as well as histone deacetylases (e.g., HDAC3, HDAC4, and HDAC7) and histone acetyl readers (e.g., BRD4) in relation to the development of bone or cartilage regenerative drug therapies. We also review how histone mutations lead to epigenomic catastrophe and cause musculoskeletal tumors. The combined body of molecular and genetic studies focusing on epigenetic regulators indicates that these proteins are critical for normal skeletogenesis and viable candidate drug targets for short-term local pharmacological strategies to mitigate musculoskeletal tissue degeneration. AB Guidance is provided in a European setting on the assessment and treatment of postmenopausal women at risk from fractures due to osteoporosis.IntroductionThe International Osteoporosis Foundation and European Society for Clinical and Economic Aspects of Osteoporosis and Osteoarthritis published guidance for the diagnosis and management of osteoporosis in 2013. This manuscript updates these in a European setting.MethodsSystematic reviews were updated.ResultsThe following areas are reviewed: the role of bone mineral density measurement for the diagnosis of osteoporosis and assessment of fracture risk; general and pharmacological management of osteoporosis; monitoring of treatment; assessment of fracture risk; case-finding strategies; investigation of patients; health economics of treatment. The update includes new information on the evaluation of bone microstructure evaluation in facture risk assessment, the role of FRAX (R) and Fracture Liaison Services in secondary fracture prevention, long-term effects on fracture risk of dietary intakes, and increased fracture risk on stopping drug treatment.ConclusionsA platform is provided on which specific guidelines can be developed for national use.

TI Strategies for optimising musculoskeletal health in the 21st century
SO BMC MUSCULOSKELETAL DISORDERS
LA English
DT Review
DE Ageing; Musculoskeletal health; Musculoskeletal disorders; Global burden; Joint diseases; Osteoarthritis (OA); Rheumatoid arthritis (RA); Low back pain (LBP); Osteoporosis (OP); Sarcopenia; Obesity; Type II diabetes; Metabolic disease
ID nonsteroidal antiinflammatory drugs; quality-of-life; knee osteoarthritis; chondroitin sulfate; rheumatoid-arthritis; articular-cartilage; global burden; gait analysis; animal-model; chronic pain
AB We live in a world with an ever-increasing ageing population. Studying healthy ageing and reducing the socioeconomic impact of age-related diseases is a key research priority for the industrialised and developing countries, along with a better mechanistic understanding of the physiology and pathophysiology of ageing that occurs in a number of age-related musculoskeletal disorders. Arthritis and musculoskeletal disorders constitute a major cause of disability and morbidity globally and result in enormous costs for our health and social-care systems. By gaining a better understanding of healthy musculoskeletal ageing and the risk factors associated with premature ageing and senescence, we can provide better care and develop new and better-targeted therapies for common musculoskeletal disorders. This review is the outcome of a two-day multidisciplinary, international workshop sponsored by the Institute of Advanced Studies entitled "Musculoskeletal Health in the 21st Century" and held at the University of Surrey from 30th June-1st July 2015. The aim of this narrative review is to summarise current knowledge of musculoskeletal health, ageing and disease and highlight strategies for prevention and reducing the impact of common musculoskeletal diseases.

TI Cost-effectiveness evaluation of glucosamine for osteoarthritis based on simulation of individual patient data obtained from aggregated data in published studies
SO AGING CLINICAL AND EXPERIMENTAL RESEARCH
LA English
DT Article
DE Osteoarthritis; Cost-effectiveness; Glucosamine
ID knee osteoarthritis; double-blind; european-society; economic-aspects; sulfate; recommendations; osteoporosis; progression; management; symptoms
AB BackgroundThe economic evaluation of treatments usually requires access to individual patient data, which is difficult to obtain. Moreover, in osteoarthritis, health utility scores are unavailable and can be assessed only using a validated equation model based on various clinical data. We aimed to develop and validate a methodology to simulate individual health utility scores from aggregated clinical data available in published studies to calculate the cost-effectiveness of different glucosamine preparations (i.e., crystalline glucosamine sulfate, glucosamine sulfate, and glucosamine hydrochloride) used for osteoarthritis.MethodsWe developed a method to simulate individual utility values and validated the model by comparing the results obtained with the simulation and the results of one trial where the utility scores are available. Then, we simulated the utility scores of 10 published trials that used different glucosamine preparations. The utility estimates were used to calculate the quality-adjusted life year (QALY) using the area-under-the-curve method. Costs were for the glucosamine product only. The incremental cost/effectiveness ratio (ICER) was then calculated.ResultsThe values of utility scores calculated from data sources and those simulated with the model were similar. From 10 studies where utility was simulated, four used crystalline glucosamine sulfate, and six used other formulations. The ICER revealed that compared to placebo, crystalline glucosamine sulfate only was cost-effective at all

time points and up to 3years with a median ICER of 5347.2Euro/QALY at month 3, 4807.2Euro/QALY at month 6 and 11535.5Euro/QALY at year 3. The use of other formulations was not cost-effective.ConclusionUsing a new model to simulate individual health utility scores of patients included in ten published trials, ICER analysis showed that the use of crystalline glucosamine sulfate is cost-effective, while other formulations were not. The results confirm the importance of the formulation of glucosamine products.

TI The effects of total ankle arthroplasty on postural stability and loading symmetry in quiet stance
SO JOURNAL OF BIOMECHANICS
LA English
DT Article
DE Ankle; Arthritis; Balance; Postural stability; Arthroplasty
ID body-weight distribution; balance; instability; osteoarthritis; reliability; falls
AB Ankle osteoarthritis is a debilitating condition affecting about 1% of the population with approximately 50,000 new instances annually. One treatment is total ankle arthroplasty (TAA), however, its effects on balance are not well understood. This study analyzed balance over a two-year period following TAA. 408 subjects (177 left, 231 right ankles) diagnosed with end-stage ankle osteoarthritis performed quiet standing trials while center of pressure (COP) data were collected. Data were compared across three time points (pre-op, 1-year, and 2-years post-op) and between surgical and non-surgical limbs using a linear mixed model with significance set at P=0.05. COP excursions in the feet-together condition were not significantly different between limbs after 2 years in anteroposterior or mediolateral directions (P = 0.06, 0.08) after being significantly different between limbs in the anteroposterior (P=0.014) and mediolateral direction (P<0.001) pre-op. The vertical ground reaction force significantly decreased across time in the non-surgical limb, while reciprocally increasing in the surgical limb (P<0.001). After 2 years, no significant difference in vertical ground reaction force between limbs existed (P= 0.20). Limb asymmetry indices decreased at each time point in both conditions (all P < 0.001) and were not significantly different from zero after 2 years in the feet-together condition (P = 0.290). In conclusion, surgical limb balance improved compared to pre-op, resulting in increased symmetry between limbs after 2 years. Vertical ground reaction forces on both limbs converge and limb asymmetry indices approach zero two years post-op. Differences in the COP excursion-loading symmetry relationship between limbs could be useful for identifying instability in other pathologies. (C) 2018 Elsevier Ltd. All rights reserved.

TI Incidence of osteoarthritis, osteoporosis and inflammatory musculoskeletal diseases in adults with cerebral palsy: A population-based cohort study
SO BONE
LA English
DT Article
DE Cerebral palsy; Osteoarthritis; Osteoporosis; Inflammatory museuloskeletal diseases; Incidence
ID practice research datalink; young-adults; issue; risk; pain
AB Background People with cerebral palsy (CP) may be at increased risk of musculoskeletal conditions due to various factors including malnutrition and abnormal levels of skeletal loading. This study aimed to compare the incidence of osteoporosis, osteoarthritis and inflammatory musculoskeletal diseases between adults with and without CP. Methods: A population based cohort study was conducted using data from the Clinical Practice Research Datalink collected between 1987 and 2015. Adults with CP were matched to adults without CP for age, sex and general practice. Cox models, stratified by matched set and adjusted for potential confounders, were fitted to compare the risk of osteoporosis,

osteoarthritis and inflammatory musculoskeletal diseases. Results: 1705 adults with CP were matched to 5115 adults without CP. Adults with CP had an increased risk of osteoporosis in unadjusted (Hazard Ratio (HR) 3.67, 95% Confidence Interval (CI) 2.32 to 5.80, p < 0.001) and adjusted (HR 6.19, 95% CI 3.37 to 11.39, p < 0.001) analyses. No evidence of increased risk of inflammatory musculoskeletal diseases was observed in unadjusted or adjusted analyses. For osteoarthritis no evidence of increased risk was seen in the unadjusted analysis, but evidence of an increased risk was seen when the analysis was adjusted for alcohol consumption, smoking status, and mean yearly general practice (GP) visits (HR 1.54, 95% CI 1.17 to 2.02, p < 0.001). Conclusions: After accounting for potential confounding variables, we found that CP is associated with increased risk of osteoporosis and osteoarthritis. These findings provide the strongest epidemiological evidence to date for increased risk of osteoporosis and osteoarthritis in people with CP, and highlight need for clinical awareness of such conditions in this population.

TI Bone-Specific Overexpression of PITX1 Induces Senile Osteoporosis in Mice Through Deficient Self-Renewal of Mesenchymal Progenitors and Wnt Pathway Inhibition
SO SCIENTIFIC REPORTS
LA English
DT Article
ID acute lymphoblastic-leukemia; transcription factor; hindlimb; cells; children; fracture; repair; ptx1
AB The cellular and molecular mechanisms underlying senile osteoporosis remain poorly understood. In this study, transgenic mCol1 alpha 1-Pitx1 mice overexpressing paired-like homeodomain 1(PITX1), a homeobox transcription factor, rapidly develop a severe type-II osteoporotic phenotype with significant reduction in bone mass and biomechanical strength similar to that seen in humans and reminiscent of the phenotype previously observed in Sca-1(Ly6 alpha)-nu II mice. PITX1 plays a critical role in hind limb formation during fetal development, while loss of expression is associated with primary knee/hip osteoarthritis in aging humans. Through in vivo and in vitro analyses, we demonstrate that Pitxl directly regulates the self-renewal of mesenchymal progenitors and indirectly regulates osteoclast differentiation through the upregulation of Wnt signaling inhibitors DKK1, SOST, and GSK3-beta. This is confirmed by elevated levels of plasma DKK1 and the accumulation of phospho-beta-catenin in transgenic mice osteoblasts. Furthermore, overexpressed Pitxl in mice osteoblasts results in severe repression of Sca-1 (Ly6 alpha) that was previously associated with senile osteoporosis. Our study is the first to demonstrate the novel roles of PITX1 in senile osteoporosis where PITX1 regulates the self-renewal of mesenchymal stem cells or progenitor cells through Sca-1 (Ly6 alpha) repression and, in addition, inhibits the Wnt signaling pathway.

TI A nationwide observational study of locomotive syndrome in Japan using the ResearchKit: The Locomonitor study
SO JOURNAL OF ORTHOPAEDIC SCIENCE
LA English
DT Article
ID population; osteoarthritis/osteoporosis; association; disability; apple

AB Background: We developed the Locomonitor application (app), the world's first iOS app to study locomotive syndrome, using the ResearchKit and examined the prevalence and risk factors for locomotive syndrome in Japanese general individuals 20-69 years old in a nationwide cross-sectional observational study. Methods: The participants were recruited from February to August 2016. The outcome measures for the locomotive function were evaluated by locomotive syndrome risk tests (LSRTs) using the Locomonitor app. The chi-squared test, a linear-by-linear association trend analysis, and Spearman's correlation test were performed as statistical analyses. Results: A total of 2177 subjects from all prefectures in Japan were included (average 42.2 years old). The Locomo25 and Stand-Up test scores in female participants and the Two-Step test scores in male participants showed age-dependent deterioration. In the overall population, the incidence of Locomo stage 1 and 2, as evaluated by the Locomo25, Stand-Up test or Two-Step test, was 30.2% and 29.2%, respectively. In subjects without locomotive syndrome (40.5%), LSRT scores showed age-dependent deterioration in both sexes. Locomotive syndrome in participants with a body mass index (BMI) of >25 kg/m(2) was more frequent than in those with a BMI of <25 kg/m(2) (age- and gender-adjusted odds ratio [OR] 1.344 [95% confidence interval {CI} 1.03-1.75, p = 0.027]). Locomotive syndrome in participants with an exercise habit was less frequent than in those without an exercise habit (age- and gender-adjusted OR 0.499 [95% CI 1333-0.755, p < 0.0001]). Conclusions: The Locomonitor app, a newly developed remote platform, revealed that approximately 20% 30% of Japanese individuals 20-69 years old in the general population met the definition of locomotive syndrome. Locomotive syndrome in participants with obesity was more frequent than those without obesity, while locomotive syndrome in participants with an exercise habit was less frequent than those without an exercise habit. TI Correlation between hip osteoarthritis and proximal femoral fracture site: could it be protective for intracapsular neck fractures? A retrospective study on 320 cases
SO OSTEOPOROSIS INTERNATIONAL
LA English
DT Article
DE Extracapsular fractures; Hip osteoarthritis; Intracapsular fractures; Proximal femur fractures
ID bone-mineral density; risk; falls; classification; osteoporosis; reliability; pattern; knee
AB A Summary Proximal femoral fractures affect elderly people, showing high

morbidity and mortality incidence resulting in a major economic burden on national healthcare systems. Understanding the causes of these injuries is of paramount importance to prevent the serious consequences of these fractures. Introduction Hip osteoarthritis and proximal femoral fractures mainly affect elderly patients. Several authors, in their studies, tried to document a correlation between these conditions, but the results are conflicting. The aim of this study was to evaluate the relationship between hip osteoarthritis and the fracture site. Secondly, to evaluate if the grade of osteoarthritis could influence the fracture pattern. Methods A retrospective study on 320 patients admitted for hip fracture between June 2015 and December 2016 was carried on. Radiographic images were evaluated, assessing the type of fracture, presence and grade of osteoarthritis according to Kellgren-Lawrence and Tonnis classifications, and their correlations. Results Osteoarthritis was found to affect the fracture site showing a higher prevalence among subjects with extracapsular than those with intracapsular fractures ($p<0.00001$). Patients with radiographic signs of arthritis had mainly trochanteric fracture. Conversely, patients without arthritis more frequently presented a femoral neck fracture. This correlation was even more significant as the severity of the OA increased. Conclusions Results support the hypothesis that hip osteoarthritis could represent a protective factor for intracapsular fractures and a risk factor for trochanteric ones. The severity of arthritis is also associated with the fracture pattern.

TI Changes in quality of life in patients with postmenopausal osteoporosis receiving weekly bisphosphonate treatment: a 2-year multicenter study in Japan
SO JOURNAL OF BONE AND MINERAL METABOLISM
LA English
DT Article
DE Osteoporosis; Bisphosphonate; Persistence; Quality of life; Pain
ID high-risk; alendronate; fracture; level
AB We investigated changes in quality of life (QOL), including pain, in Japanese women aged55years who were diagnosed as having osteoporosis at 265 centers across Japan and treated continuously with once-weekly bisphosphonates for 24months. In 2650 evaluable patients, a significant improvement in QOL was observed from 3months after enrollment onward and maintained throughout the 2-year observation period. A significant improvement in scores was observed for all domains of the Euro QOL 5 Dimension (EQ-5D), and the pain, health perception, and posture, figure domains of the Japanese Osteoporosis QOL Questionnaire (JOQOL). Factors identified as significantly contributing to QOL change were fractures within the year before enrollment, presence of spondylosis deformans, presence of osteoarthritis, use of activated vitamin D-3, and age based on the JOQOL, and presence of spondylosis deformans, use of activated vitamin D-3, and

age based on the EQ-5D. The results suggested that the patients' perception of treatment effects, such as improvement in pain, contributes to treatment continuation. Osteoporosis patients should be informed that continuous treatment with once-weekly bisphosphonates can lead to a significant improvement in QOL regardless of concomitant locomotor diseases, to encourage them to remain on treatment. In conclusion, continuous bisphosphonate treatment improved the QOL even in patients with locomotor diseases, and the concomitant use of activated vitamin D-3 may also facilitate further improvement in QOL.

TI Assessment of Muscle Function and Physical Performance in Daily Clinical Practice: A position paper endorsed by the European Society for Clinical and Economic Aspects of Osteoporosis, Osteoarthritis and Musculoskeletal Diseases (ESCEO)
SO CALCIFIED TISSUE INTERNATIONAL
LA English
DT Review
DE Muscle function; Muscle strenght; Physical performance; Daily practice; Sarcopenia
ID dwelling older-people; chair-stand test; test-retest reliability; gait speed; grip strength; handgrip strength; walk test; usual-pace; go test; validity
AB It is well recognized that poor muscle function and poor physical performance are strong predictors of clinically relevant adverse events in older people. Given the large number of approaches to measure muscle function and physical performance, clinicians often struggle to choose a tool that is appropriate and validated for the population of older people they deal with. In this paper, an overview of different methods available and applicable in clinical settings is proposed. This paper is based on literature reviews performed by members of the European Society for Clinical and Economic Aspects of Osteoporosis and Osteoarthritis (ESCEO) working group on frailty and sarcopenia. Face-to-face meetings were organized afterwards where the whole group could amend and discuss the recommendations further. Several characteristics should be considered when choosing a tool: (1) purpose of the assessment (intervention, screening, diagnosis); (2) patient characteristics (population, settings, functional ability, etc.); (3) psychometric properties of the tool (test-retest reliability, inter-rater reliability, responsiveness, floor and ceiling effects, etc.); (4) applicability of the tool in clinical settings (overall cost, time required for the examination, level of training, equipment, patient acceptance, etc.); (5) prognostic reliability for relevant clinical outcomes. Based on these criteria and the available evidence, the expert group advises the use of grip strength to measure muscle strength and the use of 4-m gait speed or the Short Physical Performance Battery test to measure physical performance in daily practice. The tools proposed are relevant for the assessment of muscle weakness and physical performance. Subjects with low values should receive additional diagnostic workups to achieve a full diagnosis of the underlying condition responsible (sarcopenia, frailty or other).

TI CK2.3, a Mimetic Peptide of the BMP Type I Receptor, Increases Activity in Osteoblasts over BMP2
SO INTERNATIONAL JOURNAL OF MOLECULAR SCIENCES
LA English
DT Article
DE osteoporosis; femoral head; osteoarthritis; BMP2; CK2.3; BMD
ID bone-mineral density; postmenopausal women; osteoporosis; protein-2; management; fractures; spine; age
AB Bone is one of the most important organs in the human body. It provides structure, function, and protection for other vital organs; therefore, bone maintenance and homeostasis are critical processes. As humans age, their bone mineral density decreases, which leads to diseases like osteoporosis. This disease affects one in two women and one in five men aged 50 and over. As the aging population increases, the interest and significance of studying this debilitating bone disease becomes more relevant. Current therapeutic products for osteoporosis have many side effects and can be taken for a limited number of years. Most therapeutic products only focus on decreasing bone resorption, not increasing bone formation. Bone morphogenetic protein 2 is an essential growth factor that drives osteoblast differentiation and activity and is essential for bone formation. However, usage in the clinic is unsuccessful due to several side effects. Recently, a signaling disparity in bone marrow stromal cells within the bone morphogenetic protein pathway that led to decreased bone morphogenetic protein 2 responsiveness was identified in patients diagnosed with osteoporosis. However, it is unclear how other cell populations, especially osteoblasts, which are key players in bone remodeling, are affected and whether the bone morphogenetic protein pathway is affected during osteoporosis. Our research group designed a novel peptide, casein kinase 2.3, that acts downstream of the bone morphogenetic receptor type Ia and increases bone mineralization in murine cells and primary bovine osteoblasts. The aim of the study presented here was to compare the responsiveness of osteoblasts to bone morphogenetic protein 2 and casein kinase 2.3, especially in patients diagnosed with osteoporosis. Mature osteoblasts were extracted from patients diagnosed with osteoporosis or osteoarthritis from Christiana Care Hospital in Newark, Delaware. They were stimulated with either bone morphogenetic protein 2 or casein kinase 2.3, and their effect on osteoblast activity was determined. The osteoporotic patients showed no mineralization response to bone morphogenetic protein 2 stimulation, while the osteoarthritis patients significantly responded to bone morphogenetic protein 2 stimulation. Furthermore, markers for osteoblast activity were increased by casein kinase 2.3, which was in sharp contrast to bone morphogenetic protein 2. This further

supports a major bone morphogenetic protein signaling disparity in both the elderly and those suffering with osteoporosis. Both patient types did significantly respond to casein kinase 2.3. Further analysis of the bone morphogenetic protein pathway could lead to new therapeutic products for osteoporosis.

TI Mitochondria and cellular senescence: Implications for musculoskeletal ageing
SO FREE RADICAL BIOLOGY AND MEDICINE
LA English
DT Review
DE Cellular senescence; Senotherapies; Senolytics; Mitochondria; Ageing; Sarcopenia; Osteoporosis; Osteoarthritis
ID dna-damage; skeletal-muscle; life-span; satellite cells; secretory phenotype; stem-cells; dysfunction; tissue; contributes; accumulation
AB Musculoskeletal ageing and its associated diseases are major contributors to the loss of independence and reduced quality of life in older people. Several recent studies indicate that cellular senescence is a contributor to age-related loss of function in various organs including muscle, bones and joints. Importantly, these studies indicate that therapies targeting specifically senescent cells have great therapeutic potential in improving musculoskeletal health during ageing. Senescent cells are characterised by dramatic changes in mitochondrial function, metabolism and homeostasis. Mitochondrial dysfunction has been shown to contribute to senescence and the SASP. Here we review the role of cellular senescence in musculoskeletal ageing as well as the potential mechanisms by which mitochondrial dysfunction may impact on the induction and development of the senescent phenotype.

TI The Association between Frailty and Disability among the Elderly in Rural Areas of Korea
SO INTERNATIONAL JOURNAL OF ENVIRONMENTAL RESEARCH AND PUBLIC HEALTH
LA English
DT Article
DE disability; elderly; frailty; rural
ID older-adults; impairment
AB Background: The rapid increase in the elderly population in Korea is associated with an expanded burden of health problems. The purpose of this study was to investigate the association between frailty and physical disability among Koreans using the frailty index, which was developed to assess health conditions in elderly people. Methods: We included 503 elderly people from the Namgaram-II cohort. We used the Korean version of the Kaigo-Yobo checklist as our frailty assessment tool. For the disability assessment tool, we used the Korean version of the 12-item World Health Organization Disability Assessment Schedule (WHODAS-12). We fit multiple linear regression models for men and women for each section. Our models also included variables for musculoskeletal diseases that are known to be associated with frailty, such as sarcopenia, osteoporosis, and radiologic knee osteoarthritis. Results: After correcting for social demographic characteristics, blood profiles, high blood pressure, and diabetes, the Kaigo-Yobo results showed a significant difference in frailty between men (1.53 +/- 0.74) and women (2.60 +/- 0.77), and WHODAS-12 also showed a significant difference between men (6.59 +/- 5.08) and women (15.99 +/- 5.70). After correcting for social demographic characteristics, blood profiles, high blood pressure, and diabetes, Kaigo-Yobo and WHODAS-12 were significantly associated with each other among both men (beta = 2.667) and women (beta = 3.200) ($p < 0.001$). Conclusions: The study results show an association between frailty and disability among elderly people in rural areas. Therefore, prevention should occur at the pre-frailty stage of a person's life to prevent further disability. Also, disability welfare programs should be provided to elderly people who present with frailty.

TI Diallyl disulfide alleviates inflammatory osteolysis by suppressing osteoclastogenesis via NF-κB-NFATc1 signal pathway
SO FASEB JOURNAL
LA English
DT Article
DE natural products; osteoclast; bone resorption
ID nf-kappa-b; rankl-induced osteoclastogenesis; cell-cell fusion; bone-resorption; receptor activator; in-vitro; differentiation; ligand; modulation; mechanisms
AB Skeletal homeostasis is closely effectuated by the regulation of bone formation and bone resorption. Osteoclasts are multinuclear giant cells responsible for bone resorption. Overactivated osteoclasts and excessive bone resorption result in various lytic bone diseases, such as osteoporosis, osteoarthritis, periprosthetic infection, and inflammatory aseptic loosening of orthopedic implants. In consideration of the severe side effects caused by the currently available drugs, exploitation of novel drugs has gradually attracted attention. Because of its anti-inflammatory, antioxidant, and antitumor capacities, diallyl disulfide (DADS), a major oil-soluble organosulfur ingredient compound derived from garlic, has been widely researched. However, the effects of DADS on osteoclasts and lytic bone diseases are still unknown. In this study, we investigated the effects of DADS on receptor activator of NF-kappa B ligand (RANKL)- and LPS-mediated osteoclastogenesis, LPS-stimulated proinflammatory cytokines related to osteoclasts, and LPS-induced inflammatory osteolysis. The results showed that DADS significantly inhibited RANKL-mediated osteoclast formation, fusion, and bone resorption in a dose-dependent manner via inhibiting the NF-kappa B and signal transducer and activator of transcription 3 signaling and restraining the interaction of NF-kappa B p65 with nuclear factor of activated T cells cytoplasmic 1. Furthermore, DADS also markedly suppressed LPS-induced osteoclastogenesis and reduced the production of proinflammatory cytokines with LPS stimulation to indirectly mediate osteoclast formation. Consistent with the in vitro results, DADS prevented the LPS-induced severe bone loss by blocking the osteoclastogenesis. All of the results indicate that DADS may be a potential and exploitable drug used for preventing and impeding osteolytic lesions.-Yang, J., Tang, R., Yi, J., Chen, Y., Li, X., Yu, T., Fei, J. Diallyl disulfide alleviates inflammatory osteolysis by suppressing osteoclastogenesis via NF-kappa B-NFATc1 signal pathway.

TI Adjuvant denosumab in postmenopausal patients with hormone receptor-positive breast cancer (ABCSG-18): disease-free survival results from a randomised, double-blind, placebo-controlled, phase 3 trial
SO LANCET ONCOLOGY
LA English
DT Article
ID plus zoledronic acid; clinical-practice; bone loss; therapy; women; bisphosphonates; inhibitor; rankl; metaanalysis; prevention
AB Background In postmenopausal women with hormone receptor-positive, early-stage breast cancer, treatment with adjuvant aromatase inhibitors is the standard of care, but it increases risk for osteoporosis and fractures. Results from the ABCSG-18 trial showed that use of denosumab as an adjuvant to aromatase inhibitor therapy significantly reduced clinical fractures. Disease-free survival outcomes from ABCSG-18 have not yet been reported. Methods Postmenopausal patients with early, hormone receptor-positive, non-metastatic adenocarcinoma of the breast, who had completed their initial adjuvant treatment pathway (surgery, radiotherapy, or chemotherapy, or a combination) and were receiving adjuvant aromatase inhibitors, were enrolled at 58 trial centres in Austria and Sweden into this prospective, double-blind, placebo-controlled, phase 3 trial. With permuted block randomisation (block sizes 2 and 4, stratified by previous aromatase inhibitor use, total lumbar spine bone mineral density score at baseline, and type of centre),

patients were assigned (1: 1) to receive subcutaneous denosumab (60 mg) or matching placebo every 6 months during aromatase inhibitor therapy. The primary endpoint (previously reported) was the time to first clinical fracture after randomisation. The secondary endpoint reported here is disease-free survival (defined as time from randomisation to first evidence of local or distant metastasis, contralateral breast cancer, secondary carcinoma, or death from any cause) in the intention-to-treat population. This study is registered with EudraCT (number 2005-005275-15) and ClinicalTrials.gov (number NCT00556374), and is ongoing for long-term follow-up. Findings Between Dec 18, 2006, and July 22, 2013, 3425 eligible patients were enrolled and randomly assigned; 1711 to the denosumab group and 1709 to the placebo group (with five others withdrawing consent). After a median followup of 73 months (IQR 58-95), 240 (14.0%) patients in the denosumab and 287 (16.8%) in the placebo group had disease-free survival events. Disease-free survival was significantly improved in the denosumab group versus the placebo group (hazard ratio 0.82, 95% CI 0.69-0.98, Cox p=0.0260; descriptive analysis, without controlling for multiplicity). In the denosumab group, disease-free survival was 89.2% (95% CI 87.6-90.8) at 5 years and 80.6% (78.1-83.1) at 8 years of follow-up, compared with 87.3% (85.7-89.0) at 5 years and 77.5% (74.8-80.2) and 8 years in the placebo group. No independently adjudicated cases of osteonecrosis of the jaw or confirmed atypical femoral fractures were recorded. The total number of adverse events was similar in the denosumab group (1367 [including 521 serious] adverse events) and the placebo group (1339 [515 serious]). The most common serious adverse events were osteoarthritis (62 [3.6%] of 1709 in the denosumab group vs 58 [3.4%] of 1690 in the placebo group), meniscus injury (23 [1.3%] vs 24 [1.4%]), and cataract (16 [0.9%] vs 28 [1.7%]). One (< 0.1%) treatment-related death (due to pneumonia, septic kidney failure, and cardiac decompensation) occurred in the denosumab group. Interpretation Denosumab constitutes an effective and safe adjuvant treatment for patients with postmenopausal hormone receptor-positive early breast cancer receiving aromatase inhibitor therapy. TI Appropriateness of clinical criteria for the use of SYmptomatic Slow-Acting Drug for OsteoArthritis (SYSADOA). A Delphi Method Consensus initiative among experts in Italy
SO EUROPEAN JOURNAL OF PHYSICAL AND REHABILITATION MEDICINE
LA English
DT Article
DE Osteoarthritis; Delphi technique; Consensus
ID knee osteoarthritis; glucosamine sulfate; double-blind; injection therapy; management; placebo; guidelines; replacement; chondroitin; efficacy
AB BACKGROUND: Osteoarthritis (OA) is a theme currently representing an emerging topic for its increasing incidence. It is well known that it is a chronic

disease that could lead to important long-lasting disability; this generates increasing costs for the health care system. OA treatment options vary: localization, etiology, grading and symptomatology should be considered before choosing the most adequate therapy. Currently, a modern approach to managing OA involves SYmptomatic Slow-Acting Drug for OsteoArthritis(SYSADOAs). However, while all preparations may claim to deliver a therapeutic level of glucosamine or chondroitin, not all of them are supported by clinical evidence. Recently the European Society for Clinical and Economic aspects of Osteoporosis, Osteoarthritis and musculoskeletal diseases (ESCEO), produced an evidenced based document providing practitioners with the latest clinical and economic information, thereby allowing them to optimize the management of knee OA. According to this report, only crystalline glucosamine sulphate and the pharmaceutical-grade chondroitin sulphate are considered as effective in the first line approach to treating knee OA as an alternative drug to acetaminophen. However, some OA guidelines do not agree are not concordant in recommending the use of SYSADOA, perhaps because they are generally considered as a class and distinctions among formulations are not made. AIM: Aim of this study was to identify the main aspects involved in patient selection, the choice of therapeutic agents and the safety profile in using SYSADOA. DESIGN: Delphi method Consenus Statement. POPULATION: Italian Physicians having expertise in Ostcoarthritis management. METHODS: A committee of 11 experts from Italian universities, public hospitals, territorial services. research institutes and patient associations was set up. Sixty-three clinicians from a large number of Italian medical centers specialized in osteoarthritis management took part in a Delphi process which was aimed at obtaining consensus statements among the participants. RESULTS: Large consensus was obtained for statements grouped under the following main themes: treatment indications; drug/medical devices choice; treatment efficacy. CONCLUSIONS: Results from the Italian consensus on appropriateness of OA therapies in osteoarthritis seems to be in line with the stepwise approach proposed by the ESCEO algorithm, where crystalline glucosamine sulphate shows greater clinical efficacy than other glucosamine-based formulations, according to several independent meta-analyses. CLINICAL REHABILITATION IMPACT: This study may be used as a practical reference tool to help Italian physicians treat osteoarthritis patients using SYSADOA.

AB Bone-related diseases seriously threaten people's health and research studies have been dedicated towards searching for new and effective treatment methods. Nanotechnologies have opened up a new field in recent decades and nanostructured materials, which exist in a variety of forms, are considered to be promising materials in this field. This article reviews the most recent progress in the development of nanostructured materials for bone-related diseases, including osteoporosis, osteoarthritis, bone metastasis, osteomyelitis, myeloma, and bone defects. We highlight the advantages and functions of nanostructured materials, including sustained release, bone targeting, scaffolding in bone tissue engineering, etc., in bone-related diseases. We also include the remaining challenges of these emerging materials.

TI Microsimulation model for the health economic evaluation of osteoporosis interventions: study protocol
SO BMJ OPEN
LA English
DT Article
ID core diabetes model; quality-of-life; cost-effectiveness; dubbo osteoporosis;

clinical-outcm; residual lifetime; fracture; risk; men; validation
AB Introduction Osteoporosis is a systemic skeletal disease that is characterised by reduced bone strength and increased fracture risk. Osteoporosis-related fractures impose enormous disease and economic burden to the society. Although many treatments and health interventions are proven effective to prevent fractures, health economic evaluation adds evidence to their economic merits. Computer simulation modelling is a useful approach to extrapolate clinical and economic outcomes from clinical trials and it is increasingly used in health economic evaluation. Many osteoporosis health economic models have been developed in the past decades; however, they are limited to academic use and there are no publicly accessible health economic models of osteoporosis. Methods and analysis We will develop the Australian osteoporosis health economic model based on our previously published microsimulation model of osteoporosis in the Chinese population. The development of the model will follow the recommendations for the conduct of economic evaluations in osteoporosis by the European Society for Clinical and Economic Aspects of Osteoporosis, Osteoarthritis and Musculoskeletal Diseases and the US branch of the International Osteoporosis Foundation. The model will be a state-transition semi-Markov model with memory. Clinical parameters in the model will be mainly obtained from the Dubbo Osteoporosis Epidemiology Study and the health economic parameters will be collected from the Australian arm of the International Costs and Utilities Related to Osteoporotic Fractures Study. Model transparency and validates will be tested using the recommendations from Good Research Practices in Modelling Task Forces. The model will be used in economic evaluations of osteoporosis interventions including pharmaceutical treatments and primary care interventions. A user-friendly graphical user interface will be developed, which will connect the user to the calculation engine and the results will be generated. The user interface will facilitate the use of our model by people in different sectors. Ethics and dissemination No ethical approval is needed for this study. Results of the model validation and future economic evaluation studies will be submitted to journals. The user interface of the health economic model will be publicly available online accompanied with a user manual.

TI Nanomedicines for improved targetability to inflamed synovium for treatment of rheumatoid arthritis: Multi-functionalization as an emerging strategy to optimize therapeutic efficacy
SO JOURNAL OF CONTROLLED RELEASE
LA English
DT Review
DE Nanomedicines; Multi-functionalization; Extended plasma half-life; Improved targetability and synovial internalisation; Receptor-mediated endocytosis; Superior therapeutic efficacy
ID solid lipid nanoparticles; nf-kappa-b; adjuvant-induced arthritis; collagen-induced arthritis; vasoactive-intestinal-peptide; modifying antirheumatic drugs; folate-targeted nanoparticles; antigen-induced arthritis; necrosis-factor-alpha; saint-o-sm
AB Owing to its intricate autoimmune pathophysiology and significant risks of progression to other rheumatic comorbidities (i.e., osteoporosis and osteoarthritis), a plausible therapeutic regimen is mandatory for early-stage management of rheumatoid arthritis (RA). Nevertheless, the conventional therapeutic agents particularly the corticosteroids and disease-modifying anti-rheumatic drugs (DMARDs) have shown grander success in the treatment of RA; however, long-term use of these agents is also associated with serious adverse events. To combat these issues and optimize therapeutic efficacy, nanotechnology-based interventions have been emerged as viable option. While, nanomedicines signposted superiority over the conventional pharmacological moieties; there are still many pharmacokinetic and pharmacodynamic challenges to nanomedicines following their intravenous or infra-articular administration. To circumvent these challenges, significant adaptations such as PEGylation, surface conjugation of targeting ligand(s), and site-responsive behavior (i.e., pH-, biochemical-, or thermal-responsiveness) have been implemented. Besides, multi-functionalization of nanomedicines has been emerging as an exceptional strategy to overcome pharmacokinetic challenges, improve targetability to inflamed synovium, maximise internalisation into the

activated macrophages, and improved therapeutic outcomes for treatment of RA. Therefore, this review aims to conceptualize and recapitulate the substantial evidences regarding the pharmacokinetic and pharmacodynamic superiority of multi-functionalized nanomedicines over the naked nanomedicines for site-selective targeting to inflamed synovium and rational treatment of RA and other rheumatic co-morbidities. Pharmaceutical sustainability of the multi-functionalized nanomedicines for improved biocompatibility, profound interaction with the targeting tissue/cells/sub-cellular domain, and diminished systemic toxicity has also been pondered.

TI Effect of the PTHrP(1-34) analog abaloparatide on inducing chondrogenesis involves inhibition of intracellular reactive oxygen species production
SO BIOCHEMICAL AND BIOPHYSICAL RESEARCH COMMUNICATIONS
LA English
DT Article
DE Abaloparatide; Osteoarthritis; Chondrogenesis; Mesenchymal stem cells; Reactive oxygen species
ID parathyroid-hormone; oxidative stress; cell-death; differentiation; hypertrophy; culture
AB Osteoarthritis (OA) is a degenerative joint disease characterized by a progressive loss of articular cartilage. Mesenchymal stem cells transplanted to damaged tissues are promising for OA cartilage repair. However, these cells are poor survival after transplantation and acquire hypertrophic properties during chondrogenic induction. Parathyroid hormone-related protein (PTHrP) promotes chondrogenesis and suppresses chondrocyte hypertrophic differentiation. Additionally, PTHrP was reported to have antioxidant effects. The synthetic PTHrP(1-34) analog abaloparatide (ABL) is a newly approved drug for osteoporosis therapy. It is unknown whether ABL stimulates chondrogenesis and affects intracellular reactive oxygen species (ROS) production. By using mouse embryonic

limb bud mesenchymal stem cells in micromass culture as an in vitro model of chondrogenic differentiation, we found that mesenchymal stem cells in micromass cultures spontaneously produced ROS, and N-acetyl-L-cysteine, a potent antioxidant, enhanced chondrogenesis. The effect of ABL on stimulation of chondrogenesis is involved in its inhibition of intracellular ROS generation. These novel findings support the use of ABL for the damaged cartilage regeneration. TI Vitamin K as a Powerful Micronutrient in Aging and Age-Related Diseases: Pros and Cons from Clinical Studies
SO INTERNATIONAL JOURNAL OF MOLECULAR SCIENCES
LA English
DT Review
DE vitamin K; vitamin K-dependent proteins; cardiovascular diseases; skeletal health; inflammaging; pathological calcification; inflammation
ID matrix gla-protein; bone-mineral density; hormone replacement therapy; community-dwelling adults; vascular smooth-muscle; coronary-heart-disease; postmenopausal women; menaquinone-7 supplementation; hemodialysis-patients; older-adults
AB Vitamin K is a multifunctional micronutrient implicated in age-related diseases such as cardiovascular diseases, osteoarthritis and osteoporosis. Although vitamin K-dependent proteins (VKDPs) are described to have a crucial role in the pathogenesis of these diseases, novel roles have emerged for vitamin K, independently of its role in VKDPs carboxylation. Vitamin K has been shown to act as an anti-inflammatory by suppressing nuclear factor kappa B (NF-kappa B) signal transduction and to exert a protective effect against oxidative stress by blocking the generation of reactive oxygen species. Available clinical evidences indicate that a high vitamin K status can exert a protective role in the inflammatory and mineralization processes associated with the onset and progression of age-related diseases. Also, vitamin K involvement as a protective super-micronutrient in aging and inflammaging is arising, highlighting its future use in clinical practice. In this review we summarize current knowledge regarding clinical data on vitamin K in skeletal and cardiovascular health, and discuss the potential of vitamin K supplementation as a health benefit. We describe the clinical evidence and explore molecular aspects of vitamin K protective role in aging and age-related diseases, and its involvement as a modulator in the interplay between pathological calcification and inflammation processes.

DT Article
DE Azanitrile; Cathepsin K inhibitors; Chondrocyte; Dedifferentiation; Osteoarthritis
ID azadipeptide nitrile inhibitors; human articular chondrocytes; cartilage formation; highly potent; osteoporosis; expression; odanacatib; redifferentiation; degeneration; quantity
AB Selective proteinase inhibitors have demonstrated utility in the investigation of cartilage degeneration mechanisms and may have clinical use in the management of osteoarthritis. The cysteine protease cathepsin K (CatK) is an attractive target for arthritis therapy. Here we report the synthesis of two cathepsin K inhibitors (CKIs): racemic azanitrile derivatives CKI-E and CKI-F, which have better inhibition properties on CatK than the commercial inhibitor odanacatib (ODN). Their IC50 values and inhibition constants (K-i) have been determined in vitro. Inhibitors demonstrate differential selectivity for CatK over cathepsin B, L and S in vitro, with Ki amounting to 1.14 and 7.21 nM respectively. We analyzed the effect of these racemic inhibitors on viability in different cell types. The human osteoblast-like cell line MG63, MOVAS cells (a murine vascular smooth muscle cell line) or murine primary chondrocytes, were treated either with CKI-E or with CKI-F, which were not toxic at doses of up to 5 mu M. Primary chondrocytes subjected to several passages were used as a model of phenotypic loss of articular chondrocytes, occurring in osteoarthritic cartilage. The efficiency of CKIs regarding CatK inhibition and their specificity over other proteases were validated in primary chondrocytes subjected to several passages. Racemic CKI-E and CKI-F at 0.1 and 1 mu M significantly inhibited CatK activity in dedifferentiated chondrocytes, even better than the commercial CatK inhibitor ODN. The enzymatic activity of other proteases such as matrix metalloproteinases or aggrecanases were not affected. Taken together, these findings support the possibility to design CatK inhibitors for preventing cartilage degradation in different pathologies.

TI Exosomal long noncoding RNAs in aging and age-related diseases
SO IUBMB LIFE
LA English
DT Review
DE age-related diseases; aging; exosomes; lncRNAs
ID emerging role; potential biomarkers; transferrin receptor; mediated transfer; senescent cells; up-regulation; cancer; micrornas; vesicles; proliferation
AB Molecules secreted by cells into the internal environment during aging, including those secreted in exosomes, have long been a matter of concern. Those cells that absorb exosomes, also known as recipient cells, exhibit certain phenotypic changes because of the regulatory role of functional molecules (including proteins and nucleic acids) released in exosomes. Involvement of

noncoding RNAs (ncRNAs) in the regulation of aging has received increasing attention, and long ncRNAs (lncRNAs) have become one of the research hotspots in recent years. LncRNAs carried by exosomes play a role in intercellular communication between adjacent and distant cells. Moreover, exosomal lncRNAs promote the decline of organ functions and the development of age-related diseases, including atherosclerosis, Type 2 diabetes, osteoporosis, osteoarthritis, rheumatoid arthritis, Parkinson's disease, multiple sclerosis, and cancer. Here, we review the regulatory roles of exosomal lncRNAs in aging and age-related diseases.

TI Tapentadol prolonged release for pain control in a frail obese patient: a case report
SO EUROPEAN REVIEW FOR MEDICAL AND PHARMACOLOGICAL SCIENCES
LA English
DT Article
DE Tapentadol; Fragile patients; Chronic pain; Rehabilitation

ID oxycodone controlled-release; opioid therapy; double-blind; osteoarthritis; management; efficacy; moderate; safety; disease; burden
AB We present the case of a 59-year-old woman with third-grade obesity and severe comorbidities including osteoporosis, dyslipidemia, diabetes mellitus, hypertension, night eating following bariatric biliary-intestinal by-pass surgery, severe fibromyalgia, poly-arthrosis, lumbar disc herniation in L5S1, sleep disorders and sleep apnea syndrome, and emotional disorders with anxiety and depression, who suffered from chronic pain unresponsive to a combination of multiple analgesics. After a period of metabolic and nutritional rehabilitation. analgesic treatment with tapentadol prolonged release (PR) was started and gradually increased to a daily dose of 300 mg with optimal pain control and a marked improvement in the quality of life and autonomy. Therapy suspension was followed by rebound pain with a worsening in functional capacity, and thus, the patient requested a new rehabilitation treatment, with new benefits. Analgesia is of paramount importance in fragile patients who are undergoing a rehabilitation period, in order to improve compliance with the rehabilitation protocols and increase the success of behavioral therapy. Tapentadol PR can be an effective analgesic therapy for pain control in several settings. Its peculiar tolerability profile improves the acceptability of tapentadol, even in patients with multiple previous analgesic treatments.

AB Oleanolic acid (OA) has recently become a research hotspot in the treatment of many human diseases, especially osteoporosis and arthritis. However, the mechanisms are not elucidated completely. We aimed to elucidate the target and the mechanism via which OA inhibited osteoclast differentiation. We used TRAP staining and toluidine blue dye to test OA effect on osteoclastogenesis and bone resorption respectively. We detected the expression level of osteoclast differentiation related genes, estrogen receptor alpha (ER alpha) and miR-503. We blocked ER alpha with its specific blocker, methylpiperidino pyrazole (MPP). We antagonized the function of miR-503 with antagomir-503-5p. RT-PCR and ELISA kits were used to investigate the effects of OA on miR-503 formation and maturation-relevant enzymes Dicer and Drosha at gene and protein levels. The data suggested that OA inhibited osteoclastogenesis and bone resorption. OA upregulated ER alpha and miR-503 expression levels, inhibited RANK expression. MPP significantly attenuated the OA effect including inhibiting osteoclastogenesis, inhibiting bone resorption and up-regulating miR-503 expression. It showed that ER alpha was the target of OA and OA up-regulated miR-503 expression through ER alpha. Antagomir-503-5p inhibited the function of miR-503 and attenuated the inhibition of OA on osteoclastogenesis, suggesting that OA inhibited osteoclast by up-regulating miR-503 expression. In addition, OA up-regulated miR-503 by up-regulating Dicer expression. In conclusion, OA inhibits RANKL-induced osteoclastogenesis via ER alpha/miR-503/ RANK signaling pathway in RAW264.7 cells.

ID musculoskeletal stress markers; coronoid-olecranon septum; supratrochlear foramen; entheseal changes; humerus; age; perforation; fractures; death
AB The aetiology of septal aperture formation is still an open question. The influence of bone robusticity, osteoarthritis, osteoporosis, and the size and shape of ulnar processes has been discussed. Some researchers have shown that weaker muscles lead to greater joint hypermobility, the impingement of ulnar processes on the humeral lamina, and, consequently, septal aperture formation. Assuming this theory is correct, the question is whether flexion or extension or both play a role in septal lamina perforation. The aim of the study was to examine the mechanical hypothesis of septal aperture formation in samples of skeletal material derived from an early medieval cemetery in Ostrow Lednicki (Poland). A total of 136 pairs of bones (humeri and ulnae) were examined. Septal aperture was scored as present or absent. Entheseal changes in ulna were used as markers of activity patterns, especially involving elbow extension and flexion. Entheseal changes were assessed based on a three-point rating scale. A significant negative correlation between septal aperture and triceps muscles was noted in right bones in females (tau = -0.331) and in both sexes combined (tau = -0.322). The relationship between septal aperture and the brachialis muscle was positive but non-significant. This means that looser triceps lead to greater looseness of the elbow, greater protrusion of the olecranon process, and consequent septal aperture formation. Different results were obtained for the brachialis, which may suggest that forearm flexion does not significantly affect septal lamina perforation.

TI Comorbidities in Patients With End-Stage Knee OA: Prevalence and Effect on Physical Function

SO ARCHIVES OF PHYSICAL MEDICINE AND REHABILITATION
LA English
DT Article
DE Comorbidity; Knee; Osteoarthritis; Quality of life; Rehabilitation
ID 6-minute walk test; muscle strength; quadriceps strength; older-adults; reported outcm; national-health; lumbar spine; total hip; osteoarthritis; disability
AB Objective: To investigate the prevalence of comorbidities and their effect on physical function, quality of life (QOL), and pain, in patients with end-stage knee osteoarthritis (OA). Design: A cross-sectional study. Setting: A rehabilitation facility at university hospital. Participants: Patients (N = 577; 503 women and 74 men) diagnosed with end-stage knee OA between October 2013 and June 2018. Intervention: Not applicable. Main Outcome Measures: Comorbidities were as follows: osteoporosis, presarcopenia, degenerative spine disease, diabetes, and hypertension. All patients completed the following performance-based physical function tests: stair-climbing test (SCT), 6-minute walk test (6MWT), timed Up and Go (TUG) test, and gait analysis. Self-reported physical function and pain were measured using Western Ontario McMaster Universities Osteoarthritis Index (WOMAC) and a visual analog scale (VAS), respectively, and self-reported QOL was measured using EuroQoL 5 dimensions (EQ-5D) questionnaire. Results: Univariate analyses revealed that patients with osteoporosis had significantly higher scores in SCT ascent, SCT descent, TUG, WOMAC pain tests, and lower scores in 6MWT, gait speed, and cadence tests than those without osteoporosis. Patients with presarcopenia recorded higher scores in SCT ascent, TUG, EQ-5D, and lower scores in 6MWT and gait speed tests than those without presarcopenia. Patients with degenerative spine disease showed higher scores in WOMAC pain and lower scores in gait speeds than those without degenerative spine disease. Patients with diabetes showed higher scores in SCT ascent than those without diabetes, and patients with hypertension showed lower scores in 6MWT than those without hypertension. After adjusting age, sex, and body mass index, SCT descent retained significant association with osteoporosis, SCT ascent showed independent association with presarcopenia and diabetes, and WOMAC pain revealed significant association with degenerative spine disease. Conclusion: The results confirm associations between comorbidities, performance-based and self-reported physical functions, and QOL in patients with end-stage knee OA. TI Formal and informal healthcare behaviours of women with chronic illness: A cross-sectional analysis of 1925 women
SO INTERNATIONAL JOURNAL OF CLINICAL PRACTICE
LA English
DT Article
ID alternative medicine; self-care; complementary; adults
AB Aim: To describe the healthcare behaviours of Australian women (45 years and over) diagnosed with a chronic illness. Methods: This is a cross-sectional sub-study of the 45 and Up Study-the largest study of healthy ageing conducted in the Southern Hemisphere-including 1,932 Australian women (45 years and older) with a self-reported diagnosis of either depression, asthma, diabetes, osteoarthritis or osteoporosis. Questionnaires were posted to eligible participants between September and December 2016 and included self-reported use of formal and

informal health services and healthcare behaviours, and health practitioner recommendations and monitoring of informal care. Descriptive statistics were used to describe the sample characteristics and chi-square tests assessed associations between variables. Results: The average age of participants was 69. We found that 53.7% of the women used informal healthcare products or practices for their chronic illness (eg exercise, nutritional supplements). These women were significantly (P < 0.001) more likely to consult with all types of health practitioners, compared with women not using informal healthcare. Physical activity and nutritional supplements were the most commonly recommended product or practice by all healthcare practitioners. However, informal healthcare behaviours were not regularly recommended or monitored by health practitioners. Conclusions: Women use a range of informal products and practices to manage chronic illness, but many fail to communicate with their health practitioners about such use. Future research should consider how to encourage better communication between health practitioners and patients related to informal healthcare for chronic illness to help ensure safe, effective, coordinated patient management.

TI The role of GPCRs in bone diseases and dysfunctions
SO BONE RESEARCH
LA English
DT Review
ID protein-coupled-receptor; hormone-releasing-hormone; genome-wide association; adolescent idiopathic scoliosis; fatty-acid receptor; metabotropic glutamate-receptor; regulates osteoclast function; calcium-sensing receptor; prostaglandin-e receptor; glucagon-like peptide-1
AB The superfamily of G protein-coupled receptors (GPCRs) contains immense structural and functional diversity and mediates a myriad of biological processes upon activation by various extracellular signals. Critical roles of GPCRs have been established in bone development, remodeling, and disease. Multiple human GPCR mutations impair bone development or metabolism, resulting in osteopathologies. Here we summarize the disease phenotypes and dysfunctions caused by GPCR gene mutations in humans as well as by deletion in animals. To date, 92 receptors (5 glutamate family, 67 rhodopsin family, 5 adhesion, 4 frizzled/taste2 family, 5 secretin family, and 6 other 7TM receptors) have been associated with bone diseases and dysfunctions (36 in humans and 72 in animals). By analyzing data from these 92 GPCRs, we found that mutation or deletion of different individual GPCRs could induce similar bone diseases or dysfunctions, and the same individual GPCR mutation or deletion could induce different bone diseases or dysfunctions in different populations or animal models. Data from human diseases or dysfunctions

identified 19 genes whose mutation was associated with human BMD: 9 genes each for human height and osteoporosis; 4 genes each for human osteoarthritis (OA) and fracture risk; and 2 genes each for adolescent idiopathic scoliosis (AIS), periodontitis, osteosarcoma growth, and tooth development. Reports from gene knockout animals found 40 GPCRs whose deficiency reduced bone mass, while deficiency of 22 GPCRs increased bone mass and BMD; deficiency of 8 GPCRs reduced body length, while 5 mice had reduced femur size upon GPCR deletion. Furthermore, deficiency in 6 GPCRs induced osteoporosis; 4 induced osteoarthritis; 3 delayed fracture healing; 3 reduced arthritis severity; and reduced bone strength, increased bone strength, and increased cortical thickness were each observed in 2 GPCR-deficiency models. The ever-expanding number of GPCR mutation-associated diseases warrants accelerated molecular analysis, population studies, and investigation of phenotype correlation with SNPs to elucidate GPCR function in human diseases.

TI A chronological map of 308 physical and mental health conditions from 4 million

individuals in the English National Health Service
SO LANCET DIGITAL HEALTH
LA English
DT Article
ID pathophysiology; diseases; profile; asthma; onset; care
AB Background To effectively prevent, detect, and treat health conditions that affect people during their lifecourse, health-care professionals and researchers need to know which sections of the population are susceptible to which health conditions and at which ages. Hence, we aimed to map the course of human health by identifying the 50 most common health conditions in each decade of life and estimating the median age at first diagnosis. Methods We developed phenotyping algorithms and codelists for physical and mental health conditions that involve intensive use of health-care resources. Individuals older than 1 year were included in the study if their primary-care and hospital-admission records met research standards set by the Clinical Practice Research Datalink and they had been registered in a general practice in England contributing up-to-standard data for at least 1 year during the study period. We used linked records of individuals from the CALIBER platform to calculate the sex-standardised cumulative incidence for these conditions by 10-year age groups between April 1, 2010, and March 31, 2015. We also derived the median age at diagnosis and prevalence estimates stratified by age, sex, and ethnicity (black, white, south Asian) over the study period from the primary-care and secondary-care records of patients. Findings We developed case definitions for 308 disease phenotypes. We used records of 2 784 138 patients for the calculation of cumulative incidence and of 3 872 451 patients for the calculation of period prevalence and median age at diagnosis of these conditions. Conditions that first gained prominence at key stages of life were: atopic conditions and infections that led to hospital admission in children (<10 years); acne and menstrual disorders in the teenage years (10-19 years); mental health conditions, obesity, and migraine in individuals aged 20-29 years; soft-tissue disorders and gastro-oesophageal reflux disease in individuals aged 30-39 years; dyslipidaemia, hypertension, and erectile dysfunction in individuals aged 40-59 years; cancer, osteoarthritis, benign prostatic hyperplasia, cataract, diverticular disease, type 2 diabetes, and deafness in individuals aged 60-79 years; and atrial fibrillation, dementia, acute and chronic kidney disease, heart failure, ischaemic heart disease, anaemia, and osteoporosis in individuals aged 80 years or older. Black or south-Asian individuals were diagnosed earlier than white individuals for 258 (84%) of the 308 conditions. Bone fractures and atopic conditions were recorded earlier in male individuals, whereas female individuals were diagnosed at younger ages with nutritional anaemias, tubulointerstitial nephritis, and urinary disorders. Interpretation We have produced the first chronological map of human health with cumulative-incidence and period-prevalence estimates for multiple morbidities in parallel from birth to advanced age. This can guide clinicians, policy makers, and researchers on how to formulate differential diagnoses, allocate resources, and target research priorities on the basis of the knowledge of who gets

which diseases when. We have published our phenotyping algorithms on the CALIBER open-access Portal which will facilitate future research by providing a curated list of reusable case definitions. Copyright (C) 2019 The Author(s). Published by Elsevier Ltd.

ID finite-element-analysis; quantitative computed-tomography; fracture risk prediction; mineral density; hip fracture; lumbar spine; score tbs; fragility fractures; proximal femur; older men
AB Purpose The purpose of this paper was to review the available approaches for bone strength assessment, osteoporosis diagnosis and fracture risk prediction, and to provide insights into radiofrequency echographic multi spectrometry (REMS), a non-ionizing axial skeleton technique. Methods A working group convened by the European Society for Clinical and Economic Aspects of Osteoporosis and Osteoarthritis met to review the current image-based methods for bone strength assessment and fracture risk estimation, and to discuss the clinical perspectives of REMS. Results Areal bone mineral density (BMD) measured by dual-energy X-ray absorptiometry (DXA) is the consolidated indicator for osteoporosis diagnosis and fracture risk assessment. A more reliable fracture risk estimation would actually require an improved assessment of bone strength, integrating also bone quality information. Several different approaches have been proposed, including additional DXA-based parameters, quantitative computed tomography, and quantitative ultrasound. Although each of them showed a somewhat improved clinical performance, none satisfied all the requirements for a widespread routine employment, which was typically hindered by unclear clinical usefulness, radiation doses, limited accessibility, or inapplicability to spine and hip, therefore leaving several clinical needs still unmet. REMS is a clinically available technology for osteoporosis diagnosis and fracture risk assessment through the estimation of BMD on the axial skeleton reference sites. Its automatic processing of unfiltered ultrasound signals provides accurate BMD values in view of fracture risk assessment. Conclusions New approaches for improved bone strength and fracture risk estimations are needed for a better management of osteoporotic patients. In this context, REMS represents a valuable approach for osteoporosis diagnosis and fracture risk prediction.

TI Chondrocyte enlargement is a marker of osteoarthritis severity
SO OSTEOARTHRITIS AND CARTILAGE
LA English
DT Article
DE Osteoarthritis; Chondrocyte size; Hypertrophic markers; Cartilage
ID cartilage; differentiation; hypertrophy; growth; bone
AB Objective: We aimed to assess whether an increase in chondrocyte size might be a feature of the articular cartilage (AC) hypertrophic-like phenotype both in experimental and in human osteoarthritis (OA). The anatomical location of these enlarged cells in the cartilage layers was also evaluated. Methods: Experimental OA was carried out in female rabbits alone or in combination with osteoporosis (OPOA). The rabbits were subjected to destabilization knee surgery to develop OA. Osteoporosis was induced with ovariectomy and methylprednisolone administration. Human OA samples obtained from knee replacement surgery were also studied. Cartilage lesions and chondrocyte size were assessed in AC sections. Immunostaining of type-X collagen and metalloproteinase-13 were used as markers of the AC hypertrophic transformation. Both the cell size and the gene expression of type-X collagen were further analyzed in primary murine chondrocyte cultures. Results: Compared to healthy AC, chondrocyte size was increased both in experimental and in human OA, in correlation with the severity of cartilage damage. No differences in chondrocyte size were found between deeper or more superficial regions of AC. In cell cultures, accretion of hypertrophic markers and cell enlargement were found to occur synchronized. Conclusions: We observed an enhancement in the mean size of chondrocytes at the OA cartilage, which showed correlation with cartilage damage, both in human and in experimental OA. The enlarged chondrocytes were homogeneously distributed throughout the AC.

Our results suggest that chondrocyte size could be a reliable measure of disease progression, of potential use in the histopathological assessment of OA cartilage.

TI Xian-Ling-Gu-Bao induced inflammatory stress rat liver injury: Inflammatory and oxidative stress playing important roles
SO JOURNAL OF ETHNOPHARMACOLOGY
LA English
DT Article

DE Xian Ling Gu Bao; Osteoarthritis; Hepatotoxicity; Inflammation factor; Oxidative stress
ID necrosis-factor-alpha; kupffer cell activation; toll-like receptors; fatty liver; cartilage degeneration; cytochrome-p450 2e1; endotoxin levels; 1st multicenter; herbal fufang; double-blind
AB Ethnopharmacological relevance: Xian-Ling-Gu-Bao (XLGB) Fufang is an herbal formula that has been used in clinical settings to treat osteoporosis, osteoarthritis, aseptic bone necrosis, and climacteric syndrome. Despite its uses, XLGB treatment has been linked to potential liver injury. To date, there is a lack of clear demonstration of such toxicity in animal models. Aim of the study: As animal models fail to reproduce the XLGB hepatotoxicity reported in humans, because human hepatocytes are clearly more sensitive to XLGB, this study was designed to investigate a more reliable animal model of such toxicity. Materials and methods: We randomized rats into five groups, as follows: CON (control), XLGB, lipopolysaccharide (LPS), L-XLGB/LPS (XLGB, 0.125 g/kg; LPS, 0.1 mg/kg), and XLGB/LPS (XLGB, 1.25 g/kg; LPS, 0.1 mg/kg). These groups were treated with 0.5% sodium carboxymethyl cellulose (CMC-Na), XLGB suspension, normal saline, or LPS. The first administration of XLGB [0.125 g/kg or 1.25 g/kg, by mouth (PO)] or its solvent (0.5% CMC-Na) was delivered, and then food was removed. Twelve hours after the first administration of XLGB, rats received LPS [0.1 mg/kg, intravenously (IV)] or saline control. After 30 min, a second administration of XLGB (0.125 g/kg or 1.25 g/kg, PO) or solvent was administered. The rats were anesthetized at 12 h or 24 h following the second administration of XLGB. Liver function was evaluated by measuring liver weight, liver microscopy, serum biochemistry and plasma microRNA-122 (miR-122). The plasma levels of 27 cytokines were measured to evaluate inflammation. Moreover, the expression of cytochrome P450 2E1 (CYP2E1), nicotinic adenine dinucleotide phosphate (NADPH) oxidase and inducible nitric oxide synthase (iNOS) at protein levels were observed; immunofluorescence and immunohistochemistry were used to confirmed the hepatotoxicity of XLGB. Results: Hepatotoxicity in male rats with moderate inflammation induced by XLGB was indicated by liver histopathology, serum biochemical analysis, serum miR-122 levels, and immunofluorescent assessments. We observed significant increases in liver weight and liver indexes in male rats with moderate inflammation in response to XLGB. Histopathological assessment further showed that extensive hepatocellular necrosis and inflammatory infiltration were evident in rats co-treated with XLGB/LPS. The levels of serum transaminases [alanine aminotransferase (ALT), aspartate aminotransferase (AST), gamma-glutamyl transferase (GGT)], total bilirubin (TBIL) and triglyceride (TG), which are markers of liver function, were also significantly increased by XLGB/LPS treatment. Similarly, miR-122 was significantly elevated in XLGB/LPS treated rats relative to other groups. An immunofluorescent assessment showed extensive apoptosis in hepatocytes from these co-treated rats. What is more, XLGB can dose-dependently induce liver injury in male rats with moderate inflammation. Hepatic CYP2E1, neutrophil chemotactic factor (NCF-1), iNOS, and NOX-2 (an NADPH oxidase subunit) levels were increased in response to

XLGB treatment, and staining for DMPO nitrone adducts further showed elevated oxidative stress level in XLGB/LPS-treated rats relative to the other experimental groups. Conclusion: LPS and XLGB co-treatment in rats led to marked hepatotoxicity. This toxicity was associated with disrupted lipid metabolism, extensive liver necrosis and inflammatory infiltration, apoptosis, and expression of oxidative stress-related proteins. These results demonstrate a valuable model for the study of iDILI in the context XLGB treatment, and further provide insights into the potential mechanisms by which XLGB may induce hepatotoxicity in humans.

TI Do rheumatoid arthritis patients have more major complications and length of stay after lower extremities fracture surgery? A nationwide data with propensity score matching

SO MEDICINE
LA English
DT Article
DE hospitalization length; lower extremities fracture surgery; major complication; rheumatoid arthritis
ID charlson comorbidity index; total knee arthroplasty; hip fracture; risk; mortality; outcm; osteoarthritis; epidemiology; osteoporosis; predictors
AB Patients with rheumatoid arthritis (RA) have a high risk of cardiovascular diseases and fractures. This retrospective cohort study explored whether patients with RA face higher complication risks or longer hospital stays than other patients when they had a lower limb fracture that required the surgery. Patients aged >45 years who received lower limb fracture surgeries between 2005 and 2012 were selected from the National Health Insurance Research Database, and 10 related variables including sex and age were used in propensity score matching to pair RA patients with non-RA patients in a 1:4 ratio. The final study sample comprised 1109 patients with RA and 4436 non-RA patients. The results indicated that 5.57% of the study sample had postoperative complications, accounting for 5.05% of patients with RA and 5.70% of the control group. After conditional logistic regression analysis was performed, the risk of major complications has no significant differences between patients with RA and the control group (odds ratio [OR] = 0.87; 95% confidence interval [CI]: 0.61-1.24; P>.05). However, the comorbidity severity score exerted a significant effect on complications; patients with scores = 3 were 2.78 times more likely to experience complications (OR=2.78; 95% CI 1.52-5.07). When considering different types of complications, patients with RA were less likely to be exposed to the risk of stroke (OR=0.48). After controlling all related factors, no significant differences were observed in the complication risks or deaths between the 2 groups (P>.05). Regarding hospitalization length, the average stay for all patients was 8.12 days; after controlling related factors, the hospitalization length for patients with RA was 0.97 times that of the control group, which was nonsignificant (P>.05). These results may provide some information to healthcare professionals when providing treatments.

TI Executive summary of the European guidance for the diagnosis and management of osteoporosis in postmenopausal women
SO CALCIFIED TISSUE INTERNATIONAL
LA English
DT Review
DE Bone mineral density; Diagnosis of osteoporosis; Fracture risk assessment; FRAX; Health economics; Treatment of osteoporosis
AB A guidance on the assessment and treatment of postmenopausal women at risk from fractures due to osteoporosis was recently published in Osteoporosis International as a joint effort of the International Osteoporosis Foundation and European Society for Clinical and Economic Aspects of Osteoporosis and Osteoarthritis (Kanis et al. in Osteoporos Int 10.1007/s00198-018-4704-5, 2018). This manuscript updates the previous guidelines document, published in 2013 (Kanis et al. in Osteoporos Int 24:23-57, 2013) and is written in a European perspective. The present article reports and summarizes the main recommendations included in this 2018 guidance document.

TI Sirtuins and FoxOs in osteoporosis and osteoarthritis
SO BONE
LA English
DT Article
DE Aging; Autophagy; Chondrocytes; Osteoblasts; Osteoclasts; Osteocytes; Oxidative stress; Senescence; ROS; Wnt signaling
ID transcription factor foxo3a; oxidative stress; beta-catenin; articular chondrocytes; cellular senescence; gene-expression; bone-formation; cartilage homeostasis; mammalian sirtuins; forkhead proteins
AB The sirtuin family of NAD-dependent protein deacetylases promotes longevity and counteracts age-related diseases. One of the major targets of Sirtuins are the FoxO family of transcription factors. FoxOs play a major role in the adaptation of cells to a variety of stressors such as oxidative stress and growth factor deprivation. Studies with murine models of cell-specific loss- or gain-of-function of Sirtuins or FoxOs and with Sirtuinl stimulators have provided novel insights into the function and signaling of these proteins on the skeleton. These studies have revealed that both Sirtuins and FoxOs acting directly in cartilage and bone cells are critical for normal skeletal development, homeostasis and that their dysregulation might contribute to skeletal disease. Deacetylation of FoxOs by Sirtl in osteoblasts and osteoclasts stimulates bone formation and inhibits bone resorption, making Sirtl ligands promising therapeutic agents for diseases of low bone mass. While a similar link has not been established in chondrocytes, Sirtl and FoxOs both have chondroprotective actions, suggesting that Sirtl activators may have similar efficacy in preventing cartilage degeneration due to aging or injury. In this review we summarize these advances and discuss their implications for the pathogenesis of age-related osteoporosis and osteoarthritis.

AB Osteo-articular diseases are characterized by a dysregulation of joint and/or bone homeostasis. These include diseases affecting the joints originally, such as osteoarthritis and rheumatoid arthritis, or the bone, such as osteoporosis. Inflammation and the involvement of Wingless-related integration site (Wnt) signaling pathways are key pathophysiological features of these diseases resulting in tissue degradation by matrix-degrading enzymes, namely matrix metalloproteinases (MMPs) and a disintegrin and metalloproteinases with thrombospondin motifs (ADAMTs), secreted by the joint resident cells and/or by infiltrating immune cells. Activation of Wnt signaling pathways is modulated by different families of proteins, including Dickkopfs and the secreted Frizzled-related proteins (sFRPs). The sFRP family is composed of five secreted glycoproteins in mammals that regulate Wnt signaling in the extracellular compartment. Indeed, sFRPs are able to bind both to the soluble Wnt ligands and to their cell membrane receptors, the Frizzled proteins. Their expression profile is altered in osteo-articular diseases, suggesting that they could account for the abnormal activation of Wnt pathways. In the present article, we review how sFRPs are more than simple antagonists of the Wnt signaling pathways and discuss their pathophysiological relevance in the context of osteo-articular diseases. We detail their Wnt-dependent and their Wnt-independent roles, with a particular emphasis on their ability to modulate the inflammatory response and extracellular matrix (ECM) remodeling. We also discuss their potential therapeutic use with a focus on bone remodeling, osteo-articular cancers, and tissue engineering.

TI Fracture types affect clinical outcomes of patients managed within the fracture liaison and osteoporosis medication management services
SO SCIENTIFIC REPORTS
LA English
DT Article
ID hip fracture; practice framework; mortality; capture; reduce
AB Osteoporosis medication in fragility fracture patients is associated with better outcomes. However, limited studies have investigated whether fracture types affect outcomes among patients undergoing treatment. We performed a secondary data analysis on participants from a fracture liaison service and an osteoporosis medication management service. Participants (n = 974) were regrouped into hip fracture (HF), vertebral fracture (VF), HF + VF, and NO HF/VF groups at baseline. Bivariate and multivariate logistic regressions were performed to identify baseline correlates on one-year mortality, incident refractures, and falls. Baseline characteristics were different among fracture groups. The HF group was oldest, with the lowest body mass index (BMI), lowest FRAX (R) T-score and had the highest 10-year fracture risk. After intervention, the HF group still had the highest mortality, but the HF + VF group had the highest refracture and incident fall rates. In the multivariate regression analysis, prevalent HF and VF, lower BMI and albumin level, and having chronic kidney disease or cancer were associated with higher mortality rates. HF + VF patients had the highest refracture risk. Prevalent HF and VF, older age and higher BMI, and having cancer or osteoarthritis were associated with a greater fall risk. HF and VF are associated with adverse outcomes, even under an optimal fracture care.

TI Algorithm for the Use of Biochemical Markers of Bone Turnover in the Diagnosis, Assessment and Follow-Up of Treatment for Osteoporosis
SO ADVANCES IN THERAPY
LA English
DT Article
DE Algorithm; Bone; Bone biomarker; CTX; Osteoporosis; P1NP; Rheumatology
ID postmenopausal women; fracture risk; double-blind; international osteoporosis; vertebral fractures; metabolism markers; randomized-trial; denosumab; teriparatide; risedronate
AB Introduction Increased biochemical bone turnover markers (BTMs) measured in serum are associated with bone loss, increased fracture risk and poor treatment adherence, but their role in clinical practice is presently unclear. The aim of this consensus group report is to provide guidance to clinicians on how to use BTMs in patient evaluation in postmenopausal osteoporosis, in fracture risk prediction and in the monitoring of treatment efficacy and adherence to osteoporosis medication. Methods A working group with clinical scientists and osteoporosis specialists was invited by the Scientific Advisory Board of European Society on Clinical and Economic Aspects of Osteoporosis, Osteoarthritis and Musculoskeletal Diseases (ESCEO). Results Serum bone formation marker PINP and resorption marker beta CTX-I are the preferred markers for evaluating bone turnover in the clinical setting due to their specificity to bone, performance in clinical studies, wide use and relatively low analytical variability. BTMs cannot be used to diagnose osteoporosis because of low sensitivity and specificity, but can be of value in patient evaluation where high values may indicate the need to investigate some causes of secondary osteoporosis. Assessing serum levels of beta CTX-I and PINP can improve fracture prediction slightly, with a gradient of risk of about 1.2 per SD increase in the bone marker in addition to clinical risk factors and bone mineral density. For an individual patient, BTMs are not useful in projecting bone loss or treatment efficacy, but it is recommended that serum PINP and beta CTX-I be used to

monitor adherence to oral bisphosphonate treatment. Suppression of the BTMs greater than the least significant change or to levels in the lower half of the reference interval in young and healthy premenopausal women is closely related to treatment adherence. Conclusion In conclusion, the currently available evidence indicates that the principal clinical utility of BTMs is for monitoring oral bisphosphonate therapy.

TI Harnessing a Novel Inhibitory Role of miR-16 in Osteogenesis by Human Mesenchymal Stem Cells for Advanced Scaffold-Based Bone Tissue Engineering
SO TISSUE ENGINEERING PART A
LA English
DT Article
DE nonviral delivery; miRNA miR-16; scaffold; osteogenesis; human mesenchymal stem cells
ID collagen-based scaffolds; positive regulation; gene delivery; in-vitro; differentiation; regeneration; proliferation; expression; nanohydroxyapatite; micrornas
AB MicroRNA (miRNA) therapeutics is increasingly being developed to either target bone-related diseases such as osteoporosis and osteoarthritis or as the basis for novel bone tissue engineering strategies. A number of miRNAs have been reported as potential osteo-therapeutics but no consensus has yet been established on the optimal target. miR-16 has been studied extensively in nonosteogenic functions and used as functionality reporter target in the development of nonviral miRNA delivery platforms. This study hypothesized that miR-16 may also play an inhibitory role in osteogenesis due to its ability to directly target Smad5 and AcvR2a. This study thus aimed to assess the potential of miR-16 inhibition to increase osteogenesis in human mesenchymal stem cells (hMSCs) using a previously established miRNA delivery platform composed of nanohydroxyapatite (nHA) particles as nonviral vectors in combination with collagen-nHA scaffolds designed specifically for bone repair. Initial results showed that antagomiR-16 delivery efficiently increased the relative levels of both putative targets and Runx2, the key transcription factor for osteogenesis, while also increasing osteocalcin levels. Furthermore, significant increases in mineral calcium deposition by hMSCs were found in both monolayer and most importantly in scaffold-based osteodifferentiation studies, ultimately demonstrating that miR-16 inhibition further enhances the therapeutic potential of a scaffold with known potential for bone repair applications and thus holds significant therapeutic potential as a novel bone tissue engineering strategy. Furthermore, we suggest that harnessing the additional functions known to miR-16 by incorporating either its enhancers or inhibitors to tissue-specific tailored scaffolds provides exciting opportunities for a diverse range of therapeutic indications.

TI Exercise as a prescription for patients with various diseases
SO JOURNAL OF SPORT AND HEALTH SCIENCE
LA English
DT Review
DE Diseases; Exercise prescription; Patients
ID quality-of-life; low-back-pain; randomized controlled-trial; high-intensity interval; chronic heart-failure; coronary-artery-disease; chronic kidney-disease; obstructive pulmonary-disease; rotator cuff tendinopathy; breast-cancer patients
AB A growing understanding of the benefits of exercise over the past few decades has prompted researchers to take an interest in the possibilities of exercise therapy. Because each sport has its own set of characteristics and physiological complications that tend to occur during exercise training, the effects and underlying mechanisms of exercise remain unclear. Thus, the first step in probing the effects of exercise on different diseases is the selection of an optimal exercise protocol. This review summarizes the latest exercise prescription treatments for 26 different diseases: musculoskeletal system diseases (low back pain, tendon injury, osteoporosis, osteoarthritis, and hip fracture), metabolic system diseases (obesity, type 2 diabetes, type 1 diabetes, and nonalcoholic fatty liver disease), cardio-cerebral vascular system diseases (coronary artery disease, stroke, and chronic heart failure), nervous system diseases (Parkinson's disease, Huntington's disease, Alzheimer's disease, depression, and anxiety disorders), respiratory system diseases (chronic obstructive pulmonary disease, interstitial lung disease, and after lung transplantation), urinary system diseases (chronic kidney disease and after kidney transplantation), and cancers (breast cancer, colon cancer, prostate cancer, and lung cancer). Each exercise prescription is displayed in a corresponding table. The recommended type, intensity, and frequency of exercise prescriptions are summarized, and the effects of exercise therapy on the prevention and rehabilitation of different diseases are discussed. TI Viewpoint on on the role of tissue maintenance in ageing: focus on biomarkers of bone, cartilage, muscle, and brain tissue maintenance
SO AGEING RESEARCH REVIEWS
LA English
DT Article
DE Biomarkers; Tissue maintenance; Bone; Cartilage; Muscle; Brain
ID oligomeric matrix protein; mild cognitive impairment; c-terminal telopeptide; alzheimers-disease; turnover markers; ii collagen; serum sclerostin; skeletal-muscle; biochemical markers; synovial-fluid
AB Specific hallmarks are thought to underlie the ageing process and age-related functional decline. In this viewpoint, we put forward the hypothesis that disturbances in the process of tissue maintenance are an important common denominator that may lie in between specific hallmarks of ageing (i.e. damage and responses to damage) and their ultimate (patho)physiological consequences (i.e. functional decline and age-related disease). As a first step towards verifying or falsifying this hypothesis, it will be important to measure biomarkers of tissue maintenance in future studies in different study populations. The main aim of the current paper is to discuss potential biomarkers of tissue maintenance that could be used in such future studies. Among the many tissues that could have been chosen to explore our hypothesis, to keep the paper manageable, we chose to focus on a selected number of tissues, namely bone, cartilage, muscle, and the brain, which are important for mobility and cognition and affected in several common age-related diseases, including osteoporosis, osteoarthritis, sarcopenia, and neurodegenerative diseases. Furthermore, we discuss the advantages and limitations of potential biomarkers for use in (pre)clinical studies. The proposed biomarkers should be validated in future research, for example by measuring these in humans with different rates of ageing.

ID michael reaction acceptors; cystatin-c; catalytic mechanism; drug discovery; emerging roles; proteases; reactivity; inducers; disease; cancer
AB Cathepsins are the most abundant cysteine proteases involved in many physiological processes. The imbalance between the natural cysteine protease inhibitors and cathepsins leads to many pathological conditions such as cancer, osteoporosis, and osteoarthritis. Thus, cysteine cathepsins have turn out to be an attractive therapeutic target for the development of new inhibitors. In this paper, the computational study of the inhibition mechanism of cysteine protease by chalcone-based inhibitors has been carried out by means of quantum chemical calculations by employing DFT method. The present study exposes how the processes of activation of the reactive centers of the chalcone derivatives and the nucleophilic attack by the cysteine residue at the electrophilic reactive site of the chalcone take place in the catalytic active site. The obtained results reveal that the inhibition reaction proceeds in a stepwise manner and the attack of the cysteine residue will be either at carbonyl carbon C32 (pathway 1) or beta-carbon C33 (pathway 2). The low positive activation (5.61 and 4.58 kcal/mol) and reaction (1.60 and 9.70 kcal/mol) energies corresponding to both the pathways along with the

positive backward difference (2)rho(r) values for C32/33-S6 bonds imply that the overall reaction is endothermic and the nature of inhibitor is reversible covalent.

TI Changes in femoral bone mineral density after total knee arthroplasty: a systematic review and meta-analysis
SO ARCHIVES OF OSTEOPOROSIS

LA English
DT Review
DE Bone mineral density; Bone loss; Femur; Total knee arthroplasty; Meta-analysis; Periprosthetic fracture
ID x-ray absorptiometry; 1-year follow-up; distal femur; total hip; periprosthetic fracture; replacement; osteoarthritis; epidemiology; prevalence; osteoporosis
AB BackgroundBone loss after total knee arthroplasty (TKA) may lead to periprosthetic fractures that are associated with significant costs (morbidity, economic, etc.) and pose a challenge to operative fixation. This meta-analysis quantifies the change in bone mineral density (BMD) of the distal femur after primary TKA.MethodsA systematic review of six databases was performed by two independent reviewers. Studies that reported bone density after knee arthroplasty were identified and inclusion/exclusion criteria was applied. Data were extracted and analyzed using the Comprehensive Meta-Analysis Software.ResultsFourteen studies were included in the analysis. The average decrease in BMD was 0.09 [0.05, 0.13], 0.14 [0.08, 0.20], 0.16 [0.10, 0.23], and 0.16 [0.12, 0.20] g/cm(2) at 3, 6, 12, and 24months, respectively, corresponding to a 9.3%, 13.2%, 15.8%, and 15.4% BMD loss. A high degree of heterogeneity existed between the studies (I-2>90% at most time points).ConclusionIn summary, there is a rapid and significant 15% decrease in BMD in the first 6months after TKA that is sustained to 24months. Better understanding regarding how perioperative optimization of bone health may affect BMD loss and the incidence of periprosthetic fracture is essential.Level of evidenceTherapeutic Level II.

TI Diabetes Is Associated with Musculoskeletal Pain, Osteoarthritis, Osteoporosis, and Rheumatoid Arthritis
SO JOURNAL OF DIABETES RESEARCH
LA English
DT Article
ID physical-activity; alcohol-consumption; danish adults; exercise; management; hba(1c); health; risk
AB Aim. To investigate the associations between diabetes and musculoskeletal pain, osteoarthritis, osteoporosis, and rheumatoid arthritis. Methods. Self-reported data were provided by the nationwide Danish National Health Survey 2013. Inclusion criteria were age >= 40 years and known diabetes status. The exposure variable was diabetes, and the outcome variables included musculoskeletal pain during the last 14 days in three body sites (back/lower back, limbs, and shoulder/neck), osteoarthritis, osteoporosis, and rheumatoid arthritis. Logistic regression analyses adjusted for age, gender, BMI, education, marital status, and physical activity were performed. Results. 9,238 participants with diabetes were 65.6 +/- 11.0 (mean +/- SD) years old; 55.6% were males. 99,980 participants without diabetes were 59.2 +/- 11.8 years old; 46.7% were males. Diabetes was associated with back/lower back pain (OR 1.2 (CI 95% 1.1-1.2), p<0.001), pain in the limbs (1.4 (1.3-1.4), p<0.001), shoulder/neck pain (1.2 (1.1-1.3), p<0.001), osteoarthritis (1.3 (1.2-1.4), p<0.001), osteoporosis (1.2 (1.1-1.4), p=0.010), and rheumatoid arthritis (1.6 (1.4-1.7), p<0.001). In participants with diabetes, physical activity was associated with reduced pain (e.g., back/lower back pain (0.7 (0.6-0.7), p<0.001)). Conclusion. Diabetes was associated with elevated odds of having musculoskeletal pain. Diabetes was also associated with elevated odds of having osteoarthritis, osteoporosis, and rheumatoid arthritis. The most frequent disease in individuals with diabetes was osteoarthritis. The reported pain may have negative impacts on the level of physical activity. Health-care professionals should remember to inform patients with diabetes that musculoskeletal pain, osteoarthritis, osteoporosis, and rheumatoid arthritis are not contraindications to exercise training.

TI P2X7, a critical regulator and potential target for bone and joint diseases
SO JOURNAL OF CELLULAR PHYSIOLOGY
LA English

DT Review
DE bone cancer; osteoporosis; P2X7 receptor; rheumatoid arthritis; the stress fracture injury
ID nf-kappa-b; collagen-induced arthritis; p2x(7) receptor; mineral density; rheumatoid-arthritis; extracellular nucleotides; functional polymorphisms; purinergic receptors; nlrp3 inflammasome; fluid shear
AB Abundant evidence indicted that P2X7 receptor show a essential role in human health and some human diseases including hypertension, atherosclerosis, pulmonary inflammation, tuberculosis infection, psychiatric disorders, and cancer. P2X7 receptor also has an important role in some central nervous system diseases such as neurodegenerative disorders. Recently, more research suggested that P2X7 receptor also plays a crucial role in bone and joint diseases. But the effect of P2X7 receptor on skeletal and joint diseases has not been systematically reviewed. In this article, the role of P2X7 receptor in skeletal and joint diseases is elaborated. The activation of P2X7 receptor can ameliorate osteoporosis by inducing a fine balance between osteoclastic resorption and osteoblastic bone formation. The activation of P2X7 receptor can relieve the stress fracture injury by increasing the response to mechanical loading and inducing osteogenesis. But the activation of P2X7 receptor mediates the cell growth and cell proliferation in bone cancer. In addition, the activation of P2X7 receptor can aggravate the process of some joint diseases such as osteoarthritis, rheumatoid arthritis, and acute gouty arthritis. The inhibition of P2X7 receptor can alleviate the pathological process of joint disease to some extent. In conclusion, P2X7 receptor may be a critical regulator and therapeutic target for bone and joint diseases.

DE Aging; Falls; Male mobility; Osteoporosis; Sarcopenia
ID dwelling older-adults; bone-mineral density; vitamin-d supplementation; fish-oil

supplementation; sarcopenic obesity; muscle mass; physical function; adaptive response; american-college; national-health
AB Maintaining mobility is an important aspect of health and well-being in older men. This literature review describes several modifiable and nonmodifiable risk factors impacting bone, muscle, and joint health. Exercise and nutritional interventions may help to prevent the progressive deterioration in bones, muscles, and joints impacting mobility in later life. Limitations in mobility are increasingly recognized as a major public health problem due to an aging population and growing number of older individuals affected by disabling comorbidities. Despite increasing numbers and debilitating consequences, there are no guidelines providing recommendations on strategies to maintain mobility for healthy aging among older men. This narrative review aims to fill this literature gap. PubMed, Scopus, and Google Scholar databases were searched using predefined search terms. Primary studies, exploratory analyses, cross-sectional surveys, meta-analyses, evidence-based clinical reviews, and guidelines from nationally recognized societies focusing on mobility in older men and key elements including bone, muscle and joint health, and balance were selected. Several modifiable and nonmodifiable risk factors have been reported in the literature that impact bone, muscle, and joint health and predispose older men to falls and fractures. The most common conditions impacting bones, muscles, and joints are osteoporosis, sarcopenia, and osteoarthritis, respectively. In addition to being key contributors to disability in the elderly, these conditions are all associated with a higher mortality risk. Although more studies are required, current evidence supports the use of various nonpharmacological (mainly exercise and nutrition) and/or pharmacological treatment modalities to help prevent and/or reverse these conditions. Incorporating lifestyle interventions involving exercise and nutrition at a younger age can help prevent the age-related, progressive deterioration in bones, muscles, and joints that can reduce mobility in later life. Established barriers to physical activities (e.g., poor health, social isolation) in men are important to consider for optimizing outcomes.

DT Review
DE EPIGENETICS; DNA METHYLATION; MICRORNA; LONG NON-CODING RNA; HISTONE; EPIGENOMEWIDE ASSOCIATION STUDIES; OSTEOPOROSIS; OSTEOARTHRITIS

ID mesenchymal stem-cells; differentially methylated regions; wide dna methylation; long noncoding rna; osteogenic differentiation; gene-expression; histone deacetylases; osteoblast differentiation; articular chondrocytes; microrna regulation
AB Phenotypic variation in skeletal traits and diseases is the product of genetic and environmental factors. Epigenetic mechanisms include information-containing factors, other than DNA sequence, that cause stable changes in gene expression and are maintained during cell divisions. They represent a link between environmental influences, genome features, and the resulting phenotype. The main epigenetic factors are DNA methylation, posttranslational changes of histones, and higher-order chromatin structure. Sometimes non-coding RNAs, such as microRNAs (miRNAs) and long non-coding RNAs (lncRNAs), are also included in the broad term of epigenetic factors. There is rapidly expanding experimental evidence for a role of epigenetic factors in the differentiation of bone cells and the pathogenesis of skeletal disorders, such as osteoporosis and osteoarthritis. However, different from genetic factors, epigenetic signatures are cell- and tissue-specific and can change with time. Thus, elucidating their role has particular difficulties, especially in human studies. Nevertheless, epigenomewide association studies are beginning to disclose some disease-specific patterns that help to understand skeletal cell biology and may lead to development of new epigenetic-based biomarkers, as well as new drug targets useful for treating diffuse and localized disorders. Here we provide an overview and update of recent advances on the role of epigenomics in bone and cartilage diseases. (c) 2019 American Society for Bone and Mineral Research.

TI Executive summary of European guidance for the diagnosis and management of osteoporosis in postmenopausal women
SO AGING CLINICAL AND EXPERIMENTAL RESEARCH
LA English
DT Article
DE Bone mineral density; Diagnosis of osteoporosis; Fracture risk assessment; FRAX; Health economics; Treatment of osteoporosis
AB A guidance on the assessment and treatment of postmenopausal women at risk from fractures due to osteoporosis was recently published in Osteoporosis International as a joint effort of the International Osteoporosis Foundation and European Society for Clinical and Economic Aspects of Osteoporosis and Osteoarthritis (Kanis et al. Osteoporos Int, 10.1007/s00198-018-4704-5, 2018). This manuscript updates the previous guideline document, published in 2013 (Kanis et al. Osteoporos Int 24:23-57, 2013) and is written from a European perspective. The present article reports and summarizes the main recommendations included in this 2018 guidance document (Fig.1).

TI Translational Insights into Extremely Low Frequency Pulsed Electromagnetic Fields (ELF-PEMFs) for Bone Regeneration after Trauma and Orthopedic Surgery
SO JOURNAL OF CLINICAL MEDICINE
LA English
DT Review
DE extremely low frequency pulsed electromagnetic fields (ELF-PEMF); bone regeneration; fracture healing; spinal fusion; osteoporosis; bone mineral density; osteoarthritis; pain; bone cells
ID ovariectomy-induced osteoporosis; double-blind trial; electrical-stimulation; knee osteoarthritis; osteogenic differentiation; osteoclast formation; osteoblast differentiation; growth stimulation; signaling pathway; calcium-channels
AB The finding that alterations in electrical potential play an important role in the mechanical stimulation of the bone provoked hype that noninvasive extremely low frequency pulsed electromagnetic fields (ELF-PEMF) can be used to support healing of bone and osteochondral defects. This resulted in the development of many ELF-PEMF devices for clinical use. Due to the resulting diversity of the ELF-PEMF characteristics regarding treatment regimen, and reported results, exposure to ELF-PEMFs is generally not among the guidelines to treat bone and osteochondral defects. Notwithstanding, here we show that there is strong evidence for ELF-PEMF treatment. We give a short, confined overview of in vitro studies investigating effects of ELF-PEMF treatment on bone cells, highlighting likely mechanisms. Subsequently, we summarize prospective and blinded studies, investigating the effect of ELF-PEMF treatment on acute bone fractures and bone fracture non-unions, osteotomies, spinal fusion, osteoporosis, and osteoarthritis. Although these studies favor the use of ELF-PEMF treatment, they likewise demonstrate the need for more defined and better controlled/monitored treatment modalities. However, to establish indication-oriented treatment regimen, profound knowledge of the underlying mechanisms in the sense of cellular pathways/events triggered is required, highlighting the need for more systematic studies to unravel optimal treatment conditions.

TI Results of a 6-week treatment with 10 mg prednisolone in patients with hand osteoarthritis (HOPE): a double-blind, randomised, placebo-controlled trial
SO LANCET
LA English
DT Article
ID nonsteroidal antiinflammatory drugs; induced osteoporosis; criteria; risk
AB Background Hand osteoarthritis is a prevalent joint condition that has a high burden of disease and an unmet medical need for effective therapeutic options. Since local inflammation is recognised as contributing to osteoarthritic complaints, the Hand Osteoarthritis Prednisolone Efficacy (HOPE) study aimed to investigate

the efficacy and safety of short-term prednisolone in patients with painful hand osteoarthritis and synovial inflammation. Methods The HOPE study is a double-blind, randomised, placebo-controlled trial. We recruited eligible adults from rheumatology outpatient clinics at two sites in the Netherlands. Patients were considered eligible if they had symptomatic hand osteoarthritis and signs of inflammation in their distal and proximal interphalangeal (DIP/PIP) joints. For inclusion, patients were required to have four or more DIP/PIP joints with osteoarthritic nodes; at least one DIP/PIP joint with soft swelling or erythema; at least one DIP/PIP joint with a positive power Doppler signal or synovial thickening of at least grade 2 on ultrasound; and finger pain of at least 30 mm on a 100-mm visual analogue scale (VAS) that flared up during a 48-h non-steroidal anti-inflammatory drug (NSAID) washout (defined as worsening of finger pain by at least 20 mm on the VAS). Eligible patients were randomly assigned (1:1) to receive 10 mg prednisolone or placebo orally once daily for 6 weeks, followed by a 2-week tapering scheme, and a 6-week follow-up without study medication. The patients and study team were masked to treatment assignment. The primary endpoint was finger pain, assessed on a VAS, at 6 weeks in participants who had been randomly assigned to groups and attended the baseline visit. This study is registered with the Netherlands Trial Registry, number NTR5263. Findings We screened patients for enrolment between Dec 3, 2015, and May 31, 2018. Patients completed baseline visits and started treatment between Dec 14, 2015, and July 2, 2018, and the last study visit of the last patient was Oct 4, 2018. Of 149 patients assessed for eligibility, 57 (38%) patients were excluded (predominantly because they did not meet one or several inclusion criteria, most often because of an absence of synovial inflammation or of flare-ups after NSAID washout) and 92 (62%) patients were eligible for inclusion. We randomly assigned 46 (50%) patients to receive prednisolone and 46 (50%) patients to receive placebo, all of whom were included in the modified intention-to-treat analysis of the primary endpoint. 42 (91%) patients in the prednisolone group and 42 (91%) in the placebo group completed the 14-week study. The mean change between baseline and week 6 on VAS-reported finger pain was -21.5 (SD 21.7) in the prednisolone group and -5.2 (24.3) in the placebo group, with a mean between-group difference (of prednisolone vs placebo) of -16.5 (95% CI -26.1 to -6.9; p=0.0007). The number of non-serious adverse events was similar between the groups. Five serious adverse events were reported during our study: one serious adverse event in the prednisolone group (a myocardial infarction) and four serious adverse events in the placebo group (an infected traumatic leg haematoma that required surgery, bowel surgery, atrial fibrillation that required a pacemaker implantation, and symptomatic uterine myomas that required a hysterectomy). Four (4%) patients discontinued the study because of an adverse event: one (2%) patient receiving prednisolone (for a myocardial infarction) and three (7%) patients receiving placebo (for surgery of the bowel and for an infected leg haematoma and for Lyme disease arthritis of the knee). Interpretation Treatment with 10 mg prednisolone for 6 weeks is efficacious and safe for the treatment of patients with painful hand osteoarthritis and signs of

inflammation. The results of our study provide clinicians with a new short-term treatment option for patients with hand osteoarthritis who report a flare-up of their disease. Copyright (C) 2019 Elsevier Ltd. All rights reserved.

TI Murine models of accelerated aging and musculoskeletal disease
SO BONE
LA English
DT Article
DE Mouse models; Progeria; Musculoskeletal diseases; Accelerated aging; Senescence; Stem cells
ID nf-kappa-b; senescent secretory phenotype; cellular senescence; dna-repair; heterochronic parabiosis; progeroid syndrome; mouse model; early-onset; bone loss; cells
AB The primary risk factor for most musculoskeletal diseases, including osteoarthritis, osteoporosis and sarcopenia, is aging. To treat the diverse types of musculoskeletal diseases and pathologies, targeting their root cause, the aging process itself, has the potential to slow or prevent multiple age-related musculoskeletal conditions simultaneously. However, the development of approaches to delay onset of age related diseases, including musculoskeletal pathologies, has been slowed by the relatively long lifespan of rodent models of aging. Thus, to expedite the development of therapeutic approaches for age-related musculoskeletal disease, the implementation of mouse models of accelerated musculoskeletal aging are of great utility. Currently there are multiple genetically diverse mouse models that mirror certain aspects of normal human and mouse aging. Here, we provide a review of some of the most relevant murine models of accelerated aging that mimic many aspects of natural musculoskeletal aging, highlighting their relative strengths and weaknesses. Importantly, these

murine models of accelerated aging recapitulate phenotypes of musculoskeletal age-related decline observed in humans.

DT Review
DE Exosomes; microRNAs; osteoporosis; osteoarthritis; fracture healing; regeneration
ID mesenchymal stem-cells; extracellular vesicles; osteogenic differentiation; knee osteoarthritis; femoral-head; cartilage; osteoporosis; apoptosis; fracture; protein
AB Exosomes, which mediate cell-to-cell communications and provide a novel insight into information exchange, have drawn increasing attention in recent years. The homeostasis of bone metabolism is critical for bone health. The most common bone diseases such as osteoporosis, osteoarthritis and bone fractures have apparent correlations with exosomes. Accumulating evidence has suggested the potential regenerative capacities of stem cell-derived exosomes. in this review, we summarise the pathophysiological mechanism, clinical picture and therapeutic effects of exosomes in bone metabolism. We introduce the advantages and challenges in the application of exosomes. Although the exact mechanisms remain unclear, miRNAs seem to play major roles in the exosome.

TI Decrease of GSK3β Ser-9 Phosphorylation Induced Osteoblast Apoptosis in Rat Osteoarthritis Model
SO CURRENT MEDICAL SCIENCE
LA English
DT Article
DE osteonecrosis of the femoral head; GSK3 beta; phosphorylation; apoptosis; dexamethasone
ID glycogen-synthase kinase-3-beta; glucocorticoid-induced osteoporosis; femoral-head; osteonecrosis; pathway; family
AB Nowadays, the cumulative intake of glucocorticoids has become the most common pathogenic factor for non-traumatic osteonecrosis of the femoral head (ONFH). Apoptosis of osteoblasts is considered as the main reason of ONFH at the molecular level. Glycogen synthase kinase 3 (GSK3) is an important regulator of cellular differentiation and apoptosis pathway, which can modulate the balance between osteoblasts and osteoclasts. Several studies have reported about its function in osteoporosis, but little is known about it in osteonecrosis. In our study, lipopolysaccharide and methylprednisolone were utilized to establish a rat ONFH model. The phosphorylation of GSK3 Ser-9 was decreased in the model. Western blotting examination of -catenin, Bcl-2, Bax and caspase-3 revealed that the osteoblasts were apoptotic. In dexamethasone (Dex)-incubated primary osteoblasts, the expression profile of GSK3 phosphorylation and apoptotic factors were consistent with those in the rat ONFH model. To further investigate the regulation of osteonecrosis caused by GSK3, the expression and function of GSK3 were inhibited in Dex-incubated primary osteoblasts. The knockdown of GSK3 by siRNA decreased the expression of Bax and cleaved caspase-3, but increased Bcl-2 and -catenin. On the other hand, selective inhibition of GSK3 function by LiCl counteracted the activation of caspase-3 induced by Dex. Our work is the first study about the GSK3 phosphorylation in ONFH, and provides evidence for further therapeutic methods.

TI Conventional Radiography of the Hip Revisited: Correlation with Advanced Imaging
SO MAGNETIC RESONANCE IMAGING CLINICS OF NORTH AMERICA
LA English
DT Article
DE Hip; Osteonecrosis; Osteoarthritis; Bone marrow edema; Radiography; MR imaging
ID femoral-head; transient osteoporosis; pelvic radiographs; adult hip; osteoarthritis; osteonecrosis; fractures; bone; weightbearing; patterns
AB This review proposes a structured approach to analyzing conventional radiographs of adult hips by focusing on alterations of radiological bone density, femoral head contours, and the joint space. Conventional radiography enables detecting subtle changes in cortical contours and joint space width due to its high spatial resolution. It is limited to the detection of cortical changes in areas to which the x-ray beam is tangent. It has reduced sensitivity for the detection of trabecular

bone and medullary changes. Radiographic findings in common hip disorders, such as osteoarthritis, osteonecrosis, transient osteoporosis, and subchondral insufficiency fractures, are correlated to changes on MR imaging and computed tomography.

DT Review
DE Functional knee bracing; functional rehabilitative knee bracing; posterior cruciate ligament bracing (PCL bracing); anterior cruciate ligament bracing (ACL bracing); osteoarthritis bracing (OA bracing); post-op extension deficit bracing
ID posterior cruciate ligament; pneumatic brace; injury; strength; forces

AB New knee brace designs are available that have the potential to improve patient outcomes relative to traditional bracing. For the indications of post-knee injury/surgery recovery, conservative management of knee osteoarthritis (OA), total knee arthroplasty (TKA) pre-habilitation, and the treatment of post-surgical extension deficits/flexion contractures, innovative new bracing designs merit review and discussion. The researchers requested information from industry brace manufacturers, and from the information received, have selected those products considered significant improvements over traditional functional brace designs for review in this article. Clinical research supporting the benefits of the innovative products listed in the article have been cited when available. The authors are both Certified Orthotists with over 50 years of combined knee bracing experience.

TI Visfatin Connection: Present and Future in Osteoarthritis and Osteoporosis
SO JOURNAL OF CLINICAL MEDICINE
LA English
DT Review
DE osteoarthritis; osteoporosis; cartilage; bone; inflammation; catabolism; visfatin; NAMPT; TLR4; metabolic alterations

ID bone-mineral density; colony-enhancing factor; nicotinamide phosphoribosyltransferase nampt; type-2 diabetes-mellitus; visceral adipose-tissue; nad(+) salvage pathway; infrapatellar fat pad; morbidly obese women; gene-expression; articular chondrocytes
AB Musculoskeletal pathologies (MSPs) such as osteoarthritis (OA) and osteoporosis (OP), are a set of disorders that cause severe pain, motion difficulties, and even permanent disability. In developed countries, the current incidence of MSPs reaches about one in four adults and keeps escalating as a consequence of aging and sedentarism. Interestingly, OA and OP have been closely related to similar risk factors, including aging, metabolic alterations, and inflammation. Visfatin, an adipokine with an inflammatory and catabolic profile, has been associated with several OA and OP metabolic risk factors, such as obesity, insulin resistance, and type II diabetes. Furthermore, visfatin has been associated with the innate immune receptor toll-like receptor 4 (TLR4), which plays a key role in cartilage and bone inflammatory and catabolic responses. Moreover, visfatin has been related to several OA and OP pathologic features. The aim of this work is to bring together basic and clinical data regarding the common role of visfatin in these pathologies and their major shared risk factors. Finally, we discuss the pitfalls of visfatin as a potential biomarker and therapeutic target in both pathologies.

DE NSAID; Osteoarthritis; Paracetamol; Safety; SYSADOA
ID nonsteroidal antiinflammatory drugs; cyclooxygenase-2 inhibitors; economic-aspects; adverse events; metaanalysis; safety; glucosamine; outcm; risk; osteoporosis
AB Osteoarthritis (OA) is characterized by deterioration of the joints and associated

with considerable pain and disability. OA is a chronic disease that requires intervention with both non-pharmacological and pharmacological treatment modalities and, inevitably, disease progression may necessitate successive treatments throughout the course of the disease. There is increasing data on the shortfalls of current pharmacological treatment of OA, and safety concerns associated with analgesic therapy use in OA arising from increasing evidence of gastrointestinal, cardiovascular, hepatic and renal adverse events with paracetamol and non-steroidal anti-inflammatory drugs (NSAIDs). Consequently, symptomatic slow-acting drugs for OA (SYSADOAs) may now be considered as a first-line treatment for knee OA, with a particular emphasis placed on the outstanding benefit: risk ratio of pharmaceutical-grade glucosamine and chondroitin sulfate formulations. In this short communication we review recent publications concerned with the safety of paracetamol, NSAIDs and SYSADOAs. Greater understanding of the benefits and limitations of current medications will lead to better disease management in OA. Furthermore, adherence to guideline recommendations across Europe and internationally, such as those from the European Society for Clinical and Economic Aspects of Osteoporosis, Osteoarthritis and Musculoskeletal Diseases (ESCEO), will promote evidence-based medicine and patient-centric care, ultimately leading to greater physician and patient satisfaction.

TI The role of parathyroid hormone (PTH) and vitamin D in falls and hip fracture type
SO AGING CLINICAL AND EXPERIMENTAL RESEARCH
LA English
DT Article
DE Parathyroid hormone (PTH); 25 (OH) vitamin D; Hip fracture type; Falls
ID bone-mineral density; d deficiency; risk-factors; elderly-women; d level; association; prevention; neck; osteoarthritis; epidemiology
AB Background Fragility fractures of the hip are associated with high morbidity and mortality, and represent a rather devastating consequence of osteoporosis. Hip fractures are traditionally investigated as a whole, although it has been recently implied that distinct pathogenic mechanisms may lead either to trochanteric or subcapital fractures. Aims To investigate whether differences exist by hip fracture type with respect to serum 25(OH)D (vitamin D) and parathyroid hormone (PTH) levels, in addition to epidemiological and demographic data, including history of falls. Methods The inclusion criteria were met by 116 patients [48 men and 68 women; mean age 80.8 +/- 8.5 (range 62-94) years]. Patients were analyzed according to hip fracture type, history of falls, and vitamin D and PTH status. Results Older age, recurrent falls, serum levels of PTH > 65 pg/ml, and severe vitamin D deficiency were found to be associated with trochanteric fractures. Additionally, older age, female gender, PTH > 65 pg/ml, and severe vitamin D deficiency were related to recurrent falls. Meanwhile, patients with absence of PTH response to low vitamin D levels, were not repeated fallers and suffered mostly from subcapital fractures. Discussion and conclusion Elevated PTH levels predispose both to falls and trochanteric fractures, while vitamin D-deficient patients with normal PTH levels are mostly related to subcapital fractures. It is thereby indicated that different pathophysiological processes lie behind subcapital and trochanteric fractures. A better understanding of these mechanisms may assist in the development of prevention strategies for individuals recognized at risk for falls and either type of hip fracture.

TI The influence of antiresorptive bone medication on the effect of high-intensity resistance and impact training on osteoporotic fracture risk in postmenopausal women with low bone mass: protocol for the MEDEX-OP randomised controlled trial
SO BMJ OPEN
LA English
DT Article
DE bone mineral density; exercise; fracture prevention; osteoporosis; Pilates; resistance training
ID quality-of-life; mineral density; muscular strength; test-performance; grip strength; improves bone; exercise; alendronate; therapy; balance
AB Introduction Antiresorptive medications increase bone density and decrease vertebral fracture, while high-intensity resistance and impact training (HiRIT) increases balance, bone and muscle strength decreasing risk for falls and fractures. Medications are typically prescribed by doctors and exercise by exercise specialists, frequently in isolation. Objective Our primary aim is to determine the effect of an 8-month HiRIT programme with or without osteoporosis medications on bone mineral density (BMD) of the spine and hip in postmenopausal women with low bone mass. Methods and analysis One hundred and sixty postmenopausal women with low bone mass will be recruited from the community to participate in an 8-month randomised controlled trial. Participants will be on stable doses of

antiresorptive bone medication for at least 12 months (n=80) or have not taken bone medications for at least 12 months (n=80). Participants will be block randomised, stratified by medication intake, to twice-weekly 40-min supervised sessions of HiRIT or a low-intensity exercise programme (control). Primary outcomes include change in lumbar spine and total hip areal bone mineral density. Secondary outcomes include whole body, femoral neck and forearm BMD, proximal femur bone geometry and volumetric density, vertebral morphology, body composition, anthropometry, physical function, posture, rate of falls, osteoarthritis symptoms, pelvic floor health, quality of life, physical activity enjoyment, resting blood pressure, safety and compliance. All outcomes will be assessed at baseline and 8months and intention-to-treat and per-protocol analyses will be conducted. Repeated measure analysis of covariance will be used to determine intervention effects on outcome measures, controlling for initial values, compliance and other variables found to differ between groups at baseline. Ethics and dissemination The study has been approved by Griffith University Human Research Ethics Committee (Ref: 2017/739). Results will be reported in peer-reviewed journals and at conferences.

TI Osteoarthritis Changes Hip Geometry and Biomechanics Regardless of Bone Mineral DensityA Quantitative Computed Tomography Study
SO JOURNAL OF CLINICAL MEDICINE
LA English
DT Article
DE quantitative computed tomography; hip; osteoarthritis; osteoporosis
ID x-ray absorptiometry; proximal femur; cortical bone; postmenopausal women; knee osteoarthritis; fracture risk; femoral-neck; clinical-use; osteoporosis; spine
AB We aimed to compare proximal femur geometry and biomechanics in postmenopausal women with osteoarthritis (OA) and/or osteoporosis (OP), using quantitative computed tomography (QCT). A retrospective analysis of QCT scans of the proximal femur of 175 postmenopausal women was performed. Morphometric and densitometric data of the proximal femur were used to evaluate its biomechanics. We found, 21 had a normal bone mineral density (BMD), 72 had osteopenia, and 81 were diagnosed with OP. Radiographic findings of hip OA were seen in 43.8%, 52.8%, and 39.5% of the normal BMD, osteopenic, and OP groups, respectively ($p < 0.05$). OA was significantly correlated with total hip volume ($r = 0.21$), intertrochanteric cortical volume ($r = 0.25$), and trochanteric trabecular volume ($r = 0.20$). In each densitometric group, significant differences in hip geometry and BMD were found between the OA and non-OA subgroups. Hip OA and OP often coexist. In postmenopausal women, these diseases coexist in 40% of cases. Both OA and OP affect hip geometry and biomechanics. OA does so regardless of densitometric status. Changes are mostly reflected in the cortical bone. OA leads to significant changes in buckling ratio (BR) in both OP and non-OP

women.

TI Comorbidities in Patients with Rheumatoid Arthritis and Their Association with Patient-reported Outcomes: Results of Claims Data Linked to Questionnaire Survey
SO JOURNAL OF RHEUMATOLOGY
LA English
DT Article
DE EPIDEMIOLOGY; HEALTHCARE; COMORBIDITY; DEPRESSION; RHEUMATOID ARTHRITIS
ID evidence-based recommendations; cardiovascular risk-factors; prevalence; depression; health; osteoporosis; management; psoriasis; ability; cohort
AB Objective. To investigate the prevalence of comorbidities in a population-based cohort of persons with rheumatoid arthritis (RA) compared to matched controls and to examine their association with patient-reported outcomes in a survey sample. Methods. Data of 96,921 persons with RA [International Classification of Diseases, 10th ed (ICD-10) M05/M06] and 484,605 age-and sex-matched controls without RA of a German statutory health fund were studied regarding 26 selected

comorbidities (ICD-10). A self-reported questionnaire, comprising joint counts [(tender joint count (TJC), swollen joint count (SJC)], functional status (Hannover Functional Ability Questionnaire), effect of the disease (Rheumatoid Arthritis Impact of Disease), and well-being (World Health Organization 5-item Well-Being Index; WHO-5) was sent to a random sample of 6193 persons with RA, of whom 3184 responded. For respondents who confirmed their RA (n = 2535), associations between comorbidities and patient-reported outcomes were analyzed by multivariable linear regression. Results. Compared to controls, all investigated comorbidities were more frequent in persons with RA (mean age 63 yrs, 80% female). In addition to cardiovascular risk factors, the most common were osteoarthritis (44% vs 21%), depression (32% vs 20%), and osteoporosis (26% vs 9%). Among the survey respondents, 87% of those with 0-1 comorbidity but only 77% of those with >= 8 comorbidities were treated by rheumatologists. Increasing numbers of comorbidities were associated with poorer values for TJC, SJC, function, and WHO-5. Conclusion. Compared to a matched population, persons with RA present with increased prevalence of numerous comorbidities. Patients with RA and multimorbidity are at risk of insufficient rheumatological care and poorer patient-reported outcomes.

TI Symptomatic bone marrow lesions induced by reduced bone mineral density in middle-aged women: a cross-sectional Japanese population study
SO ARTHRITIS RESEARCH & THERAPY
LA English
DT Article
DE Bone marrow lesion; Bone mineral density; Bone markers; Knee osteoarthritis
ID knee osteoarthritis; biochemical markers; pain; osteoporosis; turnover; association; biomarkers; prevalence; serum; hip
AB BackgroundThe etiology of bone marrow lesions (BMLs) without knee osteoarthritis (KOA) and their association with bone fragility are unclear. We aimed to investigate the association between BMLs, bone mineral density (BMD), and bone markers in women without radiographic evidence of KOA.MethodsThis single-center cross-sectional study in a Japanese population included 266 women without radiographic evidence of KOA, which was defined as a Kellgren-Lawrence grade <2. All participants underwent coronal and sagittal T2-weighted fat-suppressed magnetic resonance imaging of their right knee. BML severity was scored according to the Whole-Organ MRI Scoring method. BMD was measured by

dual-energy X-ray absorptiometry of the forearm. Levels of bone markers (bone-alkaline phosphatase [BAP], type I procollagen N-terminal propeptide [PINP], cross-linked N-telopeptide of type I collagen [NTx], and tartrate-resistant acid phosphatase-5b [TRACP-5b]), pentosidine, and homocysteine were assessed in the serum. Knee symptoms were evaluated on the basis of the Knee injury and Osteoarthritis and Outcome Score (KOOS). Participants were divided into symptomatic knee and asymptomatic knee groups on the basis of their KOOS according to the classification criteria for early KOA. Multiple linear regression analysis was performed to evaluate the relationship between BMLs, BMD, and bone markers.ResultsThe prevalence of BML was 35.3%. Age and some bone marker levels (BAP, PINP, NTx, and TRACP-5b) were higher, and all KOOS subscale scores and BMD were lower in participants with BMLs than in those without BMLs. On multiple linear regression analysis, BMD was negatively associated with BMLs (p=0.014) in participants with symptomatic knees. There was no such association in participants with asymptomatic knees (p=0.918). Among the bone markers, BAP (p=0.006) and PINP (p=0.043) were positively associated with BMLs in participants with symptomatic knees, while BAP (p=0.038) and TRACP-5b (p=0.011) were positively associated with BMLs in participants with asymptomatic knees.ConclusionsIn symptomatic Japanese women without radiographic evidence of KOA, BMD is negatively associated and some bone markers are positively associated with BMLs after adjustment for age and BMI. Thus, maintaining systemic bone metabolism could contribute to BML prevention in patients with pre-radiographic KOA.

TI Preoperative Systemic Bone Quality Does Not Affect Tibial Component Migration in Knee Arthroplasty: A 2-Year Radiostereometric Analysis of a Hundred Consecutive Patients
SO JOURNAL OF ARTHROPLASTY
LA English
DT Article
DE RSA; bone mineral density; migration; knee arthroplasty; bone turnover markers
ID total hip-arthroplasty; outcome score koos; mineral density; trabecular metal; osteoarthritis; rsa; osteoporosis; fixation; cementation; stability
AB Background: Bone quality and other preoperative predictive factors may affect implant migration and the survival of knee arthroplasty. Methods: In a prospective cohort of 100 consecutive patients (65 women) at a mean age of 67.7 years (range 39-87 years), we investigated preoperative predictors of postoperative tibial component migration in cemented and cementless total knee arthroplasties or cemented unicompartmental knee arthroplasty. Predictors consisted of Knee Injury and Osteoarthritis Outcome Score (KOOS) and Oxford Knee Score, questionnaires, bone turnover markers of CTX and P1NP, systemic bone mineral density (BMD), and knee osteoarthritis (OA) grade. Tibial component migration was measured with radiostereometry postoperative, at 1 and 2 years of follow-up. Results: Between 1 and 2 years, 19 tibial components migrated continuously (maximum total point motion [MTPM] > 0.2 mm). In general, there was no difference in age, body mass

index, BMD, KOOSs, or OA grade between patients with continuous tibial migration compared to patients without continuous migration (P > .11). However, cementless tibial components with continuous migration had a lower KOOS pain score (more pain), lower vitamin D, and a higher bone turnover (CTX) value than patients without continuous migration. There was no association between the BMD and MTPM at 1-year follow-up regardless of prothesis type (P > .17). Patients with osteoporosis and normal BMD had similar mean tibial component MTPM at 2 years (3 prostheses combined; P = .34). Conclusion: Migration of tibial components inserted with or without bone cement was not affected by the preoperative bone quality in terms of systemic BMD, bone turnover markers, and OA grade in the knee. TI An updated algorithm recommendation for the management of knee

osteoarthritis from the European Society for Clinical and Economic Aspects of Osteoporosis, Osteoarthritis and Musculoskeletal Diseases (ESCEO)
SO SEMINARS IN ARTHRITIS AND RHEUMATISM
LA English
DT Article
DE Algorithm; Recommendations; GRADE; Treatment; Knee osteoarthritis
ID nonsteroidal antiinflammatory drugs; intraarticular hyaluronic-acid; life setting trials; quality-of-life; crystalline glucosamine sulfate; individual patient data; g-f 20; double-blind; chondroitin sulfate; hip osteoarthritis
AB Objectives: The European Society for Clinical and Economic Aspects of Osteoporosis, Osteoarthritis and Musculoskeletal Diseases (ESCEO) sought to revisit the 2014 algorithm recommendations for knee osteoarthritis (OA), in light of recent efficacy and safety evidence, in order to develop an updated stepwise algorithm that provides practical guidance for the prescribing physician that is applicable in Europe and internationally. Methods: Using the Grading of Recommendations Assessment, Development and Evaluation (GRADE) process, a summary of evidence document for each intervention in OA was provided to all members of an ESCEO working group, who were required to evaluate and vote on the strength of recommendation for each intervention. Based on the evidence collected, and on the strength of recommendations afforded by consensus of the working group, the final algorithm was constructed. Results: An algorithm for management of knee OA comprising a stepwise approach and incorporating consensus on 15 treatment recommendations was prepared by the ESCEO working group. Both "strong" and "weak" recommendations were afforded to different interventions. The algorithm highlights the continued importance of non-pharmacological interventions throughout the management of OA. Benefits and limitations of different pharmacological treatments are explored in this article, with particular emphasis on safety issues highlighted by recent literature analyses. Conclusions: The updated ESCEO stepwise algorithm, developed by consensus from clinical experts in OA and informed by available evidence for the benefits and harms of various treatments, provides practical, current guidance that will enable clinicians to deliver patient-centric care in OA practice.
